**Methods.**– The author evaluated 60 OCD patients and measured insight (apart from other clinical and laboratory variables). A revision about when we can expect from it and how insight changed OCD research is done.

**Results.**– Many authors studied insight in OCD. More studies are needed in order to fully understand why insight is so important for

OCD prognosis and therapeutical success and what makes good-insight patients so different.

**Conclusion.**– Since the beginning of insight research in OCD many things were concluded. Nevertheless, a gap still exists and some more answers are needed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Relationship between social-cognitive and social-perceptual aspects of theory of mind and neurocognitive deficits, insight level and schizotypal traits in obsessive compulsive disorder**

E. Misir<sup>1\*</sup>, E. Bora<sup>2</sup>, B.B. Akdede<sup>2</sup>

<sup>1</sup> Yozgat State Hospital, Psychiatry, Yozgat, Turkey, <sup>2</sup> Dokuz Eylül University Faculty of Medicine, Psychiatry, İzmir, Turkey

\* Corresponding author.

**Objective.**– The primary goal of the current study was to investigate different aspects of theory of mind (ToM), including social-cognitive (ToM-reasoning) and social-perceptual (ToM-decoding) in OCD. We also aimed to investigate the relationship between ToM, neurocognition and a number of clinical variables including overvalued ideas, schizotypal personality traits, level of insight and disease severity.

**Method.**– Thirty-four patient who have been diagnosed with OCD according to DSM-IV and 30 healthy controls were included. All participants were given a neuropsychological battery including tasks measuring ToM-reasoning, ToM-decoding and other neurocognitive functions. Schizotypal Personality Questionnaire (SPQ), Yale Brown Obsession and Compulsion Scale (YBOC-S) and Overvalued Ideas Scale (OVIS) were also administered.

**Results.**– The patients with OCD showed significant deficits in both aspects of ToM. ToM performances of patients were significantly correlated with neurocognitive functions. When controlled for general cognition factor, patient-control difference for ToM-reasoning ( $F=3,917$ ;  $P=0,05$ ) but not ToM-decoding remained statistically significant. ToM-reasoning impairment of patients was significantly related to schizotypal traits, the severity of OCD symptoms and poor insight. On the other hand, general cognitive factor ( $\beta=0,778$ ;  $t=3,146$ ;  $P=0,04$ ) but not other variables were significant predictors of ToM-reasoning in OCD patients in the multiple linear regression model.

**Conclusion.**– OCD is associated with ToM impairment, which is related to schizotypal traits, disease severity and poor insight, but neurocognitive deficits significantly contribute to this finding. However, ToM-reasoning impairment can be considered as a relatively distinct feature of OCD which is partly separate from general cognitive deficits.

### **Obsessive-compulsive disorder with comorbid personality disorders: Current status and understanding**

V. Prisco

AOR S. Carlo, SPDC Villa D'Agri ASL Potenza, Potenza, Italy

The aim of our study was to investigate the comorbidity between obsessive-compulsive disorder (OCD) and personality disorders (PDs), taking into account that patients with EVoccurring PDs have a more severe OCD course. Y-BOCS and SCID-II were administered to a sample of 153 patients (in and outpatients) suffering from a primary diagnosis of OCD, in order to evaluate comorbid PDs. The most common PD cluster showed in our sample was cluster B, occurring in 37 patients. Cluster C was also represented (15 patients), followed by Cluster A (8 patients). OCD with comorbid PDs shows more severe symptoms and a poorer prognosis. In particular, the most frequent comorbid PD in our sample were borderline and histrionic. Furthermore the EVoccurrence of these disorders could imply more difficulties in maintaining a good therapeutic alliance. **Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **In patients with obsessive-compulsive disorders and major depressive disorders, higher anhedonia scores are related to low self-efficacy**

D. Sadeghi Bahmani<sup>1\*</sup>, R. Eskrouchi<sup>2</sup>, M. Pirmoradi<sup>3</sup>, A. Keshavarz<sup>3</sup>, U. Lang<sup>1</sup>, E. Holsboer-Trachsler<sup>1</sup>, S. Brand<sup>1</sup>

<sup>1</sup> University of Basel Psychiatric Hospital, Center for Affective, Stress and Sleep Disorders ZASS, Basel, Switzerland, <sup>2</sup> Tehran University of Medical Sciences, Iran psychiatric hospital, Tehran, Iran, <sup>3</sup> Iran University of Medical Sciences, School of Behavioral Sciences and Mental Health, Tehran, Iran

Corresponding author.

**Background.**– Both patients with obsessive-compulsive disorders and major depressive disorders report lower quality of life. By definition, poor quality of life is associated with lower self-efficacy (SE) and anhedonia (ANH), that is, the relative lack of feelings of enjoyment, happiness and satisfaction. In the present study, we investigated the associations between symptoms of OCD and MDD, SE and ANH among patients with OCD and MDD.

**Methods.**– At total of 30 patients with OCD and 30 patients with MDD took part in the study. They completed a series of self-rating questionnaires on symptoms of OCD, MDD, ANH and SE.

**Results.**– Higher scores of OCD and MDD correlated with higher ANH and lower SE. After controlling for SE, associations between higher scores of OCD and MDD and higher ANH persisted.

**Conclusions.**– The pattern of results suggests that anhedonia seems to be a serious mental health issue both in patients with OCD and MDD independently of self-efficacy. Accordingly, treatment might focus on increasing patients' capacity to enjoy and to experience positive emotions.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0500

### **No differences in the concept of field dependency between patients with OCD and healthy controls**

D. Sadeghi Bahmani<sup>1\*</sup>, R. Eskrouchi<sup>2</sup>, M. Pirmoradi<sup>3</sup>, A. Keshavarz<sup>4</sup>, U. Lang<sup>1</sup>, E. Holsboer-Trachsler<sup>1</sup>, S. Brand<sup>1</sup>

<sup>1</sup> University of Basel Psychiatric Hospital, Center for Affective, Stress and Sleep Disorders ZASS, Basel, Switzerland, <sup>2</sup> Iran psychiatric hospital, Tehran, Iran, <sup>3</sup> School of Behavioral Sciences and Mental Health, Tehran, Iran, <sup>4</sup> Iran University of Medical Sciences, Tehran, Iran

\* Corresponding author.

**Background.**– Witkin introduced the intriguing theory of field dependency as a cognitive style. Briefly, people with a prevalently field-dependent cognitive style rely their cognitive-emotional processes rather on cues from the (social) environment, while people with a prevalently field-independent cognitive style rely their cognitive-emotional processes rather on internal and experience-based cues. Accordingly, as a rule of thumb, people with a field-independent style are more active, assertive, explorative, independent, and action-oriented. In the present study, we investigated, if and to what extent patients with OCD and healthy controls might differ in their field-dependency.

**Method.**– A total of 49 patients with obsessive-compulsive disorder and 49 healthy controls took part in the study. Participants completed questionnaires on socio-demographic and psychiatric dimensions; experts assessed participants' IQ and field-dependency.

**Results.**– Patients with OCD and healthy controls did neither descriptively, nor statistically significantly differ with respect to IQ and field-dependency/independency. OCD scores were associated neither with IQ, nor with scores of field-dependency/independency.

**Conclusions.**– Despite the apparent differences in psychiatric dimensions, patients with OCD did neither differ in IQ, nor in field-dependency/independency. It remains unclear, if and to what extent field-independency of patients with OCD might be considered a resource or an issue to cope with their disorder.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Antipsychotics and the risk of cerebrovascular accidents in the elderly population with dementia

M. Arts<sup>1</sup>, S. Petrykiv<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> Mental Health Western Northern Brabant, Geriatric Psychiatry and Neuropsychiatry, Halsteren, The Netherlands, <sup>2</sup> University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands, <sup>3</sup> Mental Health Care–Friesland GGZ-Friesland, Department of Geriatric Psychiatry, Leeuwarden, The Netherlands, <sup>4</sup> Leonardo Scientific Research Institute, Department of Geriatric Psychiatry and Neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

**Introduction.**– Antipsychotics (AP) are widely used as therapy for psychotic episodes and behavioural problems among elderly population. The efficacy of AP for the treatment of behavioural problems remain unclear, and multiple side effects are linked to the use of AP. In particular, there is an increased risk of cerebrovascular accidents (CVA) reported in the elderly. Data on differences between new-generation and old-generation antipsychotics with regard to the incidence of CVA remains controversial.

**Objectives & aims.**– We aimed to evaluate CVA caused mortality in relation to the use of antipsychotics in geriatric patients with stroke and matched controls.

**Methods.**– An literature search was conducted using Pub Med, EMBASE searching for studies reporting AP-therapy and the risk of stroke.

**Results.**– Increased cerebrovascular risk was associated with use of AP, especially in the first weeks of treatment. CVA caused mortality was 18% and occurred predominantly within 10 days after initia-

tion of AP-therapy. Classic AP-drugs were more likely to cause CVA, when compared to new-generation AP. Possible pathophysiological mechanisms include a trombo-embolic process, changing function of platelets, cardiovascular and atherosclerotic effects.

**Conclusion.**– Our findings suggest that treatment with classic AP-drugs might be particularly hazardous within the first weeks after initiation of the therapy. After 3 months, the risk stabilizes and there is no ratio to withdraw the treatment. Our data indicate that care should be taken in prescribing AP, and that regular adequate clinical controles are necessary.

### Frontotemporal dementia versus bipolar disorder. A case report

R.A. Baena Mures\*, I. Alberdi Páramo, G. Montero Hernández, L. Niell Galmes, M.I. Ramos García

Instituto de psiquiatría San Carlos, Psiquiatría, Madrid, Spain

\* Corresponding author.

**Introduction.**– Frontotemporal dementia (FTD) is a presenile disorder accounting for 20% of dementias in people aged 65 years or younger. FTD describes a group of neurodegenerative diseases featuring various combinations of behavioural changes, language abnormalities, social cognitive impairment, and executive function deficits. FTD is divided into two major clinical syndromes: the behavioural variant (bvFTD) and the language variants referred to as primary progressive aphasia. Identifying bvFTD is challenging because symptoms can be subtle in the early stages.

**Methods.**– A 65-years-old man with psychiatric previous history of Bipolar disorder. His son told us he had become increasingly irritable, with episodes of unprovoked shouting of profanities at strangers and family members. These behaviours were uncharacteristic of the patient's personality at baseline. There was no history of head trauma, loss of consciousness, seizures. Although he did not report feeling euphoric, he reported increased irritability, daytime energy, task-oriented behaviour, impulsivity, distractibility, racing thoughts, and pressured speech. A complete physical and neurologic examinations were unremarkable.

**Results.**– Atypical antipsychotics and mood stabilizers can also be used to control the behavioural symptoms of frontotemporal dementia, although data on their efficacy is limited. On the other hand, valproic acid also appears to enhance dopamine release by antipsychotics that increase the activity of 5-HT<sub>1A</sub> receptors at prefrontal level, such as quetiapine. The significant improvements seen in both affective state and behaviour of our patient soon after the start of treatment with aripiprazol and sodium valproate suggest that a controlled treatment trial with these agents in FTD might be promising.

### Quality of life of the elderly subjects consulting the polyclinic CNSS of Sfax

W. Bouattour<sup>1</sup>, F. Guermazi<sup>1</sup>, R. Sellami<sup>1</sup>, A. Feki<sup>1</sup>, R. Gouiaa<sup>2</sup>, I. Feki<sup>1</sup>, J. Masmoudi<sup>1</sup>

<sup>1</sup> University Hospital Center Hedi Chaker, Department of Psychiatry A, Sfax, Tunisia, <sup>2</sup> Ministry of Health, National Social Security Fund, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– The growing proportion of older people makes to improve their quality of life (QoL) a hot topic and a priority for the political and health authorities. **Objectives.**– To evaluate the QoL of an elderly population and to identify factors related to impaired QoL in the elderly.

**Methods.**– A cross-sectional study including 70 patients aged 65 and over consultant to the Polyclinic CNSS (National Social Security Fund) of Sfax. We evaluated the QoL using the SF-36.

**Results.**– The average age was 73 years. Impaired QoL was found in 63 (90%) patients. The standardization of initial average scores of the SF-36 showed that all dimensions of the SF-36 were altered. The main factors impairing the elderly's QoL were: female gender ( $P=0.037$ ), lower socioeconomic status ( $P=0.015$ ), lack of physical activity ( $P=0.02$ ), presence of comorbidities ( $P=0.009$ ) with a number  $\geq 2$ , especially diabetes ( $P=0.008$ ) and/or diabetes-HTA combination ( $P=0.038$ ). The alteration of the psychic dimension was correlated with isolation ( $P=0.049$ ) and the onset of a stressful event during the last 6 months ( $P=0.008$ ).

**Conclusion.**– Our results confirm that the quality of life of elderly patients is often impaired. They also show the importance of action on modifiable factors related to the impairment of quality of life namely improving the socio-economic level of this population, encouragement of regular physical activity, fight against social isolation and prevention and appropriate management of chronic diseases.

### **Aging brain of bipolar patients; a relation between bipolar disorders and dementia?**

S. Cakir<sup>\*</sup>, E. Ince, A. Fenercioglu

Istanbul University, Istanbul Faculty of Medicine, Psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Bipolar disorder (BP) is a life-long, relapsing disorder cause serious disability. Late onset illness is seen in minority of patients. Some elder patients with BP show some persistent behavioural problems and cognitive deterioration other than symptoms of mood episodes. The knowledge about etiologic or progressive relation between BP and dementia is scarce.

**Objectives.**– We described a case series; patients with BP and frontotemporal dementia (FTD) to discuss the relation between two illness.

**Methods.**– The onset of illness, description of clinical features, progression, neurocognitive tests, brain images of patients with BP and FTD are presented and discussed in the light of literature findings.

**Results.**– We presented four patients with BP. Patient A: 64 year old male, diagnosed with BP 1 for 20 years. He has been diagnosed with FTD for last 6 years. Patient B: 59 year old, female with diagnosis of BP 1 for 37 years. She was also diagnosed with mixed type dementia. Patient C: 75 year old male, diagnosed with late onset BP1 for 18 years and FTD for 6 years. Patient D: 70 year old male, late onset BP1 and FTD for 16 and 4 years respectively. We observed that late onset BP are more risky and has degenerative, aging process which prone to developed FTD.

**Conclusion.**– The patients with BP may aging with more degenerative process and FTD diagnosis may resulted from dis neurodegeneration. Some etiologic data about FTD might come out with traces of BP.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **“Ghosts from the past”: Could dementia symptoms be considered as dissociative symptoms due to previous traumatic experiences? A pilot project**

D. D'Hooghe

Traumacentre Belgium, Private Practice, Brugge, Belgium

The aim of this workshop is to reveal the interrelationship between trauma, dissociation and dementia and to demonstrate a pilot project based on this vision, running in an elderly home.

There is a growing body of research studying the stress-dementia connection. This research proposes that life traumatism could precede the appearance of dementia symptoms.

Early childhood trauma and disrupted attachment plays a crucial role in the development of dissociative psychopathology.

We could consider aging as a threatening condition in which the many developmental changes constitute stressors that make the person more vulnerable for unresolved traumatic experiences to surface.

A lot of behavioural, affective and cognitive symptoms in dementia could be labeled as hyper-aroused dissociation e.g. reliving expressed through dementia as increased physiological reactivity such as wandering, or hypo-aroused dissociation e.g. amnesia expressed through dementia as loss of memory.

The pilot project: “The mosaic of life” is based on a holistic approach blending together the environmental aspects with the interpersonal aspects.

The staff is trained in person-centered care, attachment and trauma theory and neurobiological approaches.

The team is supported through supervision and intervision, which increases their self-efficacy.

The person with dementia receives a tailor made treatment, based on a holistic assessment, consisting of psychobiological strategies, the carer - client dyad, etc.

### **Use of restraint in geronto psychiatry: A descriptive study**

M. Daoud<sup>1</sup>, Z. Azzouz<sup>1</sup>, S. Ben Fadhel<sup>1</sup>, A. Taamallah<sup>1</sup>, R. Bouzid<sup>2</sup>

<sup>1</sup> Razi Hospital, psychiatry, Mannouba, Tunisia, <sup>2</sup> Mohamed Taher Maamouri Hospital, psychiatry, Nabeul, Tunisia

\* Corresponding author.

**Introduction.**– The use of coercion within the psychiatric services is problematic and raises a range of ethical, legal, and clinical questions. “Physical restraint” is an emergency procedure used in psychiatric hospitals to control patients that pose an imminent physical danger.

**Objectives.**– The aim of our work is to analyze the indication, the risks and modalities of restraint for aged hospitalized subjects in psychiatric services.

**Methods.**– A descriptive cross sectional epidemiological study was performed in two psychiatric services in which nurses were individually interviewed using semi structured questionnaire. Five topics were explored: indication and contexts, impact on the patient, caregivers-patient relationship, perspective on the practice and feeling of caregivers.

**Results.**– Twenty-nine nurses were recruited; they all had participated in experiences of restraint. The agitation and aggressiveness were the most frequent indication (75%), and the prevention of the fall for 35%. The emotional experience of nurses was predominantly

negative type of frustration for 25% and lack of feeling for 39%. 21% of the nurses declared that it's essential to explain to the patient the modalities of the act before the restraint. 85% answered that they supervise systematically patients during restraint.

**Conclusion.**– In our investigation we found that most frequent indication of restraint was to protect the patient and the environment but it must be made with caution and moderation to avoid complications.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Cognitive impairment, a mask of depression in elderly people**

M. De Lorenzo Calzón\*, M. Gómez García, N. De Uribe Vilorio, C. Noval Canga, H. De La Red Gallego, A. Alonso Sánchez, A. Rodríguez Campos

Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

\* Corresponding author.

**Introduction.**– The diagnosis of depression in old age is usually very complex. Clinically, it appears more frequently at body levels, showing somatization processes or chronic pain as psychosomatic phenomena. Mnesic complaints are quite common, sometimes masking the presence of emotional and affective symptoms. The outward clinical manifestations, alongside the evolution of symptoms and response to antidepressant treatment remain the most widely used criteria for differential diagnosis between depression, dementia and depressive pseudodementia.

**Objectives.**– To present a clinical case study reflecting the diagnostic difficulty of depressive disorder in old age.

**Material and methods.**– Descriptive study of a clinical case and literature review of the topic.

**Results.**– We describe the case study of an 85-year-old man with psychiatric history, diagnosed with major depressive disorder. He is admitted to the Acute Care Setting for functional and emotional worsening over the last few weeks, exhibiting persecutory delusional ideas, complaints about his state of health, weight loss, lack of appetite, mnesic symptoms, odd behaviour and occasional verbal aggressiveness. The tests administered –blood test, electrocardiogram, thorax x-ray and brain scan– are all normal and so the screening tests for cognitive impairment rule out the possibility of brain damage. The patient is treated with venlafaxine (150 mg/day) and paliperidone (9 mg/day), showing good response and clinical improvement, with the previous delusional ideas disappearing and with memory errors gradually getting better.

**Conclusions.**– The differential diagnosis between dementia and depression is very complex. Depression in old age usually triggers cognitive symptoms affecting both attention and memory. Response to antidepressants with remission of symptoms suggests underlying depressive disorder pathology.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0508

### **Depression and dementia – The complex relationship**

R.L. Fernandes\*, V. Nogueira, D. Pereira, M. Mendes, M. Moreno, M. Melo

Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– Dementia and depression are the most common mental health problems in older age. Late-life depression is frequently associated with cognitive impairment. In turn, depressive symptoms are often associated with or precede a dementia syndrome. The relationship between the two disorders is bi-directional and complex and the accurate differential diagnosis remains extremely challenging.

**Objective.**– To characterize and present the current state of evidence about the relationship between depression and dementia.

**Methods.**– A literature search on Pub Med was performed using the keywords “Depression”, “Cognitive Impairment”, “Dementia” and “Pseudo-dementia”.

**Results.**– Approximately, half of the patients with late-onset depression have cognitive impairment, mostly impairments of executive functions, attention, information processing, psychomotor speed and working memory. There are several ways in which depression and dementia could be related: both being common conditions, they could occur together in the same individual by chance; cognitive impairment and depressive symptoms could both be manifestations of the same brain disease; depression could appear as a reaction to recognition of cognitive loss; depression might unmask a dementia which had until then remained undetected; there is a growing evidence suggesting that depression itself could be an independent risk factor for the future development of dementia, especially with early-onset recurrent or chronic depression. Various mechanisms have been proposed to explicate this association.

**Conclusion.**– The relationship between depression and dementia is far from clear. There are several methodological limitations in the studies that need to be sort out. This area has enormous public health implications considering our growing elder population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0509

### **The profil of Moroccan elderly psychiatric inpatients**

A. Kachouchi\*, S. Salim, I. Adali, F. Manoudi, F. Asri  
University hospital Mohammed VI, Department Of Psychiatry, Marrakech, Morocco

\* Corresponding author.

**Introduction.**– The aging of populations is a major public health issue, because of its health consequences, but also social and economic. In response to this demographic evolution, geriatrics, medicine of the elderly, developed from the end of the 1950s. In the field of psychiatry, the peculiarities that characterize the disorders of the elderly also led to a reflection on the need to propose a specific offer of care.

**Material and method.**– We conducted a descriptive cross-sectional study of all elderly patients hospitalized in the psychiatric unit of Mohammed VI University Hospital, Marrakech, from 1 February 2016 to 31 August 2016.

**Results.**– The sample studied includes 24 patients hospitalized in the psychiatric ward of Mohammed VI Marrakech Medical Center and whose diagnosis was retained on the criteria of the Diagnostic and Statistical Manual of mental disorders in its fifth version (DSMV). The average age of our sample was 62.84. 84.21% of patients ( $n=16$ ) were male with a sex ratio of 5.3. Behavioral disorders and delusional syndrome are the most common symptoms found at admission. 73.86% of patients were diagnosed with schizophrenia. 84% of the patients were on atypical neuroleptics.

**Conclusion.**– Demographic evolution already confronts psychiatrists of adults to take care of elderly patients, whose clinical characteristics (atypical clinical presentations, frequency

of somatic EVmorbidities and associated cognitive impairments, delayed therapeutic responses, etc.) require that a particular teaching and a specific offer of care can be offered as widely as possible. *Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Diagnostic and therapeutic challenges in patient with persistent delusional disorder and pneumosinus dilatans

N. Manusheva<sup>1\*</sup>, S. Bajraktarov<sup>2</sup>, S. Arsova<sup>3</sup>, V. Videnova<sup>4</sup>, E. Cvetkovska<sup>5</sup>, B. Stefanovski<sup>6</sup>

<sup>1</sup> University Psychiatry Clinic, Psychophysiology, Skopje, FYR Macedonia, <sup>2</sup> University Psychiatry Clinic, Department for affective disorders, Skopje, FYR Macedonia, <sup>3</sup> University Psychiatry Clinic, Day hospital, Skopje, FYR Macedonia, <sup>4</sup> Psychiatry Hospital “Skopje”, Emergency Psychiatry, 1000 Skopje, FYR Macedonia, <sup>5</sup> University Neurology Clinic, Neurophysiology, 1000 Skopje, FYR Macedonia, <sup>6</sup> University Psychiatry Clinic, Department for biological psychiatry, Skopje, FYR Macedonia

\* Corresponding author.

*Introduction.* – Treatment of persistent delusional disorders in old age is often complicated with non-compliance and somatic drug treatment. These circumstances can sometimes lead to presence of new symptoms such as seizures, compromised consciousness etc. *Objectives.* – To present a case with complicated clinical presentation due to the morphological changes, age and influence of the applied pharmacotherapy.

*Methods.* – Case report of a 76 years old female inpatient. We performed extensive laboratory tests; microbiological, pneumologic and neurologic examinations, neuroimaging methods (CT, MRI), EEG, psychological tests.

*Results.* – Anamnesis - alteration of consciousness and extra pyramidal symptomatology, treated several years with LAI Risperidone. CT - calcification of the basal ganglia. Toxicology screening without overdose. Laboratory analysis: sodium = 116 mEq/dL; CK = 3683 U/L; hematocrit 0,31%; leucocytes =  $9,3 \times 10^6/\text{mm}^3$  and neutrophilia 0,88%. During treatment she had two tonic-clonic seizures with amnesia. EEG: theta activity over right frontal-central area. MRI: intracranial pneumosinus dilatans without compression of the tissue. Psychologist: visual-retentive deficits and difficulties in graphomotoric performance. Neurosurgeon preferred conservative treatment.

*Conclusions.* – Several factors could explain the current clinical state of the patient. First the patient was old age female with history of treatment with SGA. We can assume that mechanism of hyponatremia is similar to other psychotropic medications i.e. secondary to the syndrome of inappropriate antidiuretic hormone (SIADH). The possible mechanism for seizures could be the presence of pneumosinus dilatans in right frontal sinus. Such patients should be diagnosed and treated with multidisciplinary approach.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Frailty evaluation in aging adults with autism spectrum disorder and intellectual disability (EFAAR study)

S. Miot<sup>1\*</sup>, S. Crépiat<sup>1</sup>, S. Couderc<sup>1</sup>, C. Michelon<sup>1</sup>, E. Pernon<sup>1</sup>, C. Jeandel<sup>2</sup>, H. Blain<sup>2</sup>, A. Baghdadli<sup>1</sup>

<sup>1</sup> Centre Ressources Autisme Languedoc-Roussillon, CHU de Montpellier, SMPEA Peyre-Plantade, Montpellier cedex 5, France, <sup>2</sup> Centre Antonin Balmès, CHU de Montpellier, Pôle de gériologie, Montpellier cedex 5, France

\* Corresponding author.

The frailty syndrome is defined as a medical state of increased vulnerability due to aging-associated decline of physiological reserves. In the Rockwood's cumulative model, a frailty index (FI) is calculated from a lot of clinical and biological criteria. In general population, this FI depends only on age. Few data are available about aging with autism spectrum disorder (ASD). Nevertheless a premature frailty is suspected.

The principal aim of our monocentric and prospective study is to determine if FI is age-dependent in a population of adults with ASD and intellectual disability (ASD-ID). Secondary objectives are to determine the frailty prevalence in our ASD-ID population and to characterize its health condition.

Our primary endpoint was the complete or selected FI (respectively 104 clinical and biological criteria or 62 criteria (criteria with frequency between 5% and 80%)). In addition, ASD severity, adaptive and intellectual functioning, somatic and psychiatric comorbidities, and treatments were evaluated. After checking FI gamma distribution by Kolmogorov-Smirnov test, log-linear univariate and multivariate regressions have been performed to determine on which variables FI depends.

To date, 41 patients aged from 20 to 63 years have been included. FI mean was 0.24-0.25. FI depends significantly on age, ASD severity (CARS), and somatic comorbidities (CIRS). Frailty prevalence ranges from 9 to 61% in accordance with the used FI threshold model. We noted high prevalence of depression (20-23%) and gastrointestinal disorders (70-73%).

Finally, ASD-ID frailty depends on a complex synergy between age, disability and somatic comorbidities. The observed FI is in favour of a premature frailty.

### Assessment of hyper- and hypodopaminergic behaviors in Parkinson's disease

K.S. Moalla<sup>\*</sup>, O. Hdiji, H. Haj Kacem, S. Sakka, N. Farhat, M. Damak, C. Mhiri

Habib Bourguiba hospital, neurology, Sfax, Tunisia

\* Corresponding author.

*Introduction.* – Behavioral changes in Parkinson's disease (PD) are complex and their pathophysiology is not yet fully understood. The dopaminergic system seems to play a major role and most of the behavioural disorders in PD can be classified into either hypodopaminergic if related to the disease itself or hyperdopaminergic if related to dopaminergic treatment.

*Objective.* – To assess for hyper- and hypodopaminergic behaviours in PD patients.

*Methods.* – A cross-sectional study was conducted at the Neurology Department, Habib Bourguiba Hospital (Sfax, Tunisia) including outpatients diagnosed with PD. We used the “Ardouin Scale of Behavior in PD” for evaluating behaviour changes in patients.

*Results.* – Thirty-six patients were enrolled. Mean age was 66.22 years and disease duration was 5.72 years. All patients were treated with dopaminergic therapy associated to anticholinergics in 16.7%. All cases reported at least one psychiatric symptom. The most common were anxiety (77.7%), depression (55.6%), irritability (55.6%) and apathy (33.3%). Psychosis and emotional outbursts were identified among 16.7% and 22.2% of patients respectively. The frequency of hyperdopaminergic behaviours was: hyperactivity (50%), excessive daytime sleepiness (22.2%) and compulsive eating (5.6%). No

exhibited aggressive hypersexuality, pathologic shopping or compulsive medication were identified.

**Conclusion.**– Neuropsychiatric symptoms are common in PD patients suggesting that they are an integral part of PD from the beginning of the disease and appears more related to disease progression than to the type of antiparkinsonian medication. The presence of such behavioural disorders indicates the need to address specific therapeutical approaches targeted toward each particular symptom.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Objectives.**– Bibliographical review of the scientific literature on the topic Glaucoma and its relation with psychotropic drugs.

**Methodology.**– Bibliographical analysis of the works already published on the subject. Identify keywords, collect primary sources, review secondary sources, make a critical review and summarize available literature.

**Results.**– Based on the keywords, we obtained 22 bibliographic sources that we considered relevant.

**Discussion/conclusions.**– Glaucoma—an optic nerve disease, responsible for a progressive (but silent) vision loss - is the 2nd worldwide cause of blindness and the first cause of reversible blindness. 60 M people worldwide with Glaucoma and an increase in incidence with age. Numbers that worry? A problem of all, no doubt. The challenge gets harder. The bidirectional relationship between Glaucoma and Mental Illness is known. 17% of patients have both Mental Illness and Glaucoma. After all—our problem is greater than others' is. Psychotropic drugs can cause Secondary Glaucoma, described in the literature as a type of angle-closure Glaucoma. How bad is our problem? Although less prevalent, angle-closure Glaucoma accounts for 50% Glaucoma-induced blindness. The conclusion? Our problem is WAY bigger than others' is. Our motion? Answer to simple questions of daily clinical practice: Which patient should make the alert sound? What symptoms should concern us? What to do and what to avoid?

### The Cotard syndrome: A case report

P. Ortega Orihuela<sup>1</sup>, A.L. Pérez Morenilla<sup>2</sup>, M.D.L.Á. Chacón Gamero<sup>3</sup>, M. Zurita Carrasco<sup>3</sup>, C. Caballero de las Olivas Díaz<sup>3</sup>, A. García Peña<sup>4</sup>, H. Díaz Díaz<sup>3</sup>, C. Rodríguez<sup>5</sup>

<sup>1</sup> Psychiatry Trainee, University Hospital Puerto Real, Chiclana, Spain; <sup>2</sup> University Hospital Puerta del Mar, Psychiatry, Cádiz, Spain; <sup>3</sup> University Hospital Puerto Real, Psychiatry, Puerto Real, Spain; <sup>4</sup> University Hospital Puerta del Mar, Psychiatry, Cádiz, Spain; <sup>5</sup> University Hospital Puerta del Mar, Psychiatry, Cádiz, Spain

\* Corresponding author.

We present the case of an 83-year-old man who was hospitalized in psychiatry after a suicide attempt, by defenestration. We have done a review of the literature on the subject of a clinical case, due to its peculiarities. He was diagnosed of Somatic Symptom Disorder (according to DSM5) with hypochondriac overvalued ideas. He required admission to the Mental Health Hospitalization Unit showing psychomotor agitation, verbiage and aggressiveness, with progressive deterioration of his mental state; it was necessary a joint follow-up was performed with a Neurology service, and the diagnosis was "unspecified Dementia".

Hypochondriacal ideas are common in the elderly. In most cases they present a depressive substrate. There are several factors that favor the development of delusional disorders in the elderly, such as physical deterioration, pluripathology, progressive loss of loved ones, previous personality and thoughts about death. All this influences the development of concerns about diseases and somatic well-being, and can trigger a picture with delusions. The treatment of this syndrome is usually complex, however, it can be treated effectively if the appropriate pharmacological combination is found for each case. Antidepressant drugs such as mirtazapine or venlafaxine, or antipsychotics such as risperidone, olanzapine, or aripiprazole are usually used. The choice of each of these drugs (or combination of both if required) should be individualized in each case, since there is no infallible treatment to treat cotard syndrome. **Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Loneliness, anxiety and widowhood at portuguese adult daycare centers: An exploratory study

J. Raposo Gomes<sup>1</sup>, M. Andrade Pinheiro<sup>2</sup>, M. Guimarães<sup>1</sup>, H. Firmino<sup>3</sup>

<sup>1</sup> Algarve Hospital and University Center, Portimão, psychiatry, Portimão, Portugal; <sup>2</sup> Centro Hospitalar do Tâmega e Sousa, Psychiatry, Penafiel, Portugal; <sup>3</sup> Coimbra Hospital and University Center, Psychiatry, Coimbra, Portugal

\* Corresponding author.

**Background.**– Widowhood, loneliness and anxiety are commonly seen together in old people staying at adult daycare centres. Human beings are social species which require secure and pleasurable surroundings to survive. Satisfying social relationships are essential for mental and physical well beings. Impaired social relationship can lead to loneliness, in specific at the time of widowhood. Since the time of dawn, loneliness is perceived as a global human phenomenon. Left untended, loneliness can have serious consequences for mental and physical health of people. This study aimed to investigate the relations between widowhood, anxiety and loneliness, how could they be detected and also starts to think about solutions to adopt.

**Methods.**– Questionnaires including socio-demographic data, UCLA Loneliness scale, Geriatric Anxiety Inventory (GAI), all of them validated to portuguese population.

**Results.**– A total of 70 individuals answered the questionnaires. 20 of them were excluded from the study by the criteria of poor cognitive state. Widowhood was more correlated with loneliness than married, single and divorced people. Loneliness was correlated with anxiety. Females report more anxiety than males. Related to loneliness, there are no significative differences in both sex.

**Conclusions.**– People who lost a spouse, report more loneliness and anxiety than the other people with other civil states. Adult daycare centers promote activities that didn't focus on intimacy and quality

of relationships. More studies are needed to understand how could we improve the quality of life of those people.

### Psychopharmacology approach of the bipolar disorder in the aged outpatient

O. Santamaria<sup>1\*</sup>, R. Navarro<sup>1</sup>, S.L. Romero<sup>2</sup>, B.O. Plasencia<sup>3</sup>, F. Gotor<sup>1</sup>

<sup>1</sup> Nuestra Señora de Valme University Hospital, Department of Psychiatry, Seville, Spain; <sup>2</sup> Virgen Macarena University Hospital, Psychiatry, Seville, Spain; <sup>3</sup> La Merced Hospital, Psychiatry, Osuna Seville, Spain

\* Corresponding author.

*Introduction.* – The difficulty in the therapeutic management of the bipolar disorder in elderly population, it is due to the high sensitivity in general pharmacological effects and in psychotropic drugs in particular. There are no specific recommendations to this age group. Most of the evidences are extrapolated from studies in middle age.

*Objectives.* – To analyze longitudinally the pharmacological route of a sample of outpatient with diagnosis of Bipolar Disorder (DSM5 Criteria) above age 65.

*Method.* – Descriptive analysis were performed about data collection from clinical histories from 9 outpatients.

*Results.* – Preliminary results from part of the sample are shown (Table 1).

*Conclusions.* – Most of the patients experienced at least three drugs prior to the current treatment. The principal reason for drug change was the presence of intolerable adverse effects. The trend is to be replaced by atypical antipsychotic or antiepileptic. The available literature is still limited to justify these indications based on empirical data.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

Table 1

	Current age	Years of evolution	Somatic backgrounds	Drugs previous to current treatment	Cause of modification	Current treatment	Side effects
N1	79	59	Arrhythmia, high blood pressure, cholecystectomy	Lithium	Renal failure	Gabapentine	Tremor, drowsiness
N2	76	60		Haloperidol, lithium, biperiden,	Extrapyrarimid syndrome	Lithium, trazodone,	Distal tremor, cognitive impairment
N3	72	25	Ischemic heart disease, high blood pressure, VHB. Essential tremor, cognitive impairment	Fluoxetine, lamotrigine, Oxcarbazepine, Haloperidol, olanzapine	Ineffective Neurotonia Extrapyrarimid syndrome Gain Weight	Quetiapine, valproic acid.	Worsening Cognitive impairment, drowsiness
N4	68	38	Diabetes mellitus	Tricyclic antidepressants, valproic acid, lithium	Drowsiness, gastric discomfort, fatigue	Risperidone, zolpidem	Tremor, dependence on zolpidem

### Isolation, frailty and dementia – A self-entertaining loop

N. Trovão<sup>1</sup>, J. Santo-Silva<sup>2</sup>, C. Paz<sup>2</sup>, R. Encarnação<sup>2</sup><sup>1</sup> Centro Hospitalar Vila Nova de Gaia Espinho, Psychiatry, Vila Nova de Gaia, Portugal; <sup>2</sup> Hospital de Magalhães Lemos, Psychiatry, Porto, Portugal

\* Corresponding author.

**Introduction.**– Social interaction is recognized as a basilar human need, which is deeply compromised in many patients suffering from dementia. Perceived social isolation has in fact been suggested as a premorbid and modifiable risk factor for dementia, although not yet fully understood.

**Objectives.**– We looked for possible mechanisms mediating the effects of social isolation on dementia onset.

**Methods.**– We conducted a selective literature review through the queries of “loneliness”, “isolation”, “cognitive” and “dementia” in Pub Med/Medline online databases, considering relevant references based on their focus on isolation parameters and explanatory models.

**Results.**– Few publications are found on our specific topic. Perceived social isolation appeared as a broad definition for subjective and objective deficits in social interactions, allowing some research so far. It has been related to cognitive decline due to lessened brain stimulation and indirectly through adverse effects frail general health, especially cardiovascular, but research still lacks specific data relating isolation to specific aetiologies of dementia.

**Conclusions.**– Social isolation, frail general health and dementia act as a triad in which each two arms constitute a risk factor for the other. Clear causal mechanisms for dementia precipitated by isolation remain to be proved.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0518

### Maintenance electroconvulsive therapy in elderly, the experience of Magalhães Lemos’s hospital, Porto, Portugal, in 2016

J. Vitória-Silva<sup>1</sup>, S. Gomes<sup>2</sup>, J. Mota<sup>3</sup>, R. Encarnação<sup>4</sup><sup>1</sup> Hospital de Magalhães Lemos, Porto, Custoias, Portugal; <sup>2</sup> Hospital de Magalhães Lemos, Psychogeriatric Unit, Porto, Portugal; <sup>3</sup> Hospital de Magalhães Lemos, ECT Unit, Porto, Portugal; <sup>4</sup> Hospital de Magalhães Lemos, Psychogeriatric Unit, Porto, Portugal

\* Corresponding author.

**Introduction.**– Before a successful acute treatment, maintenance electroconvulsive therapy (ECT) is a usual practice in elderly, because of its efficacy (HP Spaans et al., 2015), in relapse prevention safety (G Petrides et al., 2011) (DT Manly et al., 2000) however there is no general agreement (M Frederikse 2006).

**Objectives.**– Clarify the efficacy of maintenance ECT in relapse prevention.

**Methods.**– Brief review of the literature about maintenance ECT in elderly, using Pub Med and presentation of epidemiological data of ECT Unit in Magalhães Lemos’s Hospital related to this practice, during 2016.

**Results.**– In terms of ECT practice in elderly, in Magalhães Lemos’s Hospital during 2016, 21 individuals were treated with acute ECT. 14 of them started maintenance treatment and 5 of these relapse (35.7%). Of the 7 individuals that didn’t start maintenance therapy, only 1 relapse (14.2%).

**Conclusions.**– Maintenance ECT in elderly is usual but there is formal guidelines supporting it. Studies show good efficacy in relapse

prevention of severe psychopathology however, our unit data fail to show that. However, a larger population was needed to support our idea.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0519

### Frailty and depression in the elderly: Relationship between two prevalent conditions in geriatric patients

T. Teodoro<sup>1,2,3\*</sup>, M. Martins<sup>1</sup>, M.A. Botelho<sup>2,3</sup><sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal; <sup>2</sup> CEDOC, Chronic Diseases Research Center, Integrated Pathophysiological Mechanisms, Lisbon, Portugal; <sup>3</sup> NOVA Medical School/Faculdade de Ciências Médicas, Clinical Medicine Department, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– Frailty is an age-related state of decreased homeostatic response to stressors resulting in increased vulnerability and decline in physiological reserve across multiple systems. Depression is a clinical entity associated with functional decline and is a predictor of disability and morbidity. There is considerable overlap of these two clinical situations but the precise nature of their relationship is unclear.

**Objectives.**– Review about the relationship between frailty syndrome and depression in the elderly.

**Methods.**– Non-systematic review of literature using Pub Med database using keywords “Frailty” and “Depression”.

**Results.**– Frailty and depression are unarguably interrelated concepts but despite overlapping symptoms most view them as distinct syndromes. There is however some data suggesting there may be common pathophysiological mechanisms, namely a low grade proinflammatory state and dysregulation of hypothalamic pituitary adrenal axis. Comorbidity is well established but causal relationships have recently begun to be addressed. Vascular depression in particular may be a risk factor for the development of frailty probably due to the contribution of cerebrovascular burden and depression symptoms appear to be associated with greater prevalence of frailty with an important impact in longevity. Also, most severely depressed patients are more susceptible to developing frailty due to the impact of depression on lifestyle factors. On the other hand frailty is also presented as a risk factor for depressive symptoms.

**Conclusions.**– Definite data about the complex interrelationship between depression and frailty is lacking. Development of effective evidence-based intervention models is necessary and further understanding of these clinical constructs and their relationship is important for the planning of optimal care in this challenging population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Montessori Intervention for dementia in Pakistan open label feasibility study

S. Tofique<sup>1\*</sup>, N. Chaudhry<sup>1</sup>, N. Husain<sup>2</sup>, R. Dunne<sup>3</sup>, P. Glasgow<sup>4</sup>, D. Couture<sup>4</sup>, F. Shuber<sup>4</sup>, S. Minhas<sup>5</sup><sup>1</sup> Pakistan Institute of Living & Learning, Research, Karachi, Pakistan,<sup>2</sup> University of Manchester, Division of Psychology and Mental Health, Manchester, United Kingdom, <sup>3</sup> Greater Manchester Mental Health Foundation NHS Trust, Greater Manchester Mental Health Foundation NHS Trust, Manchester, United Kingdom, <sup>4</sup> Montessori teachers college, Montessori teachers college, Toronto, Canada, <sup>5</sup>

Bright Scholars Academy, Bright Scholars Academy, Mississauga, Canada

\* Corresponding author.

**Background.**– People with dementia usually develop behavioural and psychiatric symptoms (BPSD) which can lead to burden for caregivers and premature institutionalization. More than 50% dementia patients live in low and middle income countries where only less than 10% of the relevant research has been done. Lack of formal support indicates need of developing alternative forms of care and support for them. In case of BPSD, a non-pharmacological approach based on the Montessori method, may be helpful to both the person with dementia and the caregiver.

**Objectives.**– To evaluate the feasibility and acceptability of a group-based Montessori intervention for dementia for LMIC. To build capacity and capability in dementia research (researchers training, setting up PPI research group, scoping the recruitment/referral pathway, undertaking the field study)

**Methods.**– This will be a single-arm open-label feasibility and acceptability study of 12 dyads (person with dementia and their caregiver) with 12-week of Montessori intervention, delivered by trained researchers. Data will be collected using qualitative measures (semi-structured interviews, weekly diaries) and quantitative measures using a battery of baseline and follow up assessment measures.

**Conclusion.**– Carefully assessing process measures in feasibility trials is essential to successfully undertake larger-scale interventions of complex therapies in LMIC settings.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0521

### Preventing hospital admission in acutely unwell older adults

S. Vann Jones\*, S. Altaan

Cornwall Partnership Foundation Trust, Complex Care & Dementia, Launceston, United Kingdom

\* Corresponding author.

**Introduction.**– Interim Assessment and Treatment (IAT) provides funding to purchase care for urgent and specific treatment needs for Older Adults in Cornwall where the likely alternative might be an admission to hospital. Used appropriately it is much less restrictive and increases the possibility of maintaining patients in familiar surroundings. It is important for the effectiveness of IAT that specific steps are taken to ensure the most appropriate treatment and/or placement.

**Objectives.**– This audit assessed whether we are meeting the required standards of assessment and communication throughout the process. We also reviewed the outcomes from each placement (e.g. hospital admission, return home, continued placement at IAT address) as well as length of placement as proxies for the success of the process.

**Methods.**– We reviewed all patients where IAT funding had been used in the past 12 months and used a standardized data extraction form covering five key domains; assessment, placement details and outcome, information sharing, legal process and follow-up.

**Results.**– In total 12 patients received IAT funding. They received physical (100%) plus mental (91.6%) plus cognitive (66.7%) assessments for their decline prior to funding. All involved MDT discussion. Only 1 (8.3%) patient ultimately required admission to a mental health hospital. The median length of placement was 19.5 days which compared favourably to the national median inpatient stay of 78 days.

**Conclusions.**– Our IAT placements are well planned, executed and effective and in the majority of cases result in a suitable placement being found or maintained and hospital admission avoided.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0522

### The Psychotic Depression Assessment Scale (PDAS) in older adults: Clinical use and value

T. Vermeulen

University of Antwerp, Medicine, Antwerp, Belgium

**Background.**– The Psychotic Depression Assessment Scale is the first dedicated scale to measure severity of a depressive disorder with psychotic features (psychotic depression). A recent study showed promising result on the use of a semi-structured interview. The PDAS was clinically valid, scalable and responsive. Our study aimed at establishing validity of the semi-structured interview of the PDAS using independent ratings on reference instruments.

**Methods.**– A total of 62 participants of 60 years and older were recruited in 2 old age psychiatry wards in Flanders, Belgium. Severity of depression was measured by trained nurses using the PDAS. Reference instruments were the Clinical Global Impression Scale for severity (CGI-S), the Montgomery-Asberg Depression Rating Scale (MADRS), the CORE and the Inventory of Depression Severity - Self Report.

**Results.**– (Not supplied)

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Subjective well-being in older women with breast cancer in remission

S. von Humboldt, F. Carneiro, I. Leal

ISPA-Instituto Universitário, William James Center for Research, Lisbon, Portugal

\* Corresponding author.

**Objectives.**– To analyze significant differences among two groups of older women with and without breast cancer, regarding subjective well-being (SWB); to assess the association of SWB with breast cancer; and to examine the association of the affective with the cognitive dimension of SWB in both groups.

**Methods.**– We recruited 387 older women (M = 85.27; SD = 6.59; range 75–100). Measures included demographics, the Satisfaction with Life Scale and the Positive and Negative Affect Schedule.

**Results.**– Women with breast cancer in remission presented a significantly higher SWB score. Cognitive and affective dimensions of SWB were correlated to breast cancer, and were strongly associated in both groups.

**Conclusions.**– Clinical and program development may benefit from addressing SWB of older cancer survivors.

**Keywords:** Older women; Breast cancer in remission; Subjective well-being; Aging well.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0524

### Psychological challenges of older clients in person-centered therapy

S. von Humboldt, I. Leal

ISPA-Instituto Universitário, William James Center for Research, Lisbon, Portugal

**Objectives.**– Dramatic increases in life expectancy within the older population have revealed challenges specific to older adults, yet these are rarely addressed in the person centered literature. In this paper, we offer the perspective of adults experiencing old age, by using a case study of a 74-year-old older adult as well as research that supports the various challenges in old age.

**Methods.**– We explore several psycho-emotional challenges experienced by older adults—cognitive capacity, time perspective, autonomy, loss and reminiscing, and the aging body, in order to facilitate understanding of their specific needs.

**Results.**– The results show that for older adults, an empathic approach is key to creating relational depth within a therapeutic relationship so that the older client can deepen his or her personhood and his or her sense of agency.

**Conclusions.**– We assert that a genuine and authentic encounter between an older client and her or his therapist is the key to facilitating growth and development for the older client.

**Keywords:** Older client perspectives; Empathic approach; Person-centered therapy; Psycho-emotional challenges; Therapeutic relationship

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0525

### Psychiatric symptoms in brain tumor, case report

Z. Barac-Otasevic, I. Ljutica

Medical Clinical Centre of Montenegro, Psychiatry Clinic, Podgorica, Montenegro

**Case report.**– We presented patient with the diagnosed brain tumor where psychiatrist had been the first specialist to be consulted. Neurological examination was generally unremarkable with no focal signs or features of raised intracranial pressure.

CT scan demonstrated Proccessus expansivum region sellaris et suprasellaris nonfunctionalis cum compression chiasmaopticum in a 67 y male patient.

His family said that the first behaving changes such as heightened suspicion and elevated jealousy of wife is in the last year, and that symptoms grow up after retirement.

Psychiatric symptoms in patients with brain tumors are not specific enough and can have the same clinical presentation as the genuine psychiatric disorder.

It is important to use the neuroimaging in patients with abrupt beginning of psychiatric symptoms, in those with a change in mental status, or when headaches suddenly appear or in cases of treatment resistant psychiatric disorders regardless the lack of neurological symptoms.

**Keywords:** Mental disorders; Signs and symptoms; Brain neoplazma diagnosis

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0526

### Tobacco consumption pattern and psychological impact among auto rickshaw drivers in Chennai city, Tamil Nadu, India

D.L. Francis

Tamil Nadu Dr MGR Medical University, Public Health, Chennai, India

**Background.**– Tobacco use is a major preventable cause of premature death and diseases, India is the second largest consumer of tobacco in the world. The prevalence of tobacco use among adults (15 years and above) is 35% and the prevalence of overall tobacco use is 48% among males. This study is contemplated with an aim to assess the prevalence of tobacco consumption and the associated factors involved in its consumption, as this group of the population is under constant pressure and account for the workforce of the country.

**Materials and methods.**– A cross sectional descriptive study was conducted among 400 Auto Rickshaw Drivers in Chennai City. Data was collected using a Survey Proforma which comprised of a Questionnaire which can assess the frequency of consumption, age of initiation, the amount of consumption, mental stress, economic factors, any past history of disease and most importantly the awareness towards oral cancer. The data recorded was transferred and analysed using SPSS version 20. Chi-square test was used to test the significance between groups.

**Results.**– Prevalence among auto rickshaw drivers for consumption of tobacco products was very high (87%). Auto rickshaw drivers were mostly used tobacco in the form of Gutkha (72%) and bidi (40%) in comparison to other products. Awareness level among auto rickshaw driver was high (70%) but still uses tobacco products because of its addiction (66%). In the opinion of auto rickshaw drivers increase in tax may reduce it consumption and the majority of drivers (70%) think that tobacco must be banned.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The announcement of diagnosis of malignant oculo-orbital tumor in children: Impact and repercussions on parents

A. Kachouchi\*, S. Salim, I. Adali, F. Manoudi, F. Asri  
University hospital Mohammed VI, Department Of Psychiatry, Marrakech, Morocco

\* Corresponding author.

**Objectives of the study.**– The purpose of our work is to describe the experience of the parents of a child with oculo-orbital cancer and to evaluate the degree of satisfaction of these children both for the therapeutic management of their child and for the clarity of the information transmitted.

**Patients and method.**– We conducted a prospective study of interest to parents of children with cancer oro-orbital and who had been treated in the ophthalmology department of the Mohammed VI University Hospital of Marrakech over a period of one year. Data collection was done through semi-structured interviews with parents, to whom we also provided self-questionnaires to assess their lived experience at the time of diagnosis, treatment and after treatment.

**Results.**– Twelve families participated in the study. The average age of treated children was 11 months. 73% of children had retinoblastoma, and 27% had rhabdomyosarcoma. The sick child was the only child of all the families participating in the study. At the time of the announcement of the diagnosis, the father was absent in 75% of

the cases. 10% of the families considered that the doctor could not find the right words to announce the diagnosis. At the announcement of the treatment (enucleation/exenteration): all the parents did not accept immediately the proposal of the treatment. 80% of parents needed an average of 3 days to adapt to this situation. After treatment (average time of 1 month): The majority of parents (92%) expressed overall a significant satisfaction

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Emotional distress, alexithymia and coping strategies in newly diagnosed patients with cancer

I. Feki<sup>1</sup>, R. Masmoudi<sup>1</sup>, R. Sellami<sup>1</sup>, I. Ayedi<sup>2</sup>, M. Frikha<sup>2</sup>, A. Feki<sup>1</sup>, J. Masmoudi<sup>1</sup>

<sup>1</sup> Hédi Chaker University Hospital, psychiatry "A", Sfax, Tunisia; <sup>2</sup>

Habib Bourguiba University Hospital, Department of Medical Oncology, Sfax, Tunisia

\* Corresponding author.

*Introduction.*– Receiving a diagnosis of cancer may cause psychological responses such anxiety, depression and alexithymia. Patients adopt various coping strategies to deal with this situation.

*Objectives.*– To determine the prevalence of anxiety, depression and alexithymia in newly diagnosed patients with cancer and explore coping strategies used by these patients.

*Methods.*– It was a cross-sectional study involving 40 newly diagnosed patients with cancer and followed in the oncology department of Habib Bourguiba University Hospital in Sfax. The Hospital Anxiety and Depression Scale (HADS) was used to assess emotional distress. Alexithymia was assessed using the Toronto Alexithymia Scale (TAS-20). Coping was evaluated by the Ways of Coping Checklist-Revised (WCC-R); this scale measures three coping factors: problem-focused coping, emotion-focused coping, and social support seeking.

*Results.*– The average age of the patients was 54.65 years. The sex ratio (M/W) was 1.5. The colorectal cancer was the most frequent (50%) type of cancer. The average duration of disease was 4 months. 10% of patients had metastases. All patients were treated with surgery and 55% underwent radiotherapy. A high level of anxiety was found in 40% of patients, while depression was found in 30% of cases. Four patients (10%) had alexithymia. The most adopted coping strategy was problem-focused with an average score of  $31.44 \pm 3.97$ . High alexithymic patients scored higher on the emotion-focused coping and significantly lower on problem-focused coping than non alexithymic patients.

*Conclusion.*– After a cancer diagnosis, depression, anxiety and other emotional problems may occur. Psychological support can reduce emotional distress and reinforce strategies of adjustment to illness.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### The use of mirtazapine in cancer patients: A review

S. Zaini<sup>1</sup>, C.G. Ng<sup>1\*</sup>, A.H. Sulaiman<sup>1</sup>, H. Zaman Huri<sup>2</sup>, S.H. Shamsudin<sup>3</sup>

<sup>1</sup> Faculty of Medicine, University of Malaya, Department of Psychological Medicine, Kuala Lumpur, Malaysia, <sup>2</sup> Faculty of Medicine, University of Malaya, Department of Pharmacy, Kuala Lumpur, Malaysia, <sup>3</sup> International Islamic University Malaysia, Department of Pharmacy Practice, Kulliyah of Pharmacy, Kuantan, Malaysia

\* Corresponding author.

*Introduction.*– Cancer patients often have concurrent physical and psychological symptoms. These problems may become barriers towards the healing process. Antidepressants seem to be beneficial for the purpose of palliative care in this type of patients. One of the useful medications is mirtazapine, which is known as noradrenergic and specific serotonergic antidepressant (NaSSA). This

paper examines the use of mirtazapine in physical and psychological symptoms of cancer patients.

**Methods.**– Literature search was done on Pub Med (from inception to January 2017) by matching the key terms: 'noradrenergic and specific serotonergic antidepressants' or 'NaSSA' mirtazapine' AND 'cancer' or 'oncol\*' or 'malignancy' or 'carcinoma'. Eligible papers were screened at the title and abstract level. Various types of study included in this review, according to certain criteria. Additional papers were also identified by screening of reference lists.

**Results.**– A total of twelve papers were reviewed and summarized. Positive findings obtained for the use of mirtazapine in cancer patients associated with various symptoms, including depression, anxiety, cachexia, nausea, hot flashes, and pruritus. Some rare side effects are reported, including constipation, myalgia sedation, dry mouth, stimulation of appetite and weight gain.

**Conclusion.**– Mirtazapine has the potential to be beneficial for cancer patients suffering from these physical and psychological symptoms. However, more research studies with sufficient power are warranted to validate the findings.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0531

### **Differentiated approach to the study nozogeny in patients breast cancer**

O. Shushpanova

Scientific Center of Mental Health, Department of Child Psychiatry, Moscow, Russia

**Background.**– The problem of mental disorders in patients with breast cancer is relevant due to the high prevalence of pathological changes in the mental health patients, insufficient development of clinical typology of psychosomatic correlations and evaluation of the contribution of constitutional features

**Material and method.**– Study of nozogeny disorders in patients with breast cancer, manifesting at different stages of the disease, with the release of certain clinical types, taking into account premorbid characteristics of patients.

**Results.**– Anxious - depressive nozogeny reaction was recorded in 17 patients of the first sample with high direct correlation (coefficient Fechner  $F=0.76$ ,  $P<0.01$ ) with respect to accentuation of personality in the alarm type, and the weak direct link to the personal characteristics of the affective (bipolar) range ( $F=0.22$ ,  $P<0.01$ ). Anxious - nozogeny dissociative response was detected in 9 patients with hysterical  $n=5$  (55.5%) and expansive schizotypal (vershrobene)  $n=4$  (44.4%) lung cancer with a significantly significant ( $F=0.65$ ,  $P<0.01$ ) a direct correlation with constitutional hyperthymia, anxiety - hypomanic nozogeny response was observed in 4 patients c schizotypal RL ( $n=4$ ) paired with symptoms of persistent hyperthymia ( $F=0.39$ ,  $P=0.012$ ). Manifestation of a particular patient nozogeny reaction is closely correlated to its premorbid personal characteristics.

**Conclusion.**– Patho-characterological development of personality are formed on the remote catamnestic stage breast cancer and show the clinical heterogeneity of differentiation into 4 types: 1) hypochondriacal dysthymia, 2) "paranoia struggle", 3) "aberrant hypochondria" and 4) "new life".

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Body image perception, marital adjustment and sexual satisfaction in breast cancer**

G. Yıldız\*, D. Hiçdurmaz

Hacettepe University, Faculty of Nursing, Psychiatric Nursing Department, Ankara, Turkey

\* Corresponding author.

**Introduction.**– Breast cancer causes alterations in body image, threatens perception of femininity and sexuality, and may lead to problems arising from inadequacy perception in sexual and marital relationship. Breast cancer patients' partners generally form the ultimate source of social support. However, they are frequently ignored. Studies report that partners simultaneously suffer from psychosocial problems experienced by the women, and they have a negative and avoidant attitude about having close relationship with the patient and thus their sexual lives are negatively affected. Sexual problems experienced by the couples frequently arise from women's avoidant attitude with the feelings of incompetency and partners' concerns on causing unintended harm/distress on the patient. This mutual suffering and anxiety negatively affects the couple's sexual life and can lead to marital adjustment issues.

**Objective.**– The aim of the study is to review breast cancer patients' and their partners' sexual satisfaction and marital adjustment that are effected by body image perception.

**Method.**– This study was carried out as a review of literature.

**Results.**– With the support of psychoeducational interventions, it is possible that couple can cope effectively with breast cancer process, or even grow with this process. Programs focused on improving skills related to sexual and marital adjustment are effective on the improvement of women's body image perception, couples' sexual functioning and marital adjustment.

**Conclusion.**– Health care professionals should be alert on and discuss these issues with the couple during routine assessments by adopting a sensitive approach. Psychoeducational programs targeting sexual and marital adjustment should be developed and conducted.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Antidepressant-induced sexual dysfunction among fluoxetine, paroxetine, venlafaxine and mirtazapine in a naturalistic study**

Mohammed Alburaiqi, Mandhar Almaqbali

M.H. Al Breiki\*, M. AlMuqbali

Oman medical specialty board, psychiatry, Muscat, Oman

\* Corresponding author.

**Introduction.**– Antidepressants agents had been associated with a variable degree of sexual dysfunction. Failure to address this side effects to the patient may lead to non-adherence to the treatment and relapse of depression.

**Objective.**– Measuring the prevalence of sexual dysfunction in psychiatric outpatients treated with fluoxetine, paroxetine, venlafaxine or mirtazapine.

**Methods.**– This is a cross-sectional study conducted in SQU hospital Oman. All patients above 18 years of age, on above mentioned

medications for various indications were invited. Sexual side effects part of Toronto Side Effect Scale was used to assess the presence of sexual dysfunction. Male patients were asked to rate the frequency and severity of erectile dysfunction, premature ejaculation and delayed ejaculation. Both genders were asked to rate the frequency and severity of anorgasmia, decreased libido and increased libido.

**Results.**– A total of 73 patients were included. The mean age for the participants was 40 years. The number of patients on paroxetine, fluoxetine and mirtazapine was equal (21 patients for each). Meanwhile, 10 patients were on venlafaxine. The average duration of the antidepressant use was 3 years. The overall prevalence of sexual dysfunction was 34%. Paroxetine was the most common antidepressant associated with sexual dysfunction (43%). In contrast, mirtazapine was the lowest among antidepressants to cause sexual dysfunction (9.5%). Decreased libido was the most frequent reported sexual side effect.

**Conclusion.**– Sexual dysfunction is common among patients treated with antidepressants particularly selective serotonin reuptake inhibitors (SSRIs). Addressing this side effects early in treatment can improve compliance to treatment and prevent relapse.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0534

### **Asperger syndrome: Comorbidity with gender dysphoria. Case report**

A. Alvarez Astorga<sup>\*</sup>, L. Gallardo Borge, A. Alonso Sanchez, H. De la Red Gallego, M. De Lorenzo Calzón, N. De Uribe Viloria, C. Noval Canga

HCU Valladolid, Psychiatry, Valladolid, Spain

\* Corresponding author.

**Introduction.**– The number of publications describing gender identity problems in patients with Asperger's syndrome appears to be greater more frequent. Current studies highlight a striking association between autism spectrum disorders and gender dysphoria. Several researchers acknowledge that between 7.8% and 12% of transgender people suffer from an autism spectrum disorder. Although lines of work in this field are increasing, it is a controversial subject and pending clarification.

**Objectives.**– Reviewing literature to understand why this relationship could be produced.

**Methods.**– A 19-year-old patient with a history of Asperger syndrome asks for to be evaluated in the gender dysphoria unit. During tracking he presents ambivalent thoughts and feelings. He chooses different gender options at each meeting and he dresses ambiguous clothes. He presents many doubts during the interviews. He has a fantastic thought, idealistic with femininity.

**Results.**– Finally, he was not accepted to continue with the gender reassignment.

**Conclusions.**– Several theories have been described on the joint manifestation of both processes. On the one hand, the more biological theories that explain autism emphasize hormonal alterations. Other visions emphasize the importance of deficits in social interactions and social cognition and in other cases it seems that the factor that facilitates comorbidity could be the overlap of an Obsessive-compulsive disorder. Finally, given the different arguments of the problem, the decision to authorize the resignation of gender is a complicated decision to address and identify the most opportune moment remains controversial.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Evacuation of psychiatric hospital in disaster**

N. Amanat<sup>1\*</sup>, S.H. Hosseini<sup>1</sup>, H.R. Khankeh<sup>2</sup>, S. Bahrapouri<sup>1</sup>

<sup>1</sup> University of Social Welfare and Rehabilitation Sciences, Health in Emergency and Disaster, Tehran, Iran; <sup>2</sup> Karolinska Institute, Department of Clinical Science and Education, Stockholm, Sweden

\* Corresponding author.

**Introduction.**– Razi psychiatric hospital is the first and greatest rehabilitation hospital in Iran, with 1200 active beds. It was located south of Tehran near the Ray Faults, and in area, more than 100 hectares expanded. Emergencies teams are required to develop effective plans for the safe evacuation of hospitals in the events. There is most literature is devoted to evacuation of general hospital, but little data exist to evacuation of psychiatric hospital.

**Objectives.**– At this study, we are going to describe how we can do evacuation as a daily task in a psychiatric hospital.

**Methods.**– At this mixed method study, we invited key person and whom had experiences in evacuation to participate in focus group discussion. We selected four wards randomly. Two wards titled with “chronic ward” who patients are admitted to the end of their lives, and two wards selected from “education wards” who patient discharged after treatment. Patients were encourage to exit from the wards daily for teatime and fresh air or walking from emergency exit routs.

**Results.**– Most clients did not understand concept of emergencies. Because of psychotic nature of clients, evacuation in emergencies was complicated. Some client who had not insight should have been accompanied with a nursing staff or oriented patient. The full evacuation time range was 9 to 16 minutes.

**Conclusion.**– Our study, showed key opportunities to improve evacuation. The specific opportunities to use from experienced staff and inventive methods can serve to guide future evacuation of psychiatric center.

**Keywords:** Psychiatric hospital; Evacuation; Disaster

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0536

### **Effects of sertraline on seizure duration during ECT**

A. Aslan<sup>\*</sup>, Y. Gorgulu, M.B. Sonmez, R. Kose Cinar

Trakya University School of Medicine, Psychiatry, Edirne, Turkey

\* Corresponding author.

**Introduction.**– Selective serotonin reuptake inhibitors are known to lower the seizure threshold; however, some studies have claimed that antidepressant sertraline is particularly effective in preventing seizures. The particular efficacy of sertraline to prevent seizures induced by ECT is explained by its high effectiveness to reduce brain presynaptic Na and Ca channels permeability.

**Objectives.**– We aimed at exploring whether sertraline shortens the seizure duration in electroconvulsive therapy by raising seizure threshold.

**Methods.**– We retrospectively reviewed the files of patients who underwent ECT treatment in our clinic. We have analysed their seizure durations, antidepressant medications, sociodemographic factors and medical conditions.

**Results.**– While we were retrospectively reviewing the files of patients who underwent ECT treatment, we noticed that six patients who had short ECT seizure durations were taking sertraline medication. We have analysed the files of these patients in detail. All patients undergoing ECT received a general anaesthetic

regimen including propofol and esmoron. Four of them was female, and two of them was male. The ages of patients was between 23 and 71. Five of them was diagnosed with major depression and one of them had schizophrenia. Patient's sertraline doses was between 50 and 200 mg/day. In two patients it was noticed that the duration of seizures during ECT suddenly shortened after sertraline treatment was started. In one patient, sertraline dose increased and seizure duration shortened. Other three patients who were previously known to be taking sertraline medication have had brief seizures during ECT since the beginning of the ECT treatment.

**Conclusion.**– Sertraline shortens the seizure duration during ECT in some patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Introduction.**– The Research Working Group (RWG) was established in 2008 at the European Federation of Psychiatric Trainees (EFPT) Forum in Gothenburg. As a platform for trainee-led collaborative studies, it offers the possibility to work in a multicultural environment and investigate matters that concern trainees across the continent.

**Objectives.**– To evaluate the scope of the research produced by the EFPT RWG in its first decade of activity.

**Methods.**– A review was conducted to identify all the outputs, identifying completed and ongoing projects of the EFPT RWG. All former chairs were contacted and enquired about the research activities undertaken in their term, covering the last 10 years period. All publications related to projects conducted under the EFPT RWG auspices were searched in the ResearchGate profile of previous working group members and in the Pub Med database.

**Results.**– In the past 10 years of existence, the EFPT RWG has developed several projects, made dozens of presentations (both oral and poster) in several national and international psychiatric congresses and has published dozens of research articles, comments, reports and letters to the Editor. Currently there are eight ongoing projects. Remarkably, all these projects have been conducted without any funding support.

**Conclusions.**– There has been a significant number of collaborative research projects conducted in the last 10 years. The EFPT RWG is functioning as a successful platform, which facilitates international trainee-led collaborative studies, promotes an effective method to transfer knowledge, and forms the basis of a trainee-led international research network.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Self esteem of pregnant women: Results of a Tunisian study**

I. Bouzouita<sup>1\*</sup>, F. Ellouze<sup>2</sup>, H. El Kefi<sup>1</sup>, A. Baatout<sup>1</sup>, M.W. Krir<sup>1</sup>, C. Ben Cheikh<sup>1</sup>, S. Eddhif<sup>1</sup>, B. Bouguerra<sup>3</sup>, A.A. Oumaya<sup>1</sup>

<sup>1</sup> Hôpital militaire principal d'instruction de Tunis, Psychiatrie, Tunis, Tunisia; <sup>2</sup> Razi Hospital, Ibn Jazar, Manouba, Tunisia; <sup>3</sup> Charles Nicolle Hospital, Gynecology B, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Many changes can occur during pregnancy and may affect the body and the mood of women. . . Self esteem can be affected also and can have consequences on women and her different relationships.

**Objectives.**– The objective of our study is to evaluate the self esteem of pregnant women and factors which can interfere with it.

**Methods.**– We have conducted a cross-sectional study among 100 pregnant women. A questionnaire was performed to determine different demographic data. To evaluate self esteem, we used Rosenberg questionnaire of self esteem which is composed of 10 items.

**Results.**– The mean age of our 100 participants was 29,4 ± 5,6 years. 67% of the participants were of rural origin and 33% of urban origin. 62% of the sample were housewives. 25% of participant women had primary school education and 50% had secondary school education. 73% of our sample were of medium socioeconomic status. The mean pregnancy term was 25 gestational weeks ± 9 weeks. 42% of the pregnant women were in their third trimester. 60% of the participants noted that they were satisfied and enjoyed their pregnancy. The mean score of Rosenberg questionnaire was 29,4 + - 2,8 and 94% of the participants had a medium self esteem.

**Conclusions.**– Self esteem can be affected as many other fields during pregnancy. More researchs are necessary to evaluate the self esteem of women during her pregnancy and to study the factors which can affect it.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0539

### **Using physical activity in acute psychiatric inpatients**

N. Brondino<sup>1\*</sup>, E. Codrons<sup>2</sup>, M. Rocchetti<sup>1</sup>, L. Correale<sup>2</sup>, L. Fusar-Poli<sup>1</sup>, P. Politi<sup>1</sup>, M. Vandoni<sup>2</sup>

<sup>1</sup> University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy; <sup>2</sup> University of Pavia, Laboratory of Adapted Motor Activity, Department of Public Health, Experimental and Forensic Medicine, Section of Hygiene, Pavia, Italy

\* Corresponding author.

**Introduction.**– The benefits of physical activity for psychiatric patients are well known. However, there is a paucity of data regarding the use of exercise programs in inpatients. Specifically, all studies on this issue involved patients hospitalized in residential facilities for minimum 6 weeks. To the best of our knowledge there is no evidence on the potential benefit of physical activity in acute psychiatric inpatients

**Objectives.**– To evaluate the effect of physical activity on acute psychiatric inpatients admitted consecutively in a psychiatric ward

**Methods.**– Physical activity consisted in a one 1-h weekly session of supervised aerobic floor exercises. Patient's participation during hospitalization was recorded. Mean hospitalization length, number of violent behaviours, necessity of seclusion, global clinical impression were recorded for both participants and patients who did not join the exercise program during one year. These data were compared with historical data (5 years before the beginning of the study) obtained from the psychiatric ward's clinical records

**Results.**– Preliminary results showed better outcomes for patients who participate in the program compared to patients admitted in the same period who did not participate

**Conclusions.**– The use of physical exercise seems useful and feasible in the context of the psychiatric ward.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Free-T3 as a weaker biological marker for ADHD in adults compared to children

H. Caci<sup>1</sup>, P.F. Patricia<sup>2</sup>, I. Henri<sup>1</sup>

<sup>1</sup> Hôpitaux pédiatriques CHU Lenval de Nice, Pediatrics, Nice, France;

<sup>2</sup> Centre Hospitalier Universitaire de Nice, Biochemistry, Nice, France

\* Corresponding author.

**Introduction.**– Thyroid function has been less frequently studied in adults with ADHD than in children. Some authors noticed similarities between ADHD symptoms in children and the Thyroid Hormone Resistance while others concluded that the thyroid function was normal based either on total-T3, free-T3, total-T4, free-T4 or TSH (Thyroid Stimulating Hormone). We found in a previous study that free-T3 was higher in a subgroup of children with ADHD more likely to have comorbid ODD, while free-T4 and TSH were within normal range.

**Objectives.**– If free-T3 were a biological marker of ADHD then our findings in children would hold in a sample of adults with ADHD.

**Methods.**– Retrospective analyses of systematic biological assays performed before prescribing any psycho-stimulant treatment to an adult formally diagnosed with ADHD in our department since 2001.

**Results.**– No hypothyroidism or hyperthyroidism case in our sample of 83 adults (including 44 women). Biological laboratories either used IECL/Centaur or EIA/Beckman techniques. Age and free-T3 correlated ( $\rho = -.42, P < 0.001$ ). Three adults (3.62%) had free-T3 levels beyond the reference interval provided on result sheets. Free-T3 dosage was beyond the percentile 90 of the reference interval in 8 cases out of 26 with IECL/Centaur (30.77%;  $p < .003$  by binomial law) and beyond the percentile 95 in 6 cases out of 57 with EIA/Beckman (10.53%;  $p < .065$ ).

**Conclusions.**– Those proportions are smaller than those obtained in a sample of children; one reason may be the strong negative correlation between free-T3 and age. Analyses should be replicated in a multicentre prospective and controlled study.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0541

### Serotonin syndrome? An unlikely case

C. Cagigal<sup>1</sup>, M. Jesus, C. Silva

Coimbra Hospital and University Centre, Coimbra, Portugal,

Department of Psychiatry, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Serotonin Syndrome is an uncommon clinical iatrogenic condition related to the potentiation of the serotonergic action induced by drugs. It usually presents with neuropsychiatric, neurovegetative and neuromuscular clinical manifestations. The severity of the cases is highly variable, and remission may occur with simple pharmacological suspension or may lead to death.

**Objectives.**– The authors review the literature on Serotonin Syndrome, addressing a clinical case.

**Methods.**– Case report and relevant literature review.

**Results.**– A 65-year-old woman starts taking trazodone 150 mg and quetiapine 150 mg a day per insomnia at which point she began to have tremors. One month later, it was started sertraline 100 mg due to depressive symptoms and quetiapine was suspended. After a month, the tremors remained, presenting cogwheel rigidity, reason why initiates biperiden. Two days later, she went to the emergency department with exuberant tremor, hyperreflexia, agitation, confused and disoriented, and with disorganized speech. Substance abuse, infectious or metabolic disease and brain injury that might be causing the described symptoms were excluded. Following serotonin agents and biperiden withdrawal, there was full symptoms remission.

**Conclusions.**– Serotonin Syndrome is believed to be underdiagnosed and potentially fatal, and its timely identification requires a high level of suspicion. Thus, clinicians should be able to recognize this syndrome in their daily medical practice, as often polymedicated and elderly patients with increased susceptibility to drug interactions are likely to develop such condition as described.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0542

### Late-onset multiple sclerosis presenting with depression and behavioral changes: Case report

I. Chaari<sup>1</sup>, O. Hdiji, N. Farhat, H. Hajkacem, S. Sakka, M. Dammak, C. Mhiri

Habib Bourguiba Hospital, Department of Neurology, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Depression, cognitive and behavioural changes are frequently encountered in patients with multiple sclerosis (MS), but less likely to be the first manifestation of the condition. Thus, diagnosis can be delayed.

**Case report.**– We report a case of a 52 year-old woman admitted to neurology department for gait impairment that had progressed over a 5-month period. She has a medical history of high blood pressure, dyslipidemia, morbid obesity and hyperuricemia. Detailed history taking revealed that the patient experienced personality changes, depressed mood, loss of interest and pleasure 2 years beforehand. Afterwards, the family noticed an unusual aggressive behaviour that they tended to explain as a result of spousal abuse. She was initially diagnosed with major depressive disorder. She received Paroxetine 20 mg daily and anxiolytic treatment for 4 weeks without a response. Later she developed gait impairment, balance trouble, walking difficulty, as well as frequent falling. Neurological examination found frontal syndrome, static cerebellar syndrome and cognitive impairment. Cerebro-medullar MRI showed multiple demyelinating and active lesions compatible with

MS. IgG oligoclonal bands were detected at isoelectric focusing examination of cerebro-spinal fluid. McDonald diagnostic criteria 2010 for primary progressive MS were utilized. Interferon beta was prescribed along with Fluoxetine and hydroxyzine.

**Conclusion.**– This case report illustrates the diagnostic challenges associated with psychiatric symptoms of MS. Studying clinical features of patients exhibiting primary cognitive and psychiatric disorders, generally first referred to psychiatrists, allows to prevent diagnosis delay and improves the overall outcome of these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0543

### **Efficacy and tolerability of extended-release guanfacine in attention deficit hyperactivity disorder (ADHD): Review and case report**

A. De Cos Milas<sup>1\*</sup>, M. García Moreno<sup>2</sup>, M.B. Poza Cano<sup>3</sup>, L. Beatobe Carreño<sup>1</sup>

<sup>1</sup> CSM Móstoles, Hospital Universitario de Móstoles Madrid, Psychiatry, Madrid, Spain; <sup>2</sup> CSM Majadahonda, Hospital Universitario Puerta de Hierro Majadahonda Madrid, Psychiatry, Madrid, Spain; <sup>3</sup> CE San Carlos, Hospital Universitario El Escorial Madrid, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Attention Deficit Hyperactivity Disorder (ADHD) is a neurodevelopmental condition that debuts during childhood but frequently results in an unfavorable clinical condition in adults. Nowadays several pharmacological treatments are available to treat this disorder. Extended-release guanfacine has proved to improve attention and behavioural symptoms in ADHD.

**Objectives.**– To update our knowledge about ADHD pharmacological treatment and to present our clinical experience with extended-release guanfacine in the treatment of an ADHD patient with previous poor response and tolerability to other medications.

**Methods.**– We perform a systematic literature review about ADHD pharmacological treatment especially concerning extended-release guanfacine. We selected one patient diagnosed of ADHD and depressive episode from our outpatient Mental Health Service.

**Results.**– Our clinical illustration is a 20 years old male with diagnosis of ADHD since adolescence and depressive episode during the last 8 months. He received during almost 5 years different medications in order to treat the symptoms resulting from ADHD (attention deficit, impulsivity and disruptive behaviour) as methylphenidate, atomoxetine, lisdexamphetamine, risperidone and paliperidone with unfavorable response and adverse effects (irritability, insomnia and weightloss). Recent depressive symptoms were treated with citalopram, also with poor response. A treatment change to extended-release guanfacine 3 mg was introduced, with significant improvement of ADHD symptoms, and no relevant side effects associated; depressive clinic also improved.

**Conclusions.**– Our clinical experience confirms the literature evidences that extended-release guanfacine could be a valuable therapeutic option in ADHD patients with previous poor response to other treatments as stimulants medications, on behalf also of its positive side-effect profile.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **“Tacrolimus made me paranoid” – About a clinical case of tacrolimus-induced psychotic episode**

M.J. Freire\*, J. Nogueira, J. Vieira, M. Franco, N. Ribeiro, I. Fonseca, B. Barata, M. Salta, R. Sousa, G. Jesus, R. Ribeiro, A. Gamito  
Centro Hospitalar de Setúbal, Psychiatry and Mental Health, Setúbal, Portugal

\* Corresponding author.

**Introduction.**– Tacrolimus have been associated with various neurotoxic adverse reactions, but there are few case reports of tacrolimus-induced psychotic episodes.

**Objectives.**– We report a clinical case of psychosis probably induced by tacrolimus in a renal transplant recipient.

**Methods.**– Data was collected from patient and family members interviews, and clinical records consultation, during patient admission in 2016.

**Results.**– Miss SGR, 43, underwent kidney transplant in 2014, and was kept on tacrolimus 5 mg, prednisolone 5 mg and mofetil mycophenolate 1 g (daily dosages), until one month before hospitalization. SGR, with no previous psychiatric history, initiated anxiety symptoms, anorexia, insomnia and paranoid delusions with increasing functional impact, culminating in her admission to an acute psychiatric ward. One month before hospitalization tacrolimus blood levels were measured, found to be too high and, subsequently, dosage was lowered to 3 g/day, with ongoing aggravation of psychotic symptoms. During hospitalization, tacrolimus was kept at 3 mg/daily, its blood levels normalized and 9 mg of paliperidone were initiated. The patient was discharged at day 18, with no psychotic symptoms.

**Conclusions.**– The patient's absence of psychiatric history, the emergence of psychotic symptoms concomitantly with tacrolimus toxic blood levels and the clinical resolution after normalization of these concentration levels, make it very likely that this was a psychotic episode induced by tacrolimus. Other psychiatric manifestations have been described, as mania, fugue-like states or catatonia, in solid organ transplant receivers. It is mandatory to be alert to these rare adverse reactions and to adjust, or discontinue, the drug to get full clinical resolution.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0545

### **Living kidney transplantation: Preoperative assessment in the donor and recipient**

D. Galletta\*, I. Lauria, V.F. Papa, C. Annisa  
University of Naples Federico II, Neuroscience, Naples, Italy

\* Corresponding author.

**Introduction.**– The kidney transplantation isn't only medical process but it also influences the patient's body image, with difficult to accept a new part of itself (Karaminiaet al.). It's complex both for the receiving and the donor, because it's psychological, emotional, relational and social implications, as shown in literature (Gallettaet al.). It's just analysed with multidisciplinary approach with a couple of brothers, inserting other tools in the assessment (Gallettaet al.).

**Objective.**– To demonstrate the importance of the assessment of psychological profile for the evaluation of the being ready to take on the operation.

**Methods.**– It is evaluated another pair of brothers, using the following tests: SCL-90, IRI, graphics test, Raven's Progressive Matrices and Rorschach test.

**Results.**– In the donor there's a search of security in the past, tendency to coarctation and defensive attitude. He has a strong self but difficulties to act in the future, showing anxiety, stress and difficult to manage. The receiving's an immature self, exposing traits of obsessive-compulsive behaviour, negative mood and traits of anxiety. He tends to excessive adherence to reality, blockage in affections, defensive attitude seeking security in the past. Compared to donor, he seems to have the capacity to manage the difficulty.

**Conclusions.**– Living donor kidney transplantation didn't affect the lives of donors and improved many aspects of the lives of recipients (Pascasio et al.). However, psychological and social aspects may be impaired by living donation (Hazet et al.). Therefore, it's important an appropriate multidisciplinary approach, knowing the psychological status of both patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0546

### **Developing a guide for medical students to choose psychiatry in Spain**

C. Gómez Sánchez-Lafuente<sup>1</sup>, R. Reina Gonzalez<sup>2</sup>  
<sup>1</sup> Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain; <sup>2</sup> Hospital Universitario Virgen de la Victoria, General Medicine, Málaga, Spain

\* Corresponding author.

**Introduction.**– Choosing a medical specialty is not easy. In Spain, when medical students finish the university degree, they have to take an exam called popularly MIR if they want to start a specialty. If the exam is passed, that person receives a number result of his academic record during university and test result. The Spanish healthcare system offers between 220 and 250 places to start the Specialty of Psychiatry in 121 hospital across Spain.

**Objectives.**– From SERP, we had two goals. By one side, we wanted to develop a guide to help students who doubted between various specialties and psychiatry. By other side, people has general information about psychiatry residency from many hospitals as possible.

**Methods.**– We designed a semi-structured questionnaire with 30 questions specific for the purpose of this work. The questionnaire was spread by social networks and email to reach as many medical doctors undertaking postgraduate training in psychiatry as we could.

**Results.**– A total of 130 people responded to the questionnaire. 15 were not psychiatry trainees. We obtained information from 80 hospitals (66%). 33 hospitals (41%) have specific training in psychotherapy. 69 (86%) apply electroconvulsive therapy regularly. Teaching during training is given together with psychologists and nurses in 36 hospitals (45%), with psychologists in 32 (40%), only psychiatry trainees in 12 (15%). Psychiatry trainees do general emergency guards in 62 hospitals (77%).

**Conclusion.**– This guide may help medical students to discover Psychiatry Training and to choose the best hospital that fits their interests

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **A chronic schizoaffective patient treated with aripiprazole combined with EMDR therapy, ecopsychiatry and group psychotherapy after flufenazine depot treatment efficiently recovered – A case study**

M. Hasanovic<sup>1</sup>, D. Šmigalović<sup>2</sup>, D. Hrvič<sup>1</sup>, I. Omeragić<sup>3</sup>, F. Imširović<sup>3</sup>

<sup>1</sup> University Clinical Center Tuzla, Department of Psychiatry, Tuzla, Bosnia, Herzegovina; <sup>2</sup> Primary Health Care Center, Mental Health Service, Kalesija, Bosnia, Herzegovina; <sup>3</sup> Primary Health Care Center, Mental Health Service, Gradačac, Bosnia, Herzegovina

\* Corresponding author.

**Introduction.**– In clinical practice, “Difficult Patients” require adequate psychopharmacotherapy with a number of other procedures of responsible therapists and members of the therapeutic team.

**Case report.**– Man, 35, an unemployed locksmith. Unmarried, has no children, lives with his mother. He had a difficult childhood, his mother tried suicide when he was eight years old. His father was killed in the war, and the patient survived firing from enemy soldiers in war over his head with chance to be killed in age of 11 years. He tried several suicides during adolescence. From his high school period he treated by a psychiatrist. Diagnosed as a Schizo-depressive Disorder, treated with Fluphenazine Depot with Antidepressants, Benzodiazepines and Lamotrigine. Despite complex pharmacotherapy he was unstable, dysfunctional and had several hospitalizations. During the last inpatients treatment he transferred from Fluphenazine Depot to aripiprazole. After involvement in a psychotherapy group with war veterans when he recalls memories of war trauma we used EMDR therapy focuses on traumatic memory, making internal tension much easier. Also, he was included in “ecopsychiatry” activities every day from 10 to 11 a.m. with other inpatients and outpatients. The patient progressively recovered and stabilized and dismissed for outpatient treatment and involved in coordinated care. Three months after, patient takes regular therapy, has no mental problems that would make him dysfunctional.

**Conclusion.**– With “Difficult Patients” Integrative Approach and Patient Oriented Clinical Practice can give very good results and help the patient to recover progressively, to rehabilitate and to re-socialize to the maximal possible level.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The relationship between job satisfaction and personality traits among Irankhodro company expert staff**

S. Heidari<sup>1</sup>, H. Mirabzadeh Ardakani<sup>2</sup>, B. Sefidgaran<sup>3</sup>

<sup>1</sup> Behravan Psychology Center, Industrial & Organizational Department, tehran, Iran; <sup>2</sup> Behravan Psychology center, Organizational and Industrial Department, Tehran, Iran; <sup>3</sup> Behravam Psychology Center, Organizational & Industrial department, Tehran, Iran

\* Corresponding author.

Job satisfaction among employee is a crucial issue in an organization and employer plays a vital role to fulfill the needs. Keeping job satisfaction high can be of tremendous benefit to any organization as happy employees will be more likely to produce work

effectively, loyal to the organization and would help to increase the organization's performance against its competitors.

It has been assumed that personality traits can play an important role in people's dealing with the environmental issues such as work situations. The aim of this essay is to study the relationship between personality traits and job satisfaction. Explaining job satisfaction by using personality traits can enlighten whether job satisfaction depends only on type of organization or on some personality traits. So the study of this relationship is needed in this area. In this regard, present study has investigated the relationship between job satisfaction and personality traits among IranKhodro Company expert staff. To do so, personality characteristics were measured by NEO-PI-R scale and job satisfaction was measured by Job Descriptive Index (JDI scale). Accordingly the mentioned questionnaires were filled by experts of "Iran Khodro" company (111 men & women). The data analysed by Pearson correlation coefficient.

Results show that, Neuroticism/Emotional stability was associated with low job satisfaction ( $r = -0.713, P < 0.01$ ). Also Conscientiousness ( $r = 0.620$ ) and Agreeableness ( $r = 0.476$ ) was significantly correlated with job satisfaction ( $P < 0.01$ ). But the relationship between Extraversion ( $r = -0.025$ ) and Openness to experience ( $r = 0.061$ ) with job satisfaction was not significant.

The results of this study emphasize on the effective role of age ( $r = -0.301$ ) and job background ( $r = -0.330$ ) on job satisfaction. But relationship between sexuality ( $r = 0.183$ ), marriage ( $r = 0.125$ ) with job satisfaction was not significant.

### **A healthy weight group experience in a psychiatric clinic**

J. Jaber\*, J. Verissimo Jr, A.I. Tomé, J. Cardozo, P. Fontenelle, A. Hollanda, B.N. Reys

*Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil*

\* Corresponding author.

*Introduction.* – The work describes the experience of the Healthy Weight Group (HWG) realized in the period of november, 2016 to july, 2017 in a psychiatric clinic in the city of Rio de Janeiro, Rio de Janeiro, Brazil.

*Objectives.* – The program had as objectives to promote the weight reduction to levels considered healthy in those patients with overweight and with obesity, hospitalized in the clinic due to diverse mental disorders. It's aimed with the HWG the reduction of the weight of the patients, associated with the improvement of the eating habits and to the practice of regular physical exercises, thus promoting, as expected, the improvement of the physical health conditions and the life expectation of the participating patients.

*Methods.* – The patients who presented, in the initial clinical evaluation, body mass index (BMI) indicating overweight or obesity were invited to participate of the HWG. The HWG met weekly during the studied period, the patients being allowed to address over the meeting their difficulties in executing the proposed program. In the end of the meetings, each participating patient had their weight and length of the abdominal circumference measured.

*Results.* – The participation in the HWG was a factor recognized as important to motivation and to the adhesion to the proposed programs, as well as to the achievement of the observed results.

*Conclusions.* – The study realized showed that it's possible the realization, during the psychiatric hospitalization, of programs for the weight loss in population of psychiatric patients.

### **Evaluation of an antismoking program in psychiatric**

J. Jaber\*, A.I. Tomé, A. Hollanda, B.N. Reys

*Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil*

\* Corresponding author.

*Introduction.* – The work evaluated the well succeeded experience of the antismoking program, realized between the years of 2008 and 2015 in a psychiatric clinic in the city of Rio de Janeiro, Rio de Janeiro, Brazil.

*Objectives.* – The program had as objectives, evaluate the treatment of tobacco dependence in patients with disorders for the use of substances and other psychiatric disorders, and the experience of transforming the clinic therapeutic space in a free-tobacco environment, considering that the use of tobacco is responsible for a large number of preventable deaths and other damages to health.

*Methods.* – The program reached the proposed objectives, promoting the tobacco abstinence in a large number of patients, through the use of pharmacological treatment, mutual help groups, cognitive behavioural psychotherapy, occupational therapy, art therapy and moderate physical activity.

*Results.* – In a period of 12 months, after the completion of the program, 48% of the assessed patients kept in tobacco abstinence

*Conclusions.* – The realized study showed that it's possible the elimination of the tobacco in the therapeutic environment by setting clear goals, with the engagement of the whole staff and patients. The progressive reduction of the consumption of tobacco during the period of study, until its complete elimination of the physical space of the institution, was successfully reached. Besides that, the patients benefit from the Antismoking Program, as demonstrated by the fact that about half of the patients kept abstemious in relation to tobacco after 12 months of discharge from hospital.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Perceptual processes and language in rural school children**

M.C. Jimenez Martinez<sup>1</sup>, N. Gómez<sup>2</sup>, D.L. Nieto<sup>3</sup>

<sup>1</sup> Universidad Pedagógica y Tecnológica de Colombia, Grupo Desarrollo Humano Cognición y Educación Escuela de Psicología, Tunja, Colombia;

<sup>2</sup> Universidad Pedagógica y Tecnológica de Colombia, Group of statistics GAMA, Tunja, Colombia; <sup>3</sup> Universidad Pedagógica y Tecnológica de Colombia, Healt Education and Rural Development Group, Tunja, Colombia

\* Corresponding author.

*Background.* – According to Cogen (1991), perception is a complex process that is both cognitive and physiological. Perception doesn't always start within the individual but it also can start with an experience. It means as a response to stimuli. It is understood that the sensory-motor processes must be completely integrated [1], interrelated and automatized in order to learn the symbolism and acquisition of reading and writing and posterior perceptual, motor and emotional development.

*Method.* – The Escala Neuropsicológica Infantil (ENI), Matute, E; Roselli, M; Ardila, A; Ostrosky, F [2] was applied to fifty 5-12 year olds students who attend 13 rural schools. Data was analysed by an univariate analysis to determine significant differences among the selected variables according with classification criteria such as age range and levels of schooling. Three age ranges and 4 levels of schooling were considered.

*Results.* – Results show that level of schooling generates significant differences in the majority of the analysed variables. In other words,

the higher the level of the students' schooling, the better their performance in the analysed variables.

**Conclusion.**– Age doesn't provide significant differences in students' performance [3].

**Keywords:** Perception; Language; Rural children; Education

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Analysis of applied behavior treatment for children with autism spectrum disorder**

M. Jimenez -Martinez<sup>1</sup>, A. Nuñez-Rodríguez<sup>2</sup>, G. Guzmán<sup>3</sup>

<sup>1</sup> Universidad Pedagógica y Tecnológica de Colombia, Grupo Desarrollo Humano Cognición y Educación Escuela de Psicología, Tunja, Colombia; <sup>2</sup> Victory B- R.T Florida, United States, 1665 W 68 ST Suite 201, Hialeah Fl, USA; <sup>3</sup> Victory BRT, 1665 W 68 ST Suite 201, Hialeah Fl, USA

\* Corresponding author.

According to Boesch, M. C et al. (2015), people with Autism Spectrum Disorder (ASD) are at a greater risk of developing harmful behaviours, such as self-aggression and other challenging behaviours than individuals with normal development do not exhibit. The method of approach that is supported by scientific evidence for interventional procedures is applied behaviour analysis, reported by Carr, M. E. et al (2014).

**Aim.**– In order to provide evidence-based intervention for autism from this approach in practice.

**Method.**– In reference to a longitudinal approach, an intervention program was designed and implemented to serve 40 children with ASD, who were treated for one (1) year at the Victory BRT Institute in Florida, US. The behaviours targeted for reduction (excess behavioural), are the following: physical aggression, self-aggression and non-compliance. The program began with a baseline (12 consecutive days) with observations at home and others different natural contexts. The last three (3) months of the year consisted of monthly follow-up sessions to monitor the treatment implemented. The *results* were analysed by repeated measures, ANOVA Sig ( $P=0.003$ ) ( $F=8$ ). Analyses show that the critical level associated with the effect of time-content interaction is strong, so the treatment generated a positive effect by reducing the behaviours targeted in time.

**Conclusions.**– These results provide evidence that interventions from applied behaviour analysis are effective.

### **This is not my hand**

P. Jorge

Psychiatry resident at Centro Hospitalar do Médio Tejo, Hospital de Tomar, Portugal, Psychiatry, Tomar, Portugal

**Introduction.**– Alien hand syndrome (AHS) could be described as the perception that one limb “has its own volition” together with recognizable uncontrolled motor activity which pries with the voluntary movements of the unaffected limb.

**Aim and methods.**– Pub Med was used as a research source to do a review about this syndrome.

**Results.**– In 1908, Goldstein first described this syndrome as “a type of apraxia with the feeling of estrangement between the patient and his hand”. In fact, in AHS the affected limb is typically the hand, although leg (alien limb phenomena) involvement has been reported. There is a complex sense of limb foreignness, including misidentifying the limb as the examiner's. Sometimes the limb is personified: patients have named their alien hands. Patients are usually unaware of it, and could display signs of inattention of the affected limb, perceiving that it is not theirs. The movements are sometimes so bizarre that they may be misinterpreted as functional. Common causes include anterior cerebral artery strokes, midline tumors, and neurodegenerative illnesses. Rarer causes include spontaneous pneumocephalus, migraine aura, seizure and Parry–Romberg Syndrome, a presumed autoimmune disorder with progressive facial hemiatrophy.

**Discussion and conclusions.**– The course of AHS and its prognosis has not been systematically reported. The prognosis has varied from a decrease in AHS symptoms within 1 week to persistence of the symptoms after 12 months. Symptoms usually decrease in 68% of patients, whereas symptoms persisted in 32%.

### **Value the madman: Phenomenological psychopathology in the poetry of Raul Gomez Jattin**

J. Klahr\*, D. Matallana

Pontificia Universidad Javeriana, Psychiatry and Mental Health, Bogota, Colombia

\* Corresponding author.

**Introduction.**– Descriptive psychopathology aims to define abnormal experiences described by patients in order to establish their universality. Through phenomenology, it avoids focusing on pure content of ideas since they are not objective in nature and might lead to erroneous conclusions on causation. Raul Gomez Jattin was a well-known Colombian poet thought to have suffered from schizophrenia. As one biographer pointed out, in his work there is no virtual distance between the poetic self and the real self. The purpose of our work is to discuss the relevance of the content of ideas in psychopathology by analysing the psychotic experience over poetic metaphors from one author.

**Objectives.**– We intent to describe his experience on psychosis, his main suffering, his cognitive decline and his situation as an inpatient on his multiple hospitalizations through his work. Also, we would like to discuss the importance of the content of ideas not only for diagnostic purposes, but also as a tool for therapeutic alliance.

**Methods.**– We analysed his oeuvre chronologically by focusing on the content of his metaphors. Then, we compared the information with other material such as interviews and biographical information.

**Results.**– We were able to recognize ambivalence for his loved ones, grandiosity, persecution, perceptual experiences and anxiety among other symptoms. We concluded that his condition was episodic and filled with affective symptoms although deteriorating in nature.

**Conclusions.**– Minding content of ideas leads to a better understanding of the psychotic experience and could be helpful in the development of a better doctor-patient relationship.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### What helps psychiatrists to be more resilient?

M. Kudumija Slijepcevic<sup>1\*</sup>, N. Jovanovic<sup>2</sup>, G. Lydall<sup>3</sup>, D. Vidovic<sup>4</sup>, G. Bilonic<sup>5</sup>

<sup>1</sup> University of Applied Sciences Bjelovar, Department of Nursing, Bjelovar, Croatia; <sup>2</sup> Queen Mary University of London, Bart's and London School of Medicine and Dentistry, London, United Kingdom; <sup>3</sup> University College London, UK and Health & Social Care Dept, London, United Kingdom; <sup>4</sup> University Psychiatric Hospital Vrapce, Department of Psychophysiology, Zagreb, Croatia; <sup>5</sup> Sahlgrenska University Hospital Gothenburg, Clinic for Affective Disorders, Gothenburgs, Sweden

\* Corresponding author.

Resilience can be defined as one's capacity to recover from trauma and stress. Psychiatrists experience a set of speciality-specific stressors such as emotionally demanding therapeutic relationships, personal threats from violent patients, patient suicide and other rare but serious events, and perceived stigma of the profession. Being able to successfully cope with everyday work-related stress is essential for maintaining good mental and physical health.

This study aims at exploring factors involved in the development of work-related resilience among working psychiatrists.

We have interviewed five psychiatrists who work in three different countries (Croatia, Sweden and UK).

Our findings indicate that resource oriented approaches may be helpful in building resilience. We will provide a set of examples and recommendations that might help younger colleagues to build their resilience and the resilience of our profession.

### Psychiatric intervention in Tuvalu: Prior study

C.Y. Kuo

Chung Shan Medical University Hospital, Department of Psychiatry, Taichung, Taiwan R.O.C.

**Introduction.**– Tuvalu, which is one of Polynesia island nation and located in the south Pacific ocean, consisted of three reef islands and six true atolls. The limited medical service was supplied by the Princess Margaret Hospital (PMH), which is the only hospital in Tuvalu.

**Objectives.**– There has never been any psychiatrist providing the medical service in Tuvalu. Based on the cooperation between PMH and Chung Shan Medical University Hospital (CSMUH) of Taiwan, we provided the prior psychiatric intervention in Tuvalu.

**Methods.**– The mobile medical team of CSMUH had annually medical supply and helps in Tuvalu. During the stay of Oct. 18th to 27th in 2016, one psychiatrist from Taiwan joined the out-patient service in PMH. The medical staff of PMH announced this information by the public radio and invited potential patients to the

psychiatric out-patient service. The psychiatric out-patient service provided the diagnostic interview, psychotherapy, further medical treatment and follow up.

**Results.**– There were 31 patients and 63 visits (including the followed up patients) in the psychiatric out-patient service during the six work days. 64.5% were female and the age was mostly during 30 to 44 years old (41.9%). The psychiatric diagnosis were depression and anxiety disorders (45.2%), developmental disorders as mental retardation (38.7%), psychosis (25.8%), organic brain syndrome (25.8%), and others (autism, internet using disorder, attention-deficit hyperactivity disorder, domestic violence and partner relational problem).

**Conclusions.**– As the first psychiatric intervention in Tuvalu, the mental illness there should be noted and needs more attention. The further follow up is also needed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Implication on the training program for clinical psychologists in South Korea

D. Lee\*, C.R. Baeck, S.W. Choi

Duksung Women's University, Clinical Psychology, Seoul, Republic of Korea

\* Corresponding author.

**Objectives.**– The purpose of this study is to recognize and analyze the present state of training system and create a revised manual for clinical psychologists in Korea.

**Background.**– Since Korean Clinical Psychology Association (KCPA) was founded in 1964, clinical psychologists have continuously becoming experts in the field of mental health. While Korea's clinical psychology has attained boundless progress, the need for discussions on the institutional system is also increasing.

**Method.**– We conducted a survey of the clinical psychology training system in Korea. Through this survey of training programs and trainees and licensed psychologists welfare benefits, we sought to identify problems and seek solutions. it was divided into groups of trainee and licensed psychologist, and a total of 80 trainees and 281 licensed psychologists participated in the survey.

**Results.**– The results of a survey conducted by the trainee showed that the poor welfare benefits, including wages, was pointed out first, and that it felt burdened by heavy workload. The results of the licensed psychologists have indicated that a detailed answer to how clinical psychologists improve their activity and enhance the qualification of the experts.

**Conclusions.**– Through the results of the survey, we identified the problems faced by the current training system. Also, it has been suggested that the direction for the next study will be based on the actual revision of the manual. Consequently, we hope that a better training/qualification system will be adopted by revising new manuals for the clinical psychological training system, which is the goal of our research and development system.

### Conflict management in the school context: Revision on the practice

C. Lima\*, M. Silva, S. Gonçalves, A. Salgueiro

ForAll, Desenvolvimento Pessoal e Bem-Estar, Lda, Psychology, Paredes de Coura, Portugal

\* Corresponding author.

Conflict is perceived differently in the literature. On a negative light Bilhim (1996) presents conflict as a process in which subject A tries to purposefully hinder subject B's efforts towards the achievement of their goals and the development of interests, using any way of opposition that results in subject B's frustration. On the other hand, Ferreira, Neves and Caetano (2011) understand conflict as necessary and positive, stimulating innovation and creativity in regards to behaviours, attitudes and cognitions.

Torrego (2003) presents conflict mediation as a process in which a third person helps mediate the conflict resolution between two sides. In this way, and highlighting the advantages presented by Uranda in the school context, this poster summarizes strategies, benefits and agents in this specific intervention area.

Based on Piaget's studies, Telma Vinha refers that conflict is present on daily life. When conflict arises in the classroom it gives us clues about what the students need to learn. Because of this it becomes relevant to ponder the strategies that we can use in this context, so that children experience conflict as an opportunity for reflection and self-improvement.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0559

### **Collaborative circularity: A new paradigm**

G. Cunha<sup>1,2</sup>, C. Lima<sup>3,4\*</sup>, M. Bravo<sup>2</sup>, M. Figueiredo<sup>4,5</sup>

<sup>1</sup> Universidade Lusófona do Porto, Investigation, Porto, Portugal; <sup>2</sup> MEDIARE-multiportas, Investigation, Porto, Portugal; <sup>3</sup> ForAll - Desenvolvimento Pessoal e Bem-Estar, Lda., Psicologia, Paredes de Coura, Portugal; <sup>4</sup> CINTESIS, Center for Health Technology and Services Research, Investigation, Porto, Portugal; <sup>5</sup> Escola Superior de Enfermagem do Porto, Investigation, Porto, Portugal

\* Corresponding author.

The social evolution resulting from globalization, from new health and social needs, coupled with the transformations of family configurations, have determined the emergence of new paradigms, in an attempt to give an integrated response to current problems.

This integrative perspective, operating through complementarity between different areas of intervention, has as its primary purpose the training of families and individuals in the identification and mobilization of strategies for solving their problems and/or minimizing their needs. Examples of current situations that generate conflicts and difficulties in establishing effective communication patterns that imply dysfunctions in the maintenance of a healthy experience are the events associated with divorce, the regulation of parenthood, the maintenance of a positive identity after divorce and the establishing of adequate conditions for children and parents to adjust and adapt to daily living based on the evident fact of the existence of "two families". Other relational/behavioural problems require this complementarity of intervention, characterized by the contextual difficulty of establishing consensual standards regarding the functioning of the family system and/or its subsystems.

We intend to describe conceptual and interventional aspects regarding Family Mediation, Collaborative Law, Psychotherapy and Family Therapy, integrating Psychoeducational Therapy as a transversal strategy in what refers to the intervention areas mentioned.

We emphasize the specificities of each area, which enables the referencing in a paradigm of collaborative circularity. On the other hand, we emphasize transdisciplinarity as a fundamental element in the maximization of the systems' self-organization, implying greater gains in health potential, greater social value and lower economic costs for citizens&society.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0560

### **With five senses**

E. Mancha<sup>1\*</sup>, M.J. Leñero Navarrete<sup>2</sup>, H. Saiz García<sup>3</sup>, Y. D' Hiver Cantalejo<sup>4</sup>

<sup>1</sup> Servicio Navarro de Salud, CSM Ansoain, Pamplona, Spain; <sup>2</sup> Sacyl, Hospital Universitario Río Hortega, Valladolid, Spain; <sup>3</sup> Servicio Navarro de Salud, Complejo Hospitalario de Navarra, Pamplona, Spain; <sup>4</sup> Sescam, Hospital Universitario de Guadalajara, Guadalajara, Spain

\* Corresponding author.

*Objectives.*– The phase of prodromal initial manifestations or phase of high risk of developing psychosis, is characterized by a deviation from emotional, cognitive, behavioural or social functioning, and by the presence of non-specific prodromes. Delays in treatment may lead to an alteration in vital circumstances, such as school and work failure, self-harm, changes in interpersonal relationships, intrafamily conflicts. . .

*Methods.*– Analyze the case of a 32-year-old female patient with a history of abusive alcohol intake, occasional self-injurious behaviours through self-piercing cuts in the arm, hypersensitive and overly sincere temperament traits. It has the diagnosis of borderline personality disorder. The radical change in their attitude is striking: inhibition, bradypsychia, dysarthric speech, bradyphyma, increased latency of response, totally dull affection. . .

*Results.*– The first diagnostic hypothesis after assessing this patient is that of an adaptive disorder in a patient with few intellectual resources. As a second diagnostic hypothesis, we propose that we are facing a first psychotic episode with a predominance of negative symptomatology in a patient with a history of borderline personality disorder. First-order Schneider's symptoms are explored and although no hallucinatory experiences are present in the present.

*Conclusions.*– It is of vital importance that we make adequate diagnoses and in our evaluation "put the five senses". It is not the first time that a mental retardation is diagnosed when we are facing an incipient psychosis. Therefore, the intervention in this phase is aimed at detecting the disorder with the highest precocity possible and to establish the treatment most appropriate to each situation.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Artistic creativity of psychotic patients in words and in music**

V. Meden Klavora

Vlasta Meden Klavora, Prekomorskih brigad 10, Tolmin, Slovenia

Human need to express oneself is as old as the history of man. The earliest examples of human creativity are the paintings, carvings, sculptures found in the cave paintings and creations of ice age Europe. The oldest evidence is the Chauvet-Pont-d'Arc Cave in France which contains some of the best preserved figurative cave paintings in the world.

In respect to artistic creativity of the people with psychotic disorders, it was found out, that it is as old as the institutions in which they were locked up. One of the first proof of their artistic creativity are graphic leaves painted by the English artist William Hogarth in 1735 which he published with other paintings in the series of pictures entitled The Rake's Progress. In these pictures, the painter with mental disorder is also depicted.

The lecture describes the history of the first exhibitions and collections of artistic creations of psychotic patients, of which the

most important is the collection of Hans Prinzhorn in Heidelberg, Germany. It will also mention the influence of Adolf Wölfli, one of the most notable creators, who influenced the Jean Dubuffet's concept of art brut at the middle of the 20th century. The exhibitions and the collections inspired the expressionist and surrealist movements at the beginning of the 20th century.

At the end of the lecture I will introduce the artistic creativity of Hinko Smrekar. His drawings reflect the history of Slovenian psychiatry before the Second World War.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0562

### Improving communication skills in medical students

M. Milazzo<sup>1,2\*</sup>, G. Gurtner-Griffaton<sup>2,3</sup>, C. Pham-Dinh<sup>2,4</sup>, F. Ligier<sup>2,5</sup>, J.P. Kahn<sup>1,2</sup>

<sup>1</sup> Centre Psychothérapique de Nancy, Pôle de psychiatrie et psychologie clinique, Laxou, France; <sup>2</sup> Université de Lorraine, Faculté de Médecine, Vandœuvre les Nancy, France; <sup>3</sup> Centre Psychothérapique de Nancy, Centre Medico Psycho Pedagogique, Metz, France; <sup>4</sup> Centre Hospitalier Spécialisé de Lorquin, service médico psychologique régional, Metz, France; <sup>5</sup> Centre Psychothérapique de Nancy, Service de Psychiatrie Infanto juvénile, Laxou, France

\* Corresponding author.

*Background.*– Although teaching communication skills is a developing area in medical schools, there is still no 'gold standard' for evaluating such skills. This research aims to assess the reliability, validity and significance of verbal and non-verbal communication attitudes.

*Method.*– In order to improve therapeutic alliance between doctor and patient, ten 4<sup>th</sup> and 5<sup>th</sup> year medical students were enrolled in a medical psychology training program and participated in two simulation sessions at the start and the end of their training, using the same scenario. Two trained investigators watched the recording of the clinical situations and each of them independently measured a series of parameters for verbal signals (duration of speech, number of interruptions, acceptance of the doctor's preconizations) and non-verbal signals (number of times tone of voice raised, nervousness, proxemics, posture).

*Results.*– The variables relating to speech duration, number of times the voice was raised, acceptance of the doctor's preconizations) examination, nervousness of the patient and the doctor's proxemics showed a significant improvement between the two sessions, while maintaining good inter-rater reliability.

*Conclusion.*– A significant improvement can be seen in the students' communication skills between the first and the second sessions. The criteria used to assess these skills are mainly valid and reliable. It would be interesting to use these parameters to evaluate the development of medical students' communication skills in the future.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0563

### Clozapine-induced myocarditis: Case report and literature review

M. Mlika<sup>\*</sup>, A. Bejjar, M. Daoud, O. Moula, R. Ghachem Razi Hospital, B, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– Myocarditis is a rare but potentially life-threatening cardiac complication of the use of Clozapine, a second generation neuroleptic with established efficacy in resistant schizophrenia

*Methods.*– We present the case of a 26-year-old man who developed clinical signs of clozapine-induced myocarditis, two weeks following the initiation of clozapine treatment for psychosis.

*Objectives.*– We question whether a more defined monitoring pathway for myocarditis should exist, due to ambiguity around clinical investigation and high level of risk to these patients.

*Results.*– A 26-year-old man diagnosed with schizophrenia. He was previously treated with risperidone and haloperidol with no response. As NICE guidelines dictate, we started a treatment with clozapine. The treatment was initiated at 25 mg per day, and titrated up to 25 mg every 3 days. On the second week after the start of the clozapine titration, our patient had chest pain and palpitations. He was afebrile. Electrocardiography showed sinus tachycardia. Blood tests showed elevated troponin 736 ng/L (nle <19 ng/L) and mildly raised eosinophils. The clozapine has been stopped. The patient was transferred to the cardiology department with high suspicion of medication myocarditis. Cardiac ultrasound showed an ejection fraction at 55 percent without segmental kinetics abnormalities. On the basis of these results the patient was treated with captopril, atenolol and acetylsalicylate. The heart rate returned into normal level after 2 days of treatment, also did the troponin level after 15 days.

*Conclusion.*– This case highlights the importance of rapid cardiac assessment when patients receiving clozapine presents any cardiac symptoms.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Physical disabled students, aggression and verbal interaction

M. Mohammadi

Education Organization, physics, Tehran, Iran

Due to the increase of population, especially in mega cities of Iran and lack of educational facilities for all of children to study, in some schools the students with physical disabilities and mental disorders are studying with normal students. Apart from problems in academic achievement these students encounter in school compared with normal students, they are at the risk of depression and isolation. The linguistic interaction of these students with normal students is limited. There was designed a study to investigate the linguistic competence of physically-disabled students in the class and school yard. With the coordination with the school authorities, some students carried specific MP3s to record their conversations with physically-disabled students. Their behaviours in the school yard were monitored and recorded. It seems that the main culprit of their situation is known to be parents. In physical conflicts followed by expression of wrong words, they are the first side to shout and request for help from the authorities, as they knew that the authorities give rights to them. Reduction of school behaviour score which is a significant parameter in continuing education is awaiting the normal students involving in physical conflict with physically disabled students. The expectations of the teachers in the schools must be lowered of these students. The increase of linguistic interaction through collective songs can be a good solution for these students to evacuate their hostile feelings. Educating parents to consider the natural differences can help the remedy to be complemented.

### Migration, women and education: Iran case study

M. Mohammadi

Education Organization, physics, Tehran, Iran

Migration of villagers to cities can be damaging the women's status in social affairs and promotion of family. One of the most controversial problem of rural dwellers' migration to big cities is the occupation of women in low level jobs. The villagers mostly have little skills and women are deprived of knowledge and skills to cope with the new situation so that they can not find good jobs to meet the family needs. The low level jobs and income by men in black market after having migrated to the cities force women to adopt to work in dirty jobs or work as maid at homes to increase the financial capacities of the family and provide educational facilities for children. This can bring about many dangers for the family. First, children are deprived of family interaction most part of the day and most of them become trapped with illegal gangs of drug distribution. Second, women can be exploited with the burglary and shoplifting groups who use low educated and poor women. The destiny of most of these women is prison and being away from the family which in turn worsens the situation. Vocational skills provided by NGOs have helped women to sustain their life but they are not enough. The factors involving with the situation of these women are the main focus of this paper.

### Psychology in the city

F. Mozaffarnejad<sup>1</sup>, A.R. arsiya<sup>2</sup>, N. Nazarboland<sup>3</sup>

<sup>1</sup> Tehran university, psychology, tehran, Iran; <sup>2</sup> Islamic Azad University Central Tehran Branch, Architecture and Urban Planning, Tehran, Iran; <sup>3</sup> Shahid Beheshti University, psychology, Tehran, Iran

\* Corresponding author.

Psychology and urban planning have been interacting for a long time. As we look closely at cities, we find that the two sciences of psychology and urban planning have grown alongside. It is therefore not in vain that the emerging science of environmental psychology can be considered as the fruit of the psychological tree in the garden of city. Thus, along with studying impacts of early psychologists on urban planning, this study seeks a meaningful relationship between psychology and urban planning. For example, we found that concepts as justice in utopia and its management, the sense of belonging, and the importance of the leader in Plato's view, have become the famous term of justice-centered city in urban planning. A similar pattern can be seen in the opinions of Jean-Jacques Rousseau and John Locke. In this regard some exact terms such as naturalism and the city as a phenomenon in Rousseau's philosophy are also found in urban science with almost same meaning. Rooted in John Locke's approach, it becomes clear that the branch of behavioural thinking, which is one of the most important factors in today's urban planning, is derived from psychological and philosophical, educationalism, behaviourism and associative psychology. Therefore, the identification of approaches of these early thinkers and exploring their ideas in today's urban planning can help to recognize the interactions between psychological aspects and urban planning and thus understanding the issues that affect human's life and vice versa.

### Psychogenic nonepileptic seizures

#### – Case report

L. Oliveira<sup>1</sup>, F. Fonseca<sup>2</sup>

<sup>1</sup> Philippe Pinel Municipal Institute, department of psychiatry, Rio de Janeiro, Brazil; <sup>2</sup> Paulo Niemeyer State Institute of the Brain, department of psychiatry, Rio de Janeiro, Brazil

\* Corresponding author.

**Introduction.** – Psychogenic Nonepileptic Seizures (PNES) are sudden clinical manifestation and transitory on the motor sphere, sensory, cognitive and autonomic, being other times called “pseudo crisis” or “hysterical seizures”. The differential diagnose with epilepsy is a challenge for clinical, neurologists and psychiatrists.

**Objectives.** – Diagnosis and clinical management of non epileptic crises.

**Methods.** – Information of the clinical case of a patient with psychogenic non epileptic psychogenic.

**Results.** – S., 14 years old, started treatment due to “fainting” crises preceded of involuntary head, core and other members movements, and generalized tremors, trance crisis and possessions which she believed to be possessed by the devil. In general, being unleashed by stressful situations, to the point of having 20 crises a day. Referred to somatic complaints (headache, abdominal pain, nausea). Interictal electroencephalogram with focal alterations, cranium tomography with no alteration. No alterations on the physical and neurologic exams. Medicated with risperidone 1,5 mg/day, fluoxetine 20 mg/day, clonazepam 1 mg/day and weekly psychotherapy. It evolved with improvements on the crisis frequency (4 crisis/month) after 2 months of treatment.

**Conclusion.** – Non epileptic crisis (NEC) comprise in many physiological or psychological conditions that simulate epileptic seizures, this one being associated as NEC in the same person. Severe traumatic events, physical and sexual abuses during the childhood or teenage period, which generates suffering to the person, could also generate a development of convertible and dissociative reactions in patients with epilepsy. Videoelectroencefalographic monitoring is the most accurate diagnostic resource, once its clinical and semiological criteria are not specific. The therapeutic approach includes psychotherapy and psychotropic.

### Psychotropic drugs during pregnancy

S. Nascimento<sup>\*</sup>, M. Moreno, T. Filipe, M. Mendes, D. Pereira, J. Reis Centro Hospitalar Psiquiatrico De Lisboa, Psiquiatria, Lisboa, Portugal

\* Corresponding author.

**Introduction.** – Psychiatric conditions are potentially life threatening illnesses that can be successfully treated by psychotropic drugs, even during pregnancy. Initially, the clinical recommendation has been to discontinue the psychiatric medication, especially during the first trimester. The choice of whether to prescribe a drug during pregnancy is difficult and must be take into account the risks and benefits to the mother and the unborn infant.

**Objectives.** – The authors conducted a non-systematic review about the effects of psychotropic drugs in pregnancy.

**Methods.** – The authors have conducted an online search in Pub Med and Medscape with the terms “psychotropic drugs and pregnancy”, from 2011 until 2017. From the outcome, the articles considered to be relevant were collected, analysed and summarized.

**Results.** – In the past decades, the latest prospective studies have showed that most classes of psychotropic drugs seem to be relatively safe during pregnancy, also, untreated psychiatric disorders

during this period are associated with risks for both mother and child, including tragic outcomes like suicide and infanticide; also, psychotropic drugs should not be precipitously stopped, and a comprehensive evaluation and individualized treatment plan is needed for these patients.

**Conclusions.**– The lack of evidence in several areas means that definite conclusions cannot be made about the risks and benefits of all psychotropic drug use in pregnancy, and future work should focus on the proper management, including prophylactic dosing strategies and management before and after delivery.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Dealing with attention deficit hyperactivity disorder in an EFL classroom: teachers' strategies and students' engagement**

D. Luna, O. Uribe, C. Navarro\*

Universidad Industrial de Santander, Languages School, Bucaramanga, Colombia

\* Corresponding author.

This case study analyzes the impact that the strategies used in an EFL second-grade class at Instituto de Problemas de Aprendizaje (IPA) have on the level of engagement of four 8-10-year-old children diagnosed with Attention Deficit Hyperactivity Disorder (ADHD). The investigation was carried out in Colombia and the participants were a female teacher and her 15 students: four with ADHD, one girl and three boys, and 11 with other pathologies. The sampling of this investigation was specifically the four children with ADHD and the teacher. We applied a questionnaire and an interview to the teacher that contained close and open ended, short answer questions regarding beliefs and strategies that deal with ADHD. Additionally, we observed five English classes to identify the teacher's strategies and the level of students' engagement. By using a mixed method and documentary research, we found two significant aspects. First, students' level of engagement was high in three classes and medium in two. Second, the teacher implemented the strategies that we discovered in the literature, and had a positive impact on the four ADHD students, by helping them get focused and active during the five EFL classes. Nevertheless, more time for the observational sessions and further research are needed as there might be other possible influences on the four children's engagement.

### **Psychiatry in context of global health policy**

E. Neu<sup>1\*</sup>, M.C. Michailov<sup>1</sup>, B. Lichterman<sup>2</sup>, R. Neu<sup>1</sup>, T. Senn<sup>1</sup>, M.L. Gräfin von Brockdorff<sup>3</sup>, M. Holler<sup>4</sup>, C. Lütge<sup>5</sup>, M. Schratz<sup>6</sup>, G. Weber<sup>7</sup>

<sup>1</sup> Inst. Umweltmedizin c/o ICSD e.V., PharmaEVPhysiology, Munich, Germany; <sup>2</sup> Russian Postgrad., Med. Acad., Moscow, Russia; <sup>3</sup> Univ. München, Fac. Law, Munich, Germany; <sup>4</sup> Univ. Hamburg, Fac. Economics Dean, Hamburg, Germany; <sup>5</sup> Techn. Univ. München, Inst. Ethics Dir., Munich, Germany; <sup>6</sup> Univ. Innsbruck, School Education Dean, Innsbruck, Austria; <sup>7</sup> Univ. Lxbg. and Vienna, Fac. Psychology Dean, Vienna, Austria

\* Corresponding author.

**Objectives.**– Psychiatry is of fundamental importance for total human health (spiritual-mental-emotional.-social-somatic): Globalization needs renewal of psychiatry by new philosophical fundamentals related to scientific theory, metaphysics, ethics, aesthetics. Social responsibility of psychiatry needs renewal of scientific organization beginning with EPA/WPA as example.

**Methods.**– Theoretical fundamentals

**Results.**– Conception–proposals concerning:

– *enlargement of Executive Committee of EPA/WPA* by a. election of permanent 3-honorary (triumvirate principle: moral support, continuity), 3-presidents (fixed term), 3-general-secretaries; b. interdisciplinary commission to EPA/WPA incl. scientists from philosophy, psychology, physiology, pharmacology, internal-medicine, etc.; c. scientific-political commission–incl. representatives of international societies: Philosophy/FISP, medicine/CIOMS, psychology/IUPsyS, physiology/IUPS, etc.; d. Election of permanent (seniors: continuity)& fixed-term (flexibility) members to the Executive-Committee: (sub-)continental representatives from important countries (Afro-West-Asia; America; Australia, Asia-China, India, Japan; Europe: France, Germany, Russia, Spain, Italy, etc.);

– implication of *interdisciplinary topics to congress-programmes: occidental&oriental* medical-philosophy, psychology, psychiatry, etc. esp. Buddhist/Tibetan-Zen, Chinese/Tai-chi, yoga, others;

– replacement of congress/conference abstract-books by *proceedings/proper scientific journals*, similar to other societies (IUPsyS/Int. J. Psychol., SIU/Urology);

– creation of an International Academy of Psychiatry to EPA/WPA with clinics/institutes related to international university (proposed by Brit. Nobel Laureate Bertrand RUSSELL and Gustav MENSCHING) via network of national scientific-units: Common interdisciplinary research/educational programmes, personnel (similar to UNO-employees), possibility for whole life work, etc.

**Conclusions.**– Realization of proposals (1.-4) could increase scientific-political authority of EPA/WPA, continental&national societies for psychiatry, leading to model for future psychiatric education/research&application in the praxis, supporting UNO-Agenda21 for better health, education, ecology, economy in all countries.

### **Determination of the options of communication students on stigmatization against mental illness**

S. Nurdan<sup>1\*</sup>, I. Işık<sup>2</sup>, C. Zeren<sup>1</sup>, Z. Yılmaz<sup>3</sup>

<sup>1</sup> Yeditepe University Hospital, Nursing, İstanbul, Turkey; <sup>2</sup> Yeditepe University Faculty of Health Science, Nursing, İstanbul, Turkey; <sup>3</sup> Private Laser Medical Center, Nursing, Antalya, Turkey

\* Corresponding author.

**Aim.**– This study is carried out on the students who study at the communication faculty of a private university in Turkey. In this study, it was aimed to determine the opinions of the students about the stigma made to the individuals with mental illnesses and to learn the views and suggestions for the prevention of stigmatization

**Methods.**– As a qualitative study, this research was conducted with 12 students who read in the communication faculty of a foundation university in İstanbul in the 2016-2017 academic year and agreed to participate in the study. The data were collected by face-to-face interview method.

**Results.**– In individual in-depth interviews, 83.3% of the students in order to prevent stigmatization for mental illnesses argue that health programs should be done by health workers. In addition, 75% argue that society should be informed correctly and 50% of the students stated that adding courses to universities would play a major role in preventing stigmatism against mental illness.

**Conclusion.**– In the study, it was concluded that communication faculty students found the behaviour of stigma against mental illness wrong and according to participants' answers, the employees of the newly emerging media sector will approach the psychiatric patients more devoted, empathic, tolerant and respectful when they are reporting news or in the media. The fact that those who participate in the research will take the role of media in the future makes this research important.

### **Sertraline induced microscopic colitis:**

#### **A case report**

S. Petrykiv<sup>1</sup>, M. Arts<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> University of Groningen- University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands; <sup>2</sup> Mental Health Care-West North Brabant GGZ-WNB, Department of Geriatric Psychiatry and Neuropsychiatry, Bergen op Zoom, The Netherlands; <sup>3</sup> Mental Health Care Friesland GGZ-Friesland, Department of Geriatric Psychiatry, Groningen, The Netherlands; <sup>4</sup> Leonardo Scientific Research Institute, Department of Geriatric Psychiatry and Neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

**Introduction.**– Microscopic colitis (MS) is a rare inflammatory disorder of the colon, which presents with diarrhea, abdominal pain, weight loss, and has a significant impact on the quality of life. Case reports suggest that the use of SSRI's is associated with MS. However, no direct link between SSRI's and MS has been shown. Interestingly, current study provides a case of an onset of colitis de novo right after the initiation of sertraline therapy and its complete remission after sertraline cessation.

**Objectives & aims.**– Case report of a patient with an established MS after initiation of treatment with sertraline, followed by a review of the literature on the association between SSRI's and MS.

**Methods.**– An English-language literature search was conducted using Pub Med, EMBASE searching for case reports and observational studies reporting MS among patients using SSRI's.

**Results.**– A 44-year-old female patient with medical history of Obsessive-compulsive disorder was treated with sertraline 50 mg. 1dd1. Two months after initiation of sertraline she developed diarrhea, abdominal discomfort and weight loss over the past 2 months. The patient was referred to the gastroenterology clinic one month later. A total colonoscopy was performed and revealed no abnormalities. Random biopsies were taken from the ascending and descendent colon, revealing the diagnosis of MC. Sertraline was discontinued, budesonide was prescribed, and two months later diarrhea was resolved.

**Conclusion.**– Although rare, MC must be excluded in cases of chronic diarrhea. Upon MC diagnosis, suspected medication should be discontinued even before starting steroid therapy.

### **Untangled: Breaking the cycle**

O. Reda

Providence Health System, Psychiatry, Portland, USA

Natural and man-made disasters are sadly becoming common phenomena, and unfortunately, they are becoming almost the norms these days.

Due to their personal and intimate nature, man-made disasters like abuse, rape, and torture seem to affect the psyche of their survivors more negatively than natural disasters, as the latter seem to indiscriminate.

The invisible wounds and mental scars of such experiences can go unnoticed, leading to long-term dysfunction and at times trans-generational transmission of the impact of trauma.

The suffering might extend beyond psychiatric symptoms to include somatic, academic, vocational, and relational struggles.

As psychiatrists, we can either regress, react in fear, anger, or despair, and be part of the problem, or we can choose resilience and become active part of the solution. But what can psychiatrists really and realistically do in response to such incidents?

Violence puts us face to face with the dark and evil side of humanity, but choosing to take part in the healing process confirms our unshaken belief that love always trumps hate. Humans are not only capable of destruction and bloodshed, but are also capable of creating a healing environment and safe spaces for survivors to thrive.

### **The dissemination of the French school of psychiatry and its impact in the world**

S. Richa<sup>1\*</sup>, M. Masson<sup>2</sup>, S.P. Tawil<sup>3</sup>

<sup>1</sup> Saint-joseph University, Psychiatry, Beirut, Lebanon; <sup>2</sup> Clinique Garches, Psychiatry, Paris, France; <sup>3</sup> Sainte Antoine Hospital, Psychiatrie, Paris, France

\* Corresponding author.

The French School of Psychiatry has characteristics which are proper to it, and it conveys many notions related to health care, in addition to the accompaniment and the comprehension of mentally ill people and mental illness. These notions are specific to the French culture.

Thus, famous French psychiatrists have described many syndromes and discovered the first neuroleptic, chlorpromazine. Among these psychiatrists: Pinel, Esquirol, Janet, Ey, Delay and Deniker. Furthermore, the first World Psychiatry Congress was held in Paris in 1950. It was a major congress for many specialists from all the world have participated and strongly influenced the future of psychiatry in the world.

We will be describing the French School of Psychiatry's impact in the world (South America) and mainly in the French-speaking world (Romania, Africa, Lebanon and Quebec). We will also be discussing the tools, associations and publications which participate in the dissemination of this school of thought's knowledge.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Use of mechanical restraints in inpatient mental health units

S.L. Romero Guillena<sup>\*</sup>, M.Z. Perez Sosa, C. Muñoz Cauqui, J. Banda Moruno

U.G.C. Salud Mental área hospitalaria Virgen Macarena, Department of psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– In June 2016, the Committee on Bioethics of Spain approved the ethical criteria for and made some recommendations on the use of mechanical and pharmacological restraints by social and health care services.

**Objectives.**– The aim of this study was to analyze the type of mechanical restraints (MR) used in the Inpatient Mental Health Unit of the Virgen Macarena Hospital in 2015.

**Methods.**– We built a database of the MRs used in 2015 including the following variables: age, gender, reason for use, diagnosis and mean duration of MR. A descriptive observational study was conducted.

**Results.**– There were 854 admissions to the Inpatient Mental Health Unit in 2015. MR was used 84 times in 62 inpatients (7.25%). The mean duration of MR was 456.8 minutes (S.D.345.5). The mean age of patients subjected to MR was 38.84 (SD 11.40), of whom 64.5% were male. The main reason for MR was psychomotor agitation (51.6%) and the most frequent diagnosis was schizophrenia (32.8%), followed by mental retardation (16.3%).

**By diagnosis.**– MR was applied to 69.5% of inpatients with mental retardation, 19.5% and 16.6% of patients with schizophrenia. No statistically significant differences were observed in duration of MR between: Age and gender, although it was higher in male. (8.02 hours in male and 6.82 hours in female)

**Conclusions.**– Mechanical restriction was employed in 7.25% of inpatients in our unit. The profile of patients subjected to MR was a man of 38.84 years of age, presenting an episode of psychomotor agitation. The patients at a higher risk for MR were those with a diagnosis of mental retardation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Empathy levels in Romanian medical students

R.S. Romosan<sup>1\*</sup>, L. Dehelean<sup>1</sup>, M.M. Minciuna<sup>2</sup>, S. Milos<sup>2</sup>, A. Olteanu<sup>2</sup>, R. Balint<sup>2</sup>, A.M. Romosan<sup>3</sup>

<sup>1</sup> “Victor Babes” University of Medicine and Pharmacy, Neurosciences, Timisoara, Romania; <sup>2</sup> Timisoara Psychiatric Clinic, 1st year resident- Psychiatry, Timisoara, Romania; <sup>3</sup> “Victor Babes” University of Medicine and Pharmacy, Neurosciences, PhD Candidate, Timisoara, Romania

\* Corresponding author.

**Introduction.**– Being able to comprehend and connect with the emotional state of another person is essential for establishing a successful interaction between patients and health care providers.

**Objectives.**– The aim of this study was to assess empathic response in a sample of Romanian medical students: general medicine (GM), dental medicine (DM) and general nursing (GN) students.

**Methods.**– The study was carried out between 2015 and 2016 on 91 sixth-year GM students, 94 4<sup>th</sup> year DM students and 87 4<sup>th</sup> year GN students, all medical undergraduates of the University of Medicine and Pharmacy, Timisoara. To assess the level of empathy, we used the Empathy Quotient (EQ), a 60-item self-report inventory.

**Results.**– GM and DM students had lower total EQ scores than the general population, whilst GN students scored higher than the gen-

eral population. Also, GM students had lower EQ scores than DM students.

**Conclusions.**– Given the results, courses to enhance empathy in medical students could be helpful for medical students to become more sensitive in their interactions with patients, but also with other health-care team members, family and entourage.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Eleven years of clozapine experience in autism spectrum disorder: Efficacy and tolerance

M. Rothärmel<sup>1\*</sup>, F. Szymoniak<sup>1</sup>, C. Pollet<sup>2</sup>, L. Beherec<sup>3</sup>, A. Rosier<sup>4</sup>, O. Guillin<sup>1</sup>

<sup>1</sup> Centre Hospitalier du Rouvray, University Department, Sotteville-lès-Rouen, France; <sup>2</sup> Clinique Océane, Psychiatry, Le Havre, France; <sup>3</sup> Centre Hospitalier Maison Blanche, Department 7G23, Paris, France; <sup>4</sup> Centre Hospitalier du Rouvray, Centre de Ressource pour l'Autisme de Haute-Normandie, Sotteville-lès-Rouen, France

\* Corresponding author.

**Introduction.**– Autism spectrum disorders (ASD) are neurodevelopmental disorders that comprise core symptoms (repetitive, stereotyped behaviour and social communication disabilities). Moreover, many patients with ASD have disruptive behaviours like aggressiveness, temper tantrums or self-injury that interfere with their quality of life. These behaviours represent a common target for pharmacology. Beherec et al, in 2011, showed the efficacy of clozapine on disruptive behaviours for 6 patients with autism who were aged 16 years-old at least.

**Objectives.**– The aim of this study is to assess both the efficacy and tolerance of clozapine on the patients included by Beherec on a long-term: after 6 years and back the results on more patients.

**Methods.**– We conducted a retrospective study of the changes in aggressive behaviours for all patients with ASD treated with clozapine from 2011 to 2017. Disruptive behaviours and side effects were monitored during the 1 to 6 months before and after the initiation of the clozapine and on long term.

**Results.**– All the patients of Beherec's study were still on clozapine after an average of 11 years, with the same efficacy and no serious side effect. Thirteen patients were included in the replication study. Clozapine resulted in a significant 65.2% decrease in the number of the days with aggression. All the patients improved their quality of life. Once again, no serious effect side was notified.

**Conclusion.**– Our study confirms that clozapine is an efficacy and well tolerated treatment for ASD patients with disruptive behaviours and on the long term.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Family upbringing influence on the self-regulation development: A longitudinal research

E. Sedova<sup>\*</sup>, T. Goryacheva  
Pirogov Russian National Research Medical University,  
Psychological-Social Faculty, Moscow, Russia

\* Corresponding author.

According the Three-Level Model, self-regulation includes the following levels: the mental states self-regulation level, the operational level and the motivational level. The interconnection

between those levels and especially the process of self-regulation development are of the high scientific interest.

The aim of the current research is defining the role of the family upbringing in the self-regulation development in the age from 7-8 to 10-11 years.

The research sample consists of 28 students of public school having neither mental nor severe somatic disorders. The research methods includes Luria's battery of neuropsychological tests for the first self-regulation level (adapted by Semenovich, 2008), the analysis of the school progress for the second level and tests of learning motivation for the third one. The Analysis of the Familial Interaction is used for the studying the family upbringing style.

The research shows that a necessary condition for reaching the high level of self-regulation is the adequate family upbringing with a balanced system of rights and responsibilities is, while hyper- and hypo-protection prevent from maturing of conscious self-regulation.

The three-year follow-up shows that dramatic positive changes in self-regulation development can be seen in those families where the child-parent relations have shifted from the over-protection and instability to the adequate style. Still in case of severe problems of the first self-regulation level (lack of concentration, emotional instability), a special intervention program is needed.

EV0579

### **Musical hallucinations: A case report and review of the literature regarding its phenomenology**

M. Sequeira\*, B. Trancas, T. Maia

Hospital Professor Doutor Fernando Fonseca, EPE, Amadora-Portugal, Department of Psychiatry, Lisboa, Portugal

\* Corresponding author.

*Introduction.*– Musical hallucinations (MH) refers to a condition characterized by the presence of intrusive auditory musical percepts without an external auditory source. Also labeled as Oliver Sacks syndrome, auditory Charles Bonnet syndrome or musical hallucinosis (in the latter the reality test is intact), hallucinations with musical quality are currently considered to be a phenomenon whose rarity may derive from its nature but also from under-reporting; its purported heterogeneous causal mechanisms might explain the clinical nuances regarding presentation, evolution, treatment and prognosis. Often associated with diverse medical conditions, the most consistent evidence refers to the association of hearing loss, female gender and old age, accompanied of at least some degree of insight

*Objectives.*– We present a case of a 79-year-old woman experiencing MH and explore its unique characteristics and response to psychoeducation and somatic treatments.

*Methods.*– We describe a case of an elderly woman, without psychiatry history or central nervous system abnormalities/disorder, suffering from progressive hypoacusis, who has been experiencing MH for one year, focusing on the phenomenology of the experience. *Results.*– The distinctive phenomenological characteristics of the condition and particular response to increased external auditory stimuli and antipsychotic treatment are discussed in light of current knowledge.

*Conclusions.*– MH appear to be a more heterogeneous and complex phenomenon than previously thought, regarding its clinical characteristics and aetiology. A meticulous description of the phenomenological elements in its distinctive presentations may bring light to more effective and syntonic approaches, channeling positive repercussions in terms of evolution and prognosis of MH.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Dyke Davidoff Masson syndrome, impact of neuropsychiatric manifestations in a patient with systemic lupus erythematosus**

J. Sordia<sup>1</sup>\*, L. Sáenz<sup>1</sup>, A. Infante<sup>2</sup>, I.D.J. Hernández<sup>3</sup>, C. Garza<sup>1</sup>, D. Escobedo<sup>1</sup>

<sup>1</sup> Hospital Universitario “Dr. José Eleuterio González”, Departamento de Psiquiatría, Monterrey, Mexico; <sup>2</sup> Hospital Universitario “Dr. José Eleuterio González”, Servicio de Neurología, Monterrey, Mexico; <sup>3</sup> Hospital Universitario “Dr. José Eleuterio González”, Servicio de Reumatología, Monterrey, Mexico

\* Corresponding author.

*Introduction.*– Dyke Davidoff Masson syndrome (DDMS) is a rare entity due to abnormalities in brain development, either congenital or acquired, causes include: infections, tumors, trauma. It's been associated with psychiatric manifestations like psychosis and schizophrenia.

*Objective.*– To report the association of DDMS in a patient with lupus and its neuropsychiatric clinical implications.

*Methods/case.*– We present the case of a twenty year old female patient with history of systemic lupus erythematosus (SLE) since she was four, developing deep vein thrombosis and confirmed diagnosis of antiphospholipid syndrome (APS) at age nineteen; with treatment resistant epilepsy (temporal lobe epilepsy) since was fifteen. Developed an episode of severe depression one year ago, including two suicide attempts ingesting anticonvulsants. Presents to outpatient clinic of our department with behavioural symptomatology: impulsiveness, emotional dysregulation, insomnia and abulia, no established depressive or psychotic disorder. MRI revealed left cerebral hemisphere atrophy with compensatory skull thickening. Cognitive deficiencies during evaluation revealed total IQ of 65 indicating severe intellectual disability. The patient began treatment with antidepressant, continued with anticonvulsants, with partial treatment response.

*Results.*– Our patient fulfilled clinicoradiological criteria for DDMS: cerebral hemiatrophy, ipsilateral sinuses hyperpneumatization, dilated ventricles/cisternal space, mental retardation and epilepsy. It's been associated with vascular insults due to inflammatory diseases and this presentation alongside SLE supports a neuroinflammatory component for syndrome development.

*Conclusion.*– The association of DDMS/SLE could be explained by early age of onset and complications, microvascular damage being the possible mechanism. Early identification of DDMS could provide appropriate treatment for epilepsy, mental retardation and psychiatric comorbidities, improving quality of life.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Healing in the incest wound**

S. Tira\*, S. Ben Ali, C. Ben Cheikh, H. Elkefi, A. Oumaya

Hôpital militaire principal d'instruction de Tunis, psychiatry, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Statutory rape is child abuse by an adult for the purpose of sexual pleasure. Abuse affects physical and mental integrity, all the more so because it is incest. The incest word of its Latin origin “incestus”, is synonymous with impurity, defilement. It would be

a sexual relationship between persons related by a degree of kinship leading to the prohibition of marriage, usually a man (father, stepfather or close family).

*Objectives.*– Our aim is to analyze and identify through the presentation of a clinical case the psychological repercussions of an incest on an underage.

*Methods.*– Study of a clinical case concerning a 26-year-old patient who was the victim of incest from her uncle.

*Results.*– Case presentation: it is a 26-year-old patient who has been followed in psychiatry for several years and who has been addressed to us following a suicide attempt in the context of a severe depressive disorder. The psychiatric interviews revealed that the patient was the victim of an incest perpetrated by her uncle to type of sexual touching. Therapeutic management had associated antidepressants, anxiolytics, neuroleptics and psychotherapy. The evolution under treatment was marked by the persistence of the depressive disorder with numerous attempts of suicide, requiring hospitalizations in intensive care unit. The patient was treated several times in gynecology for self-harm. The patient has not consulted since her mother's death.

*Conclusion.*– Incest is a trauma that can have dramatic consequences. specialized and urgent care is essential. In this context, the identification of evocative early signs is essential.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Joint follow-up of treatment process of FMS patients

C. Tüz

Erenköy FTR Hastanesi, Psychiatry, Istanbul, Turkey

Fibromyalgia is a disorder characterized by widespread musculoskeletal pain accompanied by fatigue, sleep, memory and mood issues.

*Methods.*– In the year 2015, the diagnosis and treatment of 183 patients diagnosed with FMS in Psychiatry and PTR outpatient clinics of Erenkoy PTR Hospital were observed jointly.

Diagnosis was made by a PTR Specialist according to ACR 2010 diagnostic criteria. The severity of pain of the patients was measured by the Wide Spread Pain and Symptom Severity.

In psychiatry outpatient clinic, diagnoses were made according to DSM V diagnostic criteria. The severity of the disease was measured by HAM-D and HAM-A.

Patients diagnosed by both outpatient clinics were treated and monitored jointly by PTR and Psychiatry departments.

During the treatment, patients were made to do exercise movements and administered pregabalin 75-150 mg/day by a PTR specialist and duloxetine 30-60 mg/day by a psychiatrist.

The severity of the pain was measured by the PTR specialist using WSP and SS scales once a week for 12 weeks. On the same day, the patients were also assessed by the psychiatrist. CGI, HAM-D and HAM-A were used to determine clinical course and severity of disease of the patients.

Demographic data of the patients, subscales of both PTR and psychiatric diagnoses were determined

*Summary of results.*– At the end of the study, FMS complaints and findings significantly abated. A direct correlation was established between clinical findings of FMS and the severity of depression findings. The statistical significance of the correlation was investigated using subgrouping of the disease diagnosis.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Eye-tracking technique as an instrument in the diagnosis of autism spectrum disorder

A. Ciccarella Alves da Silva, C. Varanda\*

Universidade Paulista, Institute of Human Sciences, Santos, Brazil

\* Corresponding author.

Considering the prevalence of ASD, the unknown etiology and symptomatic evidences occurring in the first years of life, more precise techniques refining the characteristics of ASD and presenting a differentiated diagnosis as well as establishing an appropriate prognosis according to conditions presented by the patient are needed. The ocular tracking technique allows a better understanding of social cognitive functioning, due to the deficits in social interactions and social communication in ASD. This research was a bibliographical review, whose objective was to analyze scientific publications on the use of the technique of ocular tracking as an instrument in the diagnosis of Autism Spectrum Disorder (ASD). Selecting scientific publications, written in Portuguese and English, between 2006 and 2016, published in PUB MED, SciELO, LILACS and CAPES databases, including bibliographic reviews and experimental researches with positive or negative results, in order to collect data on the efficacy of the technique in neuropsychological evaluation in cases of ASD. A total of 23 articles were identified, of which 17 were published in PUB MED database and 6 in LILACS. There was an increase in production between 2012 and 2016. Regarding the type of research, 21 are experimental, whose main objectives were investigating joint attention, social attention and face processing, and two bibliographic reviews. The eye tracking technique in the experimental research as a differential in the diagnosis of ASD was efficient to present positive results in confirming diverse patterns used by the ASD group compared to groups of typical development or other genetic syndromes.

### Evaluation and comparison of public attitudes towards people with mental disorders in Poland and Egypt

K.M. Wilczynski<sup>1</sup>, E. Elsheshtawy<sup>2</sup>, E. Mazgaj<sup>3</sup>, N. Amer<sup>2</sup>, A. Jabłońska<sup>3</sup>, M. Nasser<sup>2</sup>, A. Majkut<sup>3</sup>, K. Krysta<sup>3</sup>

<sup>1</sup> Medical University of Silesia, Department of Psychiatry and Psychotherapy of Developmental Age, Katowice, Poland; <sup>2</sup> Mansoura University, Department of Psychiatry, Mansoura, Egypt; <sup>3</sup> Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

\* Corresponding author.

*Background.*– In recent years, proceeding deinstitutionalization of mentally ill, despite obvious benefits, led to the occurrence of new challenges, linked to the rapid increase in social distance and stigmatization of those afflicted. Our objective was to assess society's attitude towards mentally ill, and compare it between respondents from different cultures.

*Materials and methods.*– Study was conducted between January 2016 and September 2017 on a group of 1392 respondents originating from Poland ( $n = 1016$ ) and Egypt ( $n = 376$ ), utilizing authors' own questionnaire constructed during three-step pilot study on a group of 100 respondents.

*Outcomes.*– There was no significant difference in public attitude towards mentally ill between Poland and Egypt. Significant, although weak, association was found between age of respondent

and overall attitude towards mentally ill ( $r = 0,11$ ;  $P < 0,05$ ). 23% of respondents obtained their knowledge from media coverage.

**Conclusions.**– Despite cultural differences, public opinion on mentally ill did not differ between Poland and Egypt. Overall attitude seem to be neutral, with a majority of society being indifferent to the problems of mentally ill.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Reviewing treatment in a somatoform disorder. A case of iatrogenic pain

H. De la Red Gallego<sup>1\*</sup>, A. Álvarez Astorga<sup>1</sup>, A. Alonso Sánchez<sup>1</sup>, N. De Uribe Vilorio<sup>1</sup>, M. Gómez García<sup>1</sup>, M. De Lorenzo Calzón<sup>1</sup>, M. Hernández García<sup>1</sup>, G. Isidro García<sup>2</sup>, F. De Uribe Ladrón de Cegama<sup>1</sup>

<sup>1</sup> Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain;

<sup>2</sup> Hospital Universitario Marqués de Valdecilla, Psychiatry, Santander, Spain

\* Corresponding author.

**Introduction.**– Somatoform disorders are characterized by physical complaints that occur in the absence of a medical explanation, usually when no alteration can be objectified, and underlying psychological factors are suspected.

**Objective.**– To present a case of iatrogenic pain labelled as somatoform disorder. To identify muscle pain as a side effect of statins. To enhance the importance of an appropriate psychiatric evaluation and follow-up.

**Methods.**– A 34-years-old-male, diagnosed with Klinefelter's Syndrome, hypercholesterolemia and migraine, treated with Atorvastatine and Testosterone Cypionate. No toxic habits. General practitioner suggests psychiatric evaluation due to persistent widespread weakness and pain, which led the patient off work for nine months. No specific cause was detected and he was diagnosed with somatoform disorder.

**Results.**– During follow-up, neurological examination showed decreased sensitivity in fingers, back of feet and distal lateral face of both legs. Weakness for the extension of fingers, extension and eversion of both feet. He is diagnosed with peripheral neuropathy caused by statins, after clinical improvement following statins withdrawal.

**Conclusion.**– Somatoform disorders imply a major challenge for physicians, as there is a high risk of labelling as somatoform an undiagnosed disease. These patients are frequently polimedicated, so an iatrogenic cause should be carefully discarded. Clinicians should pay special attention to patients receiving this type of diagnosis to avoid falling into the error of not diagnosing underlying non-psychiatric medical conditions, which could eventually increase the suffering of the patient.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

Iran;

<sup>3</sup> Department of Psychology- Allameh Tabatabaiee University, Tehran, Iran

\* Corresponding author.

**Introduction.**– The study aimed to assess the relationship between mental disorders symptoms with pain coping strategies in dentistry clinics. Method: 120 people with dental pain that attended in dentistry clinics were randomly selected and responded to Rosenstein & Keefe's Pain Coping Strategies Questionnaire (PCSQ) and Derogatis's Symptom Checklist (SCL-90-R). The data were analysed with Pearson correlation coefficient.

**Results.**– Findings showed positive and significant relationship between Disastrous thought with all mental disorders symptoms; and Reinterpretation pain sensation with depression and anxiety. Also there is negative significant relationship between ignoring pain with Obsessive-compulsive, interpersonal sensitivity and Somatization; and Hope-praying with interpersonal sensitivity, depression, anxiety, paranoid ideation and psychoticism.

**Discussion.**– With regard to findings, it is recommended that in addition to drug treatment, for changing the attitudes and thinking in patients with dental pain, psychiatrists and psychologists apply psychological treatments specially cognitive-behaviour therapy to reduce abnormal thinking level about pain and as a results reduce and health problems that is related with dental pain.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

Pyelonephritis is a kidney infection caused by bacteria, which starts in the bladder and spreads through the urinary tract to one or both kidneys. Clinic is characterized by abdominal pain, low back or costar pain, dysuria (pain or stinging when urinating), pollakiuria or tenesmus.

We present the case of a 39-years-old woman diagnosed with Schizoaffective Disorder, admitted at the Psychiatry-Unit for psychopathological decompensation. After 19 days of hospitalization, and stabilized psychopathologically, the patient begins with fever, treated with paracetamol, although it persisted up to 39.5 °C, requiring urgent blood analysis, where acute phase reactants were observed; positive blood culture for E. coli and systematic urine with 500 leukocytes are shown. On examination, the patient is tachycardic, tachypnoic at rest, depressive abdomen, not painful. The patient doesn't report pain at all. She is diagnosed of acute pyelonephritis with risk of sepsis. The following days, better gen-

eral condition, while maintaining persistent tachycardia and basal oxygen desaturation. The patient didn't present any complaint of dyspnea or chest pain. A thoracic CT is performed, where a probable pulmonary thromboembolism was observed.

Pain is a complex phenomenon that covers affective and cognitive dimensions. It has been described a decrease in pain sensitivity in patients with Schizophrenia, which has been associated with a defective analysis of information associated with the activation of various brain areas and with a dopaminergic dysfunction at the reward systems. Our case is an important reminder that people with schizophrenia do not always present typical clinical features of concomitant organic pathology.

\* Corresponding author.

Purpose of the study was pain evaluation in patients affected by Temporomandibular Disorders (TMD) with dysfunctional algic symptoms, in order to identify an effective therapy for non responders to conventional treatment, so that an alternative pharmacological approach with psychotropic drugs might be indicated. This prospective observational study included 45 patients recruited in October 2016. To all patient, after obtaining informed consent, diagnosis was established with the aid of a 16 item structured clinical interview, the Oral Health Impact Profile and each patient furnished relevant data, regarding the quality of life, using the Flanagan clinic scale (QOLS). The patients sample was composed by 87% of females and 43% of males with a mean age of 40 year old. The diagnosis was one case of temporomandibular joint (TMJ) disease, four cases of muscular disease and four cases of combined TMJ disease and muscular disease. Two patients underwent physical therapy, three combination therapy and four pharmacological therapy (NSAIDs, corticosteroids and/or psychotropic drugs). Higher scores (according to Flanagan scale) corresponded to a better quality of life; we found these scores in young women with joint and muscular disease treated also with psychotropic drugs for short time. Temporomandibular disorders in patients with dysfunctional algic symptoms can be treated with physical and pharmacological conventional therapies but also alternative pharmacological approaches such as antidepressants and/or anxiolytics. The origin of these diseases have a psychological correlate which would explain the efficacy of psychotropic drugs, even in the absence of an underlying or coexisting psychiatric disorder.

### A case of chronic pelvic pain syndrome: the presentation, exploration of underlying psychodynamic issues, and management of pain in a multidisciplinary consultation liaison setting

P. Thiagayson\*, B. Wen, T.S. Lee

Singapore General Hospital, Department of Psychiatry, Singapore, Singapore

\* Corresponding author.

*Introduction.*– Chronic pelvic pain syndrome is a poorly defined condition with a complex history, unclear etiology and suboptimal response to therapy. In chronic pelvic pain syndrome, the sufferer typically undergoes extensive investigation for the underlying cause of the pain, with no organic cause identified. Sufferers of chronic pain syndromes often meet criteria for somatic symptom disorder according to the DSM-V.

*Case presentation.*– A 51-year old man with a 4 month history of penile and perineal pain was referred to our Consultation Liaison Psychiatry service for disabling pain that had been extensively worked up without any underlying organic causes found. The patient was a premorbidly high-functioning and driven individual with a very successful career. Upon further exploration, it was discovered that his wife had been diagnosed with breast cancer a week prior to him developing penile pain. The patient also had a very high level of anxiety about his pain, which responded far better to benzodiazepines than to opioid analgesia. A multidisciplinary team of specialists comprising urologists, anaesthetists subspecializing in chronic pain management, internists, psychiatrists, a physiotherapist and a psychologist managed this patient.

This poster will further describe the patient's presentation, explore his psychodynamic conflicts as a result of his wife's breast cancer diagnosis, and describe in detail how the multidisciplinary team of specialists addressed his pain using a combination of approaches including pharmacotherapy, psychotherapy, physiotherapy and social support.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Depression, physical activity and perception of menstrual pain

E. Wojtyna<sup>1\*</sup>, A. Kłyszewska<sup>2</sup>, W. Janeczek<sup>1</sup>, M. Banout<sup>1</sup>

<sup>1</sup> University of Silesia, Institute of Psychology, Katowice, Poland; <sup>2</sup>

Center Medical, Department of Medical Rehabilitation, Truskolasy, Poland

\* Corresponding author.

*Background.*– Pain during menstruation cycle is a significant problem and searching for the predictors of pain intensity remains an important challenge for modern medicine. Within factors that modify pain perception, depression and physical activity is highlighted.

*Aim.*– The aim of the study was to investigate the relations between menstrual pain (its severity, pain thresholds), depression and physical activity.

*Methods.*– Study included 80 women.

*Measuring methods.*– Thermometer of Emotions, PainMatcher (the pain thresholds), Brief Pain Inventory (the severity of pain and its impact on functioning), The International Physical Activity Questionnaires were used.

**Results.**– Depression turned out to be a significant predictor of pain severity and its impact on functioning. Also, depression decreases pain thresholds. Increasing the level of physical activity correlates with the decrease of depression level and pain severity during menstruation, and also increases pain thresholds and pain tolerance during the menstruation. Intensive physical activity turned out to be a moderator of relationship between depression and pain: the relation between depression and pain was non-significant among participants who undertake the intensive physical activity.

**Conclusions.**– Implementing intensive physical activity in women with severe menstrual symptoms can improve both mood and coping with pain.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## Personality and personality disorders

EV0591

### Tattooing meanings: From self-harm to self-identity – A clinical case

T. Abreu<sup>1\*</sup>, J.M. Rodriguez<sup>2</sup>, O. von Doellinger<sup>1</sup>

<sup>1</sup> Centro Hospitalar do Tâmega e Sousa, Psychiatry and Mental Health Department, Penafiel, Portugal; <sup>2</sup> Centro Hospitalar do Porto, Psychiatry and Mental Health Department, Gondomar, Portugal

\* Corresponding author.

**Introduction.**– A wider range of motivations may have contributed to the crescent popularity of tattooing in Western countries. Diverse social and psychological explanations to tattooing are found in literature, with some studies pointing out the pain experience and the hypothetical alternative to self-harm acts.

**Objectives.**– To reflect on the meaning of the tattoos in a specific clinical case, using a psychodynamic perspective.

**Methods.**– Clinical case report.

**Results.**– A 19-year-old male student (single-child, living alone with his mother) was attended, at an outpatient clinic, with intrusive and persistent thoughts of death and about hurting his mother, along with depressive symptoms (feelings of emptiness and self-disgust, apathy and dysregulated sleep cycle), a fragmented sense of self, primitive defense mechanisms, and severe difficulties in interpersonal relationships. He had five tattoos, four of them done in a two-month period, when he had progressively more violent thoughts towards himself and engaged in binge drinking. He said he liked tattoos but he also admitted an anguish relief through the pain. The therapeutic work with this patient encompassed the discussion of different meanings for his tattoos.

**Conclusions.**– Tattooing may reflect different social or psychological motivations and usually is not pathological. Nevertheless, it is important to be watchful to some warning signs (in this case, the impulsive and repetitive tattooing in a short time period concomitant with depressive symptoms) and to explore its meanings and associations.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0592

### Convergent validity of DSM-5 diagnosis of personality disorders as assessed by SCID-5-PD, DAPP-BQ and PID-5 in a sample of mood disorders

N. Aioub<sup>1\*</sup>, R. Williams<sup>1</sup>, M. Mazza<sup>2</sup>, P. Calanna<sup>1</sup>, M. Luigia Crosta<sup>2</sup>, G. Marchettini<sup>3</sup>, L. Janiri<sup>2</sup>

<sup>1</sup> Sapienza University of Rome, Department of Dynamic and Clinical Psychology; <sup>2</sup> Catholic University of the Sacred Heart, Institute of Psychiatry and Psychology; <sup>3</sup> LUMSA University of Rome, Human Sciences Department

\* Corresponding author.

**Introduction.**– The diagnosis of personality disorders is often little reliable, especially if only categorical and made through different methods (self-reports vs structured interviews vs performance-based instruments), so that DSM-5 has proposed a new hierarchical and multidimensional model. The relationship between personality disorders and mood disorders is complex and still unclear, and many methodological issues are open: e.g., few extensive studies, inconsistent data, lack of established etiological theories, drug-resistance of patients with comorbid personality disorders and mood disorders, and the evidence that this comorbidity predicts a worse course and outcome of treatments, even in sub-threshold forms.

**Objectives.**– This paper reports preliminary data on convergent and discriminant validity of the three models for diagnosis of personality disorders proposed by DSM 5 (categorical, typological and dimensional) in a sample of mood disorders, using a multimethod approach.

**Methods.**– A total of 30 patients with diagnosis of mood disorders as assessed by the SCID-5 were screened with patient's questionnaire of SCID-5-PD and then diagnosed using the SCID-5-PD, the Dimensional Assessment of Personality Pathology - Basic Questionnaire and the Personality Inventory for DSM-5.

**Results.**– Some associations confirm the relationship between DSM-5 categorical diagnosis and the new dimensional models, but data show also original results: e.g. avoidant personality reveals identity problems, conduct problems, emotional dysregulation and perfectionism, as well as schizotypal personality presents anhedonic affects and depression, but also persistence and perfectionism.

**Conclusions.**– New models proposed by DSM-5 appear valid, and dimensional and sub-threshold diagnoses seem more clinical useful to detect some personality pathologic features and strength unknown until now.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0593

### Self-ambivalence is related to affective ambivalence towards health

G. Arina<sup>\*</sup>, M. Iosifyan, V. Nikolaeva, L. Pechnikova  
Lomonosov Moscow State University, Department of neuro, and  
pathopsychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Attitudinal ambivalence towards health is related to some forms of risky behaviours (Hohman et al., 2014). Self-ambivalence, as a structural feature of the self-concept (DeMarree & Morrison, 2012), can be related to attitudinal ambivalence towards health.

**Objectives.**– The purpose of the study was to examine the relations between self-ambivalence and affective ambivalence towards health.

**Method.**– Adolescents completed color test (Kisel'nikov, 2017), measuring the strength of association between affective words and objects (self and health related objects). They were next divided in two groups: adolescents with low ( $n = 39$ ,  $M_{age} = 14.1$ ,  $SD = 1.43$ , 20 males) and high self-ambivalence ( $N = 41$ ,  $M_{age} = 14.54$ ,  $SD = 92$ , 16 males).

**Results.**– Mann–Whitney *U*-test with FDR revealed differences between two groups of adolescents (see Table 1.). Adolescents with higher self-ambivalence had bigger affective ambivalence towards all objects, except nutrition and hygiene, compared to adolescents with lower self-ambivalence.

Table 1. Differences between two groups of adolescents (Mann-Whitney *U*-test).

Figure 1.

Epidemiological profile of psychiatry in the Hospital III Emergencias Grau- Essalud 2012-2016	
Mood disorders	35.63%
Anxiety disorders	23.36%
addictive disorders	14.86%
psychotic disorders	14.91%
Others	9%

**Conclusions.**– Adolescents with higher self-ambivalence have bigger affective ambivalence towards health related objects, compared to adolescents with lower self-ambivalence. High self-ambivalence among adolescents is a potential factor of high affective ambivalence towards health and, consequently, risky behaviours.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Borderline personality disorder: The wounds that never cicatrize

S. Ben Ali<sup>1</sup>, S. Tira, C. Bencheikh, H. Kefi, A. Oumaya  
Military Hospital of Tunis, Psychiatry Department, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Borderline personality disorder (BPD) is the most prevalent personality disorder within most clinical settings. Approximately 15% of all inpatients (51% of inpatients with a personality disorder) and 8% of all outpatients (27% of outpatients with a personality disorder) will have a BPD. This personality disorder is at high risk of acting out with 40 to 85% attempted suicide, 50 to 80% self-harm and 10% suicide.

**Objective.**– We proposed through a clinical case and the literature review, to study the diagnostic criteria of a borderline personality disorder and to point out their mental suffering and the therapeutic management

**Method.**– Study of a clinical case concerning a 25-year-old patient who was hospitalized several times for complication of her borderline personality disorder

**Results.**– Case report: Madam X. is 25 years old. She presents borderline personality disorder complicated by recurring major depressive episodes, multiple attempts at suicide and self-

mutilation at the breasts. The therapeutic management associated antidepressants, neuroleptics, mood stabilizers and psychotherapy. The evolution was marked by a gradual stabilization despite numerous social complications and heavy gynecological sequelae.

**Conclusion.**– Sometimes the suffering of the borderline person turns out to be stronger than the therapeutic strategy. Our role is to try to relieve this suffering and to prevent the complications

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0595

### Deviations in the development of self-awareness of children from families with average-low social status

N. Burlakova<sup>1</sup>, P. Davidovich

Lomonosov Moscow State University, Faculty of Psychology-  
Department of Neuro- and Pathopsychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Methodological bases of the study were constructed within the framework of clinical psychology of Vygotsky Scientific school, a development model of the internal relations of the “Self -Other” in self-awareness of the child. The development of self-awareness and deviations are researched using (1) the aspect of genesis; (2) the psychological aspect of age; (3) the aspects of psychological adaptation and activity.

**Objectives and methods.**– The study focuses on a group of low-resource families with an average higher social status ( $n = 35$ ) living in Moscow, the children (5.5–7 years old) go to a state social assistance center.

**Methods.**– Objective description of the cultural, historical and social context of the child's development; semi-structured interview; long-term observations; CAT, S. and L. Bellak; projective drawings.

**Results.**– The typology of risk-based strategies of upbringing is formulated: authoritarian, rigid strategy as a way of adaptation to socioeconomic conditions; the type of struggle and resistance; the type of social instability; the type of social “mimicry”.

The study demonstrates stabilization of the reversibility between the “Self-Other” positions, the ability of transition to the emerging position of the rational Self with the subsequent assessing oneself, usually negatively.

The aspect of psychological adaptation is demonstrated by ability to follow the rules, recognition of an adult authority with anxiety reactions, difficulties of the child's self-expression, selectivity of friendly preferences, along with a high readiness to shift anger to equals.

**Conclusion.**– Emotional-personal maturity and self-consciousness development indicate better adaptation capabilities (than in other groups) accompanied by specific risk development zones.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0596

### Deviations in the development of self-awareness of children from families with medium-higher social status

N. Burlakova<sup>1</sup>, P. Davidovich

Lomonosov Moscow State University, Faculty of Psychology,  
Department of Neuro- and Pathopsychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Methodological bases of the study were constructed within the framework of clinical psychology of Vygotsky Scientific school, a development model of the internal relations of the “Self-Other” in self-awareness of the child. The development of self-awareness and deviations are researched using (1) the aspect of genesis; (2) the psychological aspect of age; (3) the aspects of psychological adaptation and activity.

**Objectives and methods.**– The study focuses on a group of high-resource families with average higher social status ( $n=31$ ) living in Moscow, the children (5.5–7 years old) go to a prestigious development center.

**Methods.**– Objective description of the cultural, historical and social context of the child’s development; semi-structured interview; long-term observations; CAT, S. and L. Bellak; thematic projective drawings.

**Results.**– The typology of risk-based strategies of upbringing is formulated: an authoritarian, rigid nanny as an alternative strategy of upbringing; an abrupt change in of the parents’ attitude manifestations towards the child; the type of social educational experimentation; the indulgent, supersatisfying type.

The general underdevelopment of self-awareness, a reduction in the level of differentiation and elaboration of its contents, a tendency to the absence of emotional reversibility between positions of “Self-Other” were demonstrated by examined children.

The aspect of psychological adaptation is expressed by the child’s individuality, demonstrativeness, incapacity for persistent efforts, decrease of the adult authority, and non-differentiation of relations with other children.

**Conclusion.**– Risky variants of emotional and personal development together with general underdevelopment of self-awareness determine the readiness of this group for disadaptive reactions in wider social reality.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Cloninger’s temperament and character inventories: Additional validation studies and applications in psychopathology and neuroepidemiology**

B. Calvet<sup>1,2\*</sup>, J.P. Clément<sup>1,2</sup>

<sup>1</sup> Esquirol Hospital Center, Geriatric Psychiatry, Limoges, France; <sup>2</sup> Inserm, UMR 1094, Limoges, France

\* Corresponding author.

The concept of personality is broad and polysemic. Over the ages, various theories of personality could complicate its definition. Among these theories, psychobiological approach integrates psychological and biological variables as predictors of inter-individual differences. C.R. Cloninger developed a model combining four dimensions of temperament, innate dimensions of personality strongly influenced by Genetics: Novelty Seeking, Harm Avoidance, Reward Dependence, Persistence; and three character dimensions, acquired dimensions during life and under the influence of learning and the environment: Self-directedness, Cooperativeness, Self-transcendence. It is evaluated with Temperament and Character Inventories (TCI), but whose strengths and weaknesses were not considered qualitatively in the literature. Originally developed in the field of psychopathology, this model sees these applications emerge in the field of Neurology and Neuroepidemiology. This communication aims to introduce you to this personality model by different works. These works will deal with both the evaluation of the psychometric characteristics of new tools developed from this model, as well as the use of these personality inventories in various

clinical populations. All our work demonstrating the strengths and weaknesses of French TCI and Cloninger’s model should enable the development of future studies in Francophone countries.

\* Corresponding author.

**Introduction.**– The DSM-5 Section III proposes a hybrid dimensional-categorical model of conceptualizing personality that includes assessment of impairments in personality functioning and maladaptive personality traits. PID-5– Adult is a 220 item self-rated personality trait assessment scale for adults age 18 and older. It assesses 25 personality trait facets. Specific triplets of facets (groups of three) can be combined to yield indices of the five broader trait domains of Negative Affect, Detachment, Antagonism, Disinhibition, and Psychoticism. Each item on the measure is rated on a 4-point scale. The response categories for the items are 0 = very false or often false; 1 = sometimes or somewhat false; 2 = sometimes or somewhat true; 3 = very true or often true.

**Objectives.**– The aim of this study is to demonstrate the reliability and validity of the Turkish Form of the Personality Inventory for DSM-5 Adult Version.

**Methods.**– This research was carried out with 281 patients who fulfilled the criteria of any psychiatric disorder according to DSM-5 criteria in inpatient and outpatient psychiatric clinics and 923 healthy control groups without any mental or physical disease.

**Results.**– The correlations between DSM-5 personality disorders and PID-5 25 personality trait facets are significant. Results indicated good internal consistency reliabilities and good temporal stability reliabilities for the majority of the PID-5 traits.

**Conclusions.**– These findings show that The Personality Inventory for DSM-5 is reliable and valid for Turkish.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Are Persons With Emotionally Unstable Personality Disorder Overmedicated?**

E. Dobrzynska<sup>1\*</sup>, N. Clementi<sup>2</sup>

<sup>1</sup> Cygnet Health Care, Cygnet Hospital Kewstoke, Weston-super-Mare, United Kingdom; <sup>2</sup> NHS Lothian, NHS Lothian, Edinburgh, United Kingdom

\* Corresponding author.

**Aim and hypothesis.**– The purpose of the study was to review and compare prescribing guidelines for persons with Emotionally Unstable Personality Disorder (EUPD). Our hypothesis was that those patients are overmedicated.

**Background.**– EUPD is often considered as treatment resistant challenge. While effectiveness of psychological therapies in treatment of EUPD is widely acknowledged, there is less supportive evidence for pharmacotherapy use.

**Methods.**– MEDLINE and PsycINFO databases were searched for all English-language articles published 2000-2016 containing the keywords: “Emotionally unstable personality disorder”; “Borderline personality disorder”; “Pharmacotherapy”; “Drug treatment” and “Treatment guidelines”.

**Results.**– Current NICE guidelines (2009) recommend pharmacotherapy should not be used for borderline personality disorder but for comorbid conditions only. Despite this Paton et al (2015) showed 68% of borderline patients without comorbid disorder in UK were using antidepressants, 59% antipsychotics, 59% sedatives and 23% mood stabilisers. Paolini et al (2016) confirmed polypharmacy in 83.5% of cases. In line with the American Psychiatric Association practice guideline, the Dutch and German guidelines recommend antipsychotics for cognitive-perceptual symptoms (Ingenhoven 2015). However, they question the efficacy of antidepressants on impulsivity and affective dysregulation, finding mood stabilisers more helpful.

**Conclusions.**– All guidelines recommend evidence-based psychotherapies as the first-choice in the treatment of EUPD. However, they significantly diverge in with respect to pharmacotherapy use (Ingenhoven 2015). NICE and Australian guidelines abstain from psychotropics and although it may prevent to counterproductive polypharmacy, it can also refrain from temporary pharmacological support when needed. More RCTs are needed but meanwhile using pharmacotherapeutic algorithms for specific symptom domains might be the way forward.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Schizotypal personality disorder: A case report of a mistaken diagnosis and a review of the literature**

D. Esteves de Sousa<sup>1</sup>, M. Albuquerque<sup>1</sup>, S. Gomes Pereira<sup>2</sup>, M. Costa<sup>1</sup>, P. Cintra<sup>1</sup>, L. Mendonça<sup>1</sup>, J. Tropa<sup>1</sup>

<sup>1</sup> Hospital of Cascais, *Psiquiatria e Saúde Mental, Alcabideche, Portugal*; <sup>2</sup> Egas Moniz Hospital, *Psiquiatria e Saúde Mental, Lisboa, Portugal*

\* Corresponding author.

**Introduction.**– Schizotypal personality disorder is described as a low incidence personality disorder characterized by odd, bizarre or eccentric behaviour, cognitive problems, social malfunctioning, thought disorders, obsessive ruminations and perceptual impairment.

**Objectives.**– Our aim is to conduct a systematic review in this issue and to present a clinical case of a mistaken diagnosis.

**Methods.**– Review of scientific databases - Pub Med, medscape, scientific literature - and relevant scientific literature concerning the issue addressed and other publications with the research terms “schizotypal personality disorder”; “schizotypy”; “cluster A personality disorders”; “eccentricity”. Articles in english and portuguese. The clinical case was described with data retrieved from the clinical file. In what concerns the clinical approach to the patient, taking into account the erratic behaviour and sleep disorder and disorganized thought, a low dose antipsychotic was initiated. Concurrently and due to history of low grade, non impairing cognitive disability, a full diagnostic evaluation was made for differential diagnosis (CT, serum and urine analysis and neuropsychological assessment).

**Results.**– In light of the results of the neuropsychologic suggestive of an initial stage of frontotemporal dementia, further diagnostic tests

were made and a corresponding research of scientific database. In total, we found 30 articles of which 9 were considered relevant and also 2 books.

**Conclusions.**– Frontotemporal dementia is a rare entity which has a rather difficult differential diagnosis. Sometimes its presentation overlaps with that observed in other diagnosis, such as this case. EV morbidity worsens the prognosis and often delays a specific therapeutic approach.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The role of executive functions and especially of working memory in the antisocial personality disorder: A pilot study**

D. Galletta\*, F. Micanti, A.I. Califano

*University of Naples Federico II, Neuroscience, Naples, Italy*

\* Corresponding author.

**Introduction.**– Relationship between neuropsychology and personality disorders is highly articulated. In the last few years there has been a flurry of scientific productions characterized by the aim of clarifying the possible neuropsychological and anatomical-functional correlations of personality disorders, so as to build an integrated therapeutic pathway that takes into account all spectrum of difficulties to which it must face the subject. The assessment of the cognitive and neuropsychological functioning of the individual is useful in highlighting the cognitive features characteristic of a certain type of psychological functioning and their relationship to dysfunctional personality traits, such as, the deficit of executive functions in the antisocial personality disorder. Empirical evidence shows that in subjects with APD emerging neuropsychological deficits of executive functions attributable primarily to the functioning of prefrontal areas, both at dorsolateral and at the ventromedial level. These types of patients have planning and monitoring deficits and inhibition of pre-programmed behavioural patterns.

**Objectives.**– Aim of this pilot study is to highlight the cognitive profile of subjects with a diagnosis of antisocial personality disorder, in order to make the rehabilitative path more individualized.

**Methods.**– WAIS-IV scale was administered to 4 subjects between 18 and 20 years, inserted into a battery formed by: MMPI-2, Rorschach, drawing test and TAT. Nosographic diagnosis was based on the ICD-10.

**Results.**– Four subjects showed a borderline intellectual functioning with particular impairment in the working memory, in line with what has been reported in the literature about sample subjects with APD.

**Conclusions.**– Results drive us in the direction of expanding the sample and studying more in-depth neuropsychological functioning of these patients, in order to personalize the rehabilitative plan.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0602

### **Attachment styles: Adoptions and borderline personality disorder**

D. Galletta\*, A.M. Mastrola, V. Suarato

*University of Naples Federico II, Neuroscience, Naples, Italy*

\* Corresponding author.

The work was based on a observational and phenomenological study of a group of 10 subjects, (seven females and three males) with a history of loss and adoption.

The analysis of Rorschach revealed that all subjects have index that detects the early traumatic experiences.

Three subjects, with a more long history of institutionalisation, reported an AFFECTIVITY INDEX oriented to closing, a TVI restricted, an index of significant impulsiveness, deficient mechanisms of self-control and structural rigidity, it could be associated with closing mechanisms, difficulty in relationship, use of mechanism of dissociation and other primitive defense mechanisms; characteristics that seem to converge with a disorganized style of attachment, structured in childhood.

Five subjects have an Affectivity Index oriented to the opening while a TVI introverted, basic elements of ambivalence, a lower impulsivity, but mechanisms of self-control too structured, rigidity and few structural lesions, highlighting an ambivalent trend to personal contact and also high drive's levels with trends in acting in. These characteristics seem, instead, to converge in a insecure style of attachment.

Two other subjects not covered in these two specific categories showing a net ambivalence between the indices affective and the type of interior life (TVI), high impulsiveness, deficient control mechanisms and structural lesions.

Only two subjects, that relate use of substances of abuse, have also a significant elevation of the TCI AND DCI. These characteristics seem oriented to a disorganized style of attachment, in a dissociative personality disorder.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Assessment of borderline personality disorder using the Mmpi – 2: The contribution of psy – 5 scales**

D. Galletta\*, M. Confuorto, S. De Simone, N. Vangone  
University of Naples Federico II, Neuroscience, Naples, Italy  
\* Corresponding author.

*Introduction.*– Borderline personality disorder (BPD) is characterized by a deep instability in emotions, relationships, self-image, identity and behaviour. It determines a great impairment of social, working and personal skills. People with BPD show inappropriate intense anger, paranoid ideas and impulsivity. This can make the treatment very difficult, so, identifying a BPD personality profile is important to address the clinical practice and the therapeutic work. To this aim, the Minnesota Multiphasic Personality Inventory – Second Edition (MMPI-2), a wide-ranging test created to identify the principal structural attitudes of personality and emotional disorders, it is often a very useful tool. Lately, Harkness et Al. (1995) have elaborated specific scales for personality traits: the PSY-5. As suggested by Wygant et Al. (2006), these scales can be considered as valuable tools able to provide precious information on personality disorders.

*Objectives.*– The aim of this pilot study is to evaluate the contribution provided by PSY-5 scales in the diagnosis of BPD.

*Method.*– We have administered MMPI-2 to three subjects with DBP, with particular attention to the values obtained on PSY-5 scales.

*Results.*– According with the literature, all three subjects exhibited significant elevations (T > 65) both in the PSYC scale and in the NEGE scale, highlighting emotional regulation difficulties and transient deficits in the reality exam.

*Conclusions.*– BPD's complexity requires a careful assessment that should be realized using reliable tools. MMPI-2 demonstrated to

offer an important contribution to the understanding of personality disorders, especially BPD. References not supplied

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Early maladaptive schemas among heroin addict patients treated by methadone in the North of Morocco**

W. Idrissi Samlali<sup>1</sup>, F.Z. Azzaoui<sup>2</sup>, A. Ahami<sup>1</sup>, T. Gheilan<sup>3</sup>, H. Hami<sup>4</sup>, S. Boulbaroud<sup>5</sup>

<sup>1</sup> Unit of Neurosciences and Applied Nutrition, Faculty of Sciences, Kenitra, Morocco; <sup>2</sup> Laboratory of Biology and Health, URAC 34, Faculty of Science Ben M'Sik, Casablanca, Morocco; <sup>3</sup> Pneumology UFR, Mohammed V University, Rabat, Morocco; <sup>4</sup> Laboratory of Genetics and Biometry, Faculty of Sciences, Kenitra, Morocco; <sup>5</sup> Department of Biology, Polydisciplinary Faculty, Beni Mellal, Morocco

\* Corresponding author.

*Introduction.*– The maladaptive schemas can be defined as structure or pattern of cognitive content. They represent all the process guiding our behaviours in serving the filtering and the processing of the information. A dysfunction on these schemas have a tight relationship with addictive conducts.

*Aims.*– the measure of early maladaptive schemas among heroin addict patients and comparison between overactivation of these schemas before and after treatment by the methadone.

*Patients and methods.*– The present study is carried out in a medical-psychological center in Tangiers (North of Morocco) among 101 patients (85 men and 16 women), with a mean age of 35 years old. The questionnaire SQ II of Young is administered to those patients, already diagnosed as dependent to opioid using DSM-IV, to study the dysfunctional schemas. The administration of questionnaire is realized twice; before and after treatment by the methadone.

*Results.*– The obtained results showed a significant difference between the activation of the Schemas before and after treatment ( $p < 0.001$ ) with a remarkable overactivation of “afraid of losing control” schema ( $M = 166.86$  (65.3%)) in addition to the “high requirement” schema which is significant for men ( $t = 1.97$ ,  $P = 0.048$ ) against the “vulnerability” and “emotional deficiency” among women ( $t = 4.56$ ,  $P \leq 0.001$ ).

*Conclusion.*– The substance abuse and personality disorders are often coexisting confirming a part of the hypothesis advanced by Ball and Young which postulate that the individuals displaying the criteria of substance abuse have overactivated of the maladaptive schemas of self-control or the personal rights.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0605

### **Zoophilia in an adult with borderline personality disorder: A case report**

M.W. Najar\*, W. Homri, C. Ati, F. Ellouze, N. Bram, I. Ben Romdhane, R. Labbane  
Razi Hospital, Psychiatry C department, Manouba, Tunisia

\* Corresponding author.

*Introduction.*– Zoophilia is a rare paraphilic disorder with intense sexual urges involving animals. Borderline Personality Disorder (BPD) is a common disabling mental disorder associated with difficulties in controlling emotions and impulses, a history of unstable relationships and self injury.

**Objective.**– To describe a clinical case of EVmorbid BPD and zoophilia in order to establish the relationship between these two. **Methods:** Search of the Pub Med database and Sciencedirect was conducted using the keywords: “Zoophilia”; “Borderline”; “Paraphilia”. We also reviewed the patient’s clinical records.

**Results.**– Mr SR is a single 26-year-old male who conducted several types of jobs and came to the psychiatry outpatient department after attempting suicide by immolation. He had no history of chronic physical disease. He was sexually abused when he was 12 years old. He tried different kinds of drugs and became alcoholic. He has no family support. He’s been suffering for the past 5 years from chronic sad mood, emptiness, loss of interest and unstable relationships including professional and personal ones. He also showed several kinds of impulsive risky behaviours. He started to have sexual intercourse with sheeps two years ago whilst harboring feelings of guilt. He was unable to explain the reasons why he had pleasurable sexual intercourses with animals but he mentioned having permanent and recurrent failure with women. He was diagnosed with BPD.

**Conclusion.**– Reported cases of zoophilia in BPD are limited worldwide. Further research is required to explore this association in order to offer a better psychological care.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Failure of the oedipal process and hysterical conversion as a modality of decompensation: The trauma of the loss of the object**

F. Nyegue<sup>1\*</sup>, K. Mrs THOMAS<sup>2</sup>

<sup>1</sup> Université de Nice Sophia-Antipolis, LIRCES/Psychologie and Psychoanalysis, 06204 Nice cedex 3, France; <sup>2</sup> Colorado, USA

\* Corresponding author.

The processes of psychic development and the modalities of constructing the personality of the human subject are entirely dependent on social and psycho-social environment. When in the psychoaffective organization of the group, intersubjective relations fit exclusively in a link of dependence or domination, the personality of the subject may be built with psychic characteristics. The case of the hysterical personality makes possible to better evaluate this clinical reality and on the other hand makes possible to understand the trauma clinic in its capacity to provoke a psychic fragmentation which leaves hatched other psychopathological organizations.

Mrs. K., jealous of her father’s conjugal relationship and accused to be at the origin of her mother’s violent death, had been plunged since her mother’s death and her imprisonment, into particularly hysterical symptoms, thus expressing father and mother at the same time. This clinical situation obliges to question and observe the hysteria and trauma clinics when the second is perceived like the origin of the psychopathological decompensation of the subject.

\* Corresponding author.

Personality traits can play an essential role in predicting marital satisfaction. People with personality disorders have substantial problems with starting and continuing a relationship with a partner.

The association between the dysfunctional marriage and personality problems of the partners may have the basis in the insufficient understanding of the behaviour of one or both partners. People with personality disorder experience numerous misunderstandings, misinterpretations, communicate poorly, and they are more alert to verbal and physical aggression in the interpersonal relations. They do not recognize that the basis of experienced struggles has a source in their intrapersonal processes and their relationship with the world.

Persons with certain personality disorders tend to seek and create a pathologically stable partnership. To understand the dynamics of such relationships, examining personality traits first should be essential. Understanding the maladaptive personality patterns in the context of the relationship should be beneficial for both partners.

### **Psychological profiles of male offenders: A research project in Italian prisons**

M.E. Ricci<sup>1\*</sup>, M. Conteduca<sup>1</sup>, S. Galasso<sup>1</sup>, V. Nannini<sup>2</sup>, A. Pomilla<sup>3</sup>, V. Langher<sup>2</sup>

<sup>1</sup> Order of Psychologists of Lazio, Working group “Intimate Partner Violence”, Rome, Italy; <sup>2</sup> Sapienza University of Rome, Department of Dynamic and Clinical Psychology, Rome, Italy; <sup>3</sup> Sapienza University of Rome, Department of Neurology and Psychiatry, Rome, Italy

\* Corresponding author.

**Introduction.**– Intimate Partner Violence (IPV) is a pervasive phenomenon that impacts on mental health and negatively affects social and economic aspects. The contribute proposes a research of the Lazio Order of Psychologists, in collaboration with the Italian Department of Prison Administration, aiming at identifying personality characteristics of batterers for the development of treatment strategies. Previous studies identified three types of perpetrators, thus distributed (Dutton, 2007): 30% Impulsive, 40% Instrumental and 30% Overcontrolled. While the first two are characterized by specific disorders, Borderline Personality Disorder and Antisocial Personality Disorder respectively, the third does not suit with a specific one.

**Objective.**– The aim was the assessment and the management of risk for violent recidivism of 57 man, imprisoned for crimes related to IPV.

**Method.**– The assessment of inmate envisaged clinical interviews dispensed in one or more sessions, the Rorschach Test and the PCL-R for the evaluation of psychopathy (Hare, 1993).

**Results.**– The percentage of the three types of offenders is coherent with literature, as well as personality characteristics. Moreover, a significant data emerged about overcontrolled population: violence committed is related to conflicting relationship dynamics and not abusive relationships.

**Conclusion.**– The identification of the personality characteristics of offenders and the differentiation between abusive and conflicting relationships are useful aspects to define the psychological treatability and to manage the violence. Particularly, the overcontrolled population could be more treatable because less affected from severe personality disorders. Therefore, future research should explore this population, not enough studied, in order to define adequate treatment strategies. Theoretical and clinical implications will be discussed.

### **The dark triad of personality and money addiction: Across different ethnic and sex groups**

Z. Šram

*Croatian Center for Applied Social Research, Department of Psychological Studies, Zagreb, Croatia*

**Introduction.**– An extreme desire for materialistic values might turn out to be an obsessive disorder often leading to a compulsive consumer behaviour, revealing dark and hidden side of the personality that may cause awful psychological and social consequences. Money addiction was defined in terms of terminal value preferences indicating an extreme desire for being very rich, spending a lot of money, and being able to buy anything he/she wants to.

**Objectives.**– The primary objective of this study was to find out whether and what dimensions of the Dark Triad of personality (narcissism, psychopathy, and Machiavellianism) were significant predictors of money addiction across different ethnic and sex groups.

**Methods.**– The survey was conducted on the convenience and purposive sample consisted of 1100 full aged participants, half of which were Croats and another half was the members of the Serbian ethnic minority. Multiple regression analysis were performed in order to determine how well scores on money addiction could be predicted by narcissism, psychopathy, and Machiavellianism.

**Results.**– Moderate positive correlations were found among money addiction, narcissism, psychopathy, and Machiavellianism across different ethnic and sex groups. All dimensions of the Dark Triad of personality were significant predictors of money addiction across different ethnic and sex groups.

**Conclusions.**– There was an evidence that the Dark Triad of personality is underlying money addiction regardless of belonging to different ethnic and sex groups. The money addiction in its psychological underpinning may indicate the existence of a severe personality disorder that might require a psychiatric treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Religiosity and over-implication in organic personality disorder**

S. Trifu<sup>1</sup>, M. Topana<sup>2</sup>, E.G. Carp<sup>3</sup>, A.I. Trifu<sup>4</sup>

<sup>1</sup> UMF Carol Davila, Psychiatry, Bucharest, Romania; <sup>2</sup> Titu Maiorescu University, Psychology, Bucharest, Romania; <sup>3</sup> Hospital for Psychiatry, Psychiatry, Sapunari, Romania; <sup>4</sup> Medical Military Institute, Medicine, Bucharest, Romania

\* Corresponding author.

**Motivation.**– Frontal lobe syndrome is a complex medical state manifested in a series of disturbances that occur at the level of the olfactory, visual, auditory, locomotor systems, especially at the level of the psyche, disorders that materialize in their clinical evolution in serious and irremediable psychiatric disorders such as schizophrenia.

**Objective.**– The present paper proposes the presentation of the similar diagnostic criteria encountered both in the paranoid schizophrenia symptomatology and in the disorder of organicity, respectively the differentiation criteria of the two pathologies.

**Hypothesis.**– The approach of the case is based on the assumption that the frontal lobe pathology in its clinical evolution, may constitute a prodromal trigger in the evolution of major psychiatric disorders with the deterioration of psychic functions similar to schizophrenia.

**Results.**– Having in background a possible paranoid personality structure, the patient developed from a cranio-cerebral trauma a frontal lobe pathology materialized in a psychiatric clinical condition, framed with I<sup>th</sup>-axis diagnostic elements.

**Conclusions.**– Following the analysis of the patient's life events and psychiatric evolution, we can observe the relevance and evolution over time of the features characteristic of the frontal lobe syndrome, a development that has become paranoid schizophrenia, with numerous suicide attempts.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0611

### **Borderline personality disorder – Sometimes 'sickness' and 'illness' exist where no' disease' can be found: Conceptual reflections from a Brazilian field research**

E.R. Turato, D.A.R. Silva<sup>\*</sup>, R.A. Bastos

*UNICAMP, Universidade Estadual de Campinas, Medical Psychology and Psychiatry, Laboratory of Clinical-Qualitative Research, Campinas, Brazil*

\* Corresponding author.

**Introduction.**– The essential feature of Borderline Personality Disorder (BPD) is a diffuse pattern of instability, marked impulsivity of interpersonal relationships, self-image, and affect that arises early in adult life, present in various contexts. In clinical populations, borderline personality disorder is the most common personality disorder, with a prevalence of about 10% of all psychiatric outpatients.

**Objective.**– To describe the researcher's experience as a participating observer in outpatient treatment of patients with borderline personality disorder in south-eastern Brazil.

**Method.**– The design used was participant observation, on psychiatric managements of BPD outpatient in a university public hospital in south-eastern Brazil, using a longitudinal technique of observations from March 2015 to February 2017, totalling 700 observation hours.

**Results.**– In clinical psychiatry, pharmacological guidelines make the medical practice, which focus on symptoms of a disease and are anchored on a biomedical materiality. However, in Borderline condition, ‘illness’ is a feeling, an experience of unhealthy which is entirely personal, interior to the person of the patient, in a psychosocial presentation of his ‘sickness’. Condition that makes pharmacological management difficult.

**Conclusion.**– In the possibility of thinking professional–patient relationship in borderline condition such as Michael Balint, the father of the Medical Psychology, have presented us: “Every illness is also the vehicle for a plea for love and attention. One of the commonest conflicts of man is caused by the discrepancy between his need for affection and the amount and quality of the affection which his environment is able and willing to grant him.”

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0612

### **Outpatient clinical management for patients with borderline personality disorder: A qualitative report on professional experiences of Brazilian residents in psychiatry**

E.R. Turato, D.A.R. Silva\*, R.A. Bastos

UNICAMP, Universidade Estadual de Campinas, Medical Psychology and Psychiatry, Laboratory of Clinical-Qualitative Research, Campinas, Brazil

\* Corresponding author.

**Introduction.**– Prevalence of borderline personality disorder (BPD) is estimated at 1–2% in general population, whereas in samples of the psychiatric clinical population the prevalence is approximately 15–25% of the visits. Studies on adherence to clinical treatment relate that impulsivity, manipulations, affective dissociation, suicide attempts accompanied by chronic self-harm, interfere in the adherence to treatments of the cases followed.

**Objective.**– Understanding emotional experiences and management meanings developed and reported by residents of psychiatry for patients with BPD.

**Method.**– We used the clinical-qualitative method, through semi-directed interviews with open-ended questions in depth, in an intentional sample, closed by saturation criterion with 17 psychiatry residents, interviewed in the period from December 2015 to February 2017, at the General Hospital of State University of Campinas, São Paulo State. Data processing technique consisted of the Qualitative Content Analysis.

**Results.**– Three categories of discussion were elected for this presentation - negative countertransference; emotional void; impotence in medical management. Feelings of emptiness are shared in the doctor–patient relationship, and intense human experiences in borderline condition cause a feeling of impotence in psychiatric management, associated with pharmacological and psychotherapeutic limitations. In the therapeutic relationship the countertransference was considered negative regarding to the borderline patient

**Conclusion.**– Difficulties involved in the therapeutic process should not be an impediment, but rather that it can be used as a support to offer a more profound and beneficial treatment to the patient. Studies of the long-term therapeutic process of patients with borderline personality disorder are necessary to better understand and treat their dynamics.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Philosophy and psychiatry**

EV0613

### **Binswanger, Jung and the transcendental understanding of melancholic syndrome**

V. Cicero

University of Messina, Cognitive Sciences, Psychological, Educational & Cultural Studies, Rometta Marea, Italy

**Introduction.**– Compared to the previous philosophical matrices of his psychiatry, with *Melancholie und Manie* (1960) Binswanger made a turning point: after the influence of Husserl’s descriptive phenomenology in *Logische Untersuchungen* in the 1920s, and the “Heideggerian” *Daseinanalyse* dominating the next thirty years, the 1960 volume marks Binswanger’s reconnection to posterior, transcendental-egological Husserlian phenomenology (from *Ideen* to *Cartesianische Meditationen*).

**Objectives.**– The purpose of this essay is to show that, the relationship between psychiatry and philosophy being an undeniable epistemological advantage for both—which Binswanger clearly proves with his theoretical and practical activity—the philosophical assumptions he borrows don’t seem apt to the authentic understanding of melancholy though, whereas Jung’s archipsychology has its philosophical and psychiatric papers in order to draw it.

**Methods.**– The inquiry about the foundations of philosophy and psychiatry complicity will be a hermeneutic-speculative type, that is, consisting of an “other way round” theoretical reading of texts by the authors at issue (Freud, Jung, Binswanger, Husserl, Jaspers, Heidegger) following the methodological principles of transcendental phenomenology.

**Results.**– The authentic main topic of melancholy isn’t the loss of someone or something, nor the lack of unity of intentional operations of consciousness (*protentio*, *retentio*, *praesentatio*)—outstanding forms of the structural givingness of *Dasein*—but the impossibility to freely give to himself and to others.

**Conclusion.**– “Misled” by Husserlian-Heideggerian assumptions, Binswanger failed to grasp the genuine transcendental place of melancholic syndrome. A new psychiatric-philosophical understanding of melancholy can plausibly come from a reinterpretation of Jung’s archipsychology inspired by the method of transcendental phenomenology.

EV0614

### **Psychopathology in Shakespeare’s “Macbeth”**

A. Rizouli

TEI of Thessalia, Department of Nursing, Larissa, Greece, Larissa, Greece

It has often been said that Shakespeare’s supreme achievement is in the depth and range of the characters he creates.

First of all, Lady Macbeth in Act I, scene VII, lines 54–58 tells her husband that she would dare to kill her own child and describes the violent way of her act. By these words, she tries to show her determination and to persuade Macbeth to kill the king. But, the thought of infanticide is not something strange to a postnatal woman. In postnatal psychosis the thought of harming the baby is a main characteristic

After the murder of Duncan, Macbeth is devastated by feelings of guilt. He has sleep problems and this condition worsens and becomes hallucinatory when he sees the ghost of Banquo. Lady

Macbeth is disappointed by the “madness” of her husband and she tries to apologize to their guests. In Act III, scene IV, lines 62–64 she implies that Macbeth has also auditory hallucinations because of his fear. This hallucinatory experience of Macbeth can be part of a psychotic episode. In addition, he murders his former comrades, because he is afraid of them. This fear becomes excessive and reaches the border of persecutory delusion.

In Act V, scene I Lady Macbeth rubs her hands in a compulsive manner, while she is sleepwalking. The guilt of murdering Macduff's family and King Duncan causes the obsession that she has stains of blood in her hands. Therefore, she tries to get rid of blood, by washing her hands excessively.

### **Asymmetrical impact of genetic explanations for prosocial versus antisocial behavior**

M. Lebowitz<sup>1\*</sup>, P. Appelbaum<sup>2</sup>, K. Tabb<sup>3</sup>

<sup>1</sup> Columbia University, Dept. of Psychiatry/NYSPI Unit 122, New York, USA; <sup>2</sup> Columbia University, Dept. of Psychiatry, New York, NY, USA; <sup>3</sup> Columbia University, Dept. of Philosophy, New York, NY, USA

\* Corresponding author.

*Introduction.*– As psychiatric and behavioural genomics have progressed in recent decades, genetic explanations for behaviour have become increasingly common. Some research has suggested that genetic explanations can lead people to be held less responsible for their behaviour, which could have important moral and philosophical implications. However, little is known about what factors might influence laypeople's receptivity to such explanations.

*Objectives.*– The present research examined whether the moral valence of a behaviour would influence people's willingness to attribute it to genetic causes. Our hypothesis was that people would be more willing to make genetic attributions for prosocial (i.e., morally good) behaviour than for antisocial (i.e., morally bad) behaviour.

*Methods.*– In four vignette experiments, participants were randomly assigned to read about either prosocial or antisocial behaviour and to rate the extent to which they believed the behaviour was attributable to genetic causes.

*Results.*– Across a range of stimuli, participants who read about prosocial behaviour rated genetics as having played more of a role in causing the behaviour than did those who read about antisocial behaviour. Mediation analyses suggested that this might have occurred because participants were motivated to avoid attributing antisocial behaviour to genetic causes for fear that doing so might suggest that perpetrators could avoid personal responsibility for their actions.

*Conclusions.*– Moral considerations, rather than only objective facts, appear to influence people's willingness to believe genetic explanations for behaviour.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Impact of reductionism and anti-reductionism on clinical practice today: France as case study**

S. Lézé

DSM team, IHRIM-UMR 5317, Ens de Lyon, Human Sciences, Lyon, France

*Background.*– Contemporary psychiatry is a recurrent place of disputes. One hypothesis to analyze them is to consider their conceptual nature as Jerome C. Wakefield have proposed recently. Indeed, in medicine, a “bad philosophy” has immediate practical implications.

*Aims.*– The objective of this paper is to analyze the paradigmatic case of French psychiatry against the globalization of psychiatry.

*Method.*– Studying the formation and development of the argument against “reductionism” from an epistemological history. This argument aims at resisting two processes: the implantation of American psychiatry (DSM) and the rebiologization of psychiatry (In France, the separation between neurology and psychiatry dates from 1968).

*Implications.*– What is at stake in these disputes would be the preservation of the French clinical tradition. The accusations of “reductionism” are therefore central to understanding the essential tension between rival conceptions of human nature.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Shadenfreude and envy moral emotions, as well as embodiment processes trough gesture narratives in schizophrenia and autistic spectrum disorder**

S. Baez

Universidad de los Andes, Bogotá, Psychology, Bogota, Colombia

*Introduction.*– Schizophrenia (SZ) and autism spectrum disorders (ASD) share some phenomenological, neurocognitive and genetic characteristics. Both groups of disorders are characterized by severe alterations in emotional and social functioning. The nature of such impairment and the underline processes are relevant to psychiatry.

*Objective.*– To propose a novel observational category based on embodied processes through narrative gesture such as: movement, gesture, facial expression, vocal intonation in addition to the social cognition tasks along with brain anatomy study.

*Methods.*– Ten SZ patients and 10 ASD completed tasks on face emotional recognition, moral and empathy judgment as well as moral emotions. Embodiment processes such as face expression, gestures, prosody, voice tone and body movements were assessed while patients narrated a fragment (2 minutes) of the animated cartoon Waltz with Bashir film.

*Results.*– Personal approaches towards intersubjectivity from both groups showed relevant differences between cognitive outcome and embodied processes.

*Discussion.*– Variables used evidence the multidimensional nature of the emotional and cognitive experiences as well as differential profiles in both populations.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

Germany; <sup>3</sup> All India, Inst. Med. Sci., New Delhi, India; <sup>4</sup> Univ.

Innsbruck, School Education Dean, Innsbruck, Austria; <sup>5</sup> Univ.

Luxembourg & Vienna, Fac. Psychology Dean, Vienna, Austria

\* Corresponding author.

*Objectives.*– Philosophy is regina scientiarum considering all sciences (Immanuel KANT) reflected by epistemology–ethics–aesthetics. Central position of psychiatry in medicine, psychology, sociology needs creation of philosophical psychiatry – independently from general medical–philosophy, including not only ethics, but also scientific–theoretical, metaphysical, aesthetically fundamentals. This could be supported by foundation of an International Academy for Psychiatry (IAP) (similar to Eur. Acad. Neurol. (EAN-2015–Berlin, 1<sup>st</sup>Congress).

*Conception–discussion.*– A. Epistemology. An integrative psychiatry needs enlarged fundamentals in normal&pathological neurophysiology/–morphology/–genetics, psycho–neurology (e.g. psycho–neuro–immunomodulation) related to psychopathology. An integrative psycho–neuro–therapy incl. Chinese–Indian&other traditional–medicine in education&treatment has to be discussed. Reconsideration of psychological–psychiatric notions acc. to axiology–logic–semantic is recommendable. B. Moral philosophy. Independently from various modern ethical–theories (deontology, utilitarianism, etc.) has to be considered Kant’s human obligations to himself–patients (a), other humans–medical personnel (b), sub–human, e.g. reduction of animal–experiments (c) suprahuman beings: moral&scientific frames about applications of theological–practices of great–religions for therapy (Brahmanism–Buddhism/Christianism–Mosaism/Confucianism–Taoism/Mohammedanism). C. Aesthetics. In relation to A–B interdisciplinary consideration is necessary to destine volume of paradigm–changes in psychiatry (& neurology) by non–& surgical–therapies, leading to pathophysiological & psychopathological effects (primum non nocere).

*Conclusion.*– Establishment of regular common congress–sessions of EPA/WPA with philosophical (FISP–ISB–EACME,etc.)/psychological (IUPsyS,etc.)/neurological (WFN)/physiological (IUPS,etc.)/medical societies (ISIM–ICC–FIGO–SIU–etc.) could open new scientific&political dimension in medicine, leading to humanization, higher efficacy & internationalization of science–medicine–ecology in context of UNO–Agenda21 for better health–education–etc. on global level.

*Dedication for long–time moral/scientific support of Profs.*– K. Lorenz\*/Austria, N. Karabashev, D. Orachovats, M. Rashev, N. Schipkovensky, M. Slivensky/Bulgaria, R. Aron, J. Dausset\*, J.–M. ### **Moral rationality as a mechanism of standardization of trust in a patient (with mental illness) – Doctor communication**

A.C. Cristofor<sup>1</sup>, L. Pricop<sup>2</sup>, R. Chirița<sup>1</sup>, I. Untu<sup>1</sup>, D.A. Radu<sup>1</sup>

<sup>1</sup> G.T. Popa University of Medicine and Pharmacy, Psychiatry, Iasi, Romania; <sup>2</sup> Alexandru Ioan Cuza University, Department of Interdisciplinary Research in Social Sciences and Humanities, Iasi, Romania

\* Corresponding author.

*Introduction.*– One of the essential concepts in a medic–patient relationship as viewed from a communication framework is trust. Although the number of studies which are based over a medic and patient’s trust have risen, the mechanism and nuances in making a patient trust his doctor are made even before the patient has its first contact with his doctor. This could mean that trust, as a unilat-

eral dimension, is the choice of the patient, by opting for a specific doctor or by choosing one over another, the patient has already a starting point of trust due to his power to choose to whom he will partially forfeit a part of his individual autonomy. This is not only directed to the healthcare professional, but also his health institution of choice.

*Objectives.*– An analysis from a moral rationality perspective of the mechanism that engages the patient to give up a part of his individual autonomy, as such trusting him in relation with his medic.

*Methods.*– An interdisciplinary approach (communication philosophy and ethics of communication) on how an efficient communicative action can be build based on trust. And at a practical level, testing and evaluating this structure by psychiatrists.

*Results.*– A practical communication guide for a doctor–patient (with mental illnesses) adapted to a well defined socio–cultural context.

*Conclusions.*– Stabilizing the doctor–patient relationship could take place through means such as utilize moral rationality. From here the actions which performed can be placed in the category of acts which can generate trust, confidence and reliance of the derived normative character.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Schizophrenia, mimetic theory, and the archetypal scapegoat; evolutionary functionality and conceptual validity mediated through the eye of the beholder**

D.V. Riordan

HSE South, West Cork Mental Health Services, Co. Cork, Ireland

*Introduction.*– It has been argued that schizophrenia is not a valid scientific concept.

*Objectives.*– To consider the conceptual validity of schizophrenia, using Mimetic Theory and the related Archetypal Scapegoat Hypothesis.

*Methods.*– Mimetic Theory is a theory of human nature and origins, advanced by the French intellectual René Girard. It claims that humans mimic each other’s behaviours and desires, thus facilitating social cohesion and cultural evolution, but causing rivalry and reciprocal violence. Such violence, it is argued, was curtailed by the emergence of unanimous scapegoating of single victims. The Archetypal Scapegoat Hypothesis proposes that schizophrenia was an evolutionary adaptation which provided scapegoat victims, about whom an entire community was likely to unanimously agree, thus enhancing the unifying and pacifying efficacy of scapegoating.

*Results.*– If the evolutionary function of schizophrenia was to induce communal unanimity, then the efficacy would have been primarily mediated by perceptual and cognitive biases evolving in the general population, rather than by specific traits in affected individuals.

*Conclusion.*–

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0621

### **Transference and synaptic traces: What compatibility?**

C. Rizet

University of La Rochelle, Service de Santé Universitaire, La Rochelle, France

\* Corresponding author.

Although the concept of schizophrenia may, or may not, be clinically useful, it is valid nonetheless, as it describes a real biopsychosocial phenomenon. Our apparent cross cultural tendency to classify this heterogeneous constellation of symptoms as a single category may be due to the evolution of common schemata for identifying the scapegoat victims most likely to induce communal unanimity. The defining property of schizophrenia may be found, not in the 1% of the population who express the phenotype, but in the 99% who do not.

The possibility of psychoanalytical action implies a clear reference to the Fundamentals of metapsychology which include the theory of the message and that of translation in the transference analysis. There is no reason why the circuits of the brain cannot be affected by a “psychosomatic” effect which come from the transformation of ancient representations by transference analysis.

Indeed, if we consider transference analysis as a working through which repeat and change rememoration: this process could modify (or affect) brain plasticity.

In this conference, we want to ask the question: could we think a theory of transference which include neuroscience and psychoanalysis? We propose to study this question with philosophical concepts like “the thing itself” (Kant) or the “negative” (Hegel, Spinoza).

Keywords: brain plasticity, transference, theory, rememoration, psychoanalysis.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Murray Rothbard and Thomas Szasz on compulsory commitment: Beyond the “dangerousness criteria”**

G. Santos<sup>1</sup>, J. Coelho<sup>2</sup>

<sup>1</sup> Hospital Magalhães Lemos, Psiquiatria, Porto, Portugal; <sup>2</sup> University of Oporto, Faculty of Letters, Porto, Portugal

\* Corresponding author.

Compulsory commitment refers to the court-ordered treatment when an individual is considered to have a severe mental disorder and poses an imminent risk to self or others by a qualified agent.

Respect for autonomy is the central principle endorsed by libertarians. Few philosophers have thought as rigorously about the problem of individual action as Murray Rothbard. Rothbard emphasizes the mistake of taking the “dangerousness criterion” for granted, stressing that the patient, most of the time, has not committed any criminal activity, and is only being judged by algorithmic probability. In fact, empirical data has shown that people with mental disorders are statistically less dangerous and much more law-abiding than the normal population. For Szasz, mental disorders have a mythological status and involuntary psychiatry incarceration remains one of the most perverse political devices used by a so-called therapeutic State.

In this presentation we recover a Libertarian look at the question of compulsory commitment. In the first part of our paper, we introduce the dialogue between these two philosophers, by integrating their ideas into the broader context. We explore the similarities and differences between them. Both agree that psychiatry nosology is seen as a weapon in the war of institutional psychiatry against the individual. We argue that Szasz’s and Rothbard’s conception of institutional psychiatry has often been dismissed because of the way they deal with the construct of individual autonomy as a process independent of the state, and their misperception about the scientific status of psychiatry nosology.

### **On the issue of death and suicidal ideation: A perspective from the classical Farsi literature**

H. Shahpesandy

Lincolnshire Partnership Foundation Trust, Hartsholme Centre, Lincoln, United Kingdom

The classical, post-Islamic Persian literature (covering a period between 900 and 1500 AD) is considered one of the great literatures of humanity. The issue of death is a common theme, and attempts to resolve the its mystery and find the elixir of life have been made for centuries. In general there are four different perspectives: (1) a view of glorification of death, represented mainly by Sufi mystics as Sanai, Attar and mainly Rumi admiring and seeking death to get “liberated” from the “jail” of this material world. They perceive death as the end of human suffering and reaching the desired world of reunion with the beloved. (2) The perspective of condemnation of death, mainly represented by Khayyam, who is questioning the meaning of life and views death as the “end” of man and suggests relishing life, indicating there will be “nothing” after death. (3) A realistic viewpoint on death seeing life and death as the two faces of the same coin. Sa’di and Firdausi are the main advocates of this assessment and in order to “avoid” death and become “immortal”; they suggest utilising the time on Earth as an opportunity to appreciate the life and use it creatively and make oneself a “good name”. (4) A rather diverse perspective (represented mainly by panegyric court poets); depending on the author’s state of mind; glorifying life, or occasionally expressing hopelessness.

This presentation considers how suicidal thoughts and death are presented in the works of Rudaki, influential Sufi poets, Khayyam, and others.

EV0624

### **How can we understand suffering?**

E.J.D. Singainy

Centre Hospitalier Universitaire Site Sud Reunion, Reunion, Saint-Pierre, Reunion

Suffering is an intimate, personal experience that is unique to humans. But far from being a suffocating experience, suffering is an invitation to take a closer look at the self and develop what is already embedded within: the essence of life. By adopting this logic, suffering questions not only what it means to be human but our perception of evil, the foreign, solidarity. In short, suffering examines all the great questions or ideas that define “humanness” or a certain interpretation of the human subject. This contribution is not limited to a phenomenological description of suffering, but rather seeks to look further, beyond comfort.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0625

### **Why do not use the expression “mental disease”?**

M. Vargas

Complejo Asistencial de Zamora, Psychiatry, Zamora, Spain

*Introduction.* – “Mental disease” is a broadly used expression, both in the common conversations as well as in the scientific communication. Mental diseases are accepted as the referents that justify

psychiatry as a medical discipline. Szasz antipsychiatry argument critiques this concept as invalid or inexistent [1].

*Objective.*– To defend the argument that “mental disease” is an intrinsically illogical (invalid) construct.

*Methods.*– A formal logical analysis of the proposition “mental diseases are not brain diseases” will be done. The following premises will be accepted: (1) “disease” is a construct only exactly applicable by the medical science, being any other use just metaphorical, (2) any disease is a process happening in a biological organism and can be explained according to natural laws, (3) human mind is an exclusive property of the human brains, and (4) the human mind is not fully explained by the physiology of a brain, but also any other agents are needed: physical, linguistic and cultural environment.

*Results.*– A semantic tree will confirm the invalidity of the proposition because leading to contradiction.

*Conclusion.*– The classical Szasz’s argument is valid. So, mental diseases are equal to brain diseases. The use of the construct “mental diseases” should be avoided to prevent against sterile ideological debates and the risk of neglecting of brain diseases with prominent mental or behavioural diagnostic attributes. The heuristic framework of Clinical Neuroscience contributes to unify brain’s medicine. Reference

### Post-traumatic stress disorder in residents of Fort McMurray six months after a wildfire: Prevalence rates and correlates

V. Agyapong<sup>1</sup>, M. Juhas<sup>1</sup>, J. Omegie<sup>2</sup>, E. Denga<sup>3</sup>, B. Nwarka<sup>3</sup>, I. Akinjisi<sup>3</sup>, S. Corbett<sup>4</sup>, M. Brown<sup>1</sup>, P. Chue<sup>1</sup>, A. Abba-Aji<sup>1</sup>, X.M. Li<sup>1</sup>, A. Greenshaw<sup>1</sup>

<sup>1</sup> University of Alberta, Department of Psychiatry, Edmonton, Canada; <sup>2</sup> Alberta Health Services, Department of Public Health, Fort McMurray, Canada; <sup>3</sup> University of Alberta, Department of Family Medicine, Edmonton, Canada; <sup>4</sup> Northern Lights Regional Health Centre, Department of Psychiatry, Fort McMurray, Canada

\* Corresponding author.

*Objectives.*– To assess likely prevalence of PTSD in residents of Fort McMurray six months after a wildfire and to determine the predictors of likely PTSD in the respondents.

*Methods.*– A quantitative cross-sectional survey was used to collect data through self-administered paper-based questionnaires to determine likely PTSD. The PTSD Checklist for DSM 5 Part 3 was used to assess the presence or absence of likely PTSD in respondents randomly selected from a variety of natural settings in Fort McMurray. Data were analysed with SPSS version 20 using univariate analysis with the Chi-Square Test and Binary Logistic Regression analysis.

*Results.*– One month prevalence rate among adult residents for likely PTSD six months after the disaster was 12.8% (14.9% for females and 8.7% for males). While controlling for other factors in the logistic regression model, corresponding odds ratios included 9.51 and 4.88 for those who received no or only limited support respectively from friends/family, 8.00 for those who had history of an anxiety disorder before the wildfire and 4.01 for those who received counseling after the wildfire. Respondents who presented with likely PTSD were significantly more likely to self-report increased drug abuse, but not increased alcohol use, after the fire.

*Conclusion.*– Our study has established that while support from family/friends following wildfires may be protective against likely

PTSD, a prior diagnosis of an anxiety disorder significantly increased risk for developing PTSD. Further studies are needed to explore whether receiving counselling after a wild fire alters the likelihood of individuals presenting with PTSD.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

## Posttraumatic stress disorder

EV0627

### Veteran work place violence – A case report

A. Albassam<sup>\*</sup>, P. Riess, P. Korenis  
Bronx Lebanon Hospital, Psychiatry, Bronx, USA

\* Corresponding author.

Published literature over the past decades has revealed that veterans’ posttraumatic stress disorder (PTSD) following exposures to death of fellow servicemen affects veterans’ capability to return to the civilian workplace. Recent literature estimates the impact of deployment for veterans who have been to Iraq and Afghanistan exhibiting symptoms of PTSD at 14%. DSM-5 has directly linked PTSD to violence indicating that individuals with PTSD may be quick tempered and may engage in aggressive, verbal and/or physical behaviour with little or no provocation.

Considering these factors, we present a case of a veteran who served in Afghanistan. He witnessed many of his friends in service being killed. This has left a deep impact on his ability to cope with challenges of daily living. He displayed acts of aggression manifested by destruction of property, threatening of violence and physically assaulting coworkers. This was exacerbated by feelings of shame and anger, alienation and dissociative states. Additionally, the patient indulged himself in cannabis use and energy drink binging which has further aggravated his symptoms. This case aims to generate attention to the potential threat of violence for veterans suffering from PTSD and providing recommendations to address that problem.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0628

### Specific assessment of acute and chronic post-traumatic symptoms and disorders in children

M. Battista<sup>\*</sup>, M. Gindt, S. Thümmeler, F. Maria, O. Nachon, F. Askenazy

Hôpitaux pédiatriques CHU Lenval de Nice, University Department of Child and Adolescent Psychiatry, Nice, France

\* Corresponding author.

*Introduction.*– After the terrorist attack on the ‘Promenade des Anglais’ in Nice, France, a pediatric psychological team was mobilized (psychiatrists, psychologists and other mental health workers) to take care of children and their families. Immediately, a lack of specific tools for this population appears, particularly for very young children.

*Objectives.*– Standard evaluation tools for emergency situations were developed by the center of pediatric psychotraumatism assessment in Nice.

*Results.*– Firstly, we have developed a standardized briefcase according to the age of children. This briefcase includes games, especially Playmobil<sup>®</sup>, felt-pen and colored pencil, as well as spe-

cific drugs for children. Secondly, we adapted initial certification to the age of children and specific post-traumatic stress reactions. Thirdly, we implemented a standardized evaluation in order to assess post-traumatic disorders and consequences in children (PTSD, comorbidities such as anxiety, depression and hyperactivity, social functioning, attachment and family functioning, cognitive assessment and parental evaluation of psychological difficulties).

**Conclusion.**– Standard assessment of exposed children is a necessity after a terrorist attack or mass traumatism. Indeed, more than 1.000 children and adolescents consulted in the center of psychotraumatism assessment since July 14<sup>th</sup>, 2016. Among these patients, a lot of children present PTSD with dissociative responses and depressive comorbidity. Cognitive assessment shows difficulties for attention and memory. All these symptoms severely impact children's education and social abilities, in particular attachment. Moreover, parental evaluation shows that parents are also characterized by severe and chronic PTSD symptoms.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0629

### **Risk factors and mental health consequences of sexual violence against women**

T. Bayram Kuzgun

Istanbul Arel University, Psychology, Istanbul, Turkey

**Introduction.**– Sexual violence against women is a controversial issue across the world. Sexual violence includes rape, attempted rape, or other forms of sexual assault. Mental health consequences of it should be well known by clinicians.

**Objectives.**– This study aimed to present risk factors and immediate and long term mental health consequences of sexual violence against women.

**Method.**– Literature review was conducted by using studies between 2000 and 2017.

**Results.**– Risk factors for sexual violence is having been living with an intimate partner, poverty, being young age, having a story of other sexual traumas. Acute consequences of sexual trauma consist of negative feelings such as shock, denial, fear, confusion, withdrawal, guilt or nervousness. Long term consequences of sexual trauma include PTSD, anxiety disorders, alcohol or illicit substance dependence, suicidal ideation, and suicide attempt (1)

**Conclusions.**– Risk factors is especially important to prevent sexual trauma. Acute and long term consequences of sexual violence should be well known in order to identify and serve the best treatment survivors.

EV0630

### **Theoretical models for the development and treatment of post traumatic stress disorder**

T. Bayram Kuzgun

Istanbul Arel University, Psychology, Istanbul, Turkey

**Introduction.**– PTSD diagnosis was considered as a direct consequence of a traumatic events. Diagnostic criteria for PTSD in DSM-5

include' a history of exposure to a traumatic event that meets specific situations and symptoms from each of four symptom clusters: intrusion, avoidance, negative alterations in cognitions and mood, and alterations in arousal and reactivity.

**Objectives.**– This study aimed to present four theoretical models for the development and treatment of Post Traumatic Stress Disorder.

**Method.**– Literature review was conducted to discuss the models.

**Results.**– The four models that are Learning theory model (various), Emotional processing theory (Foa), Cognitive theory (Ehlers & Clark), and Schema Theory (Horowitz; Janoff Bulman; McCann & Pearlman) have been discussed.

**Conclusions.**– Each theoretical models suggests different treatment strategies to PTSD.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **When posttraumatic stress disorder is hidden by memory impairment: A case report on posttraumatic pseudodementia**

S. Ben Saadi<sup>\*</sup>, E. Khelifa, I. Jelalia, S. Khanfir, Z. El Hechmi

Razi Hospital, Department F, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Traffic accidents are an important source of stress, damaging not only the physical integrity of the victims but also their psychic integrity. Therefore, they can represent the starting point of many psychiatric disorders.

**Objectives.**– Report an unusual clinical manifestation of the post-traumatic stress disorder.

**Methods.**– A case report on a patient who was treated in our department.

**Results.**– Mr XY, 50-year-old was referred to our department by the neurology department for a delusional syndrome. Mr XY has a history of diabetes type 2 with degenerative complications. Eighteen months earlier, he was involved in a car accident causing the immediate death of his elder son while the patient had only some bruises. One month after the accident, the patient began to present a social and professional indifference, sadness, insomnia, reduced appetite and dissociation periods during which he was talking to his deceased son. Gradually, he began to present memory impairment and lack of words with a space-time disorientation. Giving the fast worsening of the clinical signs and the refusal of the treatment and the insulin injections, the patient consulted in neurology; a cerebral CT scan showed a cortical and sub-cortical atrophy and the neuro-psychological tests a severe depressive syndrome. The patient was then hospitalized in our department and put under antidepressants and anxiolytics with a gradual improvement.

**Conclusion.**– Posttraumatic stress disorder is an under diagnosed psychiatric illness which sometimes dresses unusual aspects. That's why an early psychiatric care of the victims has to begin immediately after the traumatic event.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0632

### **What about EMDR in preschool children with post-traumatic stress disorder?**

S. Bourgou<sup>\*</sup>, A. Belhadj

CHU Mongi SLIM, Child Psychiatry Department, La Marsa, Tunisia

\* Corresponding author.

**Introduction.**– Children of any age who have experienced trauma are at high risk of developing post-traumatic stress disorder (PTSD) or another mental trouble. Eye Movement Desensitization and Reprocessing (EMDR) therapy has been proven efficacious in restoring affective regulation in post-traumatic stress disorder (PTSD) patients specially adults. But studies still limited for EMDR in preschool age children.

**Objective.**– Examine the efficiency of the EMDR to PTSD in preschool children.

**Methodology.**– Five children (3 boys and 2 girls) with PTSD diagnosis were recruited at the Child Psychiatry Department in Mongi Slim Hospital, la Marsa, Tunisia. The EMDR was indicated. The technique used tapping as bilateral stimulation when a child relative narrated the traumatic event story's.

**Results.**– The children were aged between 3 and 5 years. Three boys were direct victims: a boy was kidnapped for 2 months with verbal and psychological aggression during all the period. Another was attacked by a dog. Another was a victim of a sexual abuse. For the 2 girls, they witnessed a physical and verbal aggression of their fathers. EMDR sessions ranged from 1 to 3 in four cases. Only the case of the kidnapped boy required 5 sessions. All the patients no longer met the diagnostic criteria for PTSD both at the end of the therapy and 3 months later.

**Conclusion.**– EMDR seems to be a rapid and efficacy therapy for the treatment of post traumatic symptoms in preschool children. However, other studies are needed to assess this finding.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0633

### **Post traumatic stress disorder in children and adolescents: Clinical profile**

S. Bourgou\*, N. Ben Mabrouk, M. Hamza, F. Charfi, A. Belhadj  
CHU Mongi SLIM, Child Psychiatry Department, La Marsa, Tunisia

\* Corresponding author.

**Objectives.**– Describe clinical profile of patients aged less than 18 years with post traumatic stress disorder (PTSD).

**Methods.**– Retrospective and descriptive study conducted at the Child and Adolescent Psychiatry Department of Mongi Slim Hospital (Tunisia) from January 2013 until July 2016. We included all cases of patients followed for PTSD (DSM 5). Data was collected from their records.

**Results.**– A total of 30 cases were identified. The average age was 8,48 years. The sex ratio was 1,14. Poor family functioning was reported in the quarter of cases. Most of them had a low socio-economic status (83%). The majority of patients (63, 4%) witnessed a traumatic event occurring to others, while 33,3% experienced it directly. Physical aggression was the highly reported, followed by psychological and sexual abuse (respectively 60%, 45% and 37,7%). 14% had a road accident. A repetitive event was found in 34,5% of cases. The traumatic event occurred mostly at home (40%) and was mainly acted by a neighbor (28%). Hyper arousal and intrusion symptoms were predominant. The majority of patients (66%) have developed psychiatric comorbidities (depression, school phobia, stuttering, separation anxiety and elimination disorders). Of these, one child became blind after the trauma and one attempted suicide.

**Conclusion.**– Practitioners need to be able to recognize and treat post-traumatic stress reactions in children in order to decrease debilitating consequences.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0634

### **Narrative of trauma: Differences between specific vs. chronic traumatic events**

C. Soberón<sup>1</sup>, M. Crespo<sup>1\*</sup>, V. Fernández-Lansac<sup>1</sup>, M.M. Gómez-Gutiérrez<sup>2</sup>

<sup>1</sup> Universidad Complutense de Madrid, Clinical Psychology, Madrid, Spain; <sup>2</sup> Clinical Psychology, Madrid, Spain

\* Corresponding author.

**Introduction.**– Chronicity of exposure to traumatic events has been associated with a worse adjustment after trauma. Nevertheless, in spite of the proliferation of narrative approaches to study traumatic memories, very few studies have explored narratives characteristics in victims of single vs. chronic traumatic events.

**Objective.**– To analyse features of trauma memories in specific vs. chronic traumatic events. Method: The current study analysed and compared characteristics of both positive and traumatic/negative narratives from three age-matched women groups: (a) exposed to a single interpersonal violence episode (single-trauma group), (b) exposed to repeated intimate partner violence (chronic-trauma group), and (c) non-traumatized women (controls). Narrative variables were assessed using the Language Inquiry and Word Count (LIWC).

**Results.**– Differences in narratives variables across groups and narrative valence were explored, as well as the relationship between these narrative variables and psychological symptoms. Discussion: Altogether, this study provides further evidence about the influence that the type of traumatic event could have on the way in which interpersonal violence victims narrate and process their experiences. Clinical implications and future research directions will be discussed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0635

### **PTSD unmasked**

S. Gillard

Lived Experience, Lived Experience, Turrumurra, Australia

My presentation is an informative session around PTSD education from a lived experience point of view. As a former NSW Police Detective Sergeant who formed PTSD and depression due to work related trauma, my presentation is applicable to all emergency services, military, mental health professionals and the wider community. I discuss the stages of PTSD and depression and how a sufferer wears a mask, why they wear a mask and why a sufferer compartmentalises trauma. Due to external circumstances, a PTSD sufferer can be forced to mask their condition due to fear of career loss, stigma attached, or fear of retribution.

I will also talk about breaking down the barriers for early intervention to be realised. Resilience training, education along with peer support programs are functional methods to assist in achieving early intervention. What I will discuss in more detail, in the case of emergency services and military, are changes that will promote early intervention. I outline the feelings associated with suicide from a lived experience point of view as well as the facts around why suicide seems to be the answer by a sufferer. I will be introducing a suicide prevention resilience model which I developed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

<sup>1</sup> Institute of Neurology, Psychiatry, and Narcology of the NAMS of Ukraine, Department of Neuroses and Borderline Conditions, Kharkov, Ukraine; <sup>2</sup> Military Medical Clinical Center of the Northern Region, Clinics of Psychiatry and Narcology, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**— A clinical picture of mental health pathology in persons, who participated in military conflicts, is presented with a wide range of structurally and expressively different disorders, from psychologically understandable reactions and premorbid conditions to clinically defined forms of pathology, among them posttraumatic stress disorders (PTSD) are the matter of a significant clinical interest.

**Objection.**— The aim of the study was to investigate clinical-psychopathological variants and types of the PTSD course in servicemen of the Armed Forces.

**Methods.**— In the study 112 servicemen of the Armed Forces of Ukraine, who were direct participants of the antiterrorist operation (ATO) in eastern Ukraine in 2014–2015, were examined. The complex of the study included clinical-psychopathological methods, as well as the Mississippi Scale for Combat-Relative PTSD (M-PTSD), the Impact of Event Scale-Revised (IOES-R), and the questionnaire SCL-90-R (Derogatis Scale).

**Results.**— PTSD clinical variants were defined: anxious (33.9%), dysphoric (24.1%), asthenic (14.3%), dissociative (10.7%), mixed (10.7%), hypochondriac (3.6%), and somatoform (2.7%). An analysis of types of the PTSD course demonstrated that a stable type of the course was more frequent in hypochondriac, mixed, anxious, dissociative, and dysphoric variants—in 75.0%, 66.6%, 60.5%, 50.0%, and 48.1%, respectively ( $p < 0.05$ ); a progredient type—in 25.0%, 18.4%, 33.3%, 33.3%, and 16.7%, respectively ( $p < 0.01$ ). In patients with asthenic clinical variant a regredient type of the course prevailed (37.5%;  $p < 0.05$ ).

**Conclusions.**— On the base of the data obtained, the system of criteria for PTSD diagnosis has been clarified, that is a basis for optimization of therapeutic and preventive approaches.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

### When sleep is not enough: Examining EMDR mechanisms of action

P. Mougin\*, A. Quaderi, S. Baier

Université Côte d'Azur, Psychology, Nice, France

\* Corresponding author.

According to World Health Organization (2013), EMDR is one of the most effective therapies in the cure of PTSD. Nevertheless, a large part of its mechanisms of action remain unknown. Our research comes within the framework of the discovery of these physiological mechanisms. EMDR activates normally sleep-dependent memory processing (Stickgold, 2002). However, certain states of sleep, especially the REM sleep, can cause a high exposure to traumatic contents, stored in the hippocampus (Spencer, 2015). The hippocampus is involved in memory consolidation during REM sleep. In cases of too high traumatic network exposure, sleep is interrupted by the awakening. We hypothesize that, in the

awake period, EMDR therapy creates problem-solving and memory consolidation conditions, allowing an adaptive processing of the traumatic memory. We believe that this operation is similar to dream elaborations, without depending on the state of sleep. We will test this hypothesis by creating three experimental conditions: “sleep”, “EMDR” and “control”. Participants are confronted with traumatic images followed by recognition tasks. We will measure physiological responses during the 3 steps. The aim is to discover which condition allows the most adaptive information processing (recall of the essential information and oblivion of the insignificant details and a concurrent weakening of the response than during the exposure task), and to examine the effects of the traumatic images and EMDR on sleep.

**Learning objectives:**

- identify EMDR mechanisms of action;
- compare EMDR mechanisms with sleep mechanisms;
- experiment technology of physiological measure in EMDR therapy.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

### Psychotherapy of posttraumatic stress disorder patients in Ukraine

B. Mykhaylov<sup>1</sup>\*, O. Kudinova<sup>2</sup>, O. Serdiuk<sup>3</sup>, M. Vodka<sup>4</sup>, T. Alieva<sup>4</sup>, I. Vashkite<sup>4</sup>

<sup>1</sup> Kharkiv medical academy of postgraduate education, Psychotherapy, Kharkiv, Ukraine; <sup>2</sup> Kharkiv medical academy of postgraduate education, Psychotherapy, Kharkov, Ukraine; <sup>3</sup> Clinical sanatorium “Berezovskije Vody Resort”, Psychotherapy, Kharkiv, Ukraine; <sup>4</sup> International Charity Fund “Alexander Feldman Fund”, Psychotherapy, Kharkiv, Ukraine

\* Corresponding author.

Comprehensive psychosocial rehabilitation of 375 posttraumatic stress disorder (PTSD) combatants was exercised. Premorbid personality characteristics of patients with posttraumatic stress disorder are heterogeneous. It should be noted that all of the testees had problems in microcommunity such as, conflicts in the parents or children's family, divorce, conflicts with friends, colleagues in the aetiology of PTSD there are three groups of factors were shown:

I. Hereditary-organic. Constitutional and typological features of the central nervous system and features of the accentuated personality.

II. Psychogenic.

These are acute factors of external action.

III. Psychoorganic-comorbide. Organic complication, majority trauma origin.

The rehabilitation program was implemented in three stages.

1. The initial stage (setting therapeutic contact compliance)—2–3 days.

2. Main (rehabilitation) stage—14–18 days. Carrying out individual psychotherapy, group psychotherapy CBT-oriented, relaxation techniques with the assimilation of elements of autogenous training

(constantly), physiotherapy, exercise therapy, aromatherapy, reflexology, pharmacological (if needed).

3. Supporting (completing) stage—2–3 days. Carrying out individual psychotherapy, relaxation techniques.

**Results.**— It has been hypothesized that the basis for PTSD symptoms is chronic hyperstimulation of the Autonomic Nervous System which leads to a classic fight or flight response and subsequently many of the previously mentioned symptoms experienced by a combatant suffering from the condition. It is the responsibility of the practitioner to aid the combatant in managing PTSD in a manner

that helps them adapt to current living situations. The high efficacy were observed on 80% patients, middle range-15%, no response-5%.

### **Culpability and identification process in the clinic of trauma: Identity in the future of attacks**

F. Nyegue<sup>1\*</sup>, K. Madame THOMAS<sup>2</sup>, D.M. Mélanie<sup>2</sup><sup>1</sup> LIRCES/Université de Nice Sophia-Antipolis,PSYCHOLOGIE/psychanalyse, 06204 Nice cedex 3, France; <sup>2</sup> Université de Nice Sophia-Antipolis, Psychology, Nice, France

\* Corresponding author.

The 2015 and 2016 terrorist attacks on French soil provoked social upheavals whose mistrust between communities was only the symptom. These upheavals, far from being mere mass movements, could be analysed at the clinical level as the manifestation or symptom of a fear induced by a feeling of guilt due to the sense of belonging to the community of those designated as responsible or guilty of the terrorist drama. While it is possible to consider clinical care of patients imbued with feeling guilty in a context of inter-subjective crisis, this clinical care is more complex when the crisis involves group entities, imposing on the subject to face daily inquisitive gaze of the "other". This perception then feeds on fantasies and various affects on which the evolution of the clinical symptomatology of the patient will depend. This clinical care is all the more complex when the clinic is caught in the clinic of the child and/or the adolescent.

How, then, can we consider the individual clinic when, faced with the peculiarity of adolescence, the patient is confronted with the gaze of the other, himself suspicious and supposed to be stigmatizing?

### **Factors associated with PTSD in a group of Syrian refugee who applied to immigrant/refugee mental health special branch outpatient clinic**

E. Uygun<sup>1\*</sup>, Ö. Yıldırım<sup>1</sup>, A. Köseoğlu<sup>2</sup>, Ş. Erkoç<sup>1</sup><sup>1</sup> Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Psychiatry, Istanbul, Turkey; <sup>2</sup> Özyeğin University, Psychology, Istanbul, Turkey

\* Corresponding author.

*Introduction.*– The primer goal should be preventing of PTSD so it is so important to determine factors which associated with PTSD. The differences between those who develop and do not develop PTSD after exposure to trauma are important to determine that factors.

*Method.*–The Traumatic Events Scale was applied to syrian patients who applied to refugee mental health outpatient clinic. Clinical interviews were performed with those people who were defined as having traumatic experiences and the data forms which were prepared by the researchers were filled in. Then, test battery was given and this battery included the self-report scales.

*Results.*– In our study 35 people who had had traumatic experiences were included and 11 of them were diagnosed with PTSD. When the patients who has and has not been diagnosed with PTSD compared, a significant relationship was found among quality of life (p:0,011), well-being (p:<0,001), perceived stress (p:0,027), depression scores (p:0,005). Also, it was found that people who

were diagnosed with PTSD are talking with their relatives in Syria and having conversations on phone less often according to people who were not diagnosed with PTSD (p<0,001). The other important finding was that the development of PTSD is more related with experiencing traumatic events rather than the types of events.

*Discussion.*– As convenient with the past literature, the important thing for the developmental process of PTSD is being exposed to traumatic experiences rather than the type of the experience.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0641

### **Exploring posttraumatic stress disorder in vulnerable areas**

V. Valdez<sup>1\*</sup>, C. Santana<sup>2</sup>, J. Gonzalez<sup>1</sup>, J. Robinson<sup>1</sup><sup>1</sup> Universidad Catolica Santiago de Guayaquil, Psychiatry, Guayaquil, Ecuador; <sup>2</sup> Universidad Catolica Santiago de Guayaquil, Investigation, Guayaquil, Ecuador

\* Corresponding author.

*Intoduction.*– Violence in urban areas of south america has turned a relevant issue in mental health nowadays. Ptsd has been determined as a frequent pathology, mainly because individuals living in large cities are facing and witnessing distressing situations.

*Objective.*– To explore the PTSD prevalence and depression in vulnerable environments of guayaquil - ecuador.

*Methodology.*– Two ambulatory care centers, that belong to the ministry of health were chosen for this study, both of them located at the febres cordero paris. (low income and risky area of guayaquil). Premedical students were trained to collect the information using the davidson scale (DTS), PCL 5 and Beck Depression Inventory (BDI).

*Results.*– This is a transversal descriptive study, the total sample: 107: 75(70%) women, 32(29.9%)men. Davidson scale:positive: 34.6%, 11% men, 26% women. Pcl 5: 14%, 3% men, 12% women. BDI: Moderate 12%, extreme 5.6%.

*Conclusions.*– Overall, 34.6% shows and important evidence of PTSD in Febres Cordero parish. Depression is remarked with a moderate score 12% and a extreme score of 5.6%. These results must be a warning to the ecuadorian mental health system since most of the ambulatory care system do not count with a mental health area. Further studies must be done to determine the prevalence of ptsd, not only in guayaquil city but also in other south american cities in order to work on mental health programs.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

## **Prevention of mental disorders**

EV0642

### **Psychiatrist role in periodical medical examination of chemical industry workers**

S. Kuzmina

Kazan State Medical University, Psychiatry, Kazan, Russia

Follow to the importance of mental health of population, especially among working people, the evaluation of occupational factors were analysed.

Post-traumatic Stress Disorder 4.2.1., (indicated as F43.1 at DSM-V) and Other mental or behavioural disorders not mentioned in the preceding item where a direct link is established scientifically,

or determined by methods appropriate to national conditions and practice, between the exposure to risk factors arising from work activities and the mental and behavioural disorder(s) contracted by the worker are included into List of Occupational Diseases (ILO, 2010). In Russia we are working on the recognition of Mental Disorder(s) as an occupational one.

In Russia from 1998 till current period we continue mental health examination of workers at the chemical industry ( $n = 998$ ), who are working under exposure of noise and organic solutions (ethylene, benzoyl, phenol) on the level, not much higher than allowable to identify premorbid factors of job conditions and personality characteristics of workers who are more likely to get any mental health disturbances.

Among workers, neurotic and organic mental Sdr were diagnosed, group of people with Sdrs, which don't present in DSM-V were selected. 1. This sdrs are typical for higher experienced professionals. 2. There are general patterns in formation of psychiatry disturbances as sequence of stages: preclinical, functional and organic spts. 3. Clinical features depended of characteristic of the occupational environment were founded.

This founds could be used by psychiatrists during periodical health examination among professionals are mentioned in the list of Injunction of MH of RF N-302H.

### The main psychological factors in tendency to addiction

S.J. MosaviAmiri<sup>1\*</sup>, R. GhaemiAmiri<sup>2</sup>, S.K. MousaviAmiri<sup>2</sup>

<sup>1</sup> Department of Addiction Studies, Medical Clinic of Dr. Mosavi, Department of Addiction Studies, Amirkola, Iran; <sup>2</sup> Department of Family Studies, Medical Clinic of Dr. Ghaemi, Department of Family Studies, Amirkola, Iran

\* Corresponding author.

*Aim.* – Addiction is a multi-dimensional concept and the basis of addiction may be related to combination of environmental, social, physiological and psychological aspects. But psychological factors are more vital and challenging factors because the factors affect the thinking of individuals in first experimenting of drugs and continuing causes of addiction. So, the research investigated the main psychological factors in tendency to addiction.

*Methods.* – A total of 70 addicted people were randomly selected and abuse drug assessment inventory (ADAI) was administered on them. ADAI assesses 10 psychological factors for addictive behaviour. Chi Square formula was used to analyze the data.

*Results.* – Results showed that three psychological factors such as fear, anxiety, and sorrow are main psychological factors in tendency to addiction and also continuing causes of addiction.

*Conclusion.* – In regard to result that showed psychological factors provide main accounts for addictive tendencies, we should put more emphasize on psychological prevention and treatment methods so that, both tendency to addiction and continuing causes of addiction decrease and control.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0644

### Prevention of mental health in medical students: A personal perspective

R. Sadavarte

Liverpool Medical School United Kingdom, Undergraduate Medical School, University of Liverpool, Liverpool, United Kingdom

*Objectives.* – To analyse the reasons why young people especially medical students are at high risk of mental health disorders.

*Method.* – According to Young Minds, a leading UK charity, 1 in 3 children in the classroom have a mental health problem. A 'population-based youth focused model' must integrate all members of the multidisciplinary team. In this abstract, I wish to give my personal perspective on experiencing an unexpected emotional upheaval when starting university.

*Results.* – From my personal experience, the transition between school years to adulthood is challenging due to expectations placed upon young people. Young people moving out of home for the first time can be vulnerable and can be placed in difficult situations. These include: bullying, having an identity crisis, relationship and financial problems or be at risk of experimenting with drugs and alcohol. The millennial generation uses social media as form of expression which can have a negative impact on mental health. The GMC in the UK has formulated a guide on mental health in medical students. The mental health disorders are common, but if not diagnosed and treated well the condition may worsen given the intensity of a medical course.

*Conclusion.* – Education of mental health in schools, university and in the workplace must be promoted to ensure that the stigma is removed. Talking openly about mental health can be slippery slope, therefore, the media or celebrities with whom young person can relate better can be used as an educational tool.

### Vitamin D levels in inpatients

S. Trincado\*, L. Gonzalez, O. Uriarte, T. Ruiz de Azua, D. Peralta, G. Montero, S. Albelda, G. Irigoyen, D. Perez, E. Garnica, M. Zumarraga Red de Salud Mental de Bizkaia, Hospital de Zamudio, Zamudio, Spain

\* Corresponding author.

The aim of our survey was to determine the levels of Vitamin D in serum of our patients. The study of this vitamin in mental health is a recent area of investigation and the number of papers is nowadays increasing, most of them were published in the last 10 years. They reveal that hypovitaminosis D could be associated with various mental illnesses, particularly in depression and schizophrenia. In addition, the evidence of the anti-inflammatory and neuroprotective effect is enhancing and it is suggested that could have psychotropic function. This is especially relevant, first of all, because hypovitaminosis D is often underdiagnosed and untreated in mental health despite is more prevalent in our patients and secondly due to the elevated risk of suffer metabolic syndrome and premature mortality between patients with mental illness, mainly schizophrenia.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### The effectiveness of physical activity on psychological well-being of girl students of high school

A.A. Bayani

Department of Psychology, Azadshahr Branch, Islamic Azad University, Department of Psychology, Azadshahr, Iran

*Introduction and objective.* – The purpose of the present study was to examine the effectiveness of physical activity on psychological well-being of girl students of high school.

*Method.* – Fourth girl high school students were selected and randomly assigned to experimental and control group. Experimental group did physical activity for two month and forty minutes each day. All participants were asked to answer the Reff's Psychological Well-Being Scale.

*Results.* – The data were analysed by the Analysis of Covariance (ANCOVA). Results showed that psychological well-being of experimental group had a significant increase contrast to control group.

*Conclusion.* – Regular physical activity can lead to promotion of psychological well-being of girl students of high school.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0648

### The varieties of asthenic conditions, developed as a result of adaptation disorders amongst the foreign students

I. Belokrylov\*, V. Karnozov, G. Kirsanova, T. Lineva, E. Okonishnikova, A. Bryukhin

Peoples' Friendship University of Russia RUDN University, Department of Psychiatry and Medical Psychology, Moscow, Russia

\* Corresponding author.

*Introduction.* – The leading place amongst the neuro-psychiatric diseases in foreign students in Russia is occupied by the borderline disorders, including, first of all, asthenic conditions of various genesis. These conditions are one of the main reasons for the students to skip the classes.

*Objectives.* – Studying the clinical features of asthenic conditions in foreign students for the selection of adequate therapy for this pathology.

*Methods.* – Using clinical and experimental-psychological methods, we examined 277 foreign students, that requested the medical help for their “asthenic conditions”. The patients first contacted the general practitioners of the University Clinic. Age of the patients: 18–28 years. All of the examined students encountered disadaptive conditions related to the acclimatization, language barrier, and being away from home.

*Results.* – We divided all the cases to 5 groups. Group 1 ( $n=164$ ) – psychogenic asthenia with peculiarities dependent on the nature of psychogeny trauma, as well as premorbid and egzogenic injures in the past; Group 2 ( $n=33$ ) – adaptation asthenia (resembled a complex depression with predominance of senesto-hypochondriacal disorders); Group 3 ( $n=31$ ) – posttraumatic asthenia, Group 4 ( $n=28$ ) – somatogenic asthenia, Group 5 ( $n=21$ ) – endogenous asthenia (schizophrenia, cyclothymia, bipolar affective disorder). Each of the patient received different treatments, according to the typology above.

*Conclusions.* – Precise differential diagnostics is the basis for the adequate therapy and prevention of the asthenic disorders amongst the foreign students. The publication was prepared with the support of the RUDN University Program 5-100

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Dimensions of compliance among indian psychiatric patients

S. Dutta<sup>1</sup>, H. Naidu<sup>1</sup>, D. Prasad<sup>2</sup>

<sup>1</sup> Nur Manzil Psychiatric Centre, Department of Psychiatry, Lucknow, India; <sup>2</sup> Nur Manzil Psychiatric Centre, Child and Adolescent Guidance Clinic, Lucknow, India

\* Corresponding author.

*Introduction.* – Compliance with treatment or treatment adherence refers to the extent to which the patient takes medication as prescribed. Patients are recommended medication over months, years or a lifetime. In a country where awareness of mental illness and treatment implications is low, dropout rates are high. Noncompliance translates into relapse or recurrence increasing treatment costs and hospitalisations. Noncompliance has a human cost in terms of morbidity and mortality. Enhancing medication compliance is an important treatment goal.

*Aims and objectives.* – This study attempts the recognition of factors causing noncompliance.

*Methods.* – Sociodemographic characteristics, pattern of psychiatric help seeking, medication profile, views about illness medication and reasons for breach in treatment were studied in noncompliant outpatients over three months at a tertiary care psychiatric facility in North India.

*Results.* – Noncompliance was common among paranoid schizophrenia, early recovering mood disorder and substance use disorder patients from lower socioeconomic group. Financial constraints and concerns about long term effects of medication, sedation, weight gain and wellness hindered compliance.

*Conclusion.* – Factors affecting compliance can be thus categorized: patient characteristics (attitudes toward illness and medication, socioeconomic considerations), medication characteristics (side

effects, individual sensitivity, simple versus complicated medication regime); disease characteristics (chronicity, guilt in depression, suspiciousness in schizophrenia, substance abuse and anxiety); and clinician expertise (empathy and successful integration of pharmacology and psychotherapy). Strategies to improve treatment adherence include recognition of factors promoting noncompliance; psychoeducation about the illness and maintenance treatment, medication and side effects; simplification of medication regimes; medication compliance assistance and emphasizing the doctor-patient relationship.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Distress caused by refraining from playing sports and urbanization**

L. Fekih

uuUUN Université Abou-Bekr Belkaid Tlemcen, psychology, TLEMCEM, Algeria

The purpose of this paper is to describe the distress caused by refraining from playing sports and urbanization, a field study conducted on a sample range of individuals who live in urban areas, some of them refrain from playing sports and the others often play sports in Tlemcen city, which saw the terrible urban expansion, where the study included the impact of urbanization, refraining from playing sports on youth's mental health, selecting the psychological problems most commonly caused by refraining from playing sports, and the impact of practicing sports in alleviating stress.

The method used in this research is purely descriptive following the collected data from a sample of 160 youth aged between 25 and 35 years old. The tool that was used is Distress Test. We proceeded with some statistical techniques as percentages, variance analysis, and Independent samples t-test. The findings of this research are:

- the psychological distress caused by refraining from playing sports is main factor of: intensity of stress, incompetence, emotional, and psychosomatic problems;

- there was statistical significant difference among young people who practice sports in green spaces and others who refrain from playing sports in terms of distress, in favor of young people who practice sports;

- urbanization has several major negative impacts on mental health.

*Keywords:* Distress; Practice sports; Urbanization; Psychological problems

### **I need to talk to a psychiatrist**

E. Mancha<sup>1\*</sup>, M.J. Leñero Navarrete<sup>2</sup>, Y. D' Hiver Cantalejo<sup>3</sup>, H. Saiz García<sup>4</sup>

<sup>1</sup> Servicio Navarro de Salud, CSM Ansoain, Pamplona, Spain; <sup>2</sup> Sacyl, Hospital Universitario Rio Hortega, Valladolid, Spain; <sup>3</sup> Sescam, Hospital Universitario de Guadalajara, Guadalajara, Spain; <sup>4</sup> Servicio Navarro de Salud, Complejo Hospitalario de Navarra, Pamplona, Spain

\* Corresponding author.

*Objective.* – Differentiate pathologies that correspond to the field of Neurology of those related to Psychiatry and thus optimize referrals from Primary Care to Mental Health.

*Methods.* – To study the case of an 80-year-old woman, widow, mother of 6 children. She lives alone. It has home assistance support three days a week. Started attention in Mental Health in 1996. Initial impression of possible hypomania but there is no other source of information, nor knowledge of basic personality. There was a registered antecedent of punctual possible behavioural disorder years ago, discarding at that moment cognitive impairment. She leaves the monitoring in Mental Health but after a few years she is referred again due to a similar cause. The antidepressant is removed.

*Results.* – In successive revisions at Psychiatry no clinical improvement is evidenced, rather orienting the evolution towards demential disease, possibly a fronto-temporal dementia: the patient presents an extravagant appearance with poor personal care and vague speech, with expansive affection and disorganized behaviours. In the end she is referred to Neurology.

*Conclusions.* – The crowded consults can cause dysfunctions in mental health referrals, such as those detected in the Basque Country by an autonomous study. On the other hand, sometimes, the patient himself claims to see a specialist. In our opinion, the solution would be to grant the Family Doctor more training in Mental Health as well as to give him more time to carry out a complete clinical interview.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Practice quality and effectiveness of a compassion training intervention: The Importance of embodying the compassionate self**

M. Matos<sup>1\*</sup>, J. Duarte<sup>1</sup>, C. Duarte<sup>1</sup>, J. Pinto-Gouveia<sup>1</sup>, P. Gilbert<sup>2</sup>

<sup>1</sup> University of Coimbra, Cognitive and Behavioral Centre for Research and Intervention CINEICC, Coimbra, Portugal; <sup>2</sup> Derbyshire Healthcare NHS Foundation Trust, Centre for Compassion/Mental Health Research Unit, Derby, United Kingdom

\* Corresponding author.

Research has showed that compassion mind training (CMT) is effective on the promotion of well-being, however the impact of quality of the practice had never been explored. A recent study of the

effect of a low intensity compassionate mind training intervention on well-being, also investigated participants' qualitative and subjective experiences of the practices.

The current paper explores how participants who completed a two-week CMT program ( $n = 77$ ) experienced the compassion practices, and the impact of the quality of these experiences on the effectiveness of the intervention and the development of the compassionate self. Results reveal that more than how often participants practiced the exercises, it is their perception of helpfulness of the compassion practices and their ability to embody of the compassionate self in everyday life and in moments of difficulty that are associated with increases in compassion for the self, for others and from others, reassured self, positive affect and compassionate goals, and decreases in self-criticism, fears of compassion and stress.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0654

### **On mental health in context of philosophy, psychology and psychiatry**

M.C. Michailov<sup>1</sup>\*, E. Neu<sup>1</sup>, G. Weber<sup>2</sup>, C. Lütge<sup>3</sup>, M. Schratz<sup>4</sup>

<sup>1</sup> Inst. Umweltmedizin c/o ICS D e.V., PharmaEVPhysiology, Munich, Germany; <sup>2</sup> Univ. Lxbg. and Vienna, Fac. Psychology Dean, Vienna, Austria; <sup>3</sup> Techn. Univ. München, Inst. Ethics Dir., Munich, Germany;

<sup>4</sup> Univ. Innsbruck, School Education Dean, Innsbruck, Austria

\* Corresponding author.

*Introduction.* – Mental health is essential for holistic&multidimensional consideration of human for all anthropological sciences incl. psychology, psychiatry, pedagogy

A. On PHILOSOPHY-ANTHROPOLOGY. New model about an integral anthropology related to fundamental scientific question of Kant "what is the human?" is considered by scientific-theory&ethics conc. mental health in context of to ti enai/Aristoteles, Agaton/Platon, reason/Kant (Vernunft, Verstand, Urteilskraft).

B. On PSYCHOLOGY-PSYCHIATRY. Modern occidental philosophy, psychology, psychiatry consider mental health on level of normal and sub-consciousness (analytic psychology, e.g. Freud, etc.), oriental one includes super-consciousness - samadhi, nirvana, satori, etc. (Sri Aurobindo, Dalai Lama\*, Sri Yogendra, others) in context of future synthetic philosophy and psychology. Prominent scientists reported on similar phenomena acc. to Carrel\*, Neuhäusler, Pauli\*, Rhinne, Richet\*, Vassilev/\*Nobel Laureate in concordance with electrophysiological experiments with Yogis, Buddhist-monks acc.to Anand, Chinna, Kasamatsu, Hirai, Ornstein. Mental disorders related to neurotic reactions can be antagonized by psychosomatic practises.

C. On PSYCHOSOMATICS in ANGIO-CARDIOLOGY and GENITOURUROLOGY. Occidental and oriental psychosomatic therapy incl. mental training (Yoga, Zen-Buddhisnm) helps cardiac & radiooncological patients–arrhythmia, hypertension, incontinence, radiocystitis, etc. (see Neu et al., Weber et al. EPA 2018).

*Conclusion.* – Theoretical&practical models for an integral anthropology (A-C) could support total health education (hygiene, prophylaxis) as well as psychosomatic therapy in context of UNO-Agenda21 for better health, ecology, etc. in all countries.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0655

### **The mental health expo as an example of work early career psychiatrists' Council of Russian Society of Psychiatrists**

Y. Osadshiy

*The Diagnostic and Treatment Center, Volgograd, Psychiatry and Addiction, Volgograd, Russia*

Between May 18 and June 5, 2017, the Early Career Psychiatrists' Council of Russian Society of psychiatrists organized a series of events in Volgograd, Russia—that we called "The Mental Health Expo"—in order to promote public awareness of mental illness and to reduce stigma that still surrounds psychiatric illness in Russia. Over 1,000 people attended the different events at the Expo, making it the largest ever event in Volgograd dedicated to mental health. In addition to the interest the Expo generated among the public, it also attracted a lot of media attention.

The events at the Expo were divided into three categories:

- research and clinical practice;
- general education and public awareness;
- clinical help and rehabilitation.

Overall, the Mental Health Expo was a huge success. It revealed great interest from the general public in issues related to psychiatric illness, including in where to seek credible information and where to turn for professional consultation and help. The format—which spanned a broad range of events aimed at both mental health specialists and lay audiences—proved to be highly effective, providing a platform for successful interaction among mental health professionals, the general public, and the mass media. We hope this event can become an annual, or at least bi-annual, event in Volgograd.

### **Mental health, academic life experiences and personal competences in first-year medical students**

R. Porta-Nova

*Escola Superior de Saúde da Cruz Vermelha Portuguesa, Nursing Education, Lisbon, Portugal*

*Introduction.* – First-year medical students are very vulnerable to stressors, as a result of some experiences related to the beginning of their medical course and the demand of academic life, which may be affects their mental health.

*Objectives.* – The study aims to knowing what academic life experiences and personal competences may contribute to the mental health of first year medical students.

*Methods.* – The sample ( $n = 90$ ) is composed by first-year medical students, aged between 17 and 25 years ( $M = 18,91$ ;  $SD = 1,29$ ), being 23 male and 67 female. Participants completed a demographic questionnaire, the Academic Life Experiences Questionnaire, the Mental Health Inventory and the Self-Perception Profile for College Students.

*Results.* – To determine which personal competences and academic life experiences might predict mental health, a linear regression analysis was conducted, reaching to a model that includes the Psychological Well-Being, the Intellectual Ability and Physi-

cal Well-Being. This model explains 78% of the variance in Mental Health dimension.

**Conclusions.**– This study shows that the mental health depends of the psychological well-being, which includes wellness, emotional balance, affective stability, happiness and optimism. Also important is the intellectual ability which refers to the self-perception of the general intellectual ability. Equally, the physical well-being, considering factors like: sleep, food habits, substance abuse, contributes to their mental health. This is important to mental health promotion of medical undergraduates, where it is fundamental the creation of institutional strategies, that allow the most of individual psychological well-being, so that the students may in the best health conditions to cope with the challenges placed by the learning demands.

### **Attitude of health professionals towards mental illness in a tertiary care hospital in Islamabad, Pakistan**

S. Riaz\*, S. Mansoor

Foundation University Medical College, Psychiatry, Islamabad, Pakistan

\* Corresponding author.

**Introduction.**– People with mental illness come into contact with a wide range of health care professionals. The attitude of these professionals is an important determinant of quality of care provided to people with mental illnesses.

**Objective.**– This case series was conducted at a tertiary care hospital to assess the attitude of health professionals towards mental illness. **Method.**– Through convenience sampling, 10 health professionals working at a tertiary care hospital were invited to participate in the study. After due informed consent, the age, gender and years of professional experience of the participants were recorded; and the Mental Illness: Clinician's Attitude (MICA-4) scale was administered. Descriptive statistics were analysed using SPSS 20.0.

**Results.**– A total of 10 health professionals (2 males and 8 females) were made part of the sample, and the mean age of the participants was 26.8 years. All professionals belonged to medical and allied specialties with up to 5 years of experience. The mean score reported on MICA-4 scale was 48.2, indicating significantly stigmatizing attitude towards mental illness held by the health professionals in the sample.

**Conclusions.**– Although limited by the sample size, the findings of this case series point towards a need to plan future projects to evaluate attitudes of health professionals at a larger scale, and to develop effective remedial interventions for stigma towards mental illness.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0658

### **Effectiveness of art-based interventions in reducing stress among mental health professionals working in a shared war reality**

D. Segal-Engelchin\*, O. Sarid, E. Huss, R. Isralowitz

Ben-Gurion University of the Negev, Social Work, Beer Sheva, Israel

\* Corresponding author.

**Introduction.**– Research on mental health professionals (MHPs) exposed to a shared war reality show that they are subject to

increased levels of PTSD, emotional pressure, family conflict and vicarious symptoms.

**Objectives.**– The aim of this study was to examine the effectiveness of an art-based intervention in reducing stress among Israeli MHPs who shared war-related stress with their clients during Operation "Protective Edge" (2014). The intervention included drawing pictures that were later shared in small groups related to three topics: (1) emotions and thoughts related to the war situation; (2) resources that may help them cope with the war-related stressors; and, (3) integration of the stressful image and the resource picture. **Methods.**– To examine the intervention effect, the Subjective Units of Distress (SUDs) values of 47 MHPs were measured using a pre-post design.

**Results.**– Results indicate that MPHs' initial stress levels significantly decreased on completion of the intervention.

**Conclusions.**– The study results show the efficacy of an easily implemented art-based tool for stress reduction among MHPs operating in shared war conditions. Implications for future research and for interventions designed for MHPs operating in additional shared disasters will be discussed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The challenge of rare disease diagnosis in a case of a psychiatric patient**

A.V. Chiheri<sup>1\*</sup>, A. Duca<sup>2</sup>, A. Nirestean<sup>2</sup>, A. Racz<sup>2</sup>, C. Forro<sup>3</sup>, D. Chiheri<sup>4</sup>

<sup>1</sup> Targu Mures County Hospital, Psychiatry, Targu Mures, Romania; <sup>2</sup> Targu Mures County Hospital, Psychiatry, Targu Mures, Romania; <sup>3</sup> Emergency Clinical County Hospital Targu Mures, Neurology, Targu Mures, Romania; <sup>4</sup> University Of Medicine And Pharmacy Targu Mures, Medical Student, Targu Mures, Romania

\* Corresponding author.

It is a continuous challenge to diagnose the patients admitted to psychiatry department suffering of other medical conditions that have psychiatric manifestations.

We describe the case of a 45 year old women with previous psychiatric history, with multiple admissions in psychiatry department, presented at the emergency department for the second suicide attempt by drug intake (Abilify). The patient presented symptoms of the major depressive disorder with psychotic elements, but during the hospitalization was unresponsive to the proper antidepressants and antipsychotic treatment and had a third suicide attempt, while developing neurological symptoms (seizures, diaphoresis) and rheumatological (polyarthritits, Raynauld syndrome), so we suspected that the psychiatric disease was secondary to a brain damage. CT scan was inconclusive, but IRM showed multiple demyelination lesions in white matter, witch lead us to investigate the source of prime disease. After excluding HIV, syphilis, hepatitis, Borrelia and autoimmune encephalitis, the lupus specific antibodies were positive. So the final diagnose was neuropsychiatric systemic lupus erythematosus (NPLSE).

Neuropsychiatric manifestation of systemic lupus erythematosus can be an important complication and has a major impact on the quality of life and on the treatment success rate. It is highly recommended to consider the possibility of autoimmune encephalitis and other organic cerebral damage, in case of treatment-resistant psychiatric symptoms.

EV0660

### **Gender differences in suicide in Serbia within the period 2006–2015**

G. Dedic

*Military Medical Academy, Clinic for psychiatry, New Belgrade, Serbia*

*Background.*– Aim of this study was to examine the gender differences in all cases of suicide committed in Serbia within the period 2006–2015, including suicide rates, socio-demographic factors and methods of suicide.

*Methods.*– Data were obtained from the Statistical Office of the Republic of Serbia. Statistical analysis was done by using the crude number of committed suicide. Their classification related to the suicide method was carried out on the basis of ICD-X Code (WHO 1992).

*Results.*– Within the period 2006–2015, the total number of suicides in Serbia was 12 570, of which 73.16% were males and 26.84 females (male to female suicide ratio is 2.72). Annual suicide rate (per 100.000) showed constantly decreased from 19.4 in 2006 to 15.0 in 2015. The suicide was the most often committed by the married males and females with completed high school and by pensioners. The suicide number has been increasing with the age of the suicide committers and it was the highest in subjects of both genders aged over 65 years (39.96%). The most common suicide method in males (63.66%) and in females (58.65%) was hanging and strangling, and the second one in males was by firearm (18.80%) and in females by poisoning (18.14%).

*Conclusions.*– Suicide prevention in Serbia should be primarily oriented toward the elderly population because they were less ready to ask for doctor's help when having some problems with mental health.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0661

### **Immunopsychiatry: A new step toward personalized medicine in major psychiatric disorders**

G. Fond

*Schizophrenia Expert Center Fondation Fondamental, Créteil, Creteil, France*

The contribution of both chronic peripheral inflammation and oxidative stress to major psychiatric disorders (schizophrenia, depression, bipolar disorders) has received considerable attention in the last decade.

In clinical practice, chronic inflammation is primarily measured by an elevated blood level of C-reactive protein (CRP). Recent meta-analyses revealed an increased rate of abnormal CRP levels in one third of subjects with major psychiatric disorders compared to healthy controls. Abnormal CRP levels have been recently associated with strong cognitive impairment in schizophrenia. These results open the path for new preventive treatments for cognitive impairment associated with psychiatric disorders.

The following sources for these inflammation/oxidative stress disorders have been identified: history of childhood trauma, abdominal obesity/perivisceral fat, lack of physical activity, tobacco consumption, sleep disorders, history of infections including *Toxoplasma gondii* and reactivation of the human endogenous retrovirus type W (HERV-W). Each of these sources may be tar-

geted to yield a personalized treatment for patient suffering for psychiatric disorders.

Omega-3 fatty acids, non-steroidal anti-inflammatory agents, minocycline, N-acetyl-cystein, vitamin D, specific antibodies have already shown effectiveness in major psychiatric disorders, in monotherapy or in association with conventional treatments. In the field of microbiota research, probiotics administration is currently evaluated and preliminary results have shown effectiveness in major depressive disorders. The new challenge is to develop daily practice biomarkers in psychiatry to identify which subjects may benefit from these immunopsychiatric-targeted treatments in a precision medicine approach.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

*Introduction.*– Systemic Lupus Erythematosus is an autoimmune connective tissue disease with a still unknown etiology that adopts different clinical and immunological expressions. The annual incidence and prevalence depend on genetic, geographic and environmental factors, may appear from childhood but predominates fertile age and female sex. The prevalence of neurological manifestations in systemic lupus erythematosus is high, and its presence is a sign of poor prognosis contributing to increase mortality.

*Methodology.*– A 31-year-old woman from Syria. Refugee of war in Turkey for 4 years. She arrived in Valladolid a month ago with her husband and two children. Six days ago he started with global insomnia and progressively more irritable, aggressive, with inappropriate behaviours, soliloquies and auditory hallucinations. It also has plaques infiltrated in malar regions and nasal bridge, hemolytic anemia and lymphopenia.

*Results.*– Biopsy compatible with discoid lupus erythematosus. ANA+ Anti SSA+ antiroosomal+.

*Conclusions.*– It is important to maintain a high suspicion of SLE in patients with atypical acute psychosis. Regular CSF examination should be done early to rule out infectious processes. The management of acute psychosis in SLE there is no standardized treatment, this includes the combination of antipsychotics, as the symptomatic treatment, associated with the use of corticosteroids for the systemic control of the disease, always taking into account that these can induce the pictures psychological in relation to the dose with which they are administered.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Multidisciplinary approach towards diagnosing the anti-NMDA receptor encephalitis: Case report of a young girl with altered behavior and abnormal movements

U. Zubair<sup>1</sup>, H. Majid<sup>2</sup><sup>1</sup> PIMS, SZAMBU, Psychiatry, Islamabad, Pakistan; <sup>2</sup> PIMS, SZAMBU, Neurology, Islamabad, Pakistan

\* Corresponding author.

**Introduction.**– Autoimmune encephalitis is a rare central nervous system disorder in which the patient presents with the neuropsychiatric symptoms. Immunological investigations and multidisciplinary approach have made it possible for the health care physicians to screen and treat this rare disorder in time.

**Objective.**– To present a case of anti NMDA receptor encephalitis and highlight the benefit of multidisciplinary approach in diagnosing and managing a rare disorder in a third world country

**Methods.**– A fourteen year old girl was brought with complains of irritability, altered behaviour, abnormal movements, self biting and decreased sleep for the past 10 days. Her condition deteriorated during the admission and she became mute, immobile and drowsy. Her all base line investigations CT scan and MRI brain were normal. CPK was high and the CSF showed pleocytosis. There was diffuse slowing in the EEG. Autoimmune encephalitis profile showed presence of antibodies against the NMDA receptors.

**Results.**– Improvement in the symptoms was noted after treatment with the pulse therapy steroids and five sessions of plasmapheresis. She became mobile after two weeks and started attending the school after one month. She was put on cyclophosphamide for six months with plan to screen for the tumors regularly.

**Conclusion.**– This case report highlights the importance of multidisciplinary approach involving the neurologist, psychiatrist and immunologist in accurately diagnosing and managing a rare neurological disorder presenting mainly with the psychiatric symptoms.

## Psychopathology

EV0664

### Endogenous psychosis with religious delusions in adolescence

M. Alfimova<sup>1</sup>, V. Kaleda<sup>2</sup>, U. Popovich<sup>2</sup>, G. Kopeyko<sup>2</sup>, E. Gedevani<sup>2</sup>, O. Borisova<sup>2</sup><sup>1</sup> Mental Health Research Center, Clinical Genetics, Moscow, Russia; <sup>2</sup> Mental Health Research Center, Department of endogenous mental disorders and affective states, Moscow, Russia

\* Corresponding author.

**Introduction.**– The study of religious delusions in structure of psychosis (F20, F25) is determined by its high frequency (24%–28%), difficulties in early diagnostics, and low state of knowledge about dynamics and outcome of these disorders in adolescence. The most important issue is the differentiation among pathological varieties of religious-mystical disorders and non-pathological forms of religiosity. **Objective.**– To identify clinical and psychopathological features and prognostic significance of delusions with religious content in endogenous psychotic states in adolescence.

**Methods.**– A total of 53 male patients, aged 16 to 25 years were observed; there were applied clinical, psychopathological, psychometrical (The Dawkins scale) and statistical methods.

**Results.**– There were identified general psychopathological features of psychotic states with religious delusions, due to the specificity of adolescence age; as well there were distinguished common types of religious delusions, developing by acute primary (delusion of sin and delusion of demonic possession) and acute sensual (messianic and antagonistic delusions) mechanisms. There was revealed the role of the previous religiosity, including an overvalued religious ideas. Later on patients with acute primary mechanism of religious delusion's formation were demonstrating intensification of their religiosity. That was not typical for patients with sensual mechanism of delusion formation. The investigated cohort showed longer duration of the pre-manifest time range and the period of "untreated psychosis" than cohort of juvenile patients with other delusional fables. It also required longer hospitalization for these patients.

**Conclusions.**– The prognosis of psychosis with religious delusions developing in adolescence is quite unfavorable, that is appearingly associated with the structure of psychosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0665

### Envy – The dissection of a mortal sin

T. Duarte\*, J. Crawford, T. Ventura, M. João Centeno, T. Fialho, P. Godinho

Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Psiquiatria e Saúde Mental, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Humans have a drive to evaluate themselves by examining their abilities and outcomes in comparison to others. Envy is the pain caused by the good fortune of others, and a manifestation of primary destructiveness, to some extent constitutionally based, and worsened by adversity. It is comprised of the wish to abolish inferiority by either having another person's possession or success and/or the wish that the other person did not possess the desired characteristic or object. On the other hand, gloating or schadenfreude denotes one's joy about the shame or misfortune of another. Envy does not elicit a unique affective state or facial expression. It is a complex mix of unpleasant psychological states - inferiority, injustice, and resentment - which tend to be intentionally concealed from others. In DSM5 envy is underrepresented only appearing as a characteristic of Antisocial and Narcissic Personality Disorders, despite its great impact in others' lives.

**Objectives.**– Non-systematic literature review on envy and it's correlate with neurobiological findings.

**Methods.**– Pub Med database was searched between 2010 and 2017 and articles with the words "envy", "emotion", "fMRI" and "emotion" were included.

**Results.**– The ventral striatum plays a major role in the reward system. An increased ventral striatum activation was verified with BOLD-contrast imaging whenever envy was detected. Regional homogeneity in the inferior/middle frontal gyrus and dorsomedial prefrontal cortex positively predicted dispositional envy.

**Conclusion.**– These results suggest an association between neural representations of envy and theories of emotional processing. This may give way to biomarkers for the evaluation of outcomes in Psychiatry, supporting novel clinical interventions.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0666

### Tinnitus and psychotic symptoms: An approach to differential diagnosis

J.E. Ibáñez Vizoso<sup>1</sup>, M. Pérez Lombardo, F. García-Escribano Martín, L. Chiva San Román, V. Crossley López, Í. Alberdi Páramo  
Hospital Clínico San Carlos, Psychiatry, Madrid, Spain

\* Corresponding author.

Tinnitus is defined as a simple auditory perception in the absence of an external stimulus. It is a heterogeneous symptom in terms of its clinical presentation and aetiology, which makes a multi-disciplinary approach mandatory. Its interest in psychiatry lies in the high comorbidity with psychopathology and in the variety of disorders with which it has been associated. Among these, their relationship with psychotic disorders is specially complex. Tinnitus can precede auditory hallucinations with different insight degrees, or may be itself be considered as an hallucinatory phenomenon. Most of the times, this occurs following auditory pathology and hearing loss. However, in some rare situations we find an important overlap with psychotic symptoms in early stages of psychosis. Detecting these symptoms early is critical to diagnose high-risk states of psychosis and improving the prognosis of these patients. *Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Evaluation of mental distress

J. Lund<sup>1</sup>\*, M. Nørhølle Nielsen<sup>1</sup>, S. Hjerrild<sup>1</sup>, L.B. Jansson<sup>2</sup>  
<sup>1</sup> Aarhus University hospital, Department for Affective Disorders, Risskov, Denmark; <sup>2</sup> Psychiatric Center Hvidovre, Department of Clinical Medicine, Copenhagen, Denmark

\* Corresponding author.

*Introduction.* – The severity of mental distress is a common reason for admission—both voluntary and involuntary—and the acute prescription of psychopharmacological treatment. Further, in emergency room settings patients are triaged according to levels of expressed mental distress. The assessment of mental distress is a standard part of the psychiatric evaluation and is the result of mental state examination, albeit of often pre-reflective nature, much alike the evaluation of somatic pain, where the level of pain is assessed using behaviour, facial expression, and verbal output. The observational components underlying the objective evaluation of mental distress remain unclear.

*Objectives.* – 1. Describe components of the evaluation of expressed mental distress. 2. Elucidate whether the objective signs of mental distress are trans-diagnostic. 3. Evaluate if a short rating scale of mental distress can be constructed using the identified components.

*Methods.* – Computer-based survey amongst all staff with either in-patient or out-patient contact in a large, multidisciplinary psychiatric department in a university hospital using a phenomenological approach with open-ended questions.

*Results.* – Results are pending and will be presented at the 26th European Congress of Psychiatry.

*Conclusions.* – NA

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Anosognosia and insight – Relatives or related?

M. Moreno<sup>1</sup>\*, T. Filipe<sup>2</sup>, S. Nascimento<sup>3</sup>, A.M. Mota<sup>4</sup>, V. Nogueira<sup>5</sup>, M. Melo<sup>6</sup>, R. Fernandes<sup>7</sup>, R. Costa<sup>8</sup>

<sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Hospital de Dia, Cascais, Portugal; <sup>2</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psiquiatria Forense, Lisboa, Portugal; <sup>3</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psiquiatria Geriátrica, Lisboa, Portugal; <sup>4</sup> Centro Hospitalar Psiquiátrico de Lisboa, Ccsmo, Lisboa, Portugal; <sup>5</sup> Centro Hospitalar Psiquiátrico de Lisboa, Álcool e Novas Dependências, Lisboa, Portugal; <sup>6</sup> Centro Hospitalar Psiquiátrico de Lisboa, Cintra, Portugal; <sup>7</sup> Centro Hospitalar Psiquiátrico de Lisboa, Clínica 1, Lisboa, Portugal; <sup>8</sup> Centro Hospitalar Psiquiátrico de Lisboa, Hospital de Dia, Lisboa, Portugal

\* Corresponding author.

*Objectives.* – Bibliographical review of the scientific literature on the topic Anosognosia and Insight.

*Methodology.* – Bibliographical analysis of the works already published on the subject. Identify keywords (Insight, Critical Judgment, Psychopathology, Awareness and Anosognosia), collect primary sources, review secondary sources, make a critical review and summarize available literature.

*Results.* – Based on the keywords, we obtained 37 bibliographic sources that we considered relevant.

*Discussion/conclusions.* – Neurological disease affects 13.05% of acute and 68.9% of chronic psychiatric patients Quoting Vilayanur Subramanian, director of the Center for Brain and Cognition at the University of California, “The boundary between Neurology and Psychiatry is becoming increasingly blurred.” In this “new reality” as he describes it, it is crucial to merge some concepts and detach others. In this context a question is born: Anosognosia and Insight – Selfsame concept or two different terms? The point in History where Neurology and Psychiatry came apart seems to be the clue to the presence of terms that overlap. Despite distinct historical developments, the concepts braid – both depend on essential functions, are difficult to assess, have similar reactions and have a major impact on prognosis—our main concern.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0669

### Vestibular stimulation – Rebalancing awareness?

M. Moreno<sup>1</sup>\*, T. Filipe<sup>2</sup>, S. Nascimento<sup>3</sup>, A.M. Mota<sup>4</sup>, R. Fernandes<sup>5</sup>, R. Costa<sup>6</sup>

<sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Hospital de Dia, Cascais, Portugal; <sup>2</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psiquiatria Forense, Lisboa, Portugal; <sup>3</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psiquiatria Geriátrica, Lisboa, Portugal; <sup>4</sup> Centro Hospitalar Psiquiátrico de Lisboa, Ccsmo, Lisboa, Portugal; <sup>5</sup> Centro Hospitalar Psiquiátrico de Lisboa, Clínica 1, Lisboa, Portugal; <sup>6</sup> Centro Hospitalar Psiquiátrico de Lisboa, Hospital de Dia, Lisboa, Portugal

\* Corresponding author.

*Objectives.* – Bibliographical review of the scientific literature about the effect of Vestibular Stimulation on Insight.

*Methodology.* – Bibliographical analysis of the works already published on the subject. Identify keywords, collect sources, make a critical review and summarize available literature.

*Results.* – Based on the keywords, we obtained 15 bibliographic sources that we considered relevant.

*Discussion/conclusions.* – Anosognosia defines itself as the lack of ability to recognize symptoms due to acquired cerebral lesion. Reports in the literature suggest that Anosognosia, Neglect and Inattention improve transiently (between 30 minutes to 2 hours)

with vestibular stimulation, namely with caloric reflex. It is theorized that the lack of Insight in psychiatric diseases is the analogous symptom to the neurological lesions that causes Anosognosia. Thus, the question arises: Will vestibular stimulation cause a transient increase in insight for psychiatric illness, namely in mania and schizophrenia. The impact of being able to change people's understanding of their illness? Insight influences the course and prognosis of each psychiatric illness, being a critical element in its evolution. Although scarce, the results available in the literature are auspicious. Among the extensive network of cortical and subcortical structures that receive signals from the vestibular pathway, the anterior cingulate cortex (ACC) stands out. The ACC may be a bridge between the vestibular sensorimotor areas and areas of the prefrontal cortex (PFC). It is documented the association between the ACC and some areas of the PFC and the mental processes involved in Anosognosia and Insight, namely the capacity for self-reflection and introspection, the interpretation and assignment of correct salience to stimuli related to personal history.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0670

### **“My senses seemed sharpened. . .”**

#### **– Aberrant salience in schizophrenia**

T. Prior Filipe<sup>1\*</sup>, M. Moreno<sup>2</sup>, S. Nascimento<sup>3</sup>, J. Gama Marques<sup>4</sup>

<sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Forensic Psychiatry Department, Lisbon, Portugal; <sup>2</sup> Centro Hospitalar Psiquiátrico de Lisboa, Day Hospital, Lisbon, Portugal; <sup>3</sup> Centro Hospitalar Psiquiátrico de Lisboa, Geriatric Psychiatry Department, Lisbon, Portugal; <sup>4</sup> Centro Hospitalar Psiquiátrico de Lisboa, Schizophrenia Department, Lisbon, Portugal

\* Corresponding author.

*Introduction.*– Aberrant salience (AS), is a foundational aspect of the pathogenic model of schizophrenia. Stimulus-independent release of dopamine disrupts contextually driven salience attribution leading to inappropriate attribution of salience to external objects and internal representations. Hallucinations may arise from misinterpretation of the latter and top-down cognitive explanation prompts the formation of explanatory delusions. In schizophrenia, dysfunction has been identified in the salience neurological framework supporting the phenomenological model.

*Objectives.*– Provide an insight on the neurological framework of AS and its relation with the phenomenological model.

*Methods.*– A search was conducted on the Pub Med<sup>®</sup> using the Keywords “Aberrant salience”, and “Schizophrenia”. 15 references were selected according to relevance.

*Results.*– In schizophrenia, AS is related to reduced ventral medial prefrontal cortex activation during self-referential judgments and to a deficit in differential ventral striatal activation. Impaired anterior insular salience network (SN) activity is associated with aberrant dependence of Default Mode Network/Central Executive Network interactions on SN functioning. A defective salience network fails to signal task-relevant stimuli, resulting in disruption of the integrative processes required for stimuli efficient evaluation and adequate response selection. Reduced salience network connectivity denotes disturbance on the system effecting changes between contextually relevant functional brain states. AS may contribute to hyper-reflexivity, disturbed “grip” of the world and disturbances of intuitive social understanding.

*Conclusions.*– The integration of the phenomenological and neurocognitive findings represents an in-depth understanding of schizophrenia. Potential therapeutic interventions, such as cognitive remediation directed towards executive function, may be

enhanced for the clinical and functional improvement of patients with schizophrenia.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0671

### **Cognitive insight in first episode psychosis**

T. Prior Filipe<sup>1\*</sup>, T. Teodoro<sup>2</sup>, S. Garcia<sup>2</sup>, I. Pinto<sup>2</sup>, M.J. Avelino<sup>2</sup>, R. Mateiro<sup>2</sup>, M. Martins<sup>2</sup>, M. Moreno<sup>3</sup>, S. Nascimento<sup>4</sup>, J. Salgado<sup>2</sup>

<sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Forensic Psychiatry Department, Lisbon, Portugal; <sup>2</sup> Centro Hospitalar Psiquiátrico de Lisboa, Clinica 1, Lisbon, Portugal; <sup>3</sup> Centro Hospitalar Psiquiátrico de Lisboa, Day Hospital, Lisbon, Portugal; <sup>4</sup> Centro Hospitalar Psiquiátrico de Lisboa, Geriatric Psychiatry Department, Lisbon, Portugal

\* Corresponding author.

*Introduction.*– Lack of Insight is considered a hallmark of psychosis with an important impact on therapeutic compliance, functional outcome and prognosis. Cognitive Insight (CI), an individual's capacity to question his own beliefs upon assessment and reinterpretation, is divided into the self-reflection and the self-certainty dimensions. Low self-reflectiveness and high self-certainty define poor CI.

*Objectives.*– Understand the concept of CI, its neural substrate and its relevance in First Episode Psychosis (FEP).

*Methods.*– A search was conducted on the Pub Med<sup>®</sup> using the Keywords “Cognitive Insight”, “Insight” and “First Episode Psychosis” with an outcome of 9 articles; review of the selected references retrieved another 2; 11 references were selected according to relevance.

*Results.*– In FEP, the level of CI is linked with memory and verbal learning. Poor CI is associated with cortical volumetric reduction. Neural correlates of CI involve a network of frontal, temporal and parietal brain regions. Self-certainty, but not self-reflectiveness, positively modulate thickness covariance in a frontal network in FEP. In FEP, CI has been shown to be a better baseline predictor of overall psychopathology on a 12-month period. Self-reflectiveness is a more relevant and independent cognitive construct than self-certainty for predicting prospective symptom severity in FEP. Self-reflection and self-certainty correlate with distinct underlying cognitive processes, which may constitute therapeutic targets.

*Conclusions.*– Apart from its prognostic significance, CI is a potential target for the development of early intervention programs in FEP, including psychotherapeutic approaches, so as to improve treatment compliance and prognosis.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0672

### **Delusional metamorphosis; description, aetiology, and treatment: A case of a boanthropy in a melancholic patient treated by avicenna**

H. Shahpesandy

Lincolnshire Partnership Foundation Trust, Hartsholme Centre, Lincoln, United Kingdom

A case of a psychotically depressed man with delusional metamorphosis treated by Avicenna is reported in Abdurrrhman Jami's (1397-1478, Herat) “Seven Thrones”. A “melancholic” man is described demanding to be killed as he was convinced he was a

“cow” (boanthropy); he was mooing, crying “Hurry, cut my throat, take me to the butchery; kill me momentarily as I am losing weight”. He wouldn’t take food or remedies from any one. No healers could cure him and they felt helpless; hence turned to Avicenna who advised to tell the patient that the butcher was on his way to slaughter him. Avicenna went to the patient’s house shouting, “Where is the cow”. The patient came out, laid down, saying “I am the cow”. Avicenna bound his limbs and sharpened his knife in front of him. As a butcher would measure an animal, Avicenna inspected him and stroked his sides and back. Afterwards, he persuasively said, this “cow” is undernourished; it would be a waste to kill him now. It should be fed, never be let hungry, and when it gains weight I will kill him”. They untied the patient’s limbs and brought food in front of him. Everything they gave to him of food and medicine, he took and ate without resistance. As he was accepting food, putting on weight, the delusion of being a cow faded away, and ultimately he made improvement.

This presentation will concentrate on rare forms of delusions, delusions of transformation/metamorphosis as zooanthropy; their history, psychopathology, aetiology and treatment.

### “Internal” rhythm study in Ukrainian woman with Gerstmann syndrome

V. Tarasov<sup>1</sup>, N. Orlova<sup>2</sup>

<sup>1</sup> TMA “Psychiatry”, Acute Psychosis, Kiev, Ukraine; <sup>2</sup> Kiev MU UAFM, psychiatry, Kiev, Ukraine

\* Corresponding author.

*Introduction.* – During “internal” rhythm investigation among psychiatric patients and healthy controls we’ve revealed adult women with Gerstmann syndrome (GS). GS characterized by absence or loss of four specific neurological functions.

*Objectives.* – We present the patient with GS focusing on the clinical presentation, neurological, and psychopathological findings.

*Methods.* – Psychiatric-psychopathological examination, metronome using, retrospective review of the clinical file, and literature search.

*Results.* – An Ukrainian 33-year-old right-handed female presented since age 6 an acalculia, finger agnosia, inability to distinguish between right and left, writing disturbances. She has a family history of mental illness. Once she was successfully treated about anxiety and obsessions. She is not drug or alcohol used and abused. Blood work, including endocrine tests, brain-MRI were normal. Calculation impairments included severe inability to perform all simple mathematical operations, including forward and backward counting. Finger agnosia, and right/left confusion are also persistent, and mild dysgraphia. Also, the constructional apraxia, an inability to copy simple drawings were identified. In a series of “internal” rhythm studies were found its change on par with the change in subject’s mood. So, at the beginning of the study “internal” rhythm estimated as 144 Hz, and patient described it as a “I dance chaotically at a disco”, and psychopathologically she was hypomanic. A month later, her rhythm was estimated like 36 Hz, and she described it like “placatory”. That time, she observed depressive clinical signs. Summarizing the above, “internal” rhythm studding using the metronome is the simple and inexpensive method that helps to clinical psychologists to expand the psychopathological diagnostic.

\* Corresponding author.

Ketamine was first synthesized by an American Scientist in 1962, in 1963 patented in Belgium to be used in Veterinary anesthesia. This presentation will cover it’s changing roles in drug culture and used in Vietnam war and now recently growing interest in the use of both oral and I/V ketamine in treatment resistant depression. The advantages are fast action, wide therapeutic range and relatively lesser side effects. Will review recent study trials and will discuss it’s role ion future treatment of depression.

### Open methylphenidate trial among brain injured population in Oman with acute vs. chronic executive dysfunction

A. Al Madhani<sup>1\*</sup>, S. Al-Adawi<sup>2</sup>, A. al-Naamani<sup>2</sup>, A.S.S. Dorvlo<sup>3</sup>, A. Al Maashani<sup>4</sup>, D. Gorman<sup>5</sup>, M.M. Essa<sup>6</sup>, D.T. Burke<sup>7</sup>

<sup>1</sup> Oman Medical Speciality Board, Psychitry, Muscat, Oman; <sup>2</sup> College of Medicine and Health Sciences, Sultan Qaboos University, Department of Behavioral Medicine, Muscat, Oman; <sup>3</sup> College of Science, Sultan Qaboos University, Department of Mathematics and Statistics, Muscat, Oman; <sup>4</sup> Khoula Hospital, Ministry of Health, Department of Neurosurgery, Muscat, Oman; <sup>5</sup> The University of Auckland, Faculty of Medical and Health Sciences, New Zealand, New Zealand; <sup>6</sup> College of Agricultural and Marine Sciences, Sultan Qaboos University, Department of Food Science and Nutrition, Muscat, Oman; <sup>7</sup> Emory University School of Medicine, Department of Rehabilitation Medicine, Atlanta, Georgia, USA

\* Corresponding author.

*Background.* – Traumatic brain injury (TBI), often stemming from road traffic accidents, is leading cause of morbidity and mortality in many emerging economies such as Oman. Therefore, the issues of functional, disabilities and rehabilitation become prominent.

*Aims.* – This study tests whether treatment with methylphenidate, using quantitative measures in a consecutive series of patients with TBI, improves indices of executive functioning in an Arab population. If so, this would substantiate findings in available literature from largely Euro-American TBI populations. The second aim is to compare the performance of measures that solicit executive functioning and mood. A related aim is to explore whether methylphenidate has differential effect on acute and chronic phases of TBI.

*Method.* – 24 brain-injured (acute and chronic) functioning with ‘mild cognitive impairment’ received neuropsychological assessments that included measures tapping executive functioning. All results were compared with a group of 25 healthy control persons selected for age, gender and education in order to solicit variation in executive functioning. The brain injured participants exhibiting executive dysfunction were instituted with pharmacological intervention (methylphenidate) using ABA experimental design.

*Results.* – The TBI group appeared to perform poorly compared to the control in indices of executive functioning. Institution of

methylphenidate heightened the performance of executive functioning but not affective functioning. Acute and chronic phases of TBI had a direct bearing on performance of cognitive functioning. *Conclusion.*– This study, to our knowledge, is the first of its kind from an Arab-speaking population. It largely substantiates previous anecdotal and impressionist observations that methylphenidate has the potential to attenuate cognitive impairment in a TBI population.

### **Cannabidiol in the treatment of psychosis – A review**

B. Almeida\*, C. Fragoeiro, C. Machado, L. Monteiro Magalhães Lemos Hospital, Psiquiatria, Porto, Portugal

\* Corresponding author.

*Introduction.*– The pathological link between Cannabis sativa use and psychosis is generally accepted. Several studies investigated differences in effects of cannabis type – Cannabis containing more Cannabidiol (CBD) consistently causes less psychotic like experiences. The potential antipsychotic properties of CBD have garnered increasing attention, namely by its interaction with the Endocannabinoid System (ECS).

*Objectives.*– We aim to describe the ECS, its association with psychosis and the potential new therapeutic targets – CBC and related compounds.

*Methods.*– We performed a search in Pub Med, using the Mesh terms “Cannabinoid”, “Treatment” and “Psychosis”. We selected the studies written in English, published after 2011 and with free text available.

*Results.*– The ECS consists of cannabinoid receptors (CB1R and CB2R), endogenous cannabinoids (anandamide and arachidonoyl-glycerol) and several enzymes (FAAH and MGL). The Vanilloid type 1 channel is also activated by endogenous cannabinoids. The system is involved in regulation of emotion, reward, and cognition. Biological models that explain the potential antipsychotic effects of CBD vary from interference with ECS functioning (by modulating enzymes and receptors activity), to immunological properties. Preclinical animal studies and Clinical studies (CBD dose between 600–1200 mg) suggest that CBD may have significant antipsychotic properties with superior tolerability to currently antipsychotic drugs.

*Discussion.*– The ECS is involved in neuropsychiatric disorders and CBD may arise as a candidate to modulate this system, given its high tolerability and superior cost-effectiveness. Illuminating pharmacological pathways through which CBD reduces psychotic symptoms could also lead to the design of new synthetic agents that act through the endocannabinoid system.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Risperidone-induced thrombocytopenia: A case report**

A. Ben Haouala<sup>1</sup>, B. Amamou<sup>2</sup>, S. Fathalla<sup>1</sup>, A. Mhalla<sup>1</sup>, F. Zaafrane<sup>1</sup>, L. Gaha<sup>1</sup>

<sup>1</sup> Fattouma Bourguiba University Hospital, psychiatry, Monastir, Tunisia; <sup>2</sup> university hospital of Monastir, research laboratory vulnerability to psychosis, faculty of medicine of monastir- university of monastir, Tunisia, psychiatry, Monastir, Tunisia

\* Corresponding author.

*Introduction.*– Thrombocytopenia is a rare side effect of antipsychotic drugs that can lead to life-threatening hemorrhagic complications. Risperidone, an atypical antipsychotic, is known to have a low risk of hematotoxicity. However, some authors have reported cases of thrombocytopenia as a rare complication of this treatment. *Aim.*– Reporting the case of risperidone-induced thrombocytopenia in a 29-year-old schizophrenic patient by discussing the circumstances of the occurrence and analyzing the factors involved.

*Case report.*– Mr S., aged 29, presents a Fallot tetralogy diagnosed at birth and a schizophrenia that has evolved for 9 years. Treatment with risperidone was initiated with a progressive increase in dosage to 8 mg/d in the absence of clinical improvement. During his hospitalization in the cardiology department for an atrial flutter related to his cardiovascular disease, thrombocytopenia was discovered with a platelet level equal to 54,000/μL controlled at 23,000/μL. The red and white blood cell counts were normal. The patient underwent a clinical and para-clinical investigation of this thrombocytopenia after eliminating any hemorrhagic complication. Having eliminated any other cause of thrombocytopenia, the drug origin was suspected. When risperidone was discontinued, the platelet count normalized after six weeks at a rate of 150,000/μL.

*Conclusion.*– This case raises the issue of rare abnormalities of thrombocytes under treatment with Risperidone. So, psychiatrists should be aware of this effect and blood-profile monitoring should be conducted periodically.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Priapism secondary to chlorpromazine: About two cases**

R. Ben Soussia\*, W. Bouali, I. Marrag, L. Zarrouk CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia

\* Corresponding author.

*Introduction.*– Side effects of antipsychotics such as orthostatic hypotension, sedation, extra pyramidal and weight gain are frequently reported whereas chlorpromazine induced Priapism is a less known complication.

*Case report.*– The first case concerns Mr S. M, a 29-year-old young man who was admitted for a manic episode. Treatment was begun with chlorpromazine 100 mg. He presented a priapism at the end of 24 hours. The immediate decision was to stop the antipsychotic agents and to address the patient in the Urologic Surgery department. The patient was treated with aspiration and irrigation of the corpora cavernosa with intracavernous injection of sympathomimetic drugs followed by a surgical distal cavernoglanular shunt. The evolution was marked by the total disappearance of the priapism at the end of 6 days without side-effects. The second case is the one of Mr M. B, 26 years old, admitted for behaviour disorders in type of agitation. He was given 150 mg of chlorpromazine. A week later, he reported having a painful erection. We decided to discontinue the use of chlorpromazine and to orient the patient in the Urologic Surgery department. He was treated with aspiration and irrigation of the corpora cavernosa. This resulted in a partial detumescence. The later evolution was marked by the disappearance of the priapism, but the patient kept a premature ejaculation.

*Conclusion.*– The priapism is an urologic emergency. This iatrogenic effect of the chlorpromazine is rare but has to be known by the clinicians to prevent the erectile side-effects.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0679

### **Hypereosinophilia induced by clozapine: About 3 cases**

R. Ben Soussia<sup>1</sup>, W. Bouali, S. Younes, I. Marrag, L. Zarrouk  
 CHU Tahar Sfar, Psychiatry, Mahdia, Tunisia

\* Corresponding author.

*Introduction.*– Clozapine remains the treatment of choice for resistant schizophrenia. It is associated with several adverse effects including hypereosinophilia with an incidence varying from 4 to 62%.

*Objective.*– We report three cases of patients with hypereosinophilia under Clozapine, specifying the different therapeutic strategies for this adverse event.

*Observations.*– Case 1: Mr A, 31 years old, followed-up for resistant schizophrenia. We decided to resume the prescription of Clozapine gradually. Evolution was marked by clinical improvement at 250 mg/day, PNEo remained stable between 200 and 300 Elements/mm<sup>3</sup>. Case 2: Mr B, 32 years old, was hospitalized for resistant schizophrenia. Hypereosinophilia at 4800 cells/mm<sup>3</sup> was noted at 400 mg/day of Clozapine. In spite of this undesirable effect, we have preferred the resumption of this treatment at a very progressive dose. The PNEo numbers remained stable between 100 and 350 elements/mm<sup>3</sup>. Case 3: Mr C, 37 years old, followed-up for resistant schizophrenia and was treated with 500 mg/day of clozapine. We noted an hypereosinophilia with 3800 elements/mm<sup>3</sup> associated with hepatic cytolysis that could suggest associated visceral involvement. Given the severity of this cytolysis, our decision was to stop clozapine.

*Conclusion.*– Clozapine appears to cause an inflammatory reaction which is manifested by an increase in eosinophilic polynuclear cells. When this hypereosinophilia is isolated without visceral localization which could endanger the patient's prognosis, the resumption of treatment may be considered with a cautious and slow increase in dosage and rigorous clinical and biological monitoring.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Antipsychotics induces hyperprolactinemia: Incidence and interest of switch to aripiprazole**

W. Bouali<sup>1\*</sup>, I. Marrag<sup>2</sup>, R. Ben soussia<sup>2</sup>, L. Zarrouk<sup>2</sup>

<sup>1</sup> Hospital, Psychiatry, Mahdia, Tunisia; <sup>2</sup> Hospital, Psychiatrie, Mahdia, Tunisia

\* Corresponding author.

*Introduction.*– Generally underestimated despite its frequency, hyperprolactinemia related to antipsychotics remains the most common cause of elevated prolactin levels in people with psychiatric illnesses. The objectives of our study were to estimate the prevalence of hyperprolactinemia in patients treated with a single antipsychotic and describe its evolution after switch to aripiprazole.

*Methodology.*– This is a prospective, descriptive and interventional study of 202 patients followed at the psychiatry consultation of EPS Mahdia, treated with a single antipsychotic and meeting the criteria for exclusion and inclusion in the study. Laboratory tests including a plasma prolactin and thyroid function tests were requested for all patients and confirmed by a second dosage in case of anomaly objectified in the first one. A switch to a prolactin sparing antipsychotic (aripiprazole) has been proposed for patients with greater than 50 ng/ml prolactin.

*Results.*– The average age of the patients was 39,9 years with a sex ratio (M/F) of 1,43. The prevalence of hyperprolactinemia was 47%.

The switch to aripiprazole allowed the disappearance of clinical manifestations with an average figure of prolactin 20,14 ng/ml. The application of the Student test for paired sample allowed to find a statistically significant difference ( $p < 10^{-3}$ ).

*Conclusion.*– Hyperprolactinemia, a frequent but widely underestimated endocrine disorder, may be due to various causes including treatment with many drugs. The consequences of hyperprolactinemia are often not apparent. The onus of proof is on health professionals to monitor actively and ideally avoid hyperprolactinemia and its complications.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Recovery-oriented psychopharmacotherapy: Changing psychiatrists' attitudes and practice in an Italian public mental health service**

P. Carozza

Local Health Authority, Mental Health Department, Ferrara, Italy

*Introduction.*– It's well known that medication have Greater efficacy when the therapeutic relationship is based on trust, informed consent and shared decision making and that they alone don't develop skills and strenghts, don't replace the responsibility in the management of own life, don't replace the emotional support and the community resources needed to live independently, work, study or socialize. Furthermore, research shows that a high percentage, between 30% and 60%, don't respond or responds partially to treatment.

*Objectives.*– The presentation describes how we are changing attitudes and traditional belief of psychiatrists in the MHD of Ferrara (Italy).

*Results and conclusions.*– Results and conclusions will be reported about the following points: In the view of recovery how much drugs are helpful and how much harmful? How long medication should be taken and at what dosage? What are the limits of the drugs? What is the balance of risks and benefits? How pharmacotherapy can be integrated with other effective practice, such as IMR? What is the meaning of polipharmacotherapy (i.e. added medication to control medical illnesses? What happens if you stop taking medication? Can you trust psychiatrists manipulated by drug companies and bad-informed? How much pharmacotherapy should be integrate to psychosocial treatment, with particular reference to Illness Management and Recovery?

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The effects of atomoxetine on the spontaneous behaviour in rats – Experimental data**

A.C. Cristofor<sup>1\*</sup>, G. Rusu<sup>2</sup>, R. Chirita<sup>1</sup>, G. Popa<sup>3</sup>, L. Mititelu-Tartau<sup>2</sup>

<sup>1</sup> "Grigore T. Popa" University of Medicine and Pharmacy, Faculty of Medicine, Psychiatry, Iasi, Romania; <sup>2</sup> "Grigore T. Popa" University of Medicine and Pharmacy, Faculty of Medicine, Pharmacology-Algesiology, Iasi, Romania; <sup>3</sup> "Grigore T. Popa" University of Medicine and Pharmacy, Faculty of Pharmacy, Pharmaceutical Technology, Iasi, Romania

We aimed to investigate the effects of atomoxetine on the spontaneous behaviour in rats. Material and method: The experiments were performed on white Wistar rats (200–250 g), distributed in 3 groups of 6 animals each, which were administered orally (using

an eso-gastric device) in a single daily dose for one month, as follows: Group I (Control): 0.3 ml/100 g weight saline solution; Group II (ATM-1): atomoxetine 1 mg/kbw; Group III (ATM-3): atomoxetine 3 mg/kbw. The animals' locomotor activity and exploratory behaviour were evaluated using the LE-8811 ActimeterPanLAB apparatus, by counting the number of horizontal, vertical and stereotypic movements during eight minutes 'interval determinations'. The data were presented as mean  $\pm$  standard deviation and the statistical analysis was performed using SPSS 17.0 software for Windows—the ANOVA method, and the Newman-Keuls post-hoc test. P-values less than 0.05 were considered statistically significant compared to control group. The experimental protocol was implemented according to the recommendations of our University Committee for Research and Ethical Issues following the ethical standards of the European Community.

**Results.**— The administration of 3 mg/kbw, but not of 1 mg/kbw atomoxetine resulted in a reduction in rats 'horizontal, vertical and stereotype movements. The observed declining of exploratory and self-grooming animal activity induced by 3 mg/kbw atomoxetine could be correlated to a reduction in the animals 'anxious behaviour in the Actimeter test.

**Conclusions.**— The use of atomoxetine (3 mg/kbw) over one month period decreased the rats 'global locomotor activity and the self-grooming behaviour.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

### **Acneiform eruption by aripiprazole. good response to isotretinoin without any psychiatric relapse**

P. De Jaime Ruiz<sup>1\*</sup>, F.J. Navarro Triviño<sup>2</sup>, B. Girela Serrano<sup>3</sup>

<sup>1</sup> *Campus de la Salud, Psychiatry, Granada, Spain;* <sup>2</sup> *Hospital Santa Ana Motril, Dermatology, Granada, Spain;* <sup>3</sup> *Hospital Santa Ana Motril, Psychiatry, Granada, Spain*

Drug-induced acneiform eruptions (DAE) are inflammatory follicular reactions that resemble acne vulgaris both in morphology and distribution, which manifest clinically as papules and pustules. The DAE lesions are commonly found in the face, trunk and extremities. Drugs that have been implicated in DAE include antibiotics, hydroxychloroquine, hormonal agents and psychotropic drugs as lithium, chlorpromazine, haloperidol, and others.

We present a 34-years-old unmarried male, followed up in an outpatient Mental Care Clinic for 8 years. Diagnosed with Paranoid Schizophrenia. He previously tried different psychotropic drugs, such as Quetiapine, Clozapine and Risperidone, with partial response to all of them.

Subsequently, the patient was started on Aripiprazole 20 mg/d, showing good response. Shortly after initiating the treatment a papulopustular eruption without comedones appeared on the patient's back.

Aripiprazole-induced acneiform eruption was diagnosed after performing the dermatological assessment. Patient showed good response to low doses of oral isotretinoin maintaining the Psychopathological stabilization.

The mechanism underlying Aripiprazole-induced acneiform eruption is yet unknown. In the literature there is only one case report of acneiform eruption with Aripiprazole, in which was required to discontinue the treatment with Aripiprazole to improve his skin lesions.

In our case, we decided maintaining the treatment with Aripiprazole in association with oral isotretinoin. The combination was well tolerated: the acneiform lesions disappeared and the patient stayed psychopathologically stable. In those well-controlled patients with

Aripiprazole who present acneiform eruption, we should consider associating treatment with oral isotretinoin always keeping a close follow-up of the patient.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

### **Patient information about side effects of antipsychotic drugs on a psychiatric intensive care unit (PICU): A clinical audit**

M. Husain<sup>1\*</sup>, M. Isaac<sup>2</sup>

<sup>1</sup> *South London and the Maudsley NHS Foundation Trust, General Adult Psychiatry, London, United Kingdom;* <sup>2</sup> *South London and the Maudsley NHS Foundation Trust, Psychiatric Intensive Care, London, United Kingdom*

**Background.**— Patients are referred to a Psychiatric Intensive Care Unit (PICU) when they cannot safely be managed on an open ward due to high level of disturbance. Antipsychotics are commonly prescribed in patients on these wards. Noncompliance with medication has been identified as an important risk factor in relapse of a psychotic illness. The medications are commonly D2 and 5HT<sub>2A</sub> antagonists and it is established that these medications have a variety of side effects, some of which can affect a patient's quality of life. NICE guidelines recommend patient involvement in the selection of antipsychotic medication. A patient centred approach can improve the therapeutic relationship and has also shown to improve compliance with medications.

**Objectives.**— The aim of this audit is to determine how many patients have received information about their prescribed medication on Johnson PICU, at the Ladywell Unit in Lewisham Hospital.

**Methods.**— To determine the number of patients who received information about their medication the electronic notes of all patients admitted from 1<sup>st</sup> January 2017 to 30<sup>th</sup> June 2017 will be accessed and reviewed. Recommendations for improving clinical practice (including re-audit) will be dependent on the results.

**Results/conclusions.**— Results are to be presented at the European Congress of Psychiatry Conference in March 2018.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

**Introduction.**— Women with bipolar disorder are at high risk for relapse during the immediate postpartum period and have historically been instructed to avoid breastfeeding while taking lithium.

**Objectives.**— To provide information on the pharmacokinetics of lithium during delivery and lactation by quantifying the rate of lithium placental passage, and calculating the infant serum/maternal serum lithium concentration ratio during lactation (IS/MS).

**Method.**– The Perinatal Psychiatry and Gender Research Program Barcelona–Clínic recruited prospectively 8 women affected by bipolar disorder and treated with lithium monotherapy during late pregnancy, who elected exclusive breastfeeding taken lithium. Study variables: sociodemographic, psychopharmacologic treatment, neonatal and child outcomes. Lithium plasma concentrations in intrapartum maternal blood (MB), umbilical cord (UC) and mother–infant pairs during lactation. Lithium plasma concentrations were determined by means of an AVL 9180 electrolyte analyzer based on the ion-selective electrode (ISE) measurement principle. Detection limit was 0.10 mEq/L.

**Results.**– Lithium equilibrate across the placenta [mean (SD) UC/MB ratio 1.03 (0.03)]. The IS/MS ratio decreased by the time from 1.04 (delivery day + 2.67 day) to 0.18 (delivery day + 91.67 day). From the week seven after the childbirth the infant serum lithium concentration ranged 0.20–0.10 mEq/L. No signs of toxicity were observed in nursing infants.

**Conclusions.**– Lithium may be taken during breastfeeding. In order to monitor mother–infant dyads who were exposed to lithium during lactation, we recommend the following time–point serial blood sampling: at delivery, at 48 hours after delivery, at 7–10th days postpartum and every 6–8 week while child nursing.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

**Introduction.**– Bromdihydrochlorphenylbenzodiazepine (Phenazepam) is the Russian original benzodiazepine widely prescribed in post-Soviet countries. There is lack of data about cytochrome P450 which metabolize bromdihydrochlorphenylbenzodiazepine - it might be CYP3A family enzymes.

**Aim.**– To investigate changes of CYP3A4/5 enzymes' activity during pharmacotherapy of alcohol withdrawal syndrome with bromdihydrochlorphenylbenzodiazepine; to evaluate the influence of CYP3A5\*3 on CYP3A4/5 activity changing.

**Materials and methods.**– A total of 102 male patients with non-complicated AWS (F 10.3 by ICD-10) were involved into the study. Each participant was prescribed bromdihydrochlorphenylbenzodiazepine (Phenazepam) for 6 days. 5 ml of venous blood was collected from each participant for genotyping CYP3A5\*3 (rs776746) and 10 ml of urine for measuring CYP3A4/5 activity. 38 participants were added Pagluferal (contains phenobarbitalum, natrium coffeine-benzoate, bromisoval, papaverine) and/or Carbamazepine (“Combined pharmacotherapy” subgroup). CYP3A4/5 activity was measured by 6-b-hydroxycortisol/cortisol ratio by

fluid chromatography. Higher mean of this ratio is the sense of higher CYP3A4/5 activity.

**Results.**– According to 6-b-hydroxycortisol/cortisol ratio, CYP3A4/5 activity significantly decreased only in patients prescribed bromdihydrochlorphenylbenzodiazepine as monotherapy ( $n=64$ ;  $3.82 \pm 3.41 > 2.79 \pm 3.06$ ;  $P=0.03$ ). There was no substantial change in overall group ( $n=102$ ;  $3.35 \pm 3.25 > 3.09 \pm 3.56$ ;  $P=0.568$ ) and in “Combined pharmacotherapy” subgroup ( $n=38$ ;  $2.58 \pm 2.84 > 3.57 \pm 4.25$ ;  $P=0.265$ ). CYP3A5\*3 polymorphism (GA genotype, “rapid metabolizers”,  $n=18$ ) had no effect on 6-b-hydroxycortisol/cortisol ratio between 1st and 6th days ( $4.88 \pm 4.29 > 2.7 \pm 2.38$ ;  $P=0.102$ ).

**Conclusion.**– CYP3A4/5 activity was significantly decreased under bromdihydrochlorphenylbenzodiazepine monotherapy which could indicate the primary role of CYP3A4/5 in metabolism of this drug. CYP3A5\*3 polymorphism did not influence on CYP3A activity changing rate.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Adult attention deficit hyperactivity disorder: The evmorbidity of personality disorders that suggest the need for more holistic interventions**

U. Jain<sup>1</sup>, S. Jain<sup>2</sup>

<sup>1</sup> SMS Medical College, psychiatry, Jaipur, India; <sup>2</sup> University of Toronto, Kinesiology, Toronto, Canada

\* Corresponding author.

Previous literature shows the strength of the assortment that ADHD of the Combined Subtype EVsegregate with Cluster B Personality Disorders (PD) and ADHD of the Inattentive Subtype EVsegregate with Cluster C PD. There is very little work being done on other strategies to address the impairment related to chronic PD factors which do not disappear with drugs. However, it may facilitate some of the other interventions beginning with the motherhood of all interventions: sleep, nutrition and exercise. In this paper, evidence-based interventions are discussed related to the former but exercise, as yet in pilot form, are presented. **Method:** Ten Olympians, with childhood ADHD, were interviewed. Components of their exercise were reviewed to determine if there was a commonality to the protective factor that exercise embraced. The assessments were an open dialogue with probing questions. However, the same questions were given to each participant.

**Results.**– The factors that were consistently represented in all ten individuals that were relevant were a) mentorship/coaching b) structure of the training regimen c) early exposure before the age of 11 and d) embracing a discipline around nutrition and sleep.

**Conclusions.**– There were many other factors presented but this early discussion begins to point to resiliency strategies we should be employing within children early in their lives. All of the participants said they were on medications after they were diagnosed but did not need medications subsequent to their entry into competitive sports. This data needs to be replicated and widened to seek out factors of importance.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

**Introduction.**– Previous investigations have shown extensive use of benzodiazepines in the region of Southeastern Europe, however this is still an insufficiently explored domain.

**Objectives.**– We assessed the prevalence of benzodiazepine prescription at discharge from all university psychiatric hospitals in Serbia, to analyze factors associated with prescriptions (yes/no) and the dose.

**Methods.**– Multicenter cross-sectional study reviewed summary medical documentation of all adult patients discharged in the census period (2015), including: sex, age, place of origin, education, primary psychiatric diagnosis and other diagnoses, therapy prescribed at discharge for continuation as outpatient. Logistic regression analysis was performed separately for two dependent variables (benzodiazepine intake and the dose in users).

**Results.**– In 572 adult subjects (age  $45.2 \pm 14.0$ ; male 49.1%; index hospitalization  $28.4 \pm 11.4$  days; all diagnostic groups from ICD 10 were included) we found benzodiazepine prescribed at discharge in 83.9% cases, mean dose  $3.9 \pm 2.9$  mg lorazepam equivalents. The only socio-demographic factor associated with higher benzodiazepine prescription was lower education (OR 0.906, CI95% 0.825 – 0.994). The highest odds of benzodiazepine discharge prescription was associated with EV medication with antidepressant (OR 2.432, CI95% 1.278–4.628) and psychiatric comorbidity (OR 1.790, CI95% 1.027–3.120). Antidepressant was the strongest predictor of higher (above 2.5 mg lorazepam equivalents) daily benzodiazepine doses (OR 1.933, CI95% 1.059–3.528).

**Conclusion.**– Benefits of combined treatment with antidepressants and benzodiazepines are no longer significant after the first four weeks. Its use beyond this period exposes patients to a greater risk of withdrawal symptoms upon discontinuation. We emphasize an urgent need for guidelines in order to prevent long term benzodiazepine (mis)use.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Valproic acid – Induced neutropenia

H. Maatallah<sup>\*</sup>, A. Amina, A. Faten, K. Amira, E.H. Zouheir Razi Hospital, f, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Valproic acid, a conventional antiepileptic drug, is also used in the treatment of bipolar disorder, to provide rapid stabilization of the patient. Although thrombocytopenia is a potential threat, occurrence of suppression of the other cell lines in the bone marrow is also found rarely.

**Objective.**– To report a case of neutropenia caused by valproic acid (VPA) which promptly resolved after discontinuation.

**Case summary.**– Mr S.A., 44 years old, has been undergoing psychiatry since the age of 24 years for schizoaffective bipolar disorder under: Haloperidol 40 mg/day + chlorpromazine 200 mg/day + valproic acid 1500 mg/day + biperidene 4 mg/day. The last NFS:white cells 5500 and PNN 2800 Following a manic relapse, doses of valproic acid were increased to 2000 mg/day, the blood number of control performed on day 14 showed a drop in the rate from GB to 3600 and from PNN to 1470. A pharmacovigilance opinion was solicited and which decided on the imputability of valproic acid in front of this leuconetropenia. The patient was then resuspended with 1500 mg of valproic acid and the control made after 7 days showed a white cells rise to 5100 and PNN to 2200.

**Conclusion.**– This report of neutropenia caused by VPA emphasizes the importance of monitoring blood cell counts during therapy with this agent

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0690

### Risperidone – Induced thrombocytopenia: A case report and review of literature

H. Maatallah<sup>\*</sup>, A. Amina, A. Faten, K. Amira, E.H. Zouheir Razi Hospital, f, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Risperidone is an atypical antipsychotic drug indicated for schizophrenia. Thrombocytopenia is an uncommon but potentially dangerous side effect of antipsychotic medication. Clozapine-induced blood dyscrasia is well known, but risperidone, which has a different chemical structure and pharmacological profile, is considered to have a low risk of hematotoxicity.

**Methods.**– We describe a case of thrombocytopenia occurring during treatment with risperidone, which promptly resolved after discontinuation.

**Case report.**– Mr. H.B., age 40, is a Tunisian man admitted to an inpatient psychiatric unit for management of acute psychotic symptoms. Baseline blood count was normal and a platelet count  $170 \times 103/\mu\text{L}$ . Seven days after starting risperidone, repeat blood count shows a drop in the platelet count to  $140 \times 103/\mu\text{L}$ . Risperidone was considered the cause of thrombocytopenia and was discontinued. We started treatment with olanzapine, 10 mg/d. In next 10 days, the WBC count increases to  $6,000/\mu\text{L}$ . The ANC at  $3,100/\mu\text{L}$  and platelets at  $150 \times 103/\mu\text{L}$  remain stable throughout hospitalization. The increasing count of platelet count after stopping risperidone is highly suggestive that this agent caused thrombocytopenia.

**Conclusion.**– At any rate, the administration of atypical antipsychotics may require greater attention to cell blood count. Clinicians worldwide should also be aware of this hazardous side effect. Moreover, future research needs to address the incidence and risk factors for this rare but potentially fatal side effect.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Subjective assessment of single doses of anxiolytics: Correlation with personal characteristics and structure of psychopathology in anxiety disorders

M. Metlina<sup>1</sup>, T. Syunyakov, O. Dorofeeva, T. Kovalenok, A. Chepelyuk, G. Neznamov  
 FSBI "Zakusov institute of Pharmacology", Laboratory of Clinical Psychopharmacology, Moscow, Russia

\* Corresponding author.

**Introduction.**– The subjective evaluation (SE) of drug effect depends not only on drug pharmacodynamics, but also on patient personality traits and disorder parameters. Also, single-dose subjective evaluation may predict therapeutic response.

**Objectives.**– To evaluate SE of the anxiolytics phenazepam and fabomotizole single-doses and its relationship with objective efficacy and personality traits parameters in patients with different anxiety disorders.

**Methods.**– A total of 117 patients (mean 35,6 ± 10,3 years) with generalized anxiety disorder (GAD, F41.1, n = 36), panic disorders with agoraphobia (PD, F40.01, n = 45) and nosophobia (NP, F45.2, n = 36) participated this open-label study. All patients were treated for 14 days. Among them 37 took phenazepam 2 mg daily and 80 - fabomotizole 30 mg daily. Minnesota Multiphasic Personality Inventory, Psychiatric Symptoms Severity Evaluation Questionnaire and SE of the single dose tolerability, wish to continue treatment (WCT), activating and sedating effects.

**Results.**– In fabomotizole group SE was generally higher in PD patients, while in phenazepam group in GAD patients. Phenazepam scored more on SE of sedation. Personality traits correlated with tolerability and WCT in GAD and PD patients and with activation/sedation in GAD patients from fabomotizole group and in GAD patients from phenazepam group. SE of activation and sedation scores correlated with symptoms in GAD and PD patients from fabomotizole group and in all patients from phenazepam group.

**Conclusion.**– The study revealed that SE may be drug-, disorder- and personality trait-specific. Thus, these results indicate potential to use single-dose evaluation in the prediction of the long-term effectiveness of anxiolytics.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Clinical parameters of metabolic syndrome in schizophrenia and bipolar disorder: A cross sectional study

D.K. Mishra<sup>1</sup>\*, V.S. Pal<sup>2</sup>, P. Rastogi<sup>2</sup>, V. Niranjana<sup>2</sup>  
<sup>1</sup> S.S. Medical College Rewa, Psychiatry, Rewa, India; <sup>2</sup> M.G.M. Medical College Indore, Psychiatry, Indore, India

\* Corresponding author.

**Introduction.**– Schizophrenia and bipolar disorder are serious mental illness and need long-term antipsychotics for management. Olanzapine is most commonly used atypical antipsychotics with high risk for metabolic syndrome. Monitoring of metabolic parameters are advised but many times unavailability of biochemical parameters of metabolic syndrome clinical parameters are only can be measured, so that prevalence of impaired clinical parameters of metabolic syndrome is not known in serious mental illness. Aim: To study the clinical parameters among the schizophrenics and bipolar disorders patients taking Olanzapine.

**Methods.**– Cross-sectional assessments were done on 118 subjects (>18 years). Subjects taking Olanzapine at least for 6 months for schizophrenia and bipolar disorder was recruited from the outpatient department of a tertiary care hospitals. Data was collected on socio-demographic characteristics, Clinical parameters of metabolic syndrome as per NCEP ATP III criteria were evaluated  
**Results.**– Study sample schizophrenics was 67.80% and mean duration of illness in schizophrenics vs. Bipolar disorder was 10.18 ± 6.29 vs. 9.47 ± 6.93 years respectively. Mean dose of Olanzapine in schizophrenics vs. Bipolar disorder 13.75 ± 5.36 vs. 12.63 ± 4.75 mg per day. 50.84% subjects had central obesity, 44.06% had impaired SBP, and 40.67% impaired DBP. No statically significant difference of clinical parameters of metabolic syndrome between schizophrenia and bipolar disorder.

**Conclusion.**– Impairment in clinical parameters of metabolic syndrome was significantly higher in schizophrenia and bipolar disorder patients taking Olanzapine and there was no significant difference among schizophrenics and bipolar disorder patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Long-acting injectable aripiprazole: Sample of 26 outpatients treated with this antipsychotic in two community mental health services in Barcelona

E. Monteagudo\*, R. Sánchez, J.I. Castro, R.M. Sanchís, J. León, C. Díez Aja, L. San Emeterio, L.M. Martín, H. Manteca  
 Institut de Neuropsiquiatria i Addiccions, Parc de Salut Mar, Neuropsiquiatria i Addiccions, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Long-acting injectable (LAI) formulations of antipsychotics are treatment alternatives to oral agents [1]. They offer a reliable option for reducing rehospitalisation or treatment failure [2]. LAI aripiprazole is an alternative to the oral drug approved for the treatment of schizophrenia in 2013 [3].

**Objectives.**– The aim of this study is to describe the clinical and sociodemographic characteristics of a sample of outpatients treated with LAI aripiprazole.

**Methods.**– Retrospective study of patients treated with LAI aripiprazole in two Community Mental Health Services in May 2017. The following variables were studied: sociodemographic characteristics, diagnosis, years since diagnosis, LAI aripiprazole dose and concomitant oral treatment.

**Results.**– A total of 26 patients were studied. The clinical and sociodemographic characteristics are shown in Table 1. Figure 1 shows the different diagnostic groups. 61.5% were on antipsychotic monotherapy with aripiprazole.

Figure 1. Hazard rate scale for terrorist attack as predicted by radicalized emotions and biased thoughts.

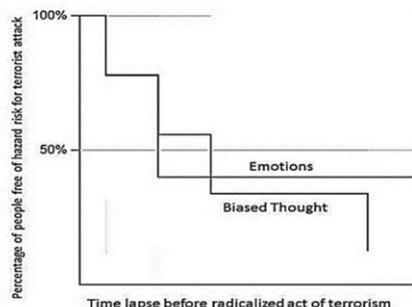

Figure 1.

PHM done

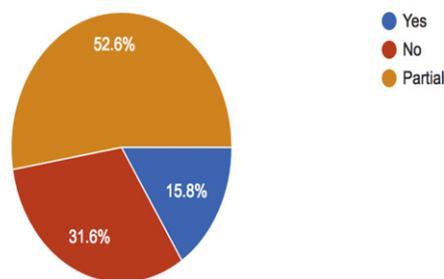

Figure 1. Classification according to diagnosis

*Discussion.*– The clinical profile is characterized by young men with a recent diagnosis. In 62% of cases medication was prescribed for off-label purposes, mainly schizoaffective and bipolar I disorder. This could imply that indications for using LAI aripiprazole might be expanded to other diagnoses. Due to the small sample no statistical inferences can be made.

Table 1. Clinical and Sociodemographic characteristics

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Evolving towards second-generation antipsychotics: Descriptive data from the hospital Universitario De Mostoles

A. Muñoz Domenjó\*, P. Muñoz-Calero Franco, R. Molina Cambra, N. Rodríguez Criado, R. Martín Aragón, J.F. Cruz Fourcade, M. Salvador Robert, F. García Sánchez, E. Ramos García, Á. Martínez Fernández  
Hospital Universitario de Móstoles, Servicio de Psiquiatría, Madrid, Spain

\* Corresponding author.

*Introduction.*– The use of depot antipsychotics is increasingly established in clinical practice. Several advantages of this route of administration have been described, being the main one the control of therapeutic adherence. Among the depot antipsychotics in our sample, there are first generation drugs (zuclopenthixol, fluphenazine decanoate and risperidone) and second generation (paliperidone palmitate (monthly and trimester) and aripiprazole). *Objectives and methods.*– The objective of the present study is to describe the use between first and second generation depot antipsychotics in our environment to evaluate if an evolution towards the second generation drugs is being performed. We have developed a database with those patients being followed up in a nursing protocol from our outpatient psychiatric center where

the patients go to the depot administration. We analysed the data obtained using SPSS.

*Results.*– The data show that in our area the use of second generation antipsychotics (74.8%) has been established, with Paliperidone palmitate being the most used (48.4%). On the other hand, the use of first generation antipsychotics is being reduced (25.1%). It's important to mention that 80% of our sample are patients with the diagnosis of Schizophrenia.

*Conclusions.*– The data show that the treatments of patients in our area are being modified in order to find drugs, which despite having similar efficacy among them, have a better metabolic profile and lower extrapyramidal side effects.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0695

### Metabolic effects of long acting injectable antipsychotics

P. Muñoz-Calero\*, A. Muñoz, R. Martín, N. Rodríguez, J.J. De Frutos  
Hospital Universitario de Móstoles, Psychiatry, Madrid, Spain

\* Corresponding author.

*Introduction.*– Since the synthesis of long acting injectable antipsychotics issues related with adherence to treatment have been partially solved and hospital readmissions related with psychotic symptoms have decreased. These advantages are related with the increasing use of this pharmacological formulation. With the creation of second generation long acting injectable antipsychotics extrapyramidal side effects are less frequent; less is known about its metabolic side effects. The aim of this study is to analyze the metabolic effects of long acting injectable antipsychotics and compare its effects between first generation antipsychotics and second generation ones.

*Material and methods.*– Data from 139 patients that are in our long acting injectable antipsychotics program were collected and analysed with SPSS.

*Results.*– Most of our patients are treated with second generation long acting injectable antipsychotics (74.8%). Only the 25.1% of our patients are treated with first generation ones. The 61,86% of our patients had overweight prior to the start of antipsychotic injectable treatment. After years of treatment the percentage of patients with overweight increased to 69,77%.

*Conclusions.*– The etiology of obesity related with psychotic disorders includes adverse effects of antipsychotics, premorbid genetic vulnerabilities, psychosocial and socioeconomic risk factors and unhealthy lifestyle. This multifactorial approach makes difficult to define which are the factors that may contribute in its majority in metabolic side effects.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Antipsychotic prescription in black and white patients with first psychotic episode – A study of hospitalized patients in Lisbon

V. Nogueira\*, R. Fernandes, I. Pinto, J. Teixeira, M.J. Avelino  
Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal

\* Corresponding author.

*Introduction.*– Prescription of antipsychotics may differ by ethnicity. Studies show that black patients are more likely to receive typical antipsychotics, long acting prescriptions, higher doses and greater number of antipsychotics than white patients. Genetic fac-

tors influencing pharmacokinetics and pharmacodynamics may contribute to a significant variability in effectiveness of antipsychotic pharmacotherapy among ethnicity.

**Objectives.**– Characterize and compare the pattern of antipsychotic prescription at discharge between black and white patients admitted with first psychotic episode.

**Methods.**– Retrospective cohort study in a hospitalized population with first psychotic episode between January/2014 and June/2016. We characterized our sample regarding ethnicity and the main outcomes of the study were antipsychotic dose, polypharmacy and type of antipsychotic.

**Results.**– A total of 125 subjects were included, of which 76.8% were white and 23.2% were black. The mean age was 27 years and most individuals were male. The mean DUP was higher in white than in black patients. Antipsychotic polypharmacy was seen in 17.2% and 9.4% among black and white population, respectively. As for the type, typical antipsychotics were prescribed in 8 patients, which represents 10.3% in black and 5.2% in white populations. A total of 18 patients were prescribed with long duration antipsychotics, 33.3% of which were black and 12.5% were white patients.

**Conclusions.**– This study highlighted ethnic differences in terms of antipsychotic prescription, especially the polypharmacy and the use of typical and long acting antipsychotics, which are significantly more frequent in black patients. There is a great need to improve treatment selection for patients with first psychotic episode.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Galactorrhea and hyperprolactinemia associated with trazodone: A case report**

H.M. Özkan

*Istanbul Rumeli Üniversitesi, Child development, İstanbul, Turkey*

Trazodone was the first second-generation antidepressant; it is a weak inhibitor of serotonin reuptake but a strong antagonist of serotonin type 2A (5HT<sub>2A</sub>) and type 2C (5HT<sub>2C</sub>) receptors. Galactorrhea associated with antidepressant use has rarely been reported in the literature. To our knowledge, this is the second case report of galactorrhea associated with trazodone use so far. Here, we report the case of a patient treated with duloxetine and quetiapine for 5 months; however, quetiapine was discontinued because of dizziness and drowsiness. Quetiapine was replaced with trazodone; however, we observed that the patient developed galactorrhea within 4 weeks of treatment initiation.

**Keywords:** Trazodone; Galactorrhea; Hyperprolactinemia

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0698

### **Patient satisfaction after switching from a monthly to a quarterly administered long-acting injectables: A case series**

G. Pardo de Santayana

*Hospital Universitario Marques De Valdecilla, Psychiatry, Santander, Spain*

**Introduction.**– One of the revolutionary events that has changed the way in which many patients have improved therapeutic adherence and treatment satisfaction, was the arrival of monthly administered

long-acting injectables (LAIs). Recently a new LAI has come out that only requires quarterly administrations.

**Aim.**– Studying patient satisfaction after switching from a monthly to a quarterly LAI with the same active principle.

**Methods.**– This is a descriptive study that pretends to assess patient satisfaction with TSQM 1.4 after switching from a monthly to a quarterly LAI, with Paliperidone as the active principle in both treatments. The sample consisted of 13 clinically stable patients diagnosed of psychosis (10 men and 3 women) with a mean age of 57.9 years that came to our psychiatric consultation from December 2016 to August 2017.

**Results.**– Patients were satisfied with the switching from a monthly to a quarterly LAI with a mean TSQM 1.4 of 71.4/79 after the second dose of the quarterly administered LAI.

**Conclusions.**– Switching from a monthly to a quarterly LAI in patients with clinically stable psychosis could be used to improve treatment satisfaction and therapeutic adherence as a result of the first.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0699

### **Prescription of benzodiazepines for adults in a mental health care clinic – Relation to gender and psychiatric diagnosis**

B. Pejuskovic<sup>1</sup>, D. Lecic-Tosevski<sup>2</sup>, A. Peljto<sup>3</sup>

<sup>1</sup> Institute of Mental Health, Department for education, Belgrade, Serbia;

<sup>2</sup> Institute of Mental Health, Director, Belgrade, Serbia;

<sup>3</sup> Institute of Mental Health, Day Hospital for Adults, Belgrade, Serbia

\* Corresponding author.

**Introduction.**– Benzodiazepines are one of the most commonly prescribed classes of medication which are often misused. The analysis of psychotropic drugs prescription has shown high prescription rate of benzodiazepines use in the psychiatric inpatients population, with an increasing trend. Potential association between psychiatric diagnostic categories or gender and benzodiazepine prescribing practice important for good clinical practice.

**Objectives.**– To examine an association between gender and psychiatric diagnosis with prescription of benzodiazepines.

**Methods.**– This study was carried out by retrospective analysis of the patient's medical charts after hospital discharge ( $n = 108$ ). Data analysis included descriptive statistics, testing the difference between groups and correlation analysis.

**Results.**– At the discharge, 66.7% of patients had benzodiazepines prescribed, with an average dose of  $4.8 \pm 3.4$  mg lorazepam dose equivalents. There was no gender difference in prescribing of benzodiazepines. Patients with a diagnosis of affective disorders had an upward dose trend of benzodiazepines.

**Conclusions.**– Benzodiazepines are frequently prescribed at discharge. It is important to carefully consider benzodiazepine prescribing practices particularly in patients with affective disorders and use of guidelines is necessary.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

<sup>1</sup> Sapienza University of Rome, Rome (Italy), NESMOS (Neuroscience, Mental Health, and Sensory Organs) Department; <sup>2</sup> Central Hospital, Bozen (Italy), Psychiatry Department; <sup>3</sup> Central Hospital, Bozen (Italy), Psychiatry Department; <sup>4</sup> Maurizio Pompili, Sapienza University of Rome, Rome (Italy), NESMOS (Neuroscience, Mental Health, and Sensory Organs) Department; <sup>5</sup> Andreas Conca, Central Hospital, Bozen (Italy), Psychiatry Department  
 \* Corresponding author.

Trends in long acting injectable (LAI) use in the Psychiatric Service of the Health Care District of Bozen, Italy, during 2013–2017

**Introduction.**– Despite their widespread use and effectiveness, LAIs are regarded with prejudice. The lack of robust data on their use results in variations in the world and over the years.

**Objectives.**– Assess trends in LAI use in 2013–2017 at the Psychiatric Service of Bozen.

**Methods.**– Parametric statistics.

**Results.**– We administered LAIs to 319 patients, with a x age ± SD of 49.5 ± 14.7 years and 58.6% males. Figure 1 shows therapy durations.

Figure 1.

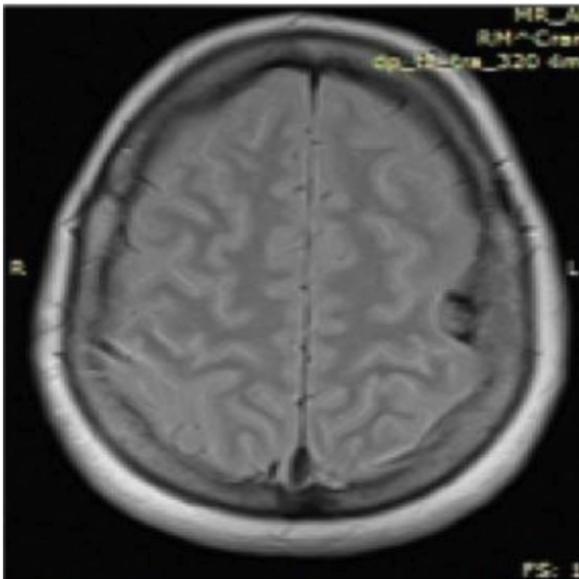

Figure 1.

The most used LAIs were: 2013 haloperidol (31.8%); 2014 haloperidol (26.5%); 2015 paliperidone (25.7%); 2016 paliperidone (24.0%); 2017 paliperidone (22.5%). Increases/decreases in dose were rather frequent, whereas the switch from one LAI to another, due to moderate-to-severe side effects or unsatisfactory improvement, was infrequent (33 cases/5 years). LAI interruption for the same reasons or for no compliance was even more infrequent (3 cases), but in 5 cases it happened for opposite reasons, i.e., stabilization and good compliance. Table 1 shows x ± SD and ranges of doses and TDM.

Table 1.

	Current age	Years of evolution	Somatic backgrounds	Drugs previous to current treatment	Cause of modification	Current treatment	Side effects
N 1	79	59	Arrhythmia, high blood pressure	Lithium	Renal failure	Gabapentine	Tremor, drowsiness
N 2	76	60	cholecystectomy	Haloperidol, lithium biperiden,	Extrapyramidal syndrome	Lithium, trazodone,	Distal tremor, cognitive impairment
N 3	72	25	Ischemic heart disease, high blood pressure, VHB. Essential tremor, cognitive impairment	Fluoxetine, lamotrigine Oxcarbazepine Haloperidol olanzapine	Infective Neutropenia Extrapyramidal syndrome Gain Weight	Quetiapine, valproic acid.	Worsening Cognitive impairment, drowsiness
N 4	68	38	Diabetes mellitus	Tricyclic antidepressants, valproic acid, lithium	Drowsiness, gastric discomfort, fatigue	Risperidone, zolpidem	Tremor, dependence on zolpidem

Figure 2.

Correlations between doses and TDM were: haloperidol  $r = -0.037$ ,  $P = 0.620$ ; paliperidone  $r = 0.290$ ,  $P = 0.000$ ; risperidone  $r = 0.219$ ,  $P = 0.006$ ; fluphenazine  $r = 0.358$ ,  $P = 0.000$ ; aripiprazole:  $r = -0.068$ ,  $P = 0.610$ ; olanzapine:  $r = -0.090$ ,  $P = 0.634$ .

**Conclusions.**– Haloperidol and paliperidone were mostly used. Drugs and doses were stable. A positive correlation between paliperidone, risperidone, and fluphenazine doses and TDM was found (Figure 2)

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0701

## Promethazine and diazepam in agitation in bipolar disorder with cocaine dependence

M. Preve<sup>\*</sup>, M. Godio, N.E. Suardi, G. Canitano, R.A. Colombo, R. Traber  
 Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

\* Corresponding author.

**Introduction.**– Agitation is characterized by excessive motor activity associated with a feeling of inner tension which is expressed on a wide spectrum of behaviours [1]. In literature the prevalence of agitation increase in dual diagnosis patients with rates of 20–30% irrespective of 10% of patients without substance dependence [2,3]. The aim of this study is to evaluate the efficacy and tolerability of the association of promethazine and diazepam in a sample of bipolar patients (BD) with cocaine intoxication (CI).

**Method.**– Twenty-five BD inpatients presenting with CI were assessed with: SCID-P, BPRS, HRSD, YMRS, UKU and CGI. We conducted a systematic literature review with the principal scientific databases (Pub Med, Embase, PsychInfo) using the key terms “Agitation”, “Promethazine” and “Diazepam”.

**Results.**– High scores at the BPRS in the items 6 (Mean=5), 4 (Mean=4), 10 (mean=4), 11 (mean=4) and 17 (Mean=5). The principal side effect at the UKU scale are sedation, and somnolence. The treatment response is in 30–60 minutes. There aren't significant cardiovascular alterations evaluated at ECG.

**Discussion and conclusion.**– Our findings suggest that this association is safety without particular side effects (only sedation and somnolence) and severe adverse events, and it's possible useful treatment strategy in BD inpatients with acute CI. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Influence of pharmacokinetic features of long acting injectable aripiprazole in pregnancy

T. Sabo<sup>1</sup>, D. Bosnjak<sup>2</sup>, V. Oreskovic<sup>3</sup>, S. Vlatkovic<sup>4</sup>, M. Zivkovic<sup>4</sup>  
<sup>1</sup> University Psychiatric Hospital Vrapče, Department for psychosis, Zagreb, Croatia; <sup>2</sup> University Psychiatric Hospital Vrapče, General Psychiatry, Zagreb, Croatia; <sup>3</sup> Psychiatric Hospital Rab, Department of psychiatry, Rab, Croatia; <sup>4</sup> University Psychiatric Hospital Vrapce, Department for psychosis, Zagreb, Croatia

\* Corresponding author.

**Introduction.**– There is still not enough data about safety of aripiprazole in pregnancy and it should be used only if the potential benefit outweighs the potential risk for the fetus. Steady-state of long acting injectable (LAI) aripiprazole is reached after the fourth monthly injection of aripiprazole. Elimination half time of 400 mg aripiprazole after steady state is 46.5 days.

**Objectives.**– To evaluate the clinical outcomes of pregnant patient who was treated with 400 mg of LAI aripiprazole for one year until unplanned pregnancy happened and to emphasize the importance of atypical antipsychotics' pharmacokinetics with the intention to help clinicians facing complex treatment decisions in pregnancy.

**Methods.**– A case report and a review of literature.

**Results.**– Female patient with schizophrenia treated with LAI aripiprazole for over a year found out that she was pregnant one month after her last LAI application. The decision was to discontinue LAI treatment and switch it to clozapine. But, taking into account the pharmacokinetics of LAI aripiprazole, clozapine was initiated after three months, which is the time for elimination and effectiveness of LAI aripiprazole. During that period and after starting with clozapine no relapse of the disease was registered nor there were signs of fetal malformations so far. Also, according to available literature, this was the first reported case of treatment with LAI aripiprazole in pregnancy.

**Conclusions.**– In some cases, use of atypical antipsychotics cannot be avoided during pregnancy. To prevent polypragmasy which can harm fetus, it is necessary to know their pharmacodynamics and pharmacokinetics.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Pramipexole: Dopaminergic augmentation in the treatment of depression

H. Saiz Garcia<sup>1</sup>, V. Periera<sup>2</sup>, M.Á. Álvarez de Mon<sup>2</sup>, Á.S. Rosero<sup>1</sup>, L. Montes<sup>1</sup>, E. Mancha<sup>1</sup>  
<sup>1</sup> Complejo Hospitalario de Navarra, Psychiatry, Pamplona, Spain; <sup>2</sup> Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

\* Corresponding author.

**Introduction.**– Pramipexole is a dopamine receptor agonist approved by the FDA for the treatment of idiopathic Parkinson's disease and restless syndrome. It has preference for the D3 receptors. It is also a full agonist with higher preference for D3 receptors as compared to D2 and D4 receptors. The antidepressive effect of pramipexole has been shown in animal models. Clinical, off-label,

use of this drug has shown good response even in major depressive disorder.

**Methodology.**– A review was conducted aiming to clarify the biological mechanisms of action of pramipexole and the clinical implications of an augmentation of dopamine instead of other neurotransmitters. The literature search was conducted in Pub Med data reviewing articles dating between 2013 and 2017.

**Results.**– Augmentation with pramipexole seems to be more effective than placebo. This treatment is beneficial for the sexual dysfunction, instead of other serotonergic agents. Pramipexole may be more effective in the treatment of bipolar depression instead of just unipolar depression.

**Conclusions.**– Following the monoamine hypothesis, patients with dopamine related symptoms of depression, may benefit from the treatment of pramipexole. Dopamine augmentation may increase pleasure, motivation, concentration and psychomotor speed. A group of depressions may benefit from dopaminergic agents instead of the first-line treatment of depression with SSRIs, SNRIs or tricyclics. Subsequent trials are need to know if long-term treatment with pramipexole leads to a long-term antidepressive response. Some trials show conflicting results. Uncertain results have been observed. More research is needed to analyze the naturalistic effect of pramipexole.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Zolpidem as a diagnostic tool in Catatonia: Case report

F. da Silva\*, P. Almeida, N. Oliveira

Hospital de Magalhães Lemos, Internamento C, Porto, Portugal

\* Corresponding author.

**Introduction.**– Catatonia is a complex clinical syndrome characterized by a broad constellation of psychomotor signs and symptoms, frequently divided in retarded and excited subtypes. Intravenous lorazepam challenge is traditionally described as a standard diagnostic tool.

**Objectives.**– To describe the case of a patient whose catatonic syndrome diagnosis was confirmed by the significant clinical improvement following administration of zolpidem.

**Methods.**– Case report and literature review.

**Results.**– A 65-year-old woman with no psychiatric history and irrelevant medical and surgical history presents to our unit with depressive symptoms accompanied by serious self-neglect, verbigeration, echolalia, catalepsy, stereotypies and episodes of psychomotor agitation. These symptoms totally disappeared every night 15 minutes after taking zolpidem, previously prescribed by her family doctor for insomnia. The patient's cohabitants described this phenomenon as “the miracle of zolpidem”, stating that every night the patient was “as usual, talking and eating normally” for one to two hours. Brain imaging, electroencephalography and blood tests did not reveal important changes. The patient was diagnosed with a depressive episode with catatonic symptoms.

**Discussion/conclusions.**– In this case, the diagnosis of catatonia was confirmed by the dramatic response to zolpidem. Other published cases (describing patients with autism, bipolar disorder, schizophrenia and schizoaffective disorder) confirm the usefulness of this z-drug as a diagnostic test in this condition. Both in our case and in the ones previously published, the clinical response occurred within 15 minutes. The short time of onset of oral zolpidem is its main advantage during diagnosis, avoiding the use of intravenous lorazepam.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0705

### Olanzapine-induced weight gain: A multifactorial side effect. A case report

J. Vitória-Silva<sup>1\*</sup>, J. Mota<sup>2</sup><sup>1</sup> Hospital de Magalhães Lemos- Porto, C Service, Custoias, Portugal; <sup>2</sup> Hospital de Magalhães Lemos, C Service, Porto, Portugal

\* Corresponding author.

**Introduction.**– Olanzapine is an atypical antipsychotic drug which may cause dosage-independent weight gain in 66.6% of patients, with a mean of 1-5 kg over a period of 4 weeks of treatment (U. Eder et al., 2001). Olanzapine-induced weight gain (OIWG) is multifactorial and many factors seems to contribute to OIWG.

**Objective.**– The goal of this study was to explore the pathophysiology and predictors of weight gain during treatment with olanzapine in psychotic patients.

**Methods.**– A reasearch on the latest literature on Pub Med was made, using the keywords: “Olanzapine”, “Weight gain”. Brief description of a case-report.

**Results.**– The main OIWG factors are: genetics, altered fat metabolism and distribution, increased appetite, older female, higher reduction in baseline BPRS and low baseline BMI patients and decreased motor activity due to sedation.

**Conclusions.**– As it may lead to non-compliance with treatment and to medical morbidity (S. Jain et al., 2006), clinicians are encouraged to better advice patients and patients should also be encouraged to monitor and, if necessary, adjust their dietary habits and exercise regularly.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0706

### Role of risperidone switch to paliperidone in reducing neuroleptic-induced extrapyramidal effects

J. Vitória-Silva<sup>1</sup>, J. Mota<sup>2</sup><sup>1</sup> Hospital de Magalhães Lemos, Porto, C Service, Custoias, Portugal; <sup>2</sup> Hospital de Magalhães Lemos, Porto, C Service, Porto, Portugal

\* Corresponding author.

**Introduction.**– Extrapyramidal side-effects (EPS) are frequently mencioned as a reason for medication discontinuation<sup>1</sup>. Antipsychotics-induced dystonia (AID), an acute form of EPS, often occurs early in the course of treatment and is commonly associated with high-potency antipsychotics, as first generation antipsychotics. Although second-generation antipsychotics (SGA) have a lower D2 receptor and higher serotonin 5-HT<sub>2A</sub> receptor affinity they may also lead to AID, particularly when prescribed at high dosage<sup>2</sup>.

**Objectives.**– The objective of author's work is to present the approaching of neuroleptic-induced dyskinesia.

**Methods.**– Review of the latest literature in Pub Med with the keywords: “Dystonia”, “Seconde geration antipsychotics”. Also a case-report is presented.

**Results.**– The authors present a 42 year-old woman, diagnosed with schkizophrenia, taking risperidone 2 mg twice a day and biperiden 4 mg a day, for an oral dystonia associated with risperidone. A swich of risperidone 2 mg twice a day to paliperidone 12 mg once a day was made. After 3 months the dosage of paliperidone could be reduced to 9 mg once a day, and the biperiden was stopped, without returning of dyscinesia.

**Conclusions.**– Anticholinergic drugs are often prescribed in order to improve those symptoms, such as biperiden or trihexyphenidyl<sup>3</sup>,

however side effects are not irrelevant. For that reason an effort has to be made in order to find the best tolerated medication for the patient. The EPS advantages offered by the atypical antipsychotics must be balanced against other important adverse effects.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0707

### Antipsychotics and weight gain – Is insulin secretion dysregulation via dopamine receptors the culprit?

R. Strumila<sup>\*</sup>, A. Lengvenyte, A. Navickas

Vilnius University, Faculty of Medicine, Clinic of Psychiatry, Vilnius, Lithuania

\* Corresponding author.

**Introduction.**– It is known that antipsychotics cause weight gain. Yet comprehensive explanations are lacking. Some suggests that antipsychotics increase appetite, but this approach is problematic as people likewise gain weight in inpatient units, where all calories are provided. Others suggest that it happens because of hormonal-metabolic changes. There is a growing body of evidence that a sensible way of obesity treatment is minimizing insulin response via low carbohydrate diets, rather than counting calories. If there is a mechanism that would link antipsychotics use, insulin response patterns and weight gain, we could have new insights into treatment approaches.

**Aims.**– To investigate whether existing evidence supports the idea that antipsychotics could disrupt insulin homeostasis.

**Method.**– A literature search in Pub Med, Google Scholar and individual journals was performed.

**Results.**– In one mouse study it was discovered, that dopamine regulates autocrine secretion of insulin response and that dopamine inhibited secretion of insulin. Studies with humans discovered dopamine D<sub>2</sub> receptor expression in human pancreatic cells and that dopamine mediates insulin secretion. Other team found D<sub>4</sub> receptors on human beta cells.

**Conclusion.**– Insulin secretion from pancreatic beta cells is modulated by autocrine regulation through dopamine receptors. These receptors may be blocked by antipsychotics, that are supposedly not selective to brain tissue. Insulin regulation could get disrupted, resulting in increased insulin secretion from beta cells. Insulin causes weight gain via variety of mechanisms. Prolonged hyperinsulinaemia may be behind weight gain. Human studies are needed to confirm this hypothesis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0708

### The possible relationship between the uses of high-dose sertraline during pregnancy with the persistent chronic gastrointestinal symptoms in childhood: A case report

M.E. Taner, M.G. Teksin Bakır

Gazi University, Department of Psychiatry, Ankara, Turkey

There're diverse reports in the literature about the association between developmental disorders of the neonatal period and antidepressant exposure during gestation. The present case is about a 4-year-old child of a woman who is suffering from chronic constipation almost unresponsive to treatment whose mother was given high-dose of sertraline during gestation. The objective's to discuss the possible association. A 37-year-old woman who pre-

sented to our clinic complaining that her son defecates very rarely. She complained of her need to check his defecation and she was obsessed with cleaning. She used sertraline 50 mg/day for depressive symptoms from the first trimester of pregnancy, continued with 200 mg/day till to the delivery and stopped medication after giving a healthy child. After a few weeks her complaints had restarted and received fluvoxamine 100 mg daily. Chronic constipation in childhood is mostly due to functional factors; one of which is intestinal neuropathy, that is unresponsive to treatment as observed in this case. Serotonin plays an active role in motility and secretion of 5-HT<sub>3</sub> and 5-HT<sub>4</sub> receptors in the gastrointestinal system (GIS). This case, exposure to high-dose sertraline during gestation and its cessation following delivery might have caused receptor desensitization and down-regulation in the infant's GIS. As his chronic constipation couldn't obtain any benefit from treatment, our hypothesis seems to be investigated. Therefore, exposure to sertraline during gestation may not end up with neurodevelopmental disorders only for the neonatal period but also further be associated with childhood period. Further studies are essential to clarify the possible relation.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Functional anomalies of cytochrome P450 2D6 in child and adolescent psychiatry: Case reports

S. Thümmler<sup>1\*</sup>, E. Dor<sup>1</sup>, A. Fernandez<sup>1</sup>, A. David<sup>1</sup>, G. Leali<sup>2</sup>, M. Battista<sup>1</sup>, F. Askenazy<sup>1</sup>, C. Verstuyft<sup>3</sup>

<sup>1</sup> Hôpitaux pédiatriques CHU Lenval de Nice, University Department of Child and Adolescent Psychiatry, Nice, France; <sup>2</sup> Hôpitaux pédiatriques CHU Lenval de Nice, Department of Child Psychiatry, Nice, France; <sup>3</sup> Hôpital Bicêtre, AP-HP, Université Paris-Sud, Service de génétique moléculaire, pharmacogénétique et hormonologie, Paris, France

\* Corresponding author.

*Introduction.* – Severe mental health disorders in children and adolescents represent a major public health problem. Despite adequate drug treatment, some patients develop pharmaEVresistant disease and/or present frequent or severe adverse events (AE). The majority of psychotropic treatments, particularly antipsychotics and antidepressants, are metabolized at hepatic level by cytochrome P450, particularly by CYP2D6. Several CYP2D6 genetic polymorphisms are described to be associated with ultrarapid (UM) or poor drug metabolism (PM), and might therefore be related to severe mental health diseases.

*Methods.* – Inpatients with pharmaEVresistance and/or frequent AE have been studied by CYP2D6 genotyping between September, 2014, and April, 2017.

*Results.* – A total of 14 patients (6 females, 8 males) aged 11 to 20 (mean 14.8) years have been genotyped for CYP2D6. Patients were diagnosed with schizophrenia ( $n=6$ ), autism spectrum disorders ( $n=3$ ), mood disorders ( $n=2$ ), intellectual deficiency with challenging behaviour ( $n=2$ ) and other ( $n=3$ ). They had a treatment history with on average 5 psychotropic, 4 antipsychotic and 2.9 CYP2D6-metabolized molecules. Six patients (42.9%) presented functional anomalies of the CYP2D6 gene: 4 patients were UM with gene duplication and 2 patients were PM. Interestingly, there was no correlation between the anomaly of metabolism (UM/PM) and pharmaEVresistance/AE.

*Conclusion.* – Functional anomalies of CYP2D6 concerned a significant number of our pediatric inpatient sample with pharmaEVresistant disease and/or severe AE. Knowledge of individual metabolism and in particular CYP2D6 genotyping should be con-

sidered for clinical workup and therapy adjustment in challenging patients in child and adolescent psychiatry, and might be associated with better treatment outcome, increased compliance and diminished AE.

### Risperidone-induced leg edema after pharmacotherapy of schizophrenia

S. Tunç<sup>1\*</sup>, H.S. Basbug<sup>2</sup>

<sup>1</sup> Kafkas University, Department of Psychiatry, Kars, Turkey; <sup>2</sup> Kafkas University, Department of Cardiovascular Surgery, Kars, Turkey

\* Corresponding author.

Drug-related peripheral leg edema is most commonly associated with steroids, nonsteroidal anti-inflammatory, antihypertensives and immunosuppressive agents. The second-generation antipsychotic risperidone is rarely associated with such edematous complications. This adverse effect of risperidone occurs with a higher incidence in higher doses according to its dose-dependent nature. In this paper, a rare case of small maintenance dose risperidone-induced peripheral leg edema in a schizophrenia patient was reported. Leg edema is a rare but serious side effect of risperidone. Although it has a dose-dependent nature and usually associates with high doses, it may also present with small maintenance doses as in this case. The patients especially who are receiving high doses of risperidone should be warned and monitored for these side effects. Despite the low incidence of edema due to risperidone usage, the likely occurrence of this adverse effect should always be taken into consideration by the psychiatrists, as it may affect patients compliance with the prescription.

### An unusual case of hair loss due to aripiprazole

Y. Yenilmez Bilgin<sup>1</sup>, I. Yagci<sup>2</sup>, S. Tunç<sup>3\*</sup>, M.I. Atagun<sup>4</sup>, H.S. Basbug<sup>5</sup>

<sup>1</sup> Mehmet Akif Ersoy Göğüs Kalp ve Damar Cerrahisi Eğitim ve Araştırma Hastanesi, Department of Psychiatry, Istanbul, Turkey; <sup>2</sup> Kars Harakani State Hospital, Department of Psychiatry, Kars, Turkey; <sup>3</sup> Kafkas University, Department of Psychiatry, Kars, Turkey; <sup>4</sup> Yıldırım Beyazıt University, Department of Psychiatry, Ankara, Turkey; <sup>5</sup> Kafkas University, Department of Cardiovascular Surgery, Kars, Turkey

\* Corresponding author.

Hair loss is one of the side effects that can be seen after medical treatments. Hair loss due to medications is a diffuse state that does not leave scars and usually reversible with stopping the treatment. The Aripiprazole is an atypical antipsychotic drug, which also has antidepressant effects. Aripiprazole has a partial agonistic effect on dopamine D<sub>2</sub> receptors and serotonin 5-HT<sub>1A</sub> receptors which differ from other atypical antipsychotic drugs. It is used in several psychiatric disorders including schizophrenia, bipolar disorders, major depressive disorder and anxiety disorders. This report aims to present a case with hair loss due to aripiprazole use that is reversed back right after stopping the treatment. Since other psychotropic medications may also stimulate hair loss, it is possible to speculate that this side effect is a class effect of medicines. However, further studies are needed to understand exact mechanisms of hair loss due to psychotropic medications.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Regulatory peptides in the adjustment disorders therapy

V. Verbenko

Medical Academy named after S.I. Georgievsky, Psychiatry, Narcology, Psychotherapy With Course of General and Medical Psychology, Simferopol, Russia

Adjustment disorders one of the most common mental disorders. This fuzzy separation between different manifestations of AD and normal adaptive responses is diagnostically difficult. In connection with this, the diagnosis and treatment of disorders are extremely topical. The clinical manifestations of adjustment disorders in different age groups (153 people), 35–50 years (257 people), 51–65 years (167 people) using the PHQ questionnaire and the questionnaire of stress resistance. The results of the study demonstrated the prevalence of reduced stress-resistance and subjective deterioration in all age groups with an increase to 50.9% in the age group 51–65 years. Pathogenetic therapy of AD is based on neurotransmitter causes and systemic therapeutic approach taking into account the safety of drugs. The use of new classes of regulatory drugs is promising. Regulatory peptides possessing a wide spectrum of biological activity in coordination of neuroendocrine, immunological, cellular and molecular interactions. The aim of the study was to study the features of the anxiolytic and stress-protective effect of the heptapeptide, synthesized analogue of the endogenous regulator of immunity of taftycin selank (Thr-Lys-Pro-Arg-Pro-Gly-Pro) - in the treatment of discharge disorders. 30 patients diagnosed with the intrusion disorder were treated with an analogue of the endogenous peptide taftcin. The use of the regulatory peptide had a corrective effect on the somatic and mental symptoms of the disorder.

### Effect of CYP3A gene polymorphism on serum concentration of quetiapine

Y. Zhang<sup>1\*</sup>, P. Cui<sup>1</sup>, J. Jiang<sup>1</sup>, W. Zhu<sup>1</sup>, Y. Li<sup>1</sup>, F. Liu<sup>2</sup>, B. Wu<sup>2</sup>, Z. Dai<sup>1</sup>, Q. Wu<sup>1</sup>

<sup>1</sup> Xi'an Mental Health Center, Pharmacy Lab, Xi'an, China; <sup>2</sup> Xi'an Mental Health Center, Science and Education Department, Xi'an, China

\* Corresponding author.

*Background.*– With the development of pharmacogenomics in recent years, more and more attention has been paid to the molecular genetic mechanism of pharmacokinetics among different individuals. Gene polymorphisms of drug metabolizing enzymes affect their retention in vivo. Quetiapine is one of the new antipsychotic drugs. It is a neurotransmitter receptor antagonist in the brain. Quetiapine is orally absorbed and metabolized in the liver. the major metabolic enzyme of Quetiapine is CYP3A.

*Objective.*– The aim of this study was to investigate the effect of CYP3A gene polymorphism on quetiapine plasma concentration.

*Methods.*– The serum concentration of quetiapine was determined by two-dimensional high performance liquid chromatography (HPLC) and the CYP3A polymorphism was measured.

*Results.*– Among 138 patients in the center, gene analysis showed that CYP3A5\*3 mutant homozygote accounted for 43.5%, CYP3A5\*3 mutant heterozygote accounted for 32%, and CYP3A5\*3 wild-type homozygote accounted for 32%. The gene polymorphism of CYP3A5 will greatly influence blood concentration of quetiapine. The serum concentration of quetiapine of CYP3A5\*3 wild homozygous patients is higher than that of CYP3A5\*3 mutant heterozygous

and homozygous patients at the same dosage, was statistically significant. In patients with CYP3A5\*3 mutant homozygotes, the same administration dose increased the probability of adverse effects of quetiapine.

*Conclusion.*– The level of serum concentration should be closely monitored during the use of antipsychotic quetiapine. The mutation of CYP3A5\*3 gene should be detected depend on patients economically eligible.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### The psychophysiological state of highly qualified athletes performing in diving with different levels of anxiety

S. Fedorchuk\*, S. Tukaiev, O. Lysenko, O. Shynkaruk  
National university of physical education and sport of Ukraine,  
Scientific research institute, Kyiv, Ukraine

\* Corresponding author.

*Introduction, aims.*– One of the main problems of sport psychology is evaluation of the influence of emotionogenic factors and personality characteristics of athletes on a performance. The aim of our investigation was to define the psychophysiological status of highly qualified athletes of sports that require complex coordination in relation to the State and Trait Anxiety.

*Methods.*– A total of 14 healthy volunteers–highly qualified athletes (diving) aged 15 to 30 years participated in this study. We used the following tests: State and Trait Anxiety Inventory by C. Spielberger, Y. Hanin, EPI Test by H. Eysenck. The diagnostic complex “Diagnost-1” (Makarenko MV, Lizogub VS) determined the psychophysiological properties of athletes.

*Results.*– We found that the higher was the level of personal anxiety of the respondents, the less stable was the speed of the complex sensorimotor selection reaction, the less was the resistance of the central nervous system to the increasing degree of fatigue. The decrease in the level of situational anxiety among athletes was noted with the growth of sports experience. Only 14.3% of respondents had average personal anxiety, the remaining 85.7% - characterized by high personal anxiety. Perhaps, in this sport it is high personal anxiety that contributes to the achievement of high sports results, is an optimizing factor according to the theory of zones of optimal functioning according to J. Khanin.

*Conclusions.*– The functional state of the central nervous system of athletes was not associated with situational anxiety, which gives grounds for a favorable prognosis of the effectiveness of their competitive activities.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Psychoemotional stress and the functional state of the neuromuscular system

S. Fedorchuk\*, O. Lysenko, O. Kolosova, T. Khalyavka  
National university of physical education and sport of Ukraine,  
Scientific research institute, Kyiv, Ukraine

\* Corresponding author.

**Purpose.** Assessment of the influence of the level of psychoemotional stress and the effectiveness of mental self-regulation on the functional state of the neuromuscular system of highly skilled athletes specializing in complex EVordination sports (on the example of diving).

**Methods.**– Study involved 14 high-class athletes (master of sport, international master of sport, honored master of sports) at the age of 15–30 years. To determine the psychophysiological properties of the nervous system of athletes, the diagnostic complex “Diagnost-1” are used. Electroneuromyography was performed on the neurodiagnostic complex “Nicolet Viking Select”. For a differentiated assessment of the level of stress, the emotional state of the respondents and also for assessing the effectiveness of mental self-regulation, a technique to select colors was used.

**Result.**– Correlation analysis showed the existence of interrelations between the effectiveness of mental self-regulation and adaptability, the intensity of existing stress, emotional stability and vegetative balance with electroneuromyographic characteristics speed of conduction of the nerve impulse along the motor fibers of the ulnar nerve and the threshold of the occurrence of the N-response. Revealed interrelations of the measured parameters can testify to the mutual influence of the functional state of the neuromuscular apparatus and the neuropsychic state of the athletes.

**Conclusion.**– Revealed interrelation of the effectiveness of mental self-regulation and adaptability, intensity of existing stress, emotional stability and vegetative balance with electroneuromyographic characteristics of athletes can have prognostic value and be used to optimize the sports development of promising young people.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Using stress profile measurement in psychiatry**

M. Slepceky, A. Kotianova, J. Prasko, M. Zatkova, M. Popelkova

*Faculty of Social Science and Health Care- Constantine the Philosopher University in Nitra, Slovak Republic, Department of Psychology Sciences, Nitra, Slovak Republic*

\* Corresponding author.

The purpose of stress is to increase internal awareness of danger and transform all the body's resources to react. There are a number of ways that people respond to stressful situations in their lives. High emotional arousal could be the cause of subsequent emotional disorders. The emotionally sensitive person reacts more intensively on environmental or internal cues, become hyper aroused a tends to scan environment for threat cues. This keeps emotional arousal high, causing internal discomfort. After environmental threat ceases, the emotionally sensitive person take longer to return to their baseline arousal level.

High emotional arousal can be objectively measured by various psycho physiological modalities as muscular tension, breathing patterns, changes in skin conduction, increased heart rate, changes in heart rate variability and so on. People stress reaction is an individual response in different psycho physiological modalities. Why make a stress assessment in CBT?

Psychiatrist and psychologist used various questioners and scale with lower validity. But subjective feelings are not always correlated with physiology and the only objective measurement can show real picture ANS functioning.

The result of stress profile analyse can be very important for exposure therapy when patients experiences can be validated by real dates. Physical and psychological symptoms also could be caused and maintained by altered physiological functioning.

Date provide us the guideline for specific biofeedback training for decreasing hyper arousal and over reactivity. After decreasing arousal we continue with psychological, mostly cognitive behavioural therapy.

\* Corresponding author.

**Introduction.**– Electroconvulsive Therapy has been used to treat depression since the 1930s. Nowadays it is widely used, especially in those patients who show lack of response with pharmacotherapeutic treatment. ECT has proven its efficacy in clinical trials. Clinical practice has allowed to progressively adjust the device parameters to achieve an adequate seizure with the least possible energy, minimizing adverse effects.

**Objectives.**– In most patients, the seizure threshold increases over the sessions, regardless of medication that increases seizure threshold such as benzodiazepines. This has as a consequence, the need to deliver higher energy amount, with the corresponding adverse effects. Flumazenil infusion is proposed as an option trying to lower the seizure threshold before the ECT, even if Benzodiazepines have not been prescribed.

**Methods.**– Case report and bibliography review.

**Results.**– ECT was considered the best treatment alternative for a 63-year-old patient with major depression who lacked response to three different pharmacological compounds (from different pharmacological families, including Lithium). Seizure threshold increased progressively, hampering the achievement of therapeutic seizures with the device maximum energy deliverance. With Flumazenil, the seizure threshold decreased, allowing the completion of ECT sessions.

**Conclusions.**– Flumazenil infusion before ECT may be a good option in order to reduce the energy needed. Adequate clinical trials should be performed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Predictive response factors of repetitive transcranial magnetic stimulation in treatment-resistant depression**

B. Calvet<sup>1,2</sup>

<sup>1</sup> Esquirol Hospital Center, Geriatric Psychiatry, Limoges, France; <sup>2</sup> Inserm, UMR1094, Limoges, France

**Introduction.**– Repetitive transcranial magnetic stimulation (rTMS) is a neurostimulation technique used in many indications, especially in psychiatry in the treatment of mood disorders. Although its efficacy in this treatment has been demonstrated, the study of predictive response factors currently remains a major challenge.

**Method.**– We conducted a retrospective study from the cohort of treatment-resistant depressed patients that received rTMS treatment in Esquirol Hospital in Limoges in order to identify response predictors at three months. Of the 416 patients treated between January 2007 and November 2015, 107 subjects have been included. The clinical characteristics of responders and non-responders at three months after treatment, but also at the end of treatment and after one month were compared. Predictors of clinical improvement objectified by the Hamilton Depression Rating Scale (HDRS) was conducted using a logistic regression model.

**Results.**– In our cohort, the response rates were 52% at the end of treatment, 61% at 1 month and 57% at 3 months. Psychiatric family history and the recurrence of thymic episodes were found to be negative predictors of response to rTMS treatment. Similarly, high subscore of depression core symptoms in HDRS could also predict a poorer response.

**Conclusion.**– Our data from a naturalistic cohort tended to prove that a number of clinical features should be taken into account in determining the profile of the treatment-resistant depressed patients that could respond to rTMS treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Introduction.**– Transcranial magnetic stimulation (TMS) is considered to be the perspective non-invasive and non-medication method of correction of clinical conditions and of brain functional state in depressive patients.

**Objectives.**– Clinical, psychological and EEG effects of combined treatment of pharmaevresistant depression included TMS were studied for better understanding of brain mechanisms of TMS therapeutic effects.

**Methods.**– High frequency rhythmic TMS (25 Hz, intensity of 60-80% of motor threshold to prevent facial muscles jerks, 40 series by 2 s with 14 s intervals, total 1600 pulses, 15 daily sessions) was applied on the left dorsolateral prefrontal cortex in 30 female patients aged 18 до 56 (mean age 36.3 ± 3.9) with pharmaevresistant depression.  
**Results.**– Even brief course of low intensity high frequency rhythmic TMS significantly facilitated and accelerated effects of antidepressants– up to 80% of previously resistant patients became responders. Positive effects of TMS included reduction of depressive and anxiety symptoms (by HDRS scores), and improvement of general patient's conditions (by SCL-90-R inventory) and of some impaired cognitive functions (by WCST test), and normalization of frequency structure of occipital EEG alpha. Some of these effects were seen after the first TMS session.

**Conclusions.**– TMS appeared to be useful method of overcoming the pharmaevresistance in depressive patients. TMS therapeutic effects seem to be mediated by activation of not only the left dorsolateral prefrontal cortex itself but also of some subcortical brain structures closely linked with it.

The study is supported by Russian Humanitarian Research Foundation Grant No.15-06-10541

### **Atropine versus hyoscine premedication for electroconvulsive therapy in major depression**

M. Ghasemi\*, A. Kheradmand, M. Hamdieh  
 Shahid Beheshti University of Medical Sciences, Taleghani Hospital, tehran, Iran

\* Corresponding author.

**Introduction.**– Electroconvulsive therapy (ECT) is a highly successful treatment for severe depression. ECT needs general anesthesia. Choosing a suitable anesthetic agents during ECT is effective on the quality and outcome of patient treatment.

**Objectives.**– This study was performed to compare haemodynamic status after Atropine and Hyoscine Premedication for electroconvulsive therapy in major depression patients.

**Methods.**– This study was a single blind Clinical Trial study. 102 patients for ECT, from an academic hospital with major depression were randomly selected and divided into three groups. Group-I received atropine, group-II received Hyoscine and group-III received no premedication. prior to, immediately, 5 minutes, 10 minutes, and 15 minutes after ECT heart rate and blood pressure were measured. Data were analysed using SPSS software, version 20.

**Results.**– The results showed that systolic blood pressure, heart rate and Rate Pressure Product of patient during injection, 5 minutes and 10 minutes after ECT in the group receiving atropine was significantly higher than the other two groups M.

**Conclusions.**– Based on the findings of present study using hyoscine as Premedication make more hemodynamic stability after ECT compared with atropine.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The effects of sleep on the intensity of skin reactions induced by transcranial electrical stimulation**

A. Kortteenniemi<sup>1\*</sup>, M. Varheenmaa<sup>1</sup>, A.K. Brem<sup>2</sup>, A.H. Javadi<sup>3</sup>, J. Wikgren<sup>4</sup>, S. Lehto<sup>1</sup>

<sup>1</sup> University of Eastern Finland, Institute of Clinical Medicine- Department of Psychiatry, Kuopio, Finland; <sup>2</sup> Max Planck Institute of Psychiatry, Psychiatry, Munich, Germany; <sup>3</sup> Keynes College, University of Kent, School of Psychology, Canterbury, United Kingdom; <sup>4</sup> University of Jyväskylä, Centre for Interdisciplinary Brain Research, Jyväskylä, Finland

\* Corresponding author.

**Introduction.**– Transcranial electrical stimulation is a promising neuromodulation method that has, for example, been used to treat depression. Controlling potential adverse effects (AEs) is necessary for clinical practice. Unlike many potential aspects potentially modulating AEs, sleep duration can be controlled.

**Objectives.**– To evaluate the effect of sleep duration on skin redness and skin sensations induced by transcranial direct current stimulation (tDCS) and transcranial random noise stimulation (tRNS) in a double-blind setting.

**Methods.**– A sample of healthy male volunteers received two 20-minute sessions of either tDCS ( $n = 41$ ; 2 mA) or sham-tDCS ( $n = 41$ ; 15s ramp-up and -down). Another sample of 60 (32 female, 28 male) volunteers received 2 sessions of tRNS and sham-tRNS in a cross-over design (20 min, 2 mA). In both studies the anode was placed over F3 and the cathode over F4. The participants reported the duration of previous night's sleep and immediate adverse effects (scale 0-100). Analyses were conducted using Zero-Inflated Poisson models, controlling for age, sex and stimulation group.

**Results.**– In the first study (tDCS), longer sleep duration predicted less intense skin sensations ( $P < 0.05$ , 0.10 to 0.14 point drop per an hour slept). In the second study (tRNS), longer sleep predicted more intense skin sensations ( $P < 0.05$ , 0.11 to 0.20 point increase per an hour slept). Skin redness was not affected.

**Conclusions.**– Sleep duration might affect skin resistance and impedance, which in turn affect dermal effects of tDCS and tRNS, respectively. However, as effects appear minimal, recommending patients to get a good night's sleep before treatment sessions may be unnecessary.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Psychotherapy**

EV0723

### **Cognitive behavior therapy for psychological disorders: Better thinking to better well-being**

R. Aly

Egyptian Association of Cognitive Behavior Therapy, President, Cairo, Egypt

"It's not the power of positive thinking, 'Beck say'. It's the power of realistic thinking. People find that when they think more realistically, they usually feel better."

Almost everyone has dark thoughts when his or her mood is bad. With depression & anxiety, though, the thoughts can be extremely negative. They can also take over and distort your view of reality. Cognitive therapy can be an effective way to defuse those thoughts. When used for psychological disorders, cognitive therapy provides a mental tool kit that can be used to challenge negative thoughts. Over the long term, cognitive therapy can change the way a depressed person sees the world.

During regular cognitive therapy sessions, a trained therapist teaches the tools of cognitive therapy. Then between sessions, the patient often does homework. That homework helps the person learn how to apply the tools to solve specific life problems.

"They make small changes in their thinking and behaviour every day," Beck says. "Then over time, these small changes lead to lasting improvement in mood and outlook."

Several studies have shown that cognitive therapy works at least as well as antidepressants in helping people with mild to moderate severity psychological disorders. Treatment with medication and/or psychotherapy can shorten depression's course and can help reduce symptoms such as fatigue and poor self-esteem that accompany those disorders.

**Learning objectives.**–

- identify basic cognitive & behavioural theory of depression;
- formulate a depression case based on the CBT Model;
- design a therapeutic program for a case of depression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **"There is a little voice inside my head": "Invisible" attachment trauma and suicide in children and healing strategies: A case study**

D. D'Hooghe

Traumacentre Belgium, Private Practice, Brugge, Belgium

This case concerns a 6-year old girl with suicidal ideation. In this particular case, I considered the suicidal thoughts to be a symptom of "invisible" attachment trauma.

Although suicide is recognized as a global public health problem, little is known about suicide in young children.

There is recent research exploring the association between attachment security and suicidality in children.

It is the quality of parenting that influence the attachment security and when this quality does not meet some specific requirements like e.g. psychobiological regulation, mentalization etc., "invisible" attachment trauma develops.

Consequences of this "invisible" attachment trauma such as no affect regulation skills, anxiety etc., can lead to suicidal behaviour

that therefore can be seen as a kind of insecure attachment behaviour.

Some data suggest that the parent-child relationship determines the development of internal working models about self and others. When there is an underlying threat of abandonment due to the unavailability of the caregiver and the child's ambivalence towards the parent, the child becomes trapped between autonomy and enmeshment, leading to suicidal disintegration.

The psychobiological effect of "invisible" trauma has the potential to illuminate the pathway to future suicide.

These findings support the efforts to develop attachment-based interventions such as "Watch, Wait, Wonder", attachment-based play, improving the child's and the parent's self-regulating skills, resource building, developing a sense of self etc., as a novel route towards suicide prevention.

EV0725

### **Psychotherapeutic interventions for ADHD in people with intellectual disabilities**

S. Elstner

*Pfeiffersche Stiftungen, MZEB, Magdeburg, Germany*

*Introduction.*– ADHD is a neurodevelopmental disorder can be which is typically diagnosed in child- and adolescent psychiatry and which can be often combined with behavioural problems. Also in people with intellectual disabilities (ID) challenging behaviour can also often be found with some comorbidity of ADHD. State of the art in treatment is a combination of pharmacological and psychotherapeutic strategies.

*Objectives.*– The study wants to give a comprehensive overview about the so far existing psychoptherapeutic strategies in ADHD in people with IDD.

*Methods.*– The database "Pub Med" was screened for psychotherapeutic strategies in ADHD by the keywords: "Psychotherapy" and "ADHD" (search history 1) and the combination "search history 1" and "intellectual" and "disability" or "disabilities".

*Results.*– The output of "search history 1" was much higher than the output of psychotherapy in ADHD for people with ID.

*Discussion.*– Although the psychotherapeutic strategies in ADHD seem to be elaborated with manuals, the group of people with ID is still neglected. There are some interesting programs for the treatment of impulsiveness and ID, which represents the beginning of treatment possibilities also for ADHD symptoms in people with ID.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Comparative analysis of the preferred coping strategies and defense psychological mechanisms in prostate cancer patients compared with patients in other cancers**

A. Gardanov<sup>1</sup>, Z. Gardanova<sup>2</sup>, B. Tsygankov<sup>3</sup>, G. Galiamova<sup>2</sup>, I. Abdullin<sup>2</sup>, A. Chernov<sup>4</sup>

<sup>1</sup> Student, Moscow State University of Medicine and Dentistry, Moscow, Russia; <sup>2</sup> Russian National Research Medical University. NI Pirogov, psychotherapy, Moscow, Russia; <sup>3</sup> Moscow State University of Medicine and Dentistry, Psychiatry, Moscow, Russia; <sup>4</sup> Russian National Research Medical University. NI Pirogov, psychotherapy, Moscow, Russia

\* Corresponding author.

*Introduction.*– Detection and diagnosis of prostate cancer for many patients is stressful. In order to cope with stress men prefer protective mechanisms. In Russia the prostate cancer takes the 6th place on prevalence and mortality among other forms of cancer at men.

*Objectives.*– The study included 56 men with prostate cancer, control group - 25 people of patients with other types of oncological diseases (intestines cancer, cancer of urinary bladder). The average age of patients was 35,7 + 6,1 years. The average duration of prostate cancer was 4,6 + 4,2 years.

*Methods.*– To find out indicators of such characteristics as levels of situational, personal anxiety, coping-strategy and expressiveness of psychological protective mechanisms techniques "Scale of uneasiness of Spilberger", by "Coping-test of Lazarus" and "Life style Index" were used. Statistical analysis of data was carried out by means of SPSS Statistics 17.0 package.

*Results.*– Correlation indicators between level situational and personal uneasiness with degree expressiveness of protection "suppression" ( $r = -0,9876$ ;  $r = -0,72901$  at  $P > 0,05$ ) show that it has high performance and holds leading position, in relation to other protection. Patients use such strategy as "search of social support" less often ( $M = 44,9$ ), however it correlates with decrease by personal uneasiness ( $r = -0,51254$ , at  $P > 0,05$ ).

*Conclusions.*– In the group of the patients with prostate cancer, high level of personal and situational anxiety was revealed. For its suppression they use preferential such protective mechanisms as "Suppression" and "Denial", unlike control group.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Obesity and psychotherapy**

R. Schwarz Gelain<sup>1</sup>, L. Araripe de Abreu e Lima<sup>2</sup>, C.D.F. Santos Filla<sup>3</sup>

<sup>1</sup> Secretaria de Saúde de Santa Helena, Psiquiatria, Curitiba, Brazil; <sup>2</sup> Clínica Médica Paraná, Psiquiatria, Cascavel, Brazil; <sup>3</sup> Hospital San Julian, Psiquiatria, CURITIBA, Brazil

\* Corresponding author.

*Introduction.*– The treatment of obesity is complex since it involves the interaction of biological and psychological factors. About two-thirds of the obese present comorbidities like the depressive and anxiety disorder; and there is often a recurrence of weight loss after weight loss diets.

*Objective.*– We present a systematic review of the literature in Portuguese concerning the treatment of obesity through psychotherapy.

*Methodology.*– This is a bibliographic review of articles published in the period 2007-2017, in which the literature indexed in the databases, scielo, pub med, science direct and google academic was searched using the following descriptors: "obesity" "Cognitive therapy", "cognitive-behavioural therapy", "and" "psychotherapy". Of the 189 articles found, 44 were used. The inclusion criteria were studies published in the last 10 years, those of greater relevance according to the theme chosen, as well as those of greater relevance today - which investigated the cognitive-behavioural psychotherapy used alone or in together with other interventions.

*Results.*– A brief introduction was made on the subject of obesity, related medical, social and psychological aspects, and then the main results of the published studies on the treatment of obesity through CBT were analysed and described.

*Conclusion.*– There is empirical evidence of the efficacy and effectiveness of psychotherapy in the treatment of obese patients, demonstrated both by the loss of anthropometric measures and by adjustments of psychological and emotional factors. In this way, obesity is a pathology that requires, in addition to the neurological

approach, psychiatric treatment through behavioural and cognitive techniques.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Formulating clinical cases, an alternative

R. Hernández Antón<sup>1\*</sup>, S. Gómez Sánchez<sup>1</sup>, H. De la Red Gallego<sup>1</sup>, M. Gómez García<sup>1</sup>, M. De Lorenzo Calzón<sup>1</sup>, C.M. Capella Meseguer<sup>1</sup>, L. Gallardo Borge<sup>2</sup>, M. Hernández García<sup>2</sup>, P. Marqués Cabezas<sup>2</sup>, A. Rodríguez Campos<sup>2</sup>, E.M. Rodríguez Vázquez<sup>1</sup>, S. Cepedello<sup>2</sup>

<sup>1</sup> MIR, Hospital Clínico Universitario de Valladolid, Valladolid, Spain;

<sup>2</sup> FEA Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

\* Corresponding author.

*Introduction.*– The formulation is a process by which the information gathered during the evaluation phase is organized into a series of hypotheses about which it is possible to understand the patient's complaint as a set of problem (s) whose solution would entail the achievement of a series of objectives, and propose a treatment strategy, predicting the modality, intensity and duration of the same and the problems that we will most likely encounter during its development.

*Methods.*– We will present a 29-year-old patient, who was in contact with Mental Health, for the first time, presenting manic symptoms. He has had obsessive thoughts of compulsions since 15 years and that over a period of time he consumed alcohol with legal repercussions. As we learned more about his biography, we saw the importance of the parents: an overprotective maternal figure and a very rigid father and problematic family dynamics

*Results:*

– Borders too rigid between father and son that impede the exchange and could have generated a disconnected system and emotional disconnection and borders too permeable between mother and son that would hinder differentiation and autonomy and would generate clumping or entanglement.

– An Inadequate hierarchy, with a weak parental subsystem and an intergenerational mother-child coalition.

*Conclusions.*– Areas of development may be affected by the trauma of attachment, according to Ainsworth ambivalent child (type C attachment).

It's very useful to formulate cases in which we find it difficult to progress or in which we see certain difficulties, because you can think of new hypotheses of what happens to the patient.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Alcohol and family roles

R. Hernández Antón<sup>1\*</sup>, C. Noval Canga<sup>2</sup>, A. Álvarez Astorga<sup>2</sup>, A. Alonso Sánchez<sup>3</sup>, I. Sevillano Benito<sup>4</sup>, E.M. Rodríguez Vázquez<sup>2</sup>, S. Cepedello Pérez<sup>5</sup>, G. Isidro García<sup>6</sup>, L. Rodríguez Andrés<sup>7</sup>, M.J. García Cantalapiedra<sup>5</sup>, U.L.D.C. Fernando<sup>5</sup>

<sup>1</sup> Hospital Clínico Universitario De Valladolid, Psiquiatría, Valladolid, Spain; <sup>2</sup> MIR, Hospital clínico Universitario de Valladolid, Valladolid, Spain; <sup>3</sup> MIR, Hospital Clínico Universitario de Valladolid, Valladolid, Spain; <sup>4</sup> FEA Psiquiatría, Hospital General de Ávila, Ávila, Spain; <sup>5</sup> FEA Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid, Spain; <sup>6</sup> FEA Psiquiatría, Hospital Universitario Valdecilla, Santander, Spain; <sup>7</sup> FEA Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid, Spain

\* Corresponding author.

*Introduction.*– The model of diagnosis and intervention in the Therapy of Couple, has as answer to two questions: what is happening to them and how we can help them.

The therapist has to maintain a position of neutrality and attention to the phenomena of complementarity and symmetry.

Types of conflicts:

- Disorders around the organization of coexistence;
- Differences in communication and conflict resolution;
- Basic disagreements regarding the definition of the relationship.

*Methods.*– A 48-year-old male, who lives with his wife and two children. Problems of dependence on alcohol since 18 years with legal consequences. Since 2011 in different programs of deshabitación, with little fulfillment. He works as a carrier. He says his only role in the family is to take the money home. We decided to introduce a novelty in the Therapy, to his wife, obtaining abstinence of two years.

*Process:* Demand; Personal data of each spouse; Family information of origin (parenting models and relational experiences); Love story; Return and contract.

*Results.*– We highlight the importance of biography, family myths and how the inequality of positions around power in dual relationships favors violence and/or psychopathology, as can be a problem of addiction.

*Conclusions.*– Dyadic interventions are feasible and joint therapies significantly reduce patients' depressive symptoms.

Alcohol is a dysfunctional way of modifying a rigid complementary relationship in which one member is always in the up position and the other in the down position.

The inequality of positions around power in complementary relationships favors violence and/or psychopathology, as it can be a problem of addiction

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0730

### On the (re)search for the conjugal model: Clinical case study

M. Figueiredo<sup>1,2</sup>, C. Lima<sup>1,3\*</sup>, M. Cruz<sup>2</sup>, Z. Charepe<sup>1,4</sup>, G. Cunha<sup>5</sup>

<sup>1</sup> CINTESIS, Center for Health Technology and Services Research, Investigation, Porto, Portugal; <sup>2</sup> Escola Superior de Enfermagem do Porto, Investigation, Porto, Portugal; <sup>3</sup> ForAll, Desenvolvimento Pessoal e Bem-Estar, Lda, Psicologia, Paredes de Coura, Portugal; <sup>4</sup> Instituto de Ciências da Saúde da Universidade Católica Portuguesa, Investigation, Porto, Portugal; <sup>5</sup> Universidade Lusófona do Porto, Investigation, Porto, Portugal

\* Corresponding author.

The EVconstruction of conjugality influences the established interactions in the family as a whole, becoming the relational model in the expression of effectiveness and conflict management.

*Objectives.*– Clinical case report, in which the members of the couple perceive themselves as having marital problems, assuming these are due to conflicts with the family of origin.

*Methods.*– Exploratory-descriptive study, using the case study as an empirical approach of constructivist onto-epistemological matrix, centered on creativity and EEvolution. We used the technique of analysis of context of action, which emerged from the interactional reciprocity of the therapeutic system, sustained in the Appreciative Inquiry.

The case described refers to Couple Therapy, with ten sessions, 2016. The members of the couple were present in all sessions

*Results.*– The family consists of the couple, male T and female B, and their son E. T and B have been married since 2008. About their marital relationship they state that it has been deteriorating because of the focus on the inherent functions as parents, and also because of

the conflicts that have arisen between B and T's parents since E's birth in 2015.

As far as the extended family is concerned, both elements of the couple come from nuclear families, with T being an only child and B having 2 siblings.

*Conclusions.*– We developed strategies which integrated the different theoretical and operational frameworks. The transformative change enabled the couple to take control of their relationship and allowed for the differentiation from the extended family, thus enabling them to decide the itinerary of their further development.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Successful psychoanalytic treatment in a young woman with panic disorder and specific phobia**

G. Martino<sup>1\*</sup>, V. Langher<sup>2</sup>, S. Cataudella<sup>3</sup>, P. Velotti<sup>4</sup>

<sup>1</sup> University of Messina, Department of Cognitive Sciences, Psychology, Education and Cultural Studies, University of Messina, Messina, Italy; <sup>2</sup> University of Rome, Department of Dynamic and Clinical Psychology, Rome, Italy; <sup>3</sup> University of Cagliari, Department of Pedagogy, Psychology, Philosophy, Cagliari, Italy; <sup>4</sup> University of Genoa, Department of Educational Studies, Genoa, Italy

\* Corresponding author.

*Introduction.*– The psychoanalytic approach is a valuable tool to be integrated in the treatment of mental disorder, and may improve self-awareness and quality of life.

We present the case of a young woman suffering from a range of symptoms, and for which all organic pathologies were excluded.

The separation of her parents took on traumatic overtures with the nth betrayal on the part of her father who remarried and abandoned her.

Tachycardia, precordial catch syndrome and paroxysmal dyspnoea provoked anxiety, concern for her health, difficulties in interpersonal relationships, so much so that she broke up with her future partner who was attracted by her fragility.

*Objectives.*– To prospectively evaluate the case of a young woman with panic disorder and specific phobia (flying) and to observe her clinical evolutions over time.

*Methods.*– The psychoanalytic approach was performed to improve patient's clinical features, also without psycho-pharmacological drugs.

*Results.*– The father complex, established early on as negative due to abandonment and the neglect she lived through, opened an instinctive escape dimension, which triggered symptoms of anxiousness and panic attacks, with a specific phobia. Analytic therapy accompanied by personal information, dreams, images and fantasies aided recognition of her own nature and showed the patient the direction of her change. She reunited with her father, achieved professional autonomy and found her true love.

*Conclusions.*– The patient has overcome her fears, re-finding depth of relationships far from any material source, concentrating on her personal development in the course of individualization, opening to the hope of coming to terms with reconciliation of opposites.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Self reflection and personal therapy during cognitive behavioral training**

J. Prasko<sup>1\*</sup>, J. Vyskocilova<sup>2</sup>, A. Grambal<sup>1</sup>, M. Slepecky<sup>3</sup>

<sup>1</sup> University Hospital Olomouc, Department of Psychiatry, Olomouc, Czech Republic; <sup>2</sup> Faculty of Humanities- Charles University Prague, Department of Ethics, Olomouc, Czech Republic; <sup>3</sup> Faculty of Social Sciences and Health Care- Constantine the Philosopher University, Department of Psychology Sciences, Nitra, Slovak Republic

\* Corresponding author.

Self-reflection in cognitive behavioural therapy is a continuous process, which is essential for the establishment of a therapeutic relationship, the professional growth of the therapist, and the ongoing development of therapeutic skills. Recognizing one's own emotions is a basic skill from which other skills necessary for both therapy and emotional self-control stem. Therapists who are skilled in understanding their inner emotions during their encounters with clients are better at making decisions, distinguishing their needs from their clients' needs, understanding transference and counter transference, and considering an optimal response at any time during a session. Self-reflection may be practiced by the therapists themselves using traditional cognitive behavioural therapy techniques, or it may be learned in the course of supervision. Recordings the therapeutic sessions and dialogue with the supervisor may be important for self-reflection. Very important part of self-reflection is personal therapy of the therapist.

Experiential training and personal therapy have rich traditions in various therapies as strategies to enhance self-awareness and therapist skills. We organized weekends for group CBT for trainees with problem solving of their own problems. Mostly the group works on interpersonal relations with partners or parents or interpersonal relations in job. Other important topic, which attendant chose were improving or of self-confidence and improving of assertivity, schema therapy with stressful live events and work with values. Structured approach to self-practice of CT techniques on their own problem seem very effective not only for solving the problems, but also for better understanding what happened with the clients during therapy.

### **Dynamic restructuring of the narrative identity: The methodology of a group therapy for patients with schizophrenia**

I. Szendi<sup>1\*</sup>, L. Farmasi<sup>2</sup>, N. Domján<sup>1</sup>

<sup>1</sup> University of Szeged, Psychiatry, Szeged, Hungary; <sup>2</sup> University of Szeged, Department of English Studies, Szeged, Hungary

\* Corresponding author.

*Introduction.*– In a cross-faculty interdisciplinary research we have developed the methodology of a group therapy on the realization that storytelling is a tool for grasping complex psychological processes, and that the production of a coherent, detailed life story is connected to numerous skills that are related to the problems patients with schizophrenia have to face.

*Objectives.*– Developing the narrative identity and narrative intelligence of people with schizophrenia through a dynamic restructuring of their life stories.

*Methods.*– Our method is based on the integration of the theories of narrative psychology, psychiatry, and cognitive and affective narratology. We ask the participants to write short life stories, which they have to gradually rewrite during the therapy. In this practice,

we focus on the selection and integration of self-defining memories into the life story. However, during the sessions we also focus on several aspects of the dialogical self-theory, and the formation of the narrative identity in oral storytelling, which entails a performative, situated practice of identity construction. Our goal is not simply to recreate the patients' life stories, but to make the process of reevaluating and rewriting of their memories a habit, to help them keep developing their life stories, which are often regarded as being reduced and rigid for people with schizophrenia.

**Conclusions.**– This method holds a new approach to the experience of the self, which perhaps contributes to the process of recovery. Our work also allows us to gain a deeper understanding of life stories in general and the self-defining and also “lighter” memories in particular.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **In transition: A combined (in- and out-patient) psychotherapeutic group for the elderly**

V.V. Vodušek<sup>1\*</sup>, K. Pavlin<sup>2</sup>

<sup>1</sup> University Psychiatric Hospital Ljubljana, Department for Gerontopsychiatry, Ljubljana, Slovenia; <sup>2</sup> Psihiatrična Ordinalcija Rudnik, Psihološki Oddelek, Ljubljana, Slovenia

\* Corresponding author.

Individual members work in the group from three to twelve months, the interval spanning hospitalisation and return to home environment, but because of group continuity a therapeutic culture develops transcending this specific interval. Group size is variable (from five to fifteen). The main inclusion criteria are: (i) depressive/anxiety symptoms; (ii) no acute psychotic symptoms; (iii) no robust cognitive decline; (iv) a declared motivation for group work. Members meet once weekly for 75 minutes, the method being a modified group-analytic technique (unstructured conversation, supporting mirroring and other interpersonal processes.) with elements of psychoeducation and cognitive techniques (clarification, cognitive restructuring).

The group is conducted by a constant therapist—a psychologist employed at the GU with group-analytic training—and a temporary EVtherapist with experience in group psychotherapy that can ensure a longer participation in the process (i.e. a minimum of three months).

The therapeutic goals of the combined group for the elderly are: (i) alleviation and understanding of symptoms; (ii) understanding of the principles of the disorder and the treatment; (iii) easing the transitions between the hospital and home environment and vice versa; (iv) neutralization of the feelings of loneliness stemming from the disorder and the specific life-stage (losses in old age); (v) instillation of hope and the perspective of a good enough life; (vi) promoting the working through and integration of the experience of decompensation; (vii) the corrective experience of working through the losses in the group (members leaving); (viii) working through of (psychological) losses and promoting insight in the consequences of them.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Using the observation of art work to facilitate therapeutic change with patients coping with schizophrenia**

H. Yaniv<sup>\*</sup>, B. Bachrach

The Hebrew University of Jerusalem, School of social work, Jerusalem, Israel

\* Corresponding author.

This poster discusses a therapeutic process carried out with patients coping with schizophrenia, which are highly suspicious of their therapists and having difficulty in forming relationships. Those circumstances led to combine seemingly a new method of creative therapeutic process utilizing the observation of artwork - a visual metaphoric instrument. The use of observing artworks, while relating to contents that arise from the artwork, had led to dissipation of fear and suspicion and gradual familiarity in the relationship, alternating between proximity and distance.

The analysis of the cases points to the potential of using the observation of art-work in certain therapeutic cases, both for the process of forming a relationship and in nurturing a process of change that includes a deep emotional dialogue. The resulting dialogue is indirect and gradual, reduces anxiety, facilitates growth and provides support for the rehabilitation process within the community.

Examples of therapeutic cases, in which this therapeutic process was used, will be presented in the poster

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Mindfulness-based cognitive therapy (MBCT) in bipolar disorder: A first tunisian experience**

Y. Zgueb

Hopital Razi, Department of Psychiatry “A”, la mannouba, Tunisia

**Introduction.**– Mindfulness based cognitive therapy (MBCT) has been mostly evaluated with remitted unipolar depressed patients and little is known about this treatment in bipolar disorder.

The present study shows the feasibility of MBCT in groups solely composed of bipolar patients of various subtypes.

**Methods.**– Bipolar outpatients (type I, II) were included and evaluated for depressive, anxious and hypomanic symptoms, as well as mindfulness skills before and after the 8 sessions of the MBCT protocol, with a follow up of 10 months.

**Results.**– Ten patients were included, of whom eight attended all 8 MBCT sessions. Most participants reported having very much benefited from the program: they were less anxious, more confident and more conscious with the present moment, although mindfulness practice decreased over time.

There was a significant improvement in depressive and anxiety symptoms as well as mindfulness skills between pre- and post-MBCT assessments. Results were maintained over the 10 months follow up period. One patient experienced a manic episode and another a major depressive episode. However, these two patients stopped their medication on their own initiative.

**Conclusions.**– MBCT is well perceived among bipolar patients. Larger and randomized controlled studies are required to further evaluate its efficacy, in particular regarding depressive and (hypo) manic relapse prevention. We need a unified protocol for bipolar patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## Quality management

EV0737

### Quality of services and reflections on staff: Two different community mental health centres in Italy compared

D. Garino<sup>1\*</sup>, D. Celona<sup>2</sup>, I. Hinnenthal<sup>3</sup>, E. Pascolo-Fabrici<sup>2</sup>, M. Balestrieri<sup>1</sup>

<sup>1</sup> Università degli Studi di Udine, Psychiatry Clinic, Udine, Italy; <sup>2</sup> Università degli Studi di Trieste, Psychiatry Clinic, Trieste, Italy; <sup>3</sup> ASL1 "Imperiense", Mental Health and Addiction Department, Imperia, Italy  
\* Corresponding author.

**Introduction.**– The WHO has repeatedly stressed the need of assessing the quality of the community mental health services. Despite of this, most of the times the everyday work leads to difficulties in taking care of the services users, operators (with burnout phenomena) and the service itself, especially in a local and global crisis frame.

**Objectives.**– This study aims to better understand how the shrinking employees' numbers has been having an impact on the quality of care and on the operators in two different environments, belonging to different regional health systems in Italy.

**Methods.**– Data analysis from the pSM<sup>®</sup> software, used by both the services, and the submission of the Maslach Burnout Inventory to the staff of two different Community Mental Health Centres.

**Results.**– The results will be discussed about the correlation between higher level of exhaustion, cynism and inefficacy, and objective parameters like workload, staffing, organization parameters.

**Conclusions.**– Burnout is a true problem within our services. Re-thinking their organization, taking the best from each experience, could have an impact on the staff and, as a result, on the users and the quality itself.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Dual diagnosis: The systemic view in the integrated coordination work between the addiction department and the mental health department in Trieste

D. Celona<sup>1</sup>, D. Garino<sup>2\*</sup>, E. Pascolo-Fabrici<sup>1</sup>, M. Balestrieri<sup>2</sup>

<sup>1</sup> Università degli Studi di Trieste, Psychiatry Clinic, Trieste, Italy; <sup>2</sup> Università degli Studi di Udine, Psychiatry Clinic, Udine, Italy  
\* Corresponding author.

**Introduction.**– The systemic theory is not only a clinic methodology for family psychotherapy. It can be considered, in a broader sense, as a lens through whom all the relationships' phenomena between people can be read. So, why don't take advantage of this view to exanimate a team work context, particularly the one that takes care of dual diagnoses, a mined and hard to be comprehended land, especially when not part of the same department as in Trieste?  
**Objectives.**– Analysis of the integrate team functioning between the addiction and the mental health department, for user with dual diagnosis.

**Methods.**– A.C.O. test for the evaluation of the emotional climate and of the organization structure of the work group that took care of a user with dual diagnosis in the 4<sup>th</sup> district of Trieste, Italy.

**Results.**– Analysing the work group in terms of cohesion and adaptability, a low level of cohesion was found, resulting in an interdependent cleaved team, with a high level of adaptability, that means a flexible team.

**Conclusions.**– This type of studies can be useful to feedback the professionals about their strong points, in this case the great adaptability, and their weak ones, in order to better them, in this case the scarce cohesion.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0739

### Reduce default rates of patients attending appointments after emergency room visit

Y.W. Lee<sup>1\*</sup>, J. Hariram<sup>1</sup>, C. Lee<sup>1</sup>, Y.Y.J. Tham<sup>2</sup>, S. Wong<sup>2</sup>, E.W.J. Low<sup>2</sup>

<sup>1</sup> Institute of Mental Health, East Panel, Singapore, Singapore; <sup>2</sup> Institute of Mental Health, Case Management Unit, Singapore, Singapore

\* Corresponding author.

**Background.**– Of patients who were seen in the Emergency Room and given subsequent appointments, there is a high non-attendance rate. This contributes to longer wait times for other patients till their appointments and also wasted time for the clinician. From an institutional point of view, while there are many non-modifiable including patient factors contributing to this, we also consider that institutional factors that could have a part to play. Here, we will describe an audit of the situation, steps taken to reduce this default rate and the results.

**Aim.**– To reduce non-attendance of appointments given to patients from the emergency room.

**Methodology.**– We will examine overall default rates as well as diagnosis-specific default rates for all patients who presented to the Emergency Room. We hypothesize that patients with a diagnosis of Acute Situational/Stress Reaction who were not admitted had a higher default rate compared to the average. These patients would have been referred to a Case Manager, who would follow up with telephonic support. We will examine possible solutions to reduce these default rates.

**Results.**– Results will be presented at the time of conference.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0740

### Audit into the did not attend (DNA) rates for appointments within the nottinghamshire perinatal psychiatry service offered with medics and perinatal psychiatric nurses (PCPNs)

S. Smith<sup>1\*</sup>, M. Dalzell, Z. Schofield

Nottingham University Hospitals, QMC Campus, Perinatal Psychiatry Service, Nottingham, United Kingdom

\* Corresponding author.

**Introduction.**– The Nottinghamshire Perinatal service offers psychiatric appointments to women during pregnancy and up to one year after birth. Psychiatric patients who miss appointments have a higher chance of deterioration in their mental state. Therefore, reducing DNA rates should be priority.

**Objectives.**– Measure the DNA rate for new patient assessments. Establish whether the DNA rate differs for medic and PCPN appointments.

Establish whether the DNA rate differs for appointments offered at the patient's home and in clinic.

**Methods.**– New referrals between 01/05/17 and 31/07/17 were recorded. The wait time for an appointment was calculated. The appointments were looked at retrospectively to ascertain whether the patient attended, cancelled or DNA. Microsoft excel was then used to look for patterns within the data.

**Results.**– Over the 3 month period 206 appointments were offered. 40 DNA (19.4%).

154/206 was PCPN appointments. 31 (20.1%) DNA.

52/206 was medic appointments. 9 (17.3%) DNA.

171/206 was clinic appointments. 38 (22.2%) DNA.

32/206 was home visits. 2 (6.25%) DNA.

The average DNA wait time was 21.83 days and the average attended appointment wait time was 21.42 days.

**Conclusions.**– DNA rates were comparable to the 19.1% DNA rate for psychiatric outpatients in England.

DNA rate between medic and PCPN appointments did not differ (19.4% and 20.1% respectively).

The DNA rate in clinic was higher than for appointments offered at home.

The DNA rate did not correlate with the wait time.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Coercive measures in inpatient psychiatry: Which data do we need? Insights into a quality management project of a psychiatric department of a German hospital**

B.S. Voigtländer\*, K.W. Scori, T. Barth

Klinikum Chemnitz gGmbH, Psychiatry, Behavioural Medicine and Psychosomatics, Chemnitz, Germany

\* Corresponding author.

**Introduction.**– Although avoiding coercive measures is highly important for quality assurance in psychiatry, there is a lack of systematic data collection and comparable studies on this issue worldwide.

**Objectives.**– Our objective was to establish a standardised method to assess data for the quality indicators “Use of restraint” and “Involuntary commitment”. The method of seclusion is not practiced in our department.

**Methods.**– We first developed a concept for a standardised, treatment case-related, computer-based and data protection proved data recording method for the quality indicator “Use of restraint”. General (socio-demographic patient data, main diagnosis, LOS) and specific assessment criteria (duration, legal legitimation, causes and type of restraint) were defined in accordance with legal regulations. This concept of data collection was implemented in the hospital information system.

Table 1. Findings I (Analysis of the 1<sup>st</sup> half of 2017)

Table 1. Differences between two groups of adolescents (Mann-Whitney U-test)

Objects	My body	My mental well-being	Health	Risky behaviors	Family	Sport	Medicine	Nutrition	Hygiene
U	457	301	451	450	557	417	561	675	629
p	.001	.001	.001	.001	.02	.001	.022	.231	.101
r	.392	.570	.391	.400	.282	.440	.274	.131	.183

**Results.**– As tables 1 and 2 illustrate, the new method to record and analyse data allows a clinic-related and unit-related evaluation in terms of the criteria frequency, duration, legal legitimation, causes and type of restraint. Results must be discussed in compliance with the legal restrictions on the use of forced medication.

Table 2. Findings II (Analysis of the 1<sup>st</sup> half of 2017)

Table 1. Clinical and sociodemographic characteristics

Variables	Results
Age (average)	36,23 years
Sex	
Men	18 (69.2%)
Women	8 (30.8%)
Years since diagnosis (average)	6,9 years
Monthly dose (average)	376,92 mg
Oral concomitant treatment	
Antipsychotics	10 (38.5%)
With other psychoactive drugs	15 (57.7%)

**Conclusions.**– The new data ascertainment method enables both longitudinal measurement with regard to clinically relevant quality criteria and issue-related research.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Rehabilitation and psychoeducation**

### **Psychological support strategies in disaster situation in Iranian vulnerable groups**

N. Amanat<sup>1</sup>, Z. Abbasi Dolatabadi<sup>2</sup>, S. Bahrampouri<sup>1</sup>, H. Seyedin<sup>3</sup>, A. Aryankhesal<sup>4</sup>

<sup>1</sup> University of Social Welfare and Rehabilitation Sciences, Health in Emergency and Disaster, Tehran, Iran; <sup>2</sup> Tehran University of Medical Sciences, Department of critical care nursing- School of nursing & midwifery, Tehran, Iran; <sup>3</sup> Iran University of Medical Sciences, Department of Health in disasters & emergencies, School of Health Management and Information Sciences, Tehran, Iran; <sup>4</sup> Iran University of Medical Sciences, Department of Health Services Management, School of Health Management and Information Sciences, Iran University of Medical Sciences- Tehran, Iran, Health Management and Economics Research Center, Tehran, Iran

\* Corresponding author.

**Introduction.**– Disasters affect personal needs in the involved area. Nevertheless after disaster, neglecting to vulnerable groups happen frequently and maybe some critical needs didn't provide in enough rang. One of these main needs is psychological support and rehabilitation after disaster. Concept of mental supporting is affected by common culture of society.

**Objective.**– The main object of this study is identification of psychological support and rehabilitation strategies for vulnerable groups after disaster in Iran.

**Method.**– This qualitative research has been conducted in Iran in 2014. We selected 15 psychological supports and rehabilitation after disaster expert persons by purposive sampling. We have done several non-structural interviews for data gathering and then analysed by content analysis method.

**Results.**– Data analysis obtained six main categories, which included 1. Screening of symptoms of vulnerable groups for mental disorders and assessment of their needs, 2. Establishment of native psychosocial support teams in the affected area, 3. Providing psychosocial interventions to prevent of psychosocial problems, 4. Restoration of lost family members in the disaster, 5. Holding mourning ceremonies in accordance with common customs, 6. Providing tools, resuming daily activities, and rebuilding damaged areas based on current trends.

**Conclusions.**– Despite the importance of mental health and the presence of appropriate numbers of specialists in the field of psychosocial support, there is no proper perspective in this area in Iran. Researchers have suggested, continues education courses for experts, such as social workers and psychologists, to be holding in order to reduce the intangible complications of emergencies and disasters in throughout the country with different cultures.

### **Walking therapy in chronic psychotic patients**

N. Brondino<sup>1\*</sup>, L. Fusar-Poli<sup>1</sup>, M. Rocchetti<sup>1</sup>, E. Codrons<sup>2</sup>, L. Correale<sup>2</sup>, M. Vandoni<sup>2</sup>, P. Politi<sup>1</sup>

<sup>1</sup> University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy; <sup>2</sup> University of Pavia, Laboratory of Adapted Motor Activity, Department of Public Health, Experimental and Forensic Medicine, Section of Hygiene, Pavia, Italy

\* Corresponding author.

**Introduction.**– Individuals with chronic psychiatric illnesses often suffered from poor general health and higher mortality level. This is the result of several intertwined factors, among which unhealthy lifestyle habits and metabolic side effects of medications play a significant role. Low levels of physical activity are consistently found in patients with chronic psychiatric diseases. Regular physical activity exerts a positive impact on both physical and mental health of patients. Nonetheless, a significant improvement in physical activity is rarely achieved due to lack of motivation or physical constrains.

**Objectives.**– To evaluate the impact of walking therapy on the physical and mental health of chronic psychotic patients

**Methods.**– we conducted an open label trial in which walking therapy was compared to a waitlist group. Each subjects participated in three one-hour weekly sessions of walking group for at least 16 weeks. Each individual was evaluated at baseline, at 8-week and 16-week follow-up. Physical parameters (resistance, flexibility, strength), metabolic indexes (BMI, waist circumference, blood

parameters) as well as mental health outcomes (negative symptoms, quality of life, happiness) were measured.

**Results.**– Preliminary data showed promising changes in physical resistance and metabolic parameters. An improvement in mental health was also observed.

**Conclusions.**– physical activity should be recommended and promoted in patients with chronic mental illnesses

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Rehabilitational psychosocial opportunities and instruments of modern psychiatry and psychosomatic medicine**

N. Burlakova<sup>1\*</sup>, V. Oleshkevich<sup>2</sup>

<sup>1</sup> Lomonosov Moscow State University, Faculty of Psychology, Department of Neuro- and Pathopsychology, Moscow, Russia; <sup>2</sup> Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Department of Health Care, Moscow, Russia

\* Corresponding author.

The situation in modern medicine seems paradoxical. The biopsychosocial approach to diagnostics and treatment is generally accepted in medical science, and psychosocial doctor-patient relations are systematically being cogitated in psychotherapy. Still, even psychosomatic medicine and psychiatry that have close ties to psychotherapy continue to apply object-oriented approach to a patient. A doctor considers a patient as a psychophysical object, thus a patient remains a passive object of manipulations. The described situation is typical for modern medicine known for its specialization and technologization.

In this context, an important aim arises: to research systematically psychological doctor-patient relations and to examine diagnostic and medical resources of these relations. Such kind of research provides us with new psychosocial resources that should be included in medical technologies as new instruments and serve therapeutic ends.

The approach to the rehabilitation should be changed: a doctor should rely on patient's inner resources – physiological as well as psychosocial. Patient's passivity is to be transformed into conscious activity, so a patient could understand not only how he/she can help himself/herself in current circumstances, but also how he/she can live and develop while suffering from a disease. To this end, a doctor should see in patient not only negative and unhealthy features, but also positive ones and rehabilitational potential. The task of a doctor is to activate within a patient this potential with the help of instruments developed by clinical psychology, consequently in time the "external" medical help could transform into the self-help of a patient.

### **The contribution of physical activity to the self-esteem and motivation of the elderly with Alzheimer's disease or moderate to severe stage disease**

C.C. Menez Filleau

Institut Claude Pompidou, Alpes Maritimes, Nice, France

**Introduction.**– To date, there are various non-pharmacological strategies to address challenges caused by Alzheimer's disease (AD). For example, in recent years, more and more studies have

shown the benefits of adapted physical activity (APA) on cognitive functions and quality of life in elderly people without cognitive impairments but as well in patients with AD.

**Objectives.**– Firstly, to measure the impact of APA sessions on self-esteem, motivation and apathy in patients with moderate or major Alzheimer's disease or related neurocognitive disorders. Secondly, to measure in a quantitative manner the impact of performing greater physical activity on activities of daily living in patients benefiting from these sessions and thirdly, to evaluate the satisfaction of patients performing these exercises.

**Methods.**– During the experimental phase, the participants will perform 12 sessions of APA, which will be carried out by a qualified sports educator. These sessions will be organized in the following manner: 15 minutes of warm-up, 30 minutes of coordination and muscle building and 15 minutes of relaxation. Participants will conduct a baseline assessment before starting the program, a second assessment right after completion and a last assessment visit after a 4-weeks break to observe possible long-term benefits at home.

**Results.**– The study is ongoing and preliminary results will be presented at the conference.

**Conclusions.**– The interest of this study lies in validating the effectiveness of such non pharmacological intervention programs and to promote its application in other clinical settings.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0746

### Parents of a child hospitalized in a psychiatric clinic: What they want and what they are willing to do

D. Dovbysh<sup>1,2\*</sup>, M. Bechuk<sup>2</sup>, A. Iliina<sup>2</sup>, N. Bytchkova<sup>2</sup>, E. Podurova<sup>2</sup>

<sup>1</sup> Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation, Department of Pedagogy and Medical Psychology- Faculty of Higher Nursing Education and Psycho Social Work, Moscow, Russia; <sup>2</sup> Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Moscow Department of Health Care, Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Moscow Department of Health Care, Moscow, Russia

\* Corresponding author.

**Objectives.**– To analyse needs of parents during hospitalization of the child in psychiatric clinic; to estimate degree of parent's readiness for cooperation with doctors and psychologists;

**Methods.**– 289 parents have participated in a research. With each of them the interview on the basis of the developed questionnaire was conducted.

**Results.**– The most important for the parents was the need for a diagnostic examination of the child (M = 3,582). The greatest willingness to cooperate parents presented in discussing a treatment plan (M = 3,707).

Statistical significant differences in groups:

– By gender of the parent: there is no difference in the understanding of the needs of the family for mothers and fathers; there are also no differences in the degree of willingness to participate in the child's treatment process;

– By the child's sex: for the parents of boys the need to increase the obedience of the child and the need to punish the child is more pronounced. Also, families of boys have fewer resources (interaction in pairs and in the family);

– By the child's age: for the parents of older children needs in child's safety (U = 41) and the reduction of stress in the family (U = 14) are higher. Also we found that the younger the child, the more parents

are ready to participate in the work of doctors and psychologists (U = 33).

**Conclusions.**– Described needs and willingness of the family to participate in the child's treatment put before specialists in child psychiatry the task of developing new standards of assistance programs

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0747

### Neuropsychological rehabilitation of patients with alcohol and drug dependence

K. Vyshinsky<sup>1</sup>, E. Fadeeva<sup>2\*</sup>

<sup>1</sup> National Medical Research Centre for Psychiatry and Narcology n.a. V. Serbsky Russian Federation Ministry of Health, Epidemiology, Moscow, Russia; <sup>2</sup> National Medical Research Centre for Psychiatry and Narcology n.a. V. Serbsky Russian Federation Ministry of Health, Department Preventive Care of Addiction Disorders, Moscow, Russia

\* Corresponding author.

Currently in the National Medical Research Centre for Psychiatry and Narcology n.a. V. Serbsky Russian Federation Ministry of Health a dynamic development of medical science is taking place, including the introduction of new methods of diagnosis, treatment and rehabilitation in practice. However neuropsychological rehabilitation has not been introduced into the systemic practice of treatment for patients with alcohol and drug dependence.

Mechanisms of early detection of narcological disorders, comprehensive socio-psychological rehabilitation and resocialization, increased compliance and adherence to treatment, adaptive capabilities and quality of life improvement require development of new methods of rehabilitation for alcoholics and drug addicts.

**Purpose.**– Studying principles of restoring disturbed higher mental functions among patients with alcohol and drug dependence; developing conceptual model of neuropsychological rehabilitation for patients with alcohol and drug dependence based on the principle of restoring higher mental functions and the formation of the motivational and semantic sphere as internal regulators of mental activity.

**Results.**– Experimental study using methods of neuropsychological rehabilitation was conducted in 72 patients with alcohol and drug dependence. These rehabilitation measures allow achieving stable improvements of morpho-functional interaction between the cerebral cortex, subcortical formations and interhemispheric interaction in patients with alcohol and drug dependence.

**Conclusion.**– Using methods of neuropsychological diagnosis and neuropsychological rehabilitation allows to increase duration of remission and restore cognitive and motivational component of personality among patients with alcohol and drug dependence syndrome.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### General characteristics and burden of family caregivers of dementia patients and differences between sexes

M. Mentis<sup>1</sup>, A. Paschou<sup>2</sup>, E. Kotrotsiou<sup>3</sup>, M. Gouva<sup>2</sup>, E. Panagioutopoulos<sup>1\*</sup>

<sup>1</sup> University of Patras, Rehabilitation Clinic Spinal Cord Injury, "Demetrios and Vera Sfikas", Department of Medicine- University of Patras- Greece, Patras, Greece; <sup>2</sup> Technological Educational Institute of Epirus, Research Laboratory Psychology of Patients Families and Health Professionals, T.E.I. of Epirus, Greece, Ioannina, Greece; <sup>3</sup> Technological Educational Institute of Thessaly, Research Laboratory of Care, T.E.I. of Thessaly, Larisa, Greece, Larisa, Greece

\* Corresponding author.

**Background.**– In Greece there are currently 200,000 people and dementia seriously affects the family environment.

**Objectives.**– The purpose of the study was to record the characteristics of family caregivers of dementia patients and to investigate possible differences in the levels of burden between male and female caregivers.

**Methods.**– The sample of the survey was 376 individuals and derived from a snowball sample from the entire region of Western Greece. Participants were eligible if diagnosis of dementia was present and if the patient and his caregiver consented to participate. The Zarit Interview was used to measure the burden.

**Results.**– 12.7% of the caregivers were men and 87.3% were women. The X<sup>2</sup> test showed a significant statistical difference between male and female caregivers (X<sup>2</sup> = 16.968, P < 0.001), as women face a heavy burden in a percentage of 43.2%, while men in a percentage of 23.8%. The average total burden was 55.95 (±12.54), for men 54.26 (±11.39) and for women 56.43 (±12.83). Non-parametric control U Mann-Whitney showed a significant statistical difference between male and female caregivers in both the overall burden (P < 0,05) and the individual dimensions (personal tension, relapse, and care management) in addition to the role-play dimension.

**Conclusions.**– The results confirmed a multitude of studies that found that women generally take on the role of family caregiver in most cases of chronic patients. The duty of community services is to "relieve" family caregivers and to promote discharging programs especially for female caregivers who are more exposed to the dangers of the burden.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0749

### Method of kinesiotherapy in medical and conductive rehabilitation of patient with motor and cognitive deficits

V. Isanova

Kazan State Medical University, Department of Neurology and Neurosurgery, Kazan, Russia

**Introduction.**– The nervous system disorders and mental impairments still remain to be among the main causes of children and adults incapacity. In the rehabilitation context, there has to be an integrated, pathogenetically valid comprehensive rehab method developed for such patients.

**Objective.**– To study the effectiveness of original methodology of rehabilitation through physical means in infantile cerebral paralysis.

**Methods.**– Method of kinesiotherapy in medical and conductive rehabilitation was tested on 15 patients with infantile cerebral paralysis (4–2 years old) during the year, the course of 4 to 6

months. We used patterns of proprioceptive stimulation of the facial and bulbar muscles in order to activate the reticular formation and obtain response. At verticalization stage pneumatic suits RPK "Atlant" was used for the implementation of motor patterns in three-dimensional space, which has intensified the alpha-gamma motor neuron system at all levels of the CNS.

**Results.**– A result of applying the kinesiotherapy with pneumatic suits RPK "Atlant" 30% of patients began to walk independently during the year. In 20% patient vocabulary and speech clarity have improved. Significantly improved sound pronunciation, positive dynamics of EVmorbid conditions such as attention deficit disorder, emotional liability and enuresis obtained. In all the children there was a reduction of spasticity by an average of 1-2 points from baseline at Ashworth Scale Score, with the advantage of the upper limbs.

**Conclusions.**– The author's method of kinesiotherapy significantly accelerated the recovery of postural control at all taken for the rehabilitation of children and to improve their quality of life.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Features of psychological rehabilitation of toddlers with congenital heart disease during heart surgery treatment

M. Kiseleva

Bakoulev Center for Cardiovascular Surgery, Rehabilitation Center for children with congenital heart disease, Korolev, Russia

Congenital heart disease (CHD) is the most widespread congenital disease and affects 0,8-1,2% of newborns. Great achievements in heart surgery have improved the outcomes for children with CHD, and increased survival rates. But still cardiac surgery makes mothers of toddlers with congenital heart disease experience considerable distress. Depression, grief and anxiety are the most widespread feelings of the mothers as the consequences for the correction of heart abnormality may be serious or even fatal. Such emotional ill being of mothers interferes with normal parent-child interactions, especially communication.

The aim of this study was to identify the role of the mothers' emotional status in their toddlers' emotional well-being. 96 diads: mothers and their toddlers, mean age 28,5 ± 1,6 months with CHD undergoing cardiac surgery were enrolled in the research.

Among the mothers–34,14% had heightened level of state anxiety, 28,6% had high level of state anxiety. 35,1% of the mothers reported depressive symptomology. We've found that the most used coping strategies among mothers of toddlers with CHD during were the following: active coping, planning, suppression of competitive activities. We've found out that 38,8% of the toddlers with CHD had 1 epicrisis period delay in their psychological development; 35,5% - had 2 epicrisis periods delay. Mothers' depression was found to be a negative factor in toddlers with CHD social and emotional functioning.

All these makes it necessary to include mothers in the process of the psychological rehabilitation of toddlers with CHD during the heart surgery treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0751

### Physical exercise as an intervention to aid recovery following first episode of psychosis in young adults

B. Lambden<sup>1</sup>, J. Berge<sup>2</sup>, Y. Forsell<sup>3</sup><sup>1</sup> Karolinska Institutet, Public Health Sciences, Stockholm, Sweden;<sup>2</sup> Lund University, Clinical addiction research unit, Lund, Sweden;<sup>3</sup> Karolinska Institutet, Public Health Sciences, Stockholm, Sweden

\* Corresponding author.

**Introduction.**– Psychosis is accompanied by loss of autonomy and sedentary behaviour impacting social and physical wellbeing. Physical exercise has shown promise in both domains to enable the recovery process. However, few studies have examined both with validated methodologies

**Objectives.**– To assess the association between physical exercise and autonomy following first episode of psychosis in young adults.

**Methods.**– Pre-post experimental design with first-episode psychosis patients (18–35 years) from three outpatient psychiatric centres in Stockholm, Sweden. The intervention consisted of a 12-week, structured, group based programme, with participants asked to attend 3 sessions per week. Autonomy was measured using four questions from the Camberwell Assessment of Needs questionnaire (physical health, social and close relationship and daily tasks). Needs and current support for each question were summed to provide a total score. Paired t-tests were used to compare changes within groups: 'no attendance' and 'any attendance'. The 'any attendance' group was then bisected into two according to those who participated in 12 or more sessions, equating to one per week, for dose-response.

**Results.**– There were 94 participants enrolled with a post-intervention response rate of 61%. Significant reductions were seen in the sum total score of needs and support  $-1.28$  (95% CIs  $-2.50, -0.05$ ) and need for further care  $-0.66$  (95% CIs  $-1.06, -0.26$ ). There was no significant evidence of a dose response association.

**Conclusion.**– The results suggest a plausible association between physical exercise and autonomy. Methodological difficulties, and the lack of true control group, undermine the study conclusions and further randomised studies are required.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0752

### Psycho-social issues faced by children from disaster struck areas and their rehabilitation in orphanages in Pakistan

T. Mansoor<sup>1,2\*</sup>, T. Yaqoob<sup>3</sup><sup>1</sup> National University of Medical Sciences, Rawalpindi, Behavioral Sciences Multidisciplinary Department, Islamabad, Pakistan;<sup>2</sup> Quaid-e-Azam University, Islamabad, Anthropology, Islamabad, Pakistan;<sup>3</sup> Fatima Jinnah Women University, Gender Studies, Rawalpindi, Pakistan

\* Corresponding author.

**Introduction.**– Human-made disasters have a different impact on adults and children where young children are most vulnerable to the negative effects of disaster owing to their lack of awareness of preventive measures and inability to cope with post-disaster stress and recovery process.

**Objective.**– This study was aimed at exploring the psychological and behavioural impact of disaster on children and the role of caregivers in the children's rehabilitation in orphanages.

**Method.**– The sample size consisted of 18 children (9 boys and 9 girls) and 9 primary caregivers (mother-maids) taken via purposive

convenience sampling from Pakistan Bait-ul-Mal's Sweet Homes Orphanages. A semi-structured interview in Urdu language was conducted to obtain desired data.

**Results.**– The results showed that disasters have a negative effect on the psycho-social state of the children in terms of increased dependency, sleep disturbances/bad dreams, sadness/emotion regulation, social withdrawal and need for social support from elders and peers. The traditional gender role socialization contributes to the risk of problems after disaster. There were gender differences in expression of emotions where girls were more expressive than boys about their traumatic experience. The girls preferred to share feelings with their peers whereas the boys were more comfortable sharing with the mother-maids than with the other children. Both the girls and boys were non-cooperative initially but the boys also showed aggressive attitude.

**Conclusion.**– Psycho-social therapeutic interventions like catharsis, play and art therapy may help the children cope with the effects of disaster. Training of caregivers can help to screen out children who need professional medical help.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0753

### The Amitim ('Friends') Program: Innovative model for social rehabilitation of people with serious mental illness (SMI) in the community

Y. Mazor<sup>\*</sup>, I. Adler-Ben Dor, N. Galor-Teperberg

Amitim Program, The Israel Association of Community Centers (IACC) and The Israeli Ministry of Health (MOH), Mental Health, Lod, Israel

\* Corresponding author.

**Introduction.**– The promotion of recovery is a central goal of public mental health systems (Power, 2009). Recovery includes the pursuit of active living (i.e., enjoyable, expressive, and meaningful leisure experiences) (Iwasaky et al., 2010; 2014), and meaningful inter-personal relationships (Iwasaky et al., 2015). While most social recreation programs for people with serious mental illness (SMI) are segregated (Adler-Ben Dor & Savaya, 2007), the Amitim program (by the Israeli Ministry of Health and the Israeli Association of Community Center) offers an innovative model of social and recreation oriented rehabilitation for 3000 people with SMI within the general community (Halperin & Boz-Mizrahi, 2009).

**Objectives and methods.**– Amitim aims to achieve; (1) the promotion of personal recovery via meaningful leisure activities in the community; through (a) monthly meetings with a mental health professional within the community center and creating with the person with SMI a "tailor made suit" to comply with his personal social recovery objectives. In addition, the person with SMI takes part in (b) leisure and volunteering activities within the community, whereby he practices social skills and participates in meaningful activities. Lastly, the person is entitled for (c) a leisure-oriented scholarship that enables him to reach his social-oriented aspirations. The second main goal of Amitim is the (2) promotion of social change with and by people with SMI, through lectures and workshops to the general community.

**Conclusion.**– To the best of our knowledge, Amitim represents a unique model that enables social-oriented recovery and social change.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Reconstructing a story – From a therapeutic narrative to social change; an innovative model for social change in people with serious mental illness in the community

Y. Mazor<sup>\*</sup>, N. Galor-Teperberg, I. Adler-Bendor, N. Shteyman  
 Amitim Program, The Israel Association of Community Centers (IACC)  
 and The Israeli Ministry of Health (MOH), Mental Health, Lod, Israel  
<sup>\*</sup> Corresponding author.

**Introduction.**– the approach of therapeutic narrative suggests that people will retell their story to themselves and then retell it to others in their environment (Zilber et al., 2008). In contrast to this approach, we aim to present a model of narrative reconstruction for social change in people with serious mental illness (SMI), aiming to combine a reduction in self-stigma (Roe & Davidson., 2005) and in social stigma. The model we shall present is part of the Amitim program (by the Israeli Ministry of Health and the Israeli Association of Community Center), which offers social rehabilitation services in the community for 3000 people with SMI, and the promotion of personal recovery and social change (Halperin & Boz-Mizrahi, 2009).

**Objective and methods.**– Amitim's story reconstruction model includes several dimensions: first, the narrative is approached through several baseline questions: who is the audience, what is the purpose, and what is the message we want to convey by telling the recovery story (Green & Brock, 2000; 2002). The story is then externalized to a text, and the narrators (i.e., people with SMI) learn to tell it in a way that enables listeners to accept it (Carlson & Erickson, 2001), and to promote social change. This in turn leads the narrators to build a new identity and learn to mediate their story to both themselves and their environment (Roe et al., 2014).

**Conclusion.**– We Aim to delineate different formats for using this model with people with SMI, based on video interviews with participants.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The development of the motor sphere of children with speech disorders

N. Menshikova<sup>1\*</sup>, T. Goryacheva<sup>2</sup>

<sup>1</sup> Center of Speech Pathology and Neurorehabilitation, Department of Medical Psychology, Moscow, Russia; <sup>2</sup> Pirogov Russian National Research Medical University RNRMU, Department of Clinical Psychology, Moscow, Russia

<sup>\*</sup> Corresponding author.

According to the World Health Organization data, nowadays the mortality rate decreases with neonatal pathology, which indicates a significant development of neonatal medicine in Russia. At the same time the number of children who underwent perinatal hypoxic-ischemic encephalopathy increases. That causes systemic speech and motor development impairments. According to the latest practice, about 15% to 43% of children have speech development disorders and this percentage increases up to 83% if the child had organic lesions of the neural system.

The research Aim is studying the features of the formation of motor functions in children with speech pathology that have hypoxic-ischemic encephalopathy in the anamnesis.

**Methods.**– A study of manual and oral praxis was conducted using static and coordination samples.

**Results.**– In some cases, the neurological status of children delayed in speech development marked by a static motor insufficiency of

mild severity. To describe this phenomenon, the “dyspraxia” term is used. Dyspraxia affects two types of praxis: oral and manual. A distinctive feature of developmental dysphasia and dyspraxia is the dissociation between the possibility of performing automated actions and the inability to perform a similar action by request.

**Conclusion.**– The research of the relationship between motor and speech disorders can contribute to the development of intervention programs improving children's speech as well as the state of their motor sphere.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Dynamic characteristics of higher mental functions in adolescents following traumatic brain injury of mild severity

S. Pervichko

Lomonosov Moscow State University, Psychology, Moscow, Russia

**Introduction.**– Early detection of the causes of psychological problems of adolescents following traumatic brain injury of mild severity (mTBI) allows the development of corrective programs. **Objectives.**– Assessment of the dynamic characteristics of the higher mental functions (HMF) and the position of their violations in the structure of the neuropsychological syndrome.

**Materials and methods.**– The study is based on the original set of techniques designed by A.R. Luria. We studied of the mental activity in its regulatory and dynamic aspects.

31 patients with mTBI (mean age was 11,5+1,3) and 20 healthy subjects (mean age was 12+1,5) took part in the study.

**Results.**– The results of the study showed that in the acute period after mTBI, the dynamic characteristics in adolescents were significantly reduced. Decrease in work capacity was noted in all patients, and in the majority (90%) it was lowered at the very beginning of the examination ( $p < 0.01$ ). 61% of the children in the experimental group also had a significant decrease in the rate of activity throughout the study ( $P = 0.000$ )

A study of attention showed that the majority of adolescents with mTBI (81%) had mild concentration difficulties, which was manifested in the need for additional time for concentration, as well as increased distraction in the performance of various samples ( $P = 0.00$ ).

**Conclusions.**– The revealed features of the disturbance of the dynamic characteristics of HMF after mTBI of mild degree will allow to provide adequate assistance to children in the rehabilitation process.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

PHI Health Center Prijedor, Vice-Director, Prijedor, Bosnia, Herzegovina; <sup>4</sup> Hospital “Dr. Mladn Stojanovic”, Department of

Psychiatry, Prijedor, Bosnia, Herzegovina

\* Corresponding author.

**Introduction.**– Case management (CM) as a rehabilitation principle with main purpose to establish best possible outcomes for people with psychotic disorders is one of basic principles comprehensive mental health care for this population group in Bosnia and Herzegovina (BH). It is an accreditation standard for community mental health centers (CMHC), focused on users with multiple needs, mainly younger patients with schizophrenia spectrum disorders.

**Aim.**– To show benefits of the CM to good outcome and better quality of life (QoL) using a examples of patients.

**Method.**– Four years (2013–2016) follow up results defined by CM instruments using medical documentation in CMHC Prijedor.

**Results.**– During the 48 months period, twelve patients had strong collaboration and support by case managers as well as all team members. It was established better insight with direct influence on reduction of auto-stigmatization, empowered self-confident, more filled up time including active attendance to new activities in CMHC (self/help group, occupational therapy) as well as outside of CMHC (user organization, educational seminars). Scores on used instruments (BPRS, SOFAS, SQLS, AVON, Risk Assessment Instruments) were significantly improved. Important was that only 3 times hospitalization has been realized

**Conclusions.**– CM principles have important influence to good outcomes for people with psychotic disorders as well as to significant improving of team work and quality of mental health services in CMHC.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Neuropsychological support and rehabilitation of children with Rett syndrome**

A. Grigoryeva<sup>1</sup>, M. Marachev<sup>2</sup>, A. Kostyleva<sup>1</sup>, D. Zhuravlev<sup>3\*</sup>

<sup>1</sup> Neurocentre, Psychology, Moscow, Russia; <sup>2</sup> Neurocentre, Psychiatry, Moscow, Russia; <sup>3</sup> Neurocentre, Neurology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Rett syndrome is a genetic neurodevelopmental disease caused by various X-linked mutations. In most cases these mutation occur in MECP2 gene (methyl CpG binding protein 2) resulting in neuron morphology and connectivity changes. That leads to a developmental regression starting at the age of 6 - 18 months. Clinical features include: loss of acquired language and motor skills, autistic-like communication and eye-contact impairment, stereotyped movements, deceleration of both head and brain growth. Later epileptic seizures, autonomic disorder, respiratory and gastrointestinal dysfunctions may arise. Effective treatment is not available at the time.

**Objectives.**– We report a case of a 3-year-old girl with Rett syndrome having typical motor, speech and communication impairment.

**Methods.**– Neuropsychological correction, Tomatis auditory sensory therapy and Balametrix cerebellar stimulation method were provided. Simultaneously the patient underwent a course of transcranial magnetic stimulation.

**Results.**– Some of the clinical features, such as absence of sound pronouncing and eye-contact, poor purposeful hand movements, gait and postural balance difficulties, improved noticeably.

**Conclusions.**– This case report describes certain positive effect of some of the rehabilitation methods, especially enhanced by transcranial magnetic stimulation, and suggests that continuous

neuropsychological support can improve the quality of life of a patient and caregivers.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Research methodology**

### **New approaches to evaluate nonverbal behavior in negative symptoms of schizophrenia**

U. Granzio<sup>1</sup>, A. Spoto, G. Vidotto

Università degli studi di Padova, Department of General Psychology, Padova, Italy

\* Corresponding author.

**Introduction.**– The evaluation of nonverbal behaviour (NVB) is considered an open challenge, especially when considering schizophrenia's negative symptoms. The complexity of both the definition and the observation of NVB lead to its poor consideration during clinical consultations. In fact, the assessment of NVB is usually performed by using a few items, which clinicians rate without having the chance of properly relating the corresponding NVBs to other symptoms.

**Objectives.**– The present study Aims to suggest a list of NVBs that can be used during both classical interviews and patient-guided observations.

**Methods.**– Two clinical psychologists and two psychiatrists used the Formal Psychological Assessment, a new methodology developed in the University of Padua, to gather items investigating NVB from validated assessment tool evaluating schizophrenia. Each selected item was connected to a subset of schizophrenia's negative symptoms described in both the DSM-5 and the scientific literature.

**Results.**– The list of 26 items investigating 13 NVBs allowed suggesting NVBs that are not exhaustively used and that can be easily observed within the standard schizophrenia's assessment. Finally, the relations among the items led to define the formal basis of an algorithmic procedure to be used in guided observations, which are driven by patients' behaviours.

**Conclusions.**– The results showed how it is possible to both observe and assess negative symptoms of schizophrenia, starting from a set of specific and well-structured NVBs. Both the classical and the patients' guided observations that can be performed using the found list of items represent new approaches to the assessment of schizophrenia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0760

### **Methodology of psychological syndrome analysis and the concept of "psychological mediation" (Vygotsky, Lurya, Zeigarnik school) in comprehensive diagnosis and personalized care**

J. Koniukhovskaia<sup>1\*</sup>, E. Pervichko<sup>1</sup>, I. Emelyanova<sup>2</sup>, V. Krjukov<sup>2</sup>, V. Krasnov<sup>2</sup>, Y. Zinchenko<sup>1</sup>

<sup>1</sup> Lomonosov Moscow State University, Psychology, Moscow, Russia;

<sup>2</sup> Moscow Research Institute of Psychiatry, Department of Affective Disorders, Moscow, Russia

\* Corresponding author.

**Introduction.**– The Russian psychological school of Vygotsky-Luria-Zeigarnik offers a holistic view of the development of higher mental functions (HMFs), which are socially acquired, mediated by social meanings, voluntarily controlled and exist as a link in a broad system of functions. **Objective.**– To show the diagnostic capabilities of the pathopsychological assessment methods and to substantiate the prospects for the creation of their English-speaking analogs.

**Methods.**– Theoretical and methodological study of the concept of symbolic mediation (Vygotsky-Luria-Zeigarnik school) and assessment of the capabilities of pathopsychological diagnostic methods of thinking and memory, interoception, emotion regulation. The case study presents 10 patients with somatoform symptoms and 10 healthy subjects, comparable in age and sex.

**Results.**– The ability to mediate is studied through the level and quality of the generalization. Two levels of mediation are distinguished: (1) operational - the ability to operate with cultural signs; (2) motivational-semantic - the pervasion of individual meanings into signs (symbols). Violations of generalization are represented by reduction and/or distortion (Zeigarnik, 1981). Our study identified and described various types of violations of signs and symbols mediation, combining partial or total reduction and/or distortion in the structure of the examined HMFs.

**Conclusion.**– Mediation is a “cross-cutting” characteristic of the psyche and reflects the individual’s ability to generalize his/her experience and regulate behaviour through symbolic means. Methods of pathopsychological diagnostics allow distinguishing the preserved and broken elements of cognitive and personal organization as a single system, that is important for comprehensive diagnosis and personalized care.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0761

### **Measuring implicit emotional appraisal of semantic stimuli in affective disorders**

M. Kovyazina<sup>1,2\*</sup>, A. Kisel'nikov<sup>1</sup>, E. Rasskazova<sup>1,3</sup>, A. Zhejmo<sup>1</sup>, N. Varako<sup>1,2</sup>, V. Barabanshchikova<sup>1</sup>

<sup>1</sup> Lomonosov Moscow State University, Psychology, Moscow, Russia;

<sup>2</sup> Research center of neurology, Neurorehabilitation and physiotherapy, Moscow, Russia; <sup>3</sup> Mental Health Research Center, Psychosomatics and psychotherapy, Moscow, Russia

\* Corresponding author.

**Introduction.**– Measuring implicit emotional appraisal of self, others, events is important for revealing targets for psychotherapy. Method of color-emotional semantic associations (Kisel'nikov et al., 2014) is an alternative to methods assessing reaction time (Emotional Stroop Test, Implicit Attitude Test). It is an experimental procedure based on vector psychophysiological model (Sokolov, 2013) that includes pairwise comparison of semantic-color and color-emotional stimuli and subsequent reconstruction of them on the semantic-emotional two-dimensional sphere.

**Objectives.**– The aim was to study opportunities of the method in people with affective complaints and affective disorders.

**Methods.**– First, 74 students filled Hospital Anxiety and Depression Scale and 12 with depression, 10 with high anxiety and 10 without complaints participated. Second, we included 7 patients with anxiety disorders, 6 patients with major depression and 13 controls.

**Results.**– Comparing to the 2-factor structure of the appraisal in controls (Valence and Arousal), in anxious and depressive students appraisal of “Me”, “World”, “Present”, “Future” becomes less intensive and the third factor of relatedness to social interactions emerges (Fontaine et al., 2007; Russel, 1991). In anxiety disorders the only factor of emotional sign remains while in depression

appraisal of “Me”, “Others” and “Past” becomes closer to sadness, fear and guilt.

**Conclusions.**– Results suggest that in people with affective complaints appraisal intensiveness and social meaning of stimuli should be addressed while for clinical disorders it is important to consider content of emotions.

The reported study was funded by RFBR according to the research project No. 17-29-02169

EV0762

### **Contribution to assertiveness reminiscence of the reference personal experience (RPE) STRATEX method**

G. Missoum

Universite Nanterre, Psychologie, Alcobendas, Spain

Lack of assertiveness is a widespread personal and professional difficulty. The STRATEX method enables to restore the subject’s confidence by enabling him or her to reminisce his or her own experience of reference.

Defined as a personal achievement experience, the Reference Personal Experience (RPE) is considered by the subject as the most accomplished experience of his or her life path. This authentic peak experience is stored in both autobiographical and semantic memories.

Mnesic anchoring of this experience needs a memory audit to facilitate its recollection. It takes the form of an interview combining the emergence of a recollected real-life experience to a structured method, called STRATEX, which puts the subject in a situation of meta-analysis and learning.

The method is made up of four parts:

- In characteristics: context, date of occurrence, performance indicators, duration;
- Content description, which permits to identify a personal and reproducible script of success;
- Emergence of positive beliefs about one’s own identity or capacities extracted from the experience;
- Finally, the reproducibility of RPE, the replication of the pattern of success.

Applying this method to a mixed-gendered sample group of 50 subjects enabled to verify its capacity to stimulate assertiveness, it showed a frequency in the emergence of positive beliefs in oneself and replications of the success scenario in their main field of action.

As a conclusion, the reminiscence of RPE enables one to find or restore the pride of being oneself.

EV0763

### **Designing an inclusive model of clinical intervention among persons diagnosed with borderline personality disorder: A research project protocol**

C. Papathanasiou\*, S. Stylianidis

Panteion University, Department of Psychology, Athens, Greece

\* Corresponding author.

**Introduction.**– There is evidence that Borderline Personality Disorder (BPD) is associated with stereotypes, prejudices and stigmatization even among mental health professionals. Negative

attitudes and behaviours from the part of the medical and nursing personnel towards people living with BPD (PLBPD) could be counter-therapeutic.

**Objectives.**– To develop an inclusive and comprehensive model of therapeutic communication and effective management of the relationship between the mental health professionals and PLBPD, taking into account the views and the experiences of both actors in terms of facilitating factors and barriers. The purpose is to inform the content of interventions in order to support change in clinical and societal level.

**Methods.**– The program consists of research, educational and communication activities. A mixed methods research approach will be implemented, including: a) interviews with psychiatrists and psychologists, b) focus groups with psychiatric nurses, c) interviews with PLBPD, d) participant observation in psychiatric wards, e) cross-sectional research with students in mental health professions, and f) on-line survey for PLBPD. The outcome will lead to a model of therapeutic communication and professional training sessions. Further communication activities are expected to contribute to social visibility and stigma tackling.

**Conclusion.**– We believe that the specific project presents a number of social innovations according to the EU standards. Specifically: a) at an epistemological level seeks to connect different theories, b) at a methodological level uses mixed methods research, c) adopts an empowering approach, d) promotes new collaborations between institutions and groups, e) seeks to create social change through public awareness and knowledge.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0764

### **Psycho-social stress and global mental health problems of last decades – Evolutionary approach involving epigenetics**

V. Rozanov

*Odessa Mechnikov National University, Clinical Psychology, Odessa, Ukraine*

**Introduction.**– Recent decades are characterized by a steady growth of the most common mental health problems like anxiety, depression, addictions and psychosomatic disturbances, as well as suicides.

**Objectives.**– Studies suggest that early life stress and allostatic load later in life can trigger epigenetic mechanisms that may lead to programming mental health problems exhibiting transgenerational inertia.

**Method.**– To integrate knowledge on the possible role of stress-induced epigenetic events in programming mental health impairments in big populations from the evolutionary perspective.

**Results.**– Evolutionary psychology is trying to explain how human traits and behaviours have emerged adaptively in the course of Darwinian-type genes propagation, while evolutionary psychiatry is discussing how these traits become counterproductive in changing environments. On the other hand, alternative evolutionary approaches are discussing how environments can trigger epigenetic mechanisms and alter transcription of vast sets of genes resulting in behavioural and psychological patterns, which are stable in the ontogenesis and may be transferred to several subsequent generations. Darwinian and non-Darwinian processes may act together, depending on the ecological and, in case of humans–social cues. Recent findings on the stress-induced epigenetic programming of long-term alterations in critical brain regions give an impression how psychosocial stress contribute to the origin

of psychopathologies. Human behaviour and perceived stress may mediate these interrelations.

**Conclusion.**– Interactions of genes and social environments, which are producing psycho-social stress and perceived stress, with the implication of stress-triggered epigenetic events suggest a logical explanation of the comparatively fast global growth of mental health problems in the last decades.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0765

### **Levels of global activity of people with severe mental disorder in ambulatory regime**

S.S. Sanchez Rus<sup>1\*</sup>, M. Ortigosa Luque<sup>1</sup>, G.M. Ruiz Martinez<sup>2</sup>, M.D. Sin Cabrero<sup>1</sup>, P. Vargas Melero<sup>1</sup>

<sup>1</sup> *Psiquiatrist, Complejo Hospitalario Jaen, Jaen, Spain;* <sup>2</sup> *MIR Psiquiatria, Complejo Hospitalario Jaen, Jaen, Spain*

\* Corresponding author.

**Introduction.**– The symptomatology, the use of medication, among other factors can cause a decrease in the participation of people with mental disorder in the activities of their daily lives.

Knowing the level of global activity that mental health patients have can help in the planning of new intervention strategies aimed at the level of independence and autonomy of these patients.

**Objectives.**– To assess the level of global activity in people with severe mental disorder who attend mental health devices on an outpatient basis.

**Method.**– Sample of 30 people with severe mental disorder.

The EEAG global functionality scale was used, characterized by:

- Evaluates psychological, social and work activity;
- Range of score from 0 to 100;
- Menor score indicates a worse level of global activity at the psychological, social and labor levels;
- Analysis of data with mean and standard deviation, calculated with SPSS version 20.0

**Results.**– People with severe mental disorder showed an M (SD)=61.97 (7.37) points on the EEAG scale.

Categorized by his psychiatric pathology according to criteria of the DSM-V was observed:

- Tr Bipolar M (DT)=63.83 (6.43) points;
- Paranoid Schizophrenia M (DT)=61.64 (5.96) points;
- Tr Schizoaffective M (DT)=63.71 (9.52) points.

**Conclusion.**– The results for the general sample and for pathologies showed “moderate symptoms” regarding the activity, presenting moderate difficulties in social, labor or school activity, characterized by a low social network and conflicts with companions.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0766

### **Reliability and validity of inventory of suggestibility – Romanian version. A factor analysis**

C. Dondas<sup>1</sup>, M. Iorga<sup>2</sup>, S. Socolov<sup>3\*</sup>, I. Dafinoiu<sup>1</sup>

<sup>1</sup> *University “Alexandru Ioan Cuza”, Psychology and Education Sciences, Iasi, Romania;* <sup>2</sup> *University of Medicine and Pharmacy “Grigore T. Popa”, Behavioral Sciences, Iasi, Romania;* <sup>3</sup> *“Gr”. T. Popa University of Medicine and Pharmacy, General Medicine, Iasi, Romania*

\* Corresponding author.

**Introduction.**– The Inventory of Suggestibility developed by Héctor González Ordí and Juan Jose Miguel-Tobal in 1999 provides a general measure of suggestibility that contains four subscales: dreaming/fantasize, absorption, emotional involvement and influencing by others.

**Objectives.**– The purpose of the study is to translate, revise and adapt the Inventory of Suggestibility from Spanish to Romanian and to identify the factor structure of the items.

**Methods.**– This scale was translated into Romanian and it was administered to 164 subjects, with the age between 18 and 62 ( $M = 24.05 \pm 6.87$ ), 61 males and 103 females. The statistical analysis of data was done using SPSS Statistics v23.0.0 for MAC.OSX.

**Results.**– The results show that Cronbach's alpha for the entire scale is  $\alpha = 0.794$ , which indicates a good internal consistency. Exploratory principal components analysis of the items identified three factors: influencing by others, absorption and dreaming/fantasize. The items from the emotional involvement scale were distributed equally among the resulting three factors. Items 18 and 7 were eliminated because they had very low item saturation, under 0.40.

**Conclusions.**– The results of the present study suggest that the total score of the Inventory of Suggestibility is an internally consistent measure of suggestibility. We can conclude that this tool can be a good measure for assessing the level of hypnotizability, it's easy to use and it can be a great substitute for more time-consuming hypnotizability scales like the Harvard Group Scale of Hypnotic Susceptibility Form A or the Stanford Hypnotic Susceptibility Scale, Form A.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## Schizophrenia and other psychotic disorders

EV0767

### Concurrent Agreement Between Brown's Locus of Control Scale (BLOCS) and Multidimensional Health Locum of Control (MHLOC) in an outpatient sample with severe mental illness

D. Adamis<sup>\*</sup>, C. Conlon, G. McCarthy  
Sligo Mental Health Services, Psychiatry, Sligo, Ireland

\* Corresponding author.

**Introduction.**– Locus of control is a personality attitude and belief that people have about themselves that they can control outcomes of events in their lives (Internals) or other external factors determine outcomes. (Externals). Locus of control amongst those with a psychiatric disorder is intrinsically linked with empowerment. Many scales have been developed to measure LOC, some general LOC like BLOCS and others more specific (MHLOC).

**Objectives.**– We assumed that general LOC is also associated with health LOC. This was examined by using two scales to find out a) if this assumption holds b) the level of the agreement between these two scales.

**Methods.**– Consecutive community dwelling outpatients diagnosed with schizophrenia, bipolar and schizoaffective disorders were recruited. Measurements: Demographics, BLOCS and MHLOC.

**Results.**– Sample: 97 participants with completed data (mean age 48.23, SD 13.76), 44 females. Fifty had been diagnosed with schizophrenia, 35 Bipolar Disorder and 11 Schizoaffective Disorder. Pearson correlations showed: MHLOC internal- BLOCS internal ( $r = 0.334$ ,  $P = 0.001$ ), MHLOC Power others-BLOCS external social

( $r = 0.226$ ,  $P = 0.026$ ), MHLOC Chance-BLOCS external others ( $r = 0.455$ ,  $P < 0.0001$ ). The overall agreement was Kendall's tau = 0.22,  $P = 0.02$ .

**Conclusions.**– The results indicate that locus of control is a personal belief which is similar for both general outcomes in the life and in specific like illness. Although the agreement between the two scales was low this was significant. Given that both scales have not been used widely in mental health patients further analysis and research may be needed to determine their validity in those populations.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Clozapine in first psychotic episode – In relation to a clinical case

B. Almeida<sup>\*</sup>, C. Fragoeiro, C. Machado, L. Monteiro  
Magalhães Lemos Hospital, Psiquiatria, Porto, Portugal

\* Corresponding author.

**Introduction.**– Although most patients with first psychotic episode respond to the initial trials of neuroleptic medication (60 – 87%), there is a subgroup that will not improve. For this population of resistant-first psychotic episode Clozapine could provide substantial advantages.

**Objectives.**– With this work, we review the literature about the use of clozapine in first psychotic episode, which patients could benefit most from it and the differences in prognostic. A clinical case is presented.

**Methods.**– We performed a search in Pub Med, using the Mesh terms "Clozapine" and "First Psychotic Episode". A detailed report of the clinical case was made, based on clinical interviews and clinical records.

**Results.**– Evidence points that 23% of the total population of psychotic patients, displayed unremitting symptoms from the time of first antipsychotic treatment—at present younger age of illness onset (< 20years) is the only predictor of resistance to initial neuroleptic treatment. These patients may benefit with a second/third trial with clozapine. In our clinical case, a male patient with 22 years was admitted in our inpatient department with a first psychotic episode. Initial trials of olanzapine, risperidone and paliperidone were tried, with no remission of symptomology. Clozapine was initiated (to 200 mg/day) with a substantial recovery.

**Conclusion.**– The benefits of clozapine as a second/third-line treatment must be investigated in first psychotic patients. Risk factors to assess, which patients would benefit from this approach, is essential, to better define and treat this population and minimize the functional and social disability that results from prolonged psychosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Prevalence of psychotic symptoms in children needing inpatient care: Relationship to diagnosis

N. Anagnostopoulou<sup>1\*</sup>, A. Alba<sup>2</sup>, J. Gaete<sup>3</sup>, D. Dima<sup>4</sup>, M. Kyriakopoulos<sup>2</sup>

<sup>1</sup> South London & Maudsley NHS Foundation Trust, Bethlem Adolescent Unit, London, United Kingdom; <sup>2</sup> South London & Maudsley NHS Foundation Trust, Acorn Lodge Children's Unit, London, United Kingdom; <sup>3</sup> Universidad de los Andes, Medical School, Santiago, Chile; <sup>4</sup> King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom

\* Corresponding author.

**Background.**– Psychotic symptoms, marking impaired reality testing, are considered a hallmark of psychotic disorders. However, several lines of research point towards these symptoms also being highly prevalent both in non-clinical populations and in other psychiatric disorders. There is also evidence to suggest that their prevalence is even higher in children and young people, reaching up to 17% in epidemiological samples. There is limited research on the prevalence of psychotic symptoms in young clinical populations. The present study aimed to assess the prevalence of psychotic symptoms in a 6 to 12-year-old clinical population of an inpatient setting.

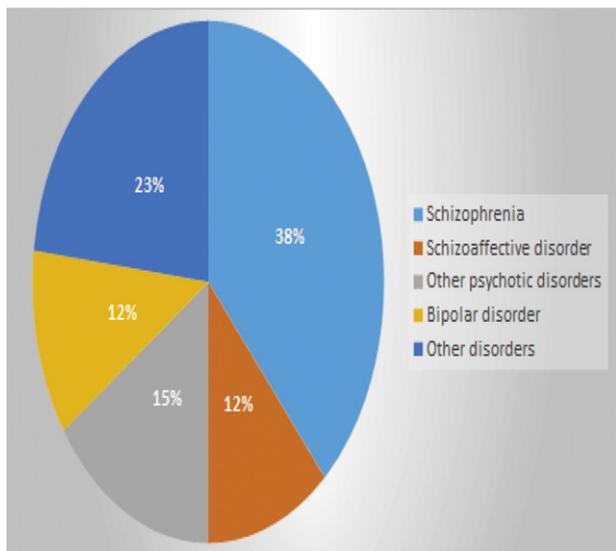

**Method.**– Clinical records of all patients of a national UK children's unit from 2009 to 2017 were examined for the presence of psychotic symptoms and their relationship to diagnosis at discharge.

**Results.**– One hundred and eighty-five (185) children were included in the study. Psychotic symptoms were highly prevalent in this young clinical population, reaching 63.8%, regardless of diagnosis at discharge. Hallucinations (58.4%) were more prevalent than delusions (35.1%). As expected, all children with schizophrenia spectrum disorders experienced psychotic symptoms.

**Conclusions.**– The present study is the first to examine the prevalence of delusions and hallucinations across diagnoses in children needing inpatient care. Psychotic symptoms were very common in children without a diagnosis of schizophrenia spectrum disorder. Given the high frequency of psychotic symptoms in this severely affected clinical population, it is possible that they represent a marker of clinical severity (Table 1)

Table 1. Psychotic Symptoms Percentages among Diagnoses

### Clozapine rechallenge after double drug-induced neutropenia

P. Argitis<sup>1</sup>, A. Karampas<sup>2</sup>, M.S. Skopelitou<sup>1</sup>, M. Poulou<sup>3</sup>, E. Nikoli<sup>4</sup>, A. Mamzeri<sup>5</sup>, K. Paschalidis<sup>6</sup>

<sup>1</sup> General Hospital of Santorini, Psychiatric, Santorini, Greece; <sup>2</sup> University Hospital of Ioannina, Psychiatric, Ioannina, Greece; <sup>3</sup> General Hospital of Santorini, Anesthesiology, Santorini, Greece; <sup>4</sup> General Hospital of Santorini, Internal Medicine, Santorini, Greece; <sup>5</sup> General Hospital of Santorini, Hematology, Santorini, Greece; <sup>6</sup> Psychiatric Hospital of Thessaloniki, Psychiatric, Thessaloniki, Greece  
\* Corresponding author.

**Introduction.**– Clozapine is an atypical antipsychotic drug, which seems to be up to 60% more effective against resistant schizophrenia than other antipsychotic drugs. Clozapine also is related with severe side effects such as neutropenia. International literature suggests rechallenging after neutropenia incidence.

**Case.**– We present an uncommon case of a forty-nine year old man suffering from treatment resistant schizophrenia. The patient was diagnosed with psychosis 24 years ago and the last year was administered clozapine for treatment at 350 mg/day with good response (PANSS negative and positive symptoms significantly improved with a slight raise at GAF scale). Three and a half months after the Clozapine initiation appeared neutropenia (WBC 3.04 10<sup>3</sup>/μL, NEU 0.63 10<sup>3</sup>/μL). We stopped clozapine administration and we tried rechallenging after the correction of neutropenia. 32 days later another incidence of neutropenia appeared (3.38 WBC 10<sup>3</sup>/μL, NEU 0.81 10<sup>3</sup>/μL). The clozapine administration stopped again and we performed a full physical examination without any pathological finding. The failure to respond to treatment with other antipsychotics after the second neutropenia and the history of suicide attempts led us to a second rechallenging with the adjustment of clozapine and the addition of 300 mg lithium carbonate/day (0.33 mEq/L ± 4). In the last 7 months, the patient has not neutropenia, but the improvement in psychopathology and its functionality is ongoing.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Metabolic syndrome and cognition in patients with schizophrenia: What is the relationship?

A. Arous\*, H. Ben Ammar, J. Mrizek, A. Aissa, Z. El Hechmi  
Razi Hospital, Departement Psychiatry F, Tunis, Tunisia

\* Corresponding author.

**Background.**– Neurocognitive impairment are core features of schizophrenia. On the other hand, the prevalence of metabolic syndrome (MetS) is higher in individuals with schizophrenia than in the general population. Yet, there is no general consensus concerning the effects of MetS on various cognitive domains in schizophrenia. **Objectives.**– The Aim of this study was to compare the association between patients with and without MetS and its contributing components with neurocognitive performance.

**Methods.**– 76 patients with stable schizophrenia were included in the study. Patients were classified as either having or not having MetS as defined by the IDF criteria. Patients completed a neurocognitive battery comprising the following tests: the Hopkins Verbal Learning Test–Revised, the Letter Digit Substitution Test, the Stroop Test, the “Double Barrage” of Zazzo test, the Modified Card Sorting Test, Verbal Fluency, the Trail Making Test–Part A and the Digit Span (DS).

**Results.**– The prevalence of MetS was 36.84%. Patients without the MetS performed significantly better on tests measuring problem solving/reasoning ( $P=0.035$ ) compared with those with MetS. There was no significant change in attention and memory scores between the two groups. Patients with Hypertension performed significantly worse on tests measuring memory ( $P=0.040$ ). Besides, there was found a negative association between hypertriglycerides and working memory ( $P=0.040$ ). Also, hyperglycemia was associated with lower scores on immediate memory ( $P=0.02$ ).

**Conclusion.**– Our findings suggest that MetS are associated with cognitive impairment especially in memory and problem solving/reasoning. These findings may support that medical treatment of the metabolic syndrome could affect cognitive performance in patients with schizophrenia.

### **Obstacles encountered when managing a Prader-Willi syndrome patient with haloperidol during an acute psychotic break**

R. Babalola<sup>\*</sup>, S. Gandhi, M. Bittner, K. Kaufman  
Rutgers, psychiatry, New Brunswick, USA

\* Corresponding author.

*Background.*– Prader-Willi syndrome (PWS) is a rare genetic disease caused by the loss of paternal expression of the 15q11-q13 region. It is characterized by neuroendocrine abnormalities but has variability in its behavioural and psychiatric presentation. 70% of cases occur from paternal deletion of the genetic region, whereas only 25% of cases occur due to maternal uniparental disomy (mUPD). Patients with mUPD appear to have higher rates of psychosis and bipolar disorder compared to those with the paternal deletion.

*Methods.*– Case analysis with Pub Med literature review of psychotic symptoms in PWS.

*Results.*– A 19-year-old PWS patient with mUPD and celiac disease presented with acute psychosis characterized by persecutory delusions, thought insertion/broadcasting, ideas of reference, increased skin excoriation, and mood lability consistent with paranoid schizophrenia. All standard laboratories and diagnostics (head CT, transvaginal ultrasound, XRs) were normal. Low dose haloperidol 2 mg bid and bantzopine 0.5 mg bid effectively decreased paranoid delusions though symptoms related to trauma by a classmate did not subside. Nocturnal agitation was treated with lorazepam 1 mg qhs. After seven days, with improved psychiatric status, the patient insisted on discontinuation of all psychotropics. However, the patient regressed necessitating resumption of haloperidol 3 mg total daily dose and lorazepam 0.5 mg qhs.

*Conclusion.*– This case report illustrates the difficulties in treating PWS patients during a psychotic break that may have resulted from an underlying traumatic event. Though there was a therapeutic response to haloperidol in controlling psychosis and agitation, the patient lacked insight concerning the need for maintenance medication and decompensated.

### **Hormonal effects of cariprazine: Post hoc analysis of pooled data from schizophrenia studies for sexual dysfunction and prolactin changes**

A. Barabassy<sup>1\*</sup>, B. Szatmári<sup>1</sup>, I. Laszlovszky<sup>1</sup>, J. Harsányi<sup>1</sup>, A. Burján<sup>1</sup>, D. Réti-Györfy<sup>1</sup>, W. Earley<sup>2</sup>, M. Patel<sup>2</sup>, G. Németh<sup>1</sup>

<sup>1</sup> Gedeon Richter Plc., Clinical Development Unit, Budapest, Hungary;

<sup>2</sup> Allergan Plc, Clinical development, Jersey City, USA

\* Corresponding author.

*Introduction.*– Long-term treatment with antipsychotics is indicated for all patients with schizophrenia. Antipsychotics can be of great benefit for a wide range of symptoms, but treatment is associated with unpleasant adverse effects. Hormonal changes (i.e. prolactin elevation) and sexual dysfunction are reported as some of the most distressing antipsychotic adverse effects and are directly related to treatment non-compliance. Antipsychotics can cause sexual dysfunction through multiple mechanisms, including hyperprolactinaemia, D2-antagonism, etc.

*Objective.*– The objective of the present poster is to present prolactin and sexual dysfunction data for cariprazine in the approved therapeutic dose-range versus placebo and comparators in patients with schizophrenia.

*Methods.*– Pooled data from 2048 cariprazine, 683 placebo, 370 risperidone and 152 aripiprazole treated patients from eight Phase 3, schizophrenia studies were analysed. Safety measures included adverse events (AEs), clinical laboratory values, physical examinations, EPS-, depression- and suicidality scales. Safety parameters were summarized using descriptive statistics.

*Results.*– Sexual dysfunction TEAEs occurred in 0.3% of placebo treated patients versus 1% of cariprazine, 2.7% of risperidone and 2% of aripiprazole treated patients. Most common sexual dysfunction TEAEs were libido decreased, erectile dysfunction, and amenorrhoea. For prolactin levels, mean decreases from baseline were seen in all treatment groups with the exception of risperidone, for which a mean increase was observed.

*Conclusion.*– Cariprazine was generally safe and well tolerated. It was associated with a mean decrease in prolactin levels and had no adverse effect on sexual dysfunction. Therefore, it could be a good alternative therapy for patients suffering from drug induced hormonal side effects.

### **Fregoli syndrome over the course of schizoaffective disorder: Case report and review of literature**

S. Ben Fadhel<sup>1\*</sup>, H. Ben Ammar<sup>2</sup>, A. Tounsi<sup>2</sup>, M. Daoud<sup>2</sup>, Z. Hechmi<sup>2</sup>

<sup>1</sup> Hospital Razi, Mannouba, Mannouba, Tunisia; <sup>2</sup> Razi Hospital, Mannouba, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– Fregoli syndrome is among delusional misidentification syndromes. It is the delusional belief that a single persecutor is masquerading as several other people, whose appearances he or she assumes at different times. We present a case in which a patient with Fregoli syndrome assaulted family members because of the belief that the persecutor disguised himself as them.

*Case report.*– Mrs WA is a 33-year-old single woman diagnosed with schizoaffective disorder. She was initially treated and stabilized with antipsychotics and mood stabilizers. She was admitted in our psychiatric ward following the assault of family members. She had no prior history of violent behaviour. The admission interview revealed various delusional beliefs: delusion of persecution against family members, delusion of bewitchment and megalomania. She also presented somatic delusions, in which her external genitalia were cut. She believed that her psychiatrist was present in the environment in different shapes and disguises; she thought he disguised himself as her mother and her brother. WA was treated with Risperidone (6 mg per day) and carbamazepine (600 mg per day). The patient improved and was discharged after two weeks.

*Conclusion.*– Fregoli syndrome is a rare category of delusional misidentification syndromes which is characterized by hostility and aggressive behaviour towards misidentified objects.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Therapeutic adherence and schizophrenia

W. Bouali<sup>1</sup>, R. Ben Soussia, S. Younes, I. Marrag, L. Zarrouk  
Hospital, Psychiatry, Mahdia, Tunisia

\* Corresponding author.

**Introduction.**– The management of schizophrenic patients most often comes up against the problem of non-compliance. The objectives of this work were to estimate the rate of non-adherence in patients with schizophrenia and to evaluate the main factors related to it.

**Patients and methods.**– This is a retrospective study carried out in the Department of Psychiatry at the Mahdia University Hospital. Therapeutic adherence was evaluated according to the criteria of Buchanan et al.

**Results.**– 50% of patients in our study population had poor adherence. The most predictive factors were hospitalization without the patient's consent ( $P=0.03$ ), overall malfunction with a GAF <30 ( $P=0.001$ ), and adverse effects of the treatment ( $P=0.05$ ). The rate of non-compliance was higher in patients over 50 years of age, male, single, with a low socio-economic status, a schizophrenia of undifferentiated type, and having a significant number of psychotic relapses.

**Conclusion.**– Significant improvement in the problem of non-adherence in schizophrenic patients requires structured and thorough intervention.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0776

### Application of an affective-type therapeutic program in cases of patients diagnosed with schizophrenia: A pilot study

D. Vega-Villa<sup>1</sup>, A. Camargo-Santodomingo<sup>2</sup>, K. Cabas-Hoyos<sup>3</sup>\*

<sup>1</sup> Universidad del Magdalena, Facultad de Salud- Programa de Psicología. Semillero de investigación "Cognición y Aprendizaje", Santa Marta, Colombia; <sup>2</sup> Universidad del Magdalena, Facultad de Salud, Estudiante Programa de Psicología, Santa Marta, Colombia; <sup>3</sup> Universidad del Magdalena, Facultad de Salud, Programa de Psicología, Santa Marta, Colombia

\* Corresponding author.

**Introduction.**– The intervention in the emotional balance and the strengthening of the self-esteem have become key factors in the mental health (Oros, 2011, 2009, Greco, 2010, Cavieres & Valdebenito, 2007).

**Objective.**– To evaluate the efficacy of an affective-type therapeutic program in patients diagnosed with schizophrenia.

**Methods.**– design of repeated measures without a control group was proposed. The brief program of affective intervention was administered to a sample of 6 patients (31 to 68 years of age, MD: 53, SD: 13,14) from the chronic patients ward and day hospital ward of a public hospital meeting criteria (ICD-10) for schizophrenia during 5 weeks. Before and after the intervention, tests were used to measure levels of anxiety (BAI), depression (BDI), self-esteem (Rosenberg) and affective balance (EBA), as well as clinical global impression: severity and improvement scales (CGI-S/I).

**Results.**– The Wilcoxon nonparametric statistic was administered. Of the two modules constructed as part of the program, the results showed only significant differences in the affective balance module ( $\alpha=0.046$ ;  $P < 0.05$ ) (See Table 1). This factor related to emotional responses and consideration of emotions in one's own life, is highlighted as vital for intervention from positive clinical psychol-

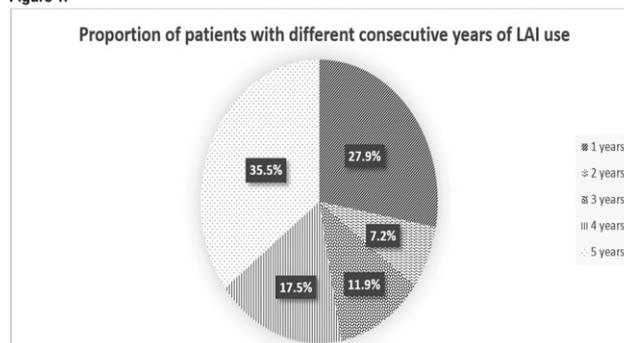

ogy in mental health (Godoy-Izquierdo, Martínez, & Godoy, 2008; Bohlmeijer, Lamers, Westerhof, 2017).

**Conclusions.**– As a pilot program developed in the Colombian Caribbean, it was innovative in one of the most important areas currently: positive mental health.

**Acknowledgment.** Fernando Troconis Hospital Staff's Support in Santa Marta, Colombia, was indispensable in the realization of this project.

Table 1. Scale scores (Wilcoxon).

### Folie a deux – A case report. How a multidisciplinary team and social media helped to solve the case

F. Caetano<sup>1\*</sup>, F. Martins Silva<sup>2</sup>, P. Magalhães<sup>2</sup>, M. Araújo<sup>1</sup>, A. Samouco<sup>3</sup>, S. Carvalho<sup>1</sup>, C. Martins<sup>1</sup>

<sup>1</sup> Magalhães Lemos Hospital, Psychiatry, Porto, Portugal; <sup>2</sup> Centro Hospitalar do Porto, Child and Adolescent Psychiatry, Porto, Portugal; <sup>3</sup> Unidade Local de Saúde do Norte Alentejano, Psychiatry, Portalegre, Portugal

\* Corresponding author.

**Introduction.**– La Folie a deux is a rare psychiatric syndrome in which a delusion is transferred from a psychotic individual to one with whom they have been in close association.

**Objectives.**– Our goal is to present a case of folie a deux emphasizing the resources used to establish the diagnosis.

**Material and Methods.**– Review of the clinical history and related literature.

**Results.**– We present a case of a married couple, with a 14-year-old daughter, brought for a psychiatric evaluation requested by child protection services. Their house had no water or electricity, with aluminium foil covering windows and pipes. The 47-year-old female, of Spanish nationality, had a medical history of retinitis pigmentosa, hypothyroidism and chronic kidney disease. The 54-year-old male, of Portuguese nationality, had no relevant medical history. No psychiatric history was found at admission. Both presented persecutory and reference delusions involving family members and the authorities. It was a challenge to figure out the case. However, with the help of a multidisciplinary team and numerous posts from Facebook we were able to find out their pre-morbid personalities and reach the final diagnosis. Both were treated with paliperidone and ultimately were discharged from the hospital to live in Spain with their relatives, previously involved in the delusion.

**Conclusions.**– This case illustrates not only a rare psychiatric condition but also how social media can be useful in building a complete clinical history.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0778

### Psychosis and suicide: A series of clinical cases

L. Castanheira<sup>1</sup>, E. Fernandes<sup>1</sup>, I. Silva<sup>1</sup>, C. Ferreira<sup>1</sup>, L. Ferreira<sup>2</sup>, T. Queirós<sup>1</sup>, F. Coelho<sup>1</sup>, J. Jerónimo<sup>1</sup>, R. Custódio<sup>1</sup>, J.M. Pereira<sup>1</sup>

<sup>1</sup> Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Psychiatry, Lisboa, Portugal; <sup>2</sup> Hospital Distrital de Santarém, Psychiatry, Santarém, Portugal

\* Corresponding author.

**Introduction.**– The estimated prevalence of suicide attempts in the general population is 2.7%, while in schizophrenic patients is 10.9%. About 5–6% of schizophrenic patients die from suicide, which is one of the main causes of premature death in schizophrenia.

**Objectives.**– Our aim is to present three clinical cases illustrative of the suicide risk in schizophrenic patients and to discuss the findings from previous studies about the theme.

**Methods.**– We used a multidisciplinary approach to the patients and reviewed the literature about the suicide risk factors in schizophrenia.

**Results.**– We describe three clinical cases of male patients diagnosed with schizophrenia, with no history of suicide attempts or known family history of suicide. The three patients present consistent characteristics with the recently published studies, which identified the following suicide risk factors in schizophrenia: male, young age, high educational level, depressive or hopeless symptoms, hallucinatory and delusional activity, psychomotor agitation/restlessness, substance abuse and chronic comorbid physical illness.

**Conclusions.**– Unemployment, previous suicide attempts, presence of insight and family history of suicide are other important risk factors. Risk of suicide is also greater after a psychotic episode or after hospital discharge. An untreated long-term psychosis negatively influences social, occupational and interpersonal functioning and it is considered as a risk factor for suicide in the first episode psychosis. Suicide prevention in schizophrenia involves optimization of adherence to therapy, psychoeducation for the disease and establishment of a therapeutic relationship with mental health professionals.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0779

### “Insight” and medication adherence in chronic psychotic disorders

M. Chakroun\*, R. Naoui, M. Daoud, S. Najjar, N. Halouani, J. Aloulou, O. Amami

Hedi Chaker University Hospital, psychiatry “B”, Sfax, Tunisia

\* Corresponding author.

**Objectives.**– Study the relation between the insight and drug adherence in patients with a chronic psychotic disorder.

**Methods.**– A cross-sectional, descriptive, and analytical study of 30 male patients with schizophrenia or schizoaffective disorder.

Data (demographic, clinical and therapeutic) was collected by a questionnaire developed for this purpose, we used the MORISKY scale “MMAS 8” with 8 items to evaluate the adherence and the scale of evaluation of the insight “Q8” with 8 items.

**Results.**– The average age was  $39.33 \pm 9$  years, half of our patients were single and 30% of them were divorced. The smoking rate was 73.3%; while the rate of cannabis use was 16.7%. All patients were hospitalized in our department with an average hospitalization rate of  $4.77 \pm 3.2$  times (50% compulsory hospitalization).

For the “MMAS 8” scale, 83.3% of the patients had poor adherence to their treatment with an average score of  $3.36 \pm 1.5$ .

For the “Insight Q8” scale, 60% of the patients had a lack of insight and they consider that they did not need a psychiatrist.

Poor adherence was significantly correlated with poor insight ( $P=0.006$ ).

**Conclusion.**– The level of insight is an independent factor for a good adherence to the treatment in chronic psychotic disorders.

Psycho-educational programs and psychotherapeutic interventions targeted at the awareness of the disorder must be developed to improve adherence and subsequently the course of the disease.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0780

### “Cannabis” use and insight in chronic psychotic disorders

M. Chakroun\*, R. Naoui, S. Najjar, M. Daoud, N. Halouani, J. Aloulou, O. Amami

Hedi Chaker University Hospital, psychiatry “B”, Sfax, Tunisia

\* Corresponding author.

**Objectives.**– Explore the influence of the insight on the use of cannabis in patients with a chronic psychotic disorder.

**Methods.**– This is a cross-sectional, descriptive, and analytical study of 30 male patients with schizophrenia or schizoaffective disorder. Data (demographic, clinical and therapeutic) was collected by a questionnaire developed for this purpose; we used “INSIGHT Q8” with 8 items to evaluate the insight.

**Results.**– The average age was  $39.33 \pm 9$  years, with an average age at onset of the disease of  $26 \pm 6$  years. Half of our patients were single and 30% of them were divorced. The smoking rate was 73.3%; while the rate of cannabis use was 16.7%. All patients were hospitalized in our department with an average hospitalization rate of  $4.77 \pm 3.2$  times (50% compulsory hospitalization, 43.3% hospitalization at the request of a third party and 6.7% free hospitalization). For the “Insight Q8” scale, 60% of the patients had a poor insight and they consider that they did not need a psychiatrist. Poor insight was significantly correlated with cannabis use ( $P < 0.05$ ).

**Conclusion.**– The level of insight is an independent factor to reduce the rate of cannabis use. Hence, the interest of a Psycho-educational programs and psychotherapeutic interventions targeted at the awareness of the disorder to improve subsequently the course of the disease.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0781

### Self-dysosmophobia: A case report

F. Cherif

Hédi Chaker University Hospital, Psychiatry A, Sfax, Tunisia

**Introduction.**– Self-dysosmophobia is the delirious conviction of the perception of an abnormal odor emanating from one’s own body.

**Objectives.**– Our Aim was to describe a clinical case of self-dysosmophobia and its treatment.

**Case report.**– We reported a case of a 47 years old Tunisian man who was hospitalised in psychiatry’s department at the age of 23 for behavioural disorders.

The patient presented agitation, little emotion, poverty of speech olfactory hallucinations and social isolation. We established the diagnosis of schizophrenia. On March 2016, the patient was hospitalized a second time for agitation, irritability, delusions and olfactory and coenesthetic hallucinations. We made the diagnosis of schizoaffective disorder.

He was treated by typical and atypical antipsychotics with a good compliance. But, the patient reported an unpleasant odor and sweat. He felt rejected and used to think that people were laughing at him. He was unable to work and to socialize.

Taking into account the resistance to the treatment, the residual olfactory perception, the lack of the dissociation, the depressive symptoms. We evoked the diagnosis of self-dysosmophobia and the patient received fluoxetine 20 mg daily and showed improvement.

**Conclusion.**– It is important that clinicians must be aware of these rare manifestations of self-dysosmophobia and discuss the diagnosis of schizophrenia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0782

### **Clinical and cognitive insight in psychosis: An overview**

F. Coelho\*, T. Queirós, C. Ferreira, L. Castanheira  
CHLN, Hospital de Santa Maria, Serviço de Psiquiatria, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Approximately 50-80% of patients with schizophrenia lack full insight. Recently, controversy has arisen about the association of clinical and cognitive insight (CI, COGI) with treatment, symptoms severity, quality of life (QL) and gender in psychotic patients.

**Objectives.**– To discuss the implications of CI and COGI in the QL and treatment of psychotic patients.

**Methods.**– We searched Pub Med database using the keywords: “Clinical insight”, “Cognitive insight” and “Psychosis” and selected the relevant articles.

**Results.**– Evidences show that a lack of insight contributes to non-adherence to treatment and poorer outcome. Patients may gain CI after treatment of the acute phases. COGI contributes to CI but is not-treatment dependent. Psychotic patients have greater insight when they have a better cognitive capacity for self-reflectiveness (SR) and less for self-certainty (SC). Higher levels of SR may generally be associated with better QL, but in patients with more severe symptoms higher SC has better outcomes. There seems to be a positive relationship between insight and depressive symptoms. In fact, it has been suggested that insight may represent a risk factor for suicide in patients with schizophrenia. The relationship between insight and gender remains unclear, but evidences show that women with a psychotic disorder may present a greater awareness of the disease

**Conclusions.**– Cognitive therapy for insight seems to be beneficial. In early stages of the treatment SR may be a better target than SC, but more studies are needed to outline the best approach, in view of enhancing QL.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0783

### **Schizophrenia and Down syndrome: Report of a case**

M. Daoud<sup>1</sup>\*, S. Ben Fadhel<sup>1</sup>, Z. Azzouz<sup>1</sup>, R. Bouzid<sup>2</sup>  
<sup>1</sup> Razi Hospital, psychiatry, Mannouba, Tunisia; <sup>2</sup> Mohamed Taher Maamouri Hospital, psychiatry, Nabeul, Tunisia

\* Corresponding author.

**Introduction.**– An increase in the prevalence of psychiatric disorders in people with intellectual disability has been reported. Prevalence

rates have been consistently demonstrated to be higher in adults with Down's syndrome than in the general population.

**Objective and method.**– The aim of our work is to report the clinical observation of a trisomy 21 patient having developed schizophrenia.

**Results.**– We are reporting the case of a 37- years old Tunisian male with mental retardation suffering for many years from insomnia, incoherency of speech, social withdrawal, stereotyped movements and impulsive behaviour. On physical examination revealed a patient with flattened nose, upward slanting eyes and a short neck. These signs suggested trisomy 21. The karyotype confirmed the diagnosis of Down's syndrome. The psychiatric evaluation found dissociation and visual hallucinations. Therefore, the patient did meet the Diagnostic and Statistical Manual of Mental Disorders (DSM) V criteria of schizophrenia.

**Conclusion.**– Many studies have been conducted looking for a link between chromosomal aberrations and schizophrenia. These studies have shown a frequent association between the two diseases. Chromosomal abnormalities described are essentially partial trisomy of chromosome 5, partial deletions, translocation, inversion at chromosomes 21, 23 and 9 and some abnormalities of the sex chromosomes.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0784

### **Factors related to suicide attempts in a population of patients with schizophrenia**

M. Daoud\*, R. Naoui, S. Najjar, M. Chakroun, N. Halouani, J. Aloulou, O. Amami

Hedi Chaker University Hospital, psychiatry B, Sfax, Tunisia

\* Corresponding author.

**Objective.**– To describe the frequency of suicide attempts in patients with schizophrenia and to study the association with socio-demographic, clinical and therapeutic factors.

**Methods.**– This is a retrospective, descriptive and comparative study of 30 schizophrenic patients admitted in the department of psychiatry “B” at the university hospital of Hédi Chaker. Sociodemographic, clinical and therapeutic data, as well as the existence or the absence of personal history of suicide attempt or adverse events was collected from patients and from medical records. Therapeutic adherence was assessed subjectively. We have arbitrarily defined poor compliance as a treatment discontinuity greater than two consecutive weeks that occurred over the past year, reported by the patient or his family.

**Results.**– The population was composed of 30 men. The average age was 39.3 years. The school level was secondary in 14 cases (46.7%). Most of them were unemployed and lived with their family. The rate of attempted suicide in our population was 40%. Comparison of the socio-demographic variables of patients with and without a history of suicide attempt had not shown statistically significant differences between the two groups. For clinical and therapeutic variables, the study found that male smoking, positive symptoms, extrapyramidal signs and poor adherence were significantly more frequent in patients with a history of suicide attempt ( $P < 0.05$ ).

**Conclusion.**– The rate of suicide attempt in Tunisia was comparable to that of Western countries. The sociodemographic characteristics of the patients had no influence on this suicidal behaviour as opposed to clinical characteristics.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0785

### The causes of suicide attempts in a population of patients with schizophrenia

M. Daoud<sup>1</sup>, R. Naoui, M. Chakroun, S. Najjar, N. Halouani, J. Aloulou, O. Amami

Hedi Chaker University Hospital, psychiatry B, sfax, Tunisia

\* Corresponding author.

**Objective.**– To describe the frequency of suicide attempts in patients with schizophrenia and to determine their causes.

**Methods.**– This is a retrospective, descriptive study of 30 schizophrenia patients admitted in the department of psychiatry “B” at the university hospital of Hédi Chaker. Sociodemographic, clinical and therapeutic data, as well as the existence or absence of a personal history of suicide attempts was collected from patients and from medical records. The statistical study was carried out using the SPSS software (18.0).

**Results.**– The population was composed of 30 men. The average age was 39.3 years and the school level was secondary in 46.7%. The majority ( $n = 19$ ; 63.3%) was single. Most of them were unemployed (63.3%) and lived with their family (85.1%). Socio-economic status was medium in 75% of cases. The mean age of onset of the disease was 30.4 years. The number of hospitalizations ranged from one to 11 hospitalizations with an average of 4.77. The main reasons given by patients to explain their passage to the suicidal act were:

- Psychotic causes ( $n = 13$ ; 43.3%) with a delirious activity or under the influence of hallucinations like suicidal injunctions:
- Depressive causes ( $n = 4$ ; 13.3%) with sadness and/or feeling of despair
- Reaction causes ( $n = 2$ , 6.7%), in particular following a stressful life event

**Conclusion.**– Identification of the causes of Suicide Attempt remains an essential step towards the development of prevention and care strategies.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0786

### A comparative study examining the relationship between CRP levels with cognitive functions and clinical severity in patients with schizophrenia

N. Demir<sup>1\*</sup>, O. Yıldırım<sup>2</sup>

<sup>1</sup> Medicine and Training Hospital, Psychiatry Department, Karabük, Turkey; <sup>2</sup> Rumeli University- Reap Hospital, Psychiatry Department, Istanbul, Turkey

\* Corresponding author.

**Objective.**– In our research, the relation between CRP's inflammatory effect, with the cognitive processes and the severity of the illness in schizophrenia has been examined.

**Methods.**– 36 patients with schizophrenia participated in our study with using SCID-I interviews. They were all between the ages of 18–60 and hadn't used psychotropic medications at least for a month. The tests that were applied to the participants were Wisconsin Card Sorting Test (WCST), Trail Making Test (TMT), Stroop Color-Word Test (SCWT), and Rey Auditory Verbal Learning Test (AVLT). CRP levels were measured with immunoturbidimetric method.

**Results.**– When relationships between CRP levels with the test scores were examined; a statistically significant associations were found between the error amounts ( $P = 0,05$ ), error corrections ( $P = 0,004$ ) of word-color reading in the Stroop test with CRP levels.

In addition, reading time of TMT-A form test and CRP levels were significantly related ( $P = 0,05$ ). No relationship was found between CRP levels with WCST and AVLT scores. And similarly, there is no relation between CRP levels and clinical severity.

**Conclusion.**– In our study, it has been shown that, in schizophrenia patients, high levels of CRP correlated to cognitive dysfunctions, such as processing speed, attention, working memory and executive function shown by Stroop test. Similar to our findings, previous reports in the literature reported a significant relationship between high levels of CRP with cognitive disorders. As a result, supplementing patients with anti-inflammatory drugs may increase their participation in social life via improving their cognitive functions. However, further study about this topic is needed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

**Introduction.**– The gender differs with respect to vulnerability to specific classes of psychopathology.

**Objective.**– We investigated effects of gender and family history of psychiatric illness on disorders of the psychosis spectrum (schizophrenia, bipolar, and schizoaffective disorders), using a large database of patients ( $n = 1132$ ) from a Mexico City psychiatric hospital.

**Methods.**– Patients had given written informed consent within the hospital. A diagnosis based on DSM-IV criteria was assigned, and psychopathology was assessed using the Positive and Negative Syndrome Scale. We used Chi-squared tests, T-tests, and two ways ANOVA, in order to assess effects of gender and family history of mental illness on premorbid characteristics, age of symptom onset, and symptom severity.

**Results.**– For both men and women, schizophrenia and bipolar diagnoses were respectively associated with a family history of each disorder. Men were more likely to have a schizophrenia diagnosis, while women were more likely to have bipolar or schizoaffective diagnoses. Across diagnoses, men experienced their first psychotic episode approximately 3 years earlier than women, and frequency distribution histograms for age of first psychotic episode revealed clear gender differences. In men, but not women, a positive family history of schizophrenia was associated with premorbid schizoid characteristics across diagnoses, and increased positive symptoms in association with a schizophrenia diagnosis. Men showed more severe negative symptoms, and premorbid schizoid behaviours were associated with an 11% increase in negative symptom severity.

**Conclusions.**– There are gender differences in the age of onset, premorbid characteristics, severity, and vulnerability to genetic liability factors.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Co-production of a therapeutic skills training programme for carers, relatives and friends with psychosis**

A. Cerga-Pashoja<sup>2</sup>, A. Doukani<sup>1</sup>, L. Gega<sup>3</sup>

<sup>1</sup> London School of Hygiene & Tropical Medicine, Department of Population Health, London, United Kingdom; <sup>2</sup> London School of Hygiene and Tropical Medicine, Department of Population Health, London, United Kingdom; <sup>3</sup> University of York, Health Sciences, York, United Kingdom

\* Corresponding author.

**Background.**– Psychosis is a complex, difficult to treat, long-term illness associated with impaired functioning and significant health-care utilisation. People with psychosis require life-long emotional and practical support, which is largely provided by the carer. Despite their significant role, the vast majority of carers do not receive any therapeutic training on how to care for someone with psychosis nor do they receive adequate support to look after their own mental well-being.

**Objectives.**– The aim of the study is to carry out formative work, to develop a cognitive behavioural therapy informed care training for carers of people with psychosis, to address their skill-based and personal self-care needs. The study objectives are to explore: (a) the practical skills and self-care needs of the carer, (b) the support needs of the patient, (c) how professionals can support the programme, and (d) which wellbeing and recovery outcomes are considered important.

**Methods.**– Six qualitative focus groups (two for professionals, carers and service-users) will be carried out to explore the objectives described. Participants will be recruited through community mental health services.

**Results.**– Qualitative data will be analysed using thematic analysis of the participants' narrative responses. Data coding will be carried out by a researcher and a clinician to ensure the themes are grounded in the original data.

**Conclusions.**– The emerging themes will inform relevant aspects of the carers' training package and help determine outcome measures that are likely to capture potential improvement in the carer's and the cared-for person's wellbeing following participation in the training.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

<sup>1</sup> Koç University Hospital, Department of Psychiatry, Istanbul, Turkey;

<sup>2</sup> Kackar State Hospital, Department of Psychiatry, Rize, Turkey; <sup>3</sup>

Bagcilar Training and Research Hospital, Department of Psychiatry,

Istanbul, Turkey; <sup>4</sup> Bakirkoy Research and Training Hospital for

Psychiatry, Neurology and Neurosurgery, Department of Psychiatry,

Istanbul, Turkey; <sup>5</sup> Private Practice, Private Practice, Istanbul, Turkey

\* Corresponding author.

**Background.**– Schizophrenia is a chronic, debilitating disorder that requires long-term treatment and regular follow-ups. In this study we aimed to evaluate the impacts of specialized outpatient units on the clinical outcome and indirect costs of schizophrenic patients by comparing the previous standard outpatient follow-ups.

**Method.**– Structured forms and follow-up records of the hospital were used to evaluate 131 patients with the diagnosis of schizophrenia, followed-up in Bakirkoy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery; Psychotic Disorders Outpatient Unit. The changes in the frequency of outpatient visits, the frequency and length of hospitalizations and the treatment compliances were compared.

**Results.**– After attending the follow-ups at Psychotic Disorders Outpatient Unit; mean frequency of outpatient visits increased 1.7-fold ( $P=0.025$ ), mean frequency of hospitalizations decreased 23.2-fold ( $P<0.001$ ), mean length of hospital stays dropped to 30.6-fold ( $P<0.001$ ) and the mean treatment compliances increased from 45.5% to 98%.

**Conclusion.**– Being followed-up for psychotic disorders in a specialized outpatient service provides patients with schizophrenia to have more frequent outpatient visits, less frequent and shorter hospitalizations and better treatment compliances; determining a significant improvement in overall clinical outcome and leading to lower the indirect costs.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Vortioxetine in the treatment of negative symptoms of schizophrenia: A case report**

E. Segura<sup>\*</sup>, L. Asensio, L. Nuevo, C. Rodriguez, L. Cabanillas, I. Gomez

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– The schizophrenia is a very heterogenous entity and a good early diagnosis and approach of the symptoms could improve prognosis and evolution. Positive symptoms have been well-studied and treated, but at long term, negative symptoms are those that induce more inability and deterioration.

The development of new antidepressants like vortioxetine with a multimodal profile could open new possibilities.

**Aim.**– Demonstrate the effectiveness of vortioxetine in the treatment of negative symptoms of schizophrenia.

**Method.**– We describe a case report of a psychotic patient treated with vortioxetine.

**Results.**– 33-year old woman with paranoid schizophrenia, previously with different diagnosis. Between 2012 and 2014 she was admitted frequently with positive symptoms and suicidal ideas. These symptoms were resistant to treatment, even to clozapine due to side effects. Finally with antipsychotic polytherapy associated to psychotherapy interventions, we achieve clinical stabilizations.

During the evolution, the patient referred negative symptoms. We introduced citalopram with a minimum improvement. We decided to change to vortioxetine.

The evolution has been progressive, with an important improvement in the affective sphere.

**Conclusions.**– Despite the limitations as it exposes a single case, the results are encouraging because they demonstrate the improvement of the patient that other antidepressant didn't get, and could be an opportunity to treat these symptoms. Vortioxetine could be an effective treatment for negative symptoms of schizophrenia associated to antipsychotics. The effects on cognitive symptoms could be explained for the multimodal profile [1].

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Schizophrenia and dissociate symptoms: Review of the literature and clinical case

L. Ferreira<sup>1\*</sup>, A. Ribeirinho Marques<sup>1</sup>, V. Gonçalves<sup>1</sup>, C. Ferreira<sup>2</sup>, L. Castanheira<sup>2</sup>, A. Rosa<sup>1</sup>

<sup>1</sup> Hospital Distrital de Santarém, Departamento de Psiquiatria e Saúde Mental, Santarém, Portugal; <sup>2</sup> Centro Hospitalar Lisboa Norte, Serviço de Psiquiatria, Lisboa, Portugal

\* Corresponding author.

*Introduction.*– Dissociative Disorders (DD) and Schizophrenia Spectrum Disorders (ESD) are described as two distinct categories in the classification systems. EDS are a heterogeneous group in which there is loss of contact with reality with hallucinations and delusions, where, like dissociation, there is a discontinuity of the normal integration of consciousness, memory, identity, emotion, perception, body representation, motor control and behaviour. Psychotic symptoms are not considered a comorbidity of DD, but dissociation has been related to the presence of positive and negative psychotic symptoms.

*Objectives.*– To discuss the findings from previous studies about the presence of DS in ESD providing a comprehensive overview of the overlap and differences of these symptoms and correlate with the clinical case.

*Methods.*– We reviewed the literature on the topic and interviewed the patient.

*Results.*– We describe the clinical case of a 36-year-old man, paranoid schizophrenia, several treatment strategies, poor adherence to treatment, which after remission of the negative symptomatology developed DS. Evidence shows that positive and negative symptoms may be present in DD, especially positive symptoms, which suggests that both diagnostic categories may share common risk factors. There is also an association between traumatic events in childhood and DS in psychotic adults.

*Conclusions.*– Dissociation is not specific to schizophrenia but may be related to traumatic experiences. For this reason, the history of trauma may be a potential mediator of dissociation in patients with schizophrenia. Therefore, it is critical that patients with ESD be routinely questioned about possible childhood adverse experiences for early intervention.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Efficacy and tolerability of aripiprazole depot in schizoaffective disorder: Case report

M. García Moreno<sup>1\*</sup>, A. de Cós Milas<sup>2</sup>, L. Beatobe Carreño<sup>2</sup>, M.B. Poza Cano<sup>3</sup>

<sup>1</sup> CSM Majadahonda, Hospital Universitario Puerta de Hierro Majadahonda, Psychiatry, Madrid, Spain; <sup>2</sup> CSM Móstoles, Hospital Universitario de Móstoles, Psychiatry, Madrid, Spain; <sup>3</sup> CE San Carlos, Hospital Universitario El Escorial, Psychiatry, Madrid, Spain

\* Corresponding author.

*Introduction.*– Aripiprazole depot has proved to improve positive, negative and cognitive symptoms in schizophrenia. It's unlikely linked to weight gain, dyslipidemia or increased prolactin levels. This scientific evidence suggests aripiprazole depot could be a favorable therapeutic option in the treatment of other psychotic disorders.

*Objectives.*– We Aim to present our clinical experience with aripiprazole depot in the treatment of psychotic and affective symptoms in patients with diagnosis of schizoaffective disorder.

*Methods.*– We selected two patients with diagnosis of schizoaffective disorder from our outpatient Mental Health Service, as clinical illustration of efficacy and tolerability of aripiprazole depot. Previously, they were treated with paliperidone palmitate and olanzapine with unfavorable side effects.

*Results.*– We present two males with diagnosis of schizoaffective disorder. Case A is a bipolar subtype, 35 years old with cannabis use history and 5 previous hospitalizations due to psychotic or manic symptoms; he was clinically stabilized with paliperidone palmitate but had sexual side effects despite low doses of antipsychotic medication. Case B is a depressive subtype, 31 years old with 2 previous hospitalizations due to psychotic and depressive symptoms; he was partially stabilized with olanzapine and paroxetine and had metabolic symptoms associated. We decided a treatment change to aripiprazole depot 400 mg in monotherapy with maintenance of clinical stability in Case A and clinical improvement in Case B. Both cases experienced disappearance of adverse effects described.

*Conclusions.*– Our clinical experience evidences that aripiprazole depot is a valuable therapeutic option in schizoaffective disorder (manic and depressive subtype), on behalf of its effectiveness and tolerance.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Anti NMDA receptor encephalitis presenting as schizophreniform psychosis in a young female, a case report

P.S. Gopan

Cghs Hospital, Psychiatry, Hyderabad, India

*Introduction.*– Anti NMDA receptor encephalitis is a rare autoimmune disorder and a life threatening condition if not adequately treated which often presents with prominent psychiatric symptoms.

*Objectives.*– To emphasize the importance of keeping in mind anti NMDA receptor encephalitis as a diagnosis in psychotic patients with neurological symptoms

*Case report.*– A 28 year old female presented with gradual onset of behavioural changes in the form of aggressiveness, suspiciousness, talking to self which then gradually progressed to decreased interaction with family members for which she was admitted. Later on she developed jerky movements of limbs with altered sensorium. She was evaluated with MRI brain which showed irregular thickened cortex with ill-defined gray white matter interface involving frontal lobes, perirolandic cortex perisylvian, Insular cortex inferior and anterior parietal lobe, EEG showed generalized slowing which changed over time and WHOLE BRAIN PET s/o encephalitis. CSF analysis positive for NMDA receptor antibodies hence diagnosed as anti NMDA receptor encephalitis. She was started on Inj Rituximab with which she showed improvement.

*Conclusion.*– The above case highlights the need for vigilance in patients presenting with psychosis and developing neurological symptoms. Further research into the pathophysiology and epidemiology of anti NMDA receptor encephalitis may provide further

support for NMDA receptor hypothesis and may open new treatment avenues.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The sense of self in the pre-onset phase of psychotic disorders**

M. Gruber<sup>1</sup>, K. Feichtinger<sup>2</sup>, K. Parth<sup>2</sup>, A. Funder<sup>2</sup>, N. Mossaheb<sup>1</sup>, Z. Litvan<sup>2</sup>, B. Hinterbuchinger<sup>1</sup>, A. Unger<sup>1</sup>, S. Doering<sup>2</sup>, V. Blueml<sup>2</sup>

<sup>1</sup> Medical University Vienna, Psychiatry and Psychotherapy, Clinical Division for Social Psychiatry, Vienna, Austria; <sup>2</sup> Medical University Vienna, Psychoanalysis and Psychotherapy, Vienna, Austria

\* Corresponding author.

*Introduction.*– The continuum of stages of psychotic disorders ranges from at risk mental state, operationalized with the ultra-high risk (UHR) criteria, to the first episode of psychosis (FEP) to recovery or schizophrenia with multiple episodes. It was found that assessment of the individual's sense of self is highly valuable for early stages in psychosis, but data is sparse.

*Objectives.*– The Aim of this ongoing research project is to explore the self functioning in patients at UHR and with FEP.

*Methods.*– The Comprehensive Assessment of At Risk Mental State (CAARMS) was used to identify persons at UHR. Individuals with FEP, with borderline personality disorder (BPD) and healthy controls (HC) were assessed with the Structured Clinical Interview for DSM Disorders (SCID I and II). Psychotic Symptoms were measured with the Positive and Negative Syndrome Scale (PANSS) and the Prodromal Questionnaire (pq-16). The structured interview of personality structure (STIPO) and the Examination of Anomalous Self-Experience (EASE) were used to rate self functioning.

*Results.*– The sample included individuals at UHR ( $n = 8$ ), with FEP ( $n = 3$ ), with BPD ( $n = 7$ ) and HC ( $n = 15$ ). In an ANOVA, individuals at UHR had a significantly weaker identity integration (STIPO,  $P < .001$ ) with a lower sense of self ( $P \leq .05$ ) compared to HC. Identity integration ( $P > .05$ ) and self disorders (EASE  $P > .05$ ) of individuals at UHR did not significantly differ from individuals with FEP or BPD.

*Conclusions.*– These preliminary results suggest that disturbances of the sense of self characterize the pre-onset phase of psychotic disorders, although this was not a distinctive feature compared to BPD.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Homicide and schizophrenia: Retrospective study on 13 years**

S. Omri\*, F. Guerhazi, N. Charfi, M. Maalej, A. Feki, J. Ben Thabet, N. Zouari, L. Zouari, M. Maalej

Hedi Chaker University Hospital, Psychiatry C, Sfax, Tunisia

\* Corresponding author.

*Introduction.*– The odd ratios for homicide are remarkably increased among subgroups of patients with schizophrenia.

*Objective.*– Raise sociodemographic, clinical and forensic characteristics of homicide in Tunisian patients suffering from schizophrenia.

*Methods.*– The study was descriptive and retrospective, including 20 male patients with a DSM 5 diagnosis of schizophrenia. They were examined, between January 2004 and September 2017 on the occasion of a penal expertise in the Department of Psychiatry C in the Hedi Chaker University Hospital, Sfax, Tunisia. The crime was a homicide or homicide attempt.

*Results.*– The mean age of our patients was 29.5 years. They were mostly single (90%) and unemployed (55%). Half of the patients were secondary school graduates (50%) and most of them had a history of psychiatric disorder (55%). Among patients followed, 90% had a low Drug compliance to treatment at the time of the offence. Ninety percent of our sample were experiencing delusions, auditory hallucinations and other positive symptoms at the time of the homicide. The majority of victims were family members (70%) or acquaintances (25%).

The 'homicide/attempted homicide' was more often not premeditated (55%) and the assessment results were in all cases irresponsibility.

*Conclusion.*– Homicide is often committed by a schizophrenic patient without psychiatric care or assistance. Appropriate management of the disease may allow earlier intervention on risk factors of homicidal acts.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0796

### **Exploring the changing service delivery and outcomes in Australia for people with psychotic illnesses**

M.C. Hanlon

University of Newcastle, School of Medicine & Public Health, Newcastle, Australia

*Introduction.*– In Australia, policy change has led to community managers - funded by the National Disability Insurance Scheme (NDIS), and managed by the National Disability Insurance Agency (NDIA) - becoming integral in the management of psychotic illness. Many people with psychotic illness have other health problems, including depression, anxiety, cardiovascular disease, cancer, asthma and obesity. The cost of psychotic illness to the Australian community is \$4.91 billion annually; so, even though it has low prevalence, it carries a high economic burden per capita. Many experience homelessness and receive less than \$500 per fortnight (compared with \$2522 for mentally healthy people the same age).

*Objectives.*– Hence, while a changed National Mental Health Plan has influenced service provision - particularly involving community-managed organisations - vocational, functional, social and welfare outcomes need to be evaluated.

*Methods.*– Thematic analysis of online surveys and semi-structured interviews with consenting stakeholders allowed a deep understanding of the challenges to this model of care, as well as the creative solutions key workers implement to overcome these significant obstacles.

*Results.*– Challenges included high caseload, financial inflexibility of the NDIS, NDIA understaffing, and underqualification of key workers. Risks to staff and participants were under-assessed and under-supervised.

*Conclusions.*– There needs to be increased numbers of social workers, qualified case workers and support staff. Key workers risk burnout and injury. The delivery of the NDIS needs to be more flexible and better managed, with significant investment increases in staffing, professional development and workers' compensation insurance.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0797

### Motor dysfunctions and negative symptoms in schizophrenia

A. Hopulele-Petri<sup>1</sup>, M. Manea<sup>2</sup><sup>1</sup> Carol Davila University Of Medicine And Pharmacy, Psychiatry, Cluj-Napoca, Romania; <sup>2</sup> Carol Davila University For Medicine And Pharmacy, Psychiatry, Bucharest, Romania

\* Corresponding author.

**Introduction.**– Negative symptoms in schizophrenia involve a complex constellation of symptoms, involving affective, volitional, behavioural and interpersonal dysfunctions. Neurological soft signs, independent of treatment are being considered endophenotypic constructs underlying schizophrenia, with significant and considerable difference between healthy controls and patient's family members. It had been suggested that these dysfunctions of sequencing and complex coordination might be associated with negative symptoms in schizophrenia. Meanwhile, motor speed is also important in schizophrenia, due to medication-induced Parkinsonism, but also due to the pre-motor functions involved in cognitive (i.e. executive functions) and volitional processes.

**Aims.**– The aims of this study consisted in evaluating the relationship between motor dysfunctions in various subdomains (speed, coordination, sequencing) and negative symptoms.

**Method.**– This ongoing study used DSM V criteria to include psychiatric inpatient diagnosed with schizophrenia. Inclusion criteria included a positive diagnosis and willingness to complete the assessment. Exclusion criteria consisted of acute and chronic neurological disorders, developmental disorders, somatic disorders with motor signs or a comorbid depressive episode. Schizophrenia symptoms were evaluated using the Positive And Negative Symptoms Scale. Motor dysfunctions were evaluated using a battery of tests, involving motor speed and imaginary motor speed (Time Up and Go task, as well as a imaginary version, the iTUG); motor sequencing and coordination (Brief Motor Scale). 21 patients have been recruited, with a target sample size of 50 to be reached by the end of February.

**Results.**– Correlational analysis revealed significant relationships between negative symptoms and motor domains, including pre-motor functioning.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0798

### Body image and stoma

J. Ines<sup>1</sup>, S. Ben Saadi<sup>2</sup>, E. Khelifa<sup>2</sup>, K. Saber<sup>2</sup>, E.H. Zouhaier<sup>2</sup><sup>1</sup> Razi Hospital, F, Mannouba, Tunisia; <sup>2</sup> Razi Hospital, Razi Hospital, F, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– The damage of the colon-rectum by a cancer confronts the patients with a very particular physical experience. The implementation of a colostomy sends back to the dimensions of the anality with the learning of the sphincter control and the toilet training.

The depreciation of the body image further to the mutilation and the induced functional modifications sends back to the problems of opening and closure of the body, the smells, the dirt and the cleanliness, the retention and the eviction. The image of the body and its change constitute a crucial problem in oncology both for the patients and for the medical teams. So the consequences of a stoma on the psychological plan will not be unimportant: anxious and depressive disorders, posttraumatic stress disorder.

**Results.**– Mr HBR, 58-year-old, presenting an adenocarcinoma of the mid rectum (T2N0), having benefited from a preoperative radio-

therapy. The anterior resection of the mid rectum was performed 3 months ago, with a temporary ileostomy. The patient would have a psychiatric history of a depressive syndrome in 2006. He was hospitalized, for an acute confusional state with a delirious syndrome, behaviour disorders and a refusal of the stoma.

**Conclusion.**– In our industrialized societies where the standards of fashion and advertising value the beautiful and the complete body, thus hurting the body of the person with stoma, where the suffering, although real, is often ignored and little evoked, it becomes from now on urgent to set up a psychological support for these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0799

### Why are you so jealous?

P. Jorge

Psychiatry resident at Centro Hospitalar do Médio Tejo, Hospital de Tomar, Portugal, Psychiatry, Tomar, Portugal

**Introduction.**– Jealousy is a complex emotion that most people have experienced at some time in life. However it can become an irrational state. Othello's syndrome (OS), named after the character in Shakespeare's play, refers to the delusion of infidelity of a significant other, which is sometimes used interchangeably with delusional or morbid jealousy.

**Aim and methods.**– Understand the causes of OS. Pub Med was used as a research source.

**Results.**– OS has been associated in different studies with psychiatric and neurological disorders including strokes, brain trauma, brain tumors, neurodegenerative disorders, encephalitis, multiple sclerosis, normal pressure hydrocephalus, endocrine disorders, and drugs. Othello's syndrome was most commonly associated with a neurological disorder compared with psychiatric disorders. This delusion appears to be associated with dysfunction of the frontal lobes, especially right frontal lobe. Delusional jealousy is also frequent problem in dementia.

**Discussion and conclusions.**– Clinicians must have a high index of suspicion of organic disease when OS presents for the first time. Frontal lobe dysfunction may be called into question in delineating the cause of the delusional jealousy seen in Othello syndrome.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Substance abuse and violence in schizophrenic patients

A. Kachouchi<sup>1</sup>, S. Said, I. Adali, F. Manoudi, F. Asri

University Hospital Mohammed VI, Department Of Psychiatry, Marrakech, Morocco

\* Corresponding author.

**Objectives.**– To evaluate the management of substance abuse in schizophrenic patients. To study the association between substance abuse and the act of violence.

**Material and method.**– Our study is retrospective, carried out in the department of psychiatry, CHU Mohammed VI in Marrakech. This is a study looking at a 4-month period in a sample of 116 schizophrenic patients according to DSM IV. The assessment of violence was made by the Aggression Questionnaire (QA, Buss and Perry, 1992)

**Results.**– It has been shown that three toxic substances are factors of physical aggression: tobacco, cannabis and alcohol. Patients who take these substances have a high average of physical aggression compared to those who do not take them. Patients who consume

tobacco and cannabis are verbally more aggressive than those who do not consume them. We found that patients who take tobacco and cannabis as well as alcohol are angrier and more hostile than those who do not take them.

**Conclusion.**– The withdrawal aid for toxic substances would clearly help to reduce the rate of aggression in schizophrenic patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0801

### Considering self-disturbance from the perspective of aberrant interoception in schizophrenia

A. Koreki<sup>1,2\*</sup>, T. Maeda<sup>2</sup>, Y. Terasawa<sup>3</sup>, M. Funayama<sup>4</sup>, M. Mimura<sup>2</sup>, M. Onaya<sup>1</sup>

<sup>1</sup> National Hospital Organization Simofusa Psychiatric Center, Department of Psychiatry, Chiba, Japan; <sup>2</sup> Keio University School of Medicine, Department of Neuropsychiatry, Tokyo, Japan; <sup>3</sup> Keio University, Department of Psychology, Tokyo, Japan; <sup>4</sup> Ashikaga Red Cross Hospital, Department of Neuropsychiatry, Ashikaga, Japan

\* Corresponding author.

Self-disturbances in schizophrenia are beginning to be explained by abnormalities in the “sense of ownership” and “sense of agency.” Although there are many factors for the emergence of the sense of ownership, one of the most important factors is interoception, which is the sense of the internal state of the body, such as the heart rate. In the present study, we compared interoceptive sensitivity between healthy controls and patients with schizophrenia. Nineteen patients and 19 controls were recruited. Their interoceptive sensibility was assessed using the heartbeat detection task. They were asked to count the number of times they felt their own heartbeat during the measurement period. The error rates were based on the discrepancy between the number of reported and actual heartbeats during the measurement period. As the control, they also performed a time estimation task, which was counting the number of seconds during the period. The error rates were calculated in a similar manner as that of the heartbeat. The results showed greater error rates in patients with schizophrenia when compared to that of the healthy controls (error rates:  $47.7 \pm 16.4\%$  versus  $23.0 \pm 13.5\%$ ,  $P < 0.0001$ ) and no significant difference in time estimation (error rates:  $21.1 \pm 15.8\%$  vs  $15.9 \pm 12.2\%$ ,  $P = 0.27$ ), suggesting that patients with schizophrenia have aberrant interoception. These results could provide an understanding of the pathophysiological mechanism of self-disturbances.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0802

### Efficiency of art therapy in the rehabilitation system schizophrenic patients

H. Kozhyna\*, A. Krystal, V. Mykhaylov, M. Markova, L. Gajchyk  
Kharkiv National Medical University, Psychiatry, narcology and medical psychology, Kharkiv, Ukraine

\* Corresponding author.

The purpose of the research is to study the dynamics of the level of social functioning in schizophrenic patients under the influence of art therapy.

**Materials and methods.**– To reach this goal, we carried out a comprehensive survey of 86 male and female inpatients aged 18 - 65 years old with a diagnosis of schizophrenia in the period

of stabilization. Art-therapeutic correction was used along with psycho-pharmacotherapy complex therapy.

**Results and discussion.**– The investigation showed that the following dynamics of artistic expression was observed in the process of art therapy: in the initial stages created image data were characterized by amorphous, vague boundaries, changes of normal and initial forms, mixing of different styles and in the last stages of art therapy created image data acquired symbolic, archetypal character, greater structure and completeness.

It was found that the level of general behavioural dysfunction in the society in the main group improved to 87.4%; dysfunction in the performance of social roles in society - 75.1%, disruption of patients in hospitals - 73.7%; dysfunction of modifying factors - 82.5%, after completion of art therapy, according to the results of a study of the social functioning of patients with schizophrenia.

The obtained data testify that the complex approach in the therapy of schizophrenia, which included psycho-pharmacotherapy in combination with art therapy, leads to restoration of social activity and successful resocialization of patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0803

### Clinical predictors of clozapine response

I. Lajmi<sup>1\*</sup>, S. Younes<sup>2</sup>, N. Halouani<sup>1</sup>, K. Hajji<sup>2</sup>, R. Naoui<sup>1</sup>, L. Zarrouk<sup>2</sup>, O. Amami<sup>1</sup>

<sup>1</sup> Hedi Chaker Hospital, Psychiatry, Sfax, Tunisia; <sup>2</sup> Tahar Sfar Hospital, Psychiatry, Mahdia, Tunisia

\* Corresponding author.

**Introduction.**– Schizophrenia is a severe, and disabling mental disorder. An evaluation of clinical predictors to clozapine was described.

**Objective.**– Identify clinical predicting factors to clozapine.

**Methods.**– This is a cross-sectional study conducted in the psychiatric department in Tahar Sfar Hospital, Mahdia, including patients diagnosed with schizophrenia or schizoaffective disorder according to the DSM V criteria and treated with clozapine. The general and clinical data were collected using a pre-established questionnaire designed for the study.

**Results.**– Of the 33 patients, 78.8% were males and 69.7% were single. The mean age was 36 years old. The mean age at the onset of the disorder was 24 years old. The beginning of the mental disorder was acute in 21.2% of the cases. The mean duration of the disease course before starting clozapine treatment was 11 years. The mean duration of treatment was 19 months. The diagnosis according to DSM V criteria was schizophrenia in 87.9 and schizoaffective disorder in 12.1% of cases. The outcome was assessed by PANSS and BPRS scales with a symptomatic remission in 63.63% of cases. The analytical study revealed a significant correlation between favorable evolution and the latest onset of the disorder ( $P = 0.04$ ), the number of previous hospitalizations ( $P = 0.009$ ), disorder's duration ( $P = 0.032$ ), male sex ( $P = 0.0004$ ) and secondary resistance ( $P < 10^{-3}$ ).

**Conclusion.**– The evaluation of clinical factors is important in our practice in order to improve the response to clozapine. Otherwise, adherence to treatment and quality of insight are determining factors of the treatment response.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0804

### Predictors of a violence in resistant schizophrenia

I. Lajmi<sup>\*</sup>, S. Younes, K. Hajji, S. Fathallah, L. Zarrouk  
CHU Tahar Sfar, Mahdia, Psychiatry, Sfax, Tunisia

\* Corresponding author.

*Introduction.*– The violence among patients resistant schizophrenia remains a subject of controversy.

Prevention of these violent acts based in identifying predictors of this behaviour.

*Aims.*– Identify clinical and psychometric predicting factors to violence.

*Methods.*– This is a cross-sectional study conducted in the psychiatric department in the EPS Mahdia, Tunisia, including patients diagnosed with schizophrenia or schizoaffective disorder according to the DSM V criteria and considered resistant as kane resistance criteria. The general, clinical and psychometric data were collected using a pre-established questionnaire designed for the study. We used the Historical Clinical Risk Management-20 (HCR20) to evaluate dangerousity.

*Results.*– The mean age of our population was 36 years. Sex-ratio (H/F) was 3.7. Most of them were from rural origin (57.6%) and single (70%). Addictive behaviour was found in 30.3% of case. The act of violence was major in 36% of case.

The analytical study revealed a significant correlation between major act of violence and addictive behaviour ( $P=0.21$ ), recent toxic use ( $P=0.04$ ) and the Hai HCR-20 score ( $P=0.044$ ).

*Conclusion.*– It emerges from this work that the major act of violence among patients with resistant schizophrenia or schizoaffective disorder is associated with addictive behaviour, recent toxic use and the HCR-20 score which are not specific factors and found in other psychiatric disorders.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### The importance of the early diagnosis of psychosis

A.A. Leonor<sup>1\*</sup>, S.E. Estefanía<sup>2</sup>, N.F. Laura<sup>2</sup>, R. Carlos<sup>2</sup>, M.M. Victoria<sup>2</sup>, B.F. Luis<sup>2</sup>, M.S. Beatriz<sup>2</sup>

<sup>1</sup> Psychiatrist, Hospital General de Ciudad Real, sevilla, Spain; <sup>2</sup> Hospital General de Ciudad Real, psychiatry, Ciudad Real, Spain

\* Corresponding author.

*Introduction.*– Psychosis is a mental state in which the individual experiences a distortion or loss of contact with reality. Symptoms include hallucinations, delusions and thought disorder. Nowadays identification of individual vulnerability is not possible, but a correct and quick diagnosis of psychotic symptoms is fundamental to be able to introduce a right treatment to patients, and to avoid the personal consequences of the symptomatology. But how can we make this early intervention?

*Objectives.*– The objective is to provide a bibliographic review of the early diagnosis and treatment of psychosis.

*Methods.*– A systematic review from the literature has been carried out by Pub Med/Medline, Cochrane, and Dialnet

*Results.*– There are a number of strategies to achieve early intervention. The first one is community education; the family doctor has to know early signs to make a rapid detection, and we have to lessen the stigma associated with mental illness. Treatment occurs in four main stages: Detection, immediate management, early and late recovery, and continuing care.

The typical course of the initial psychotic episode can be conceptualized as occurring in three phases. These are the prodromal phase, the active phase and the recovery phase.

*Conclusions.*– The early diagnosis and treatment of first episode psychosis can significantly improve the prospects of recovery and reduce longer-term impairment for many individuals. Treatment requires the integrated use of pharmacological, psychological, family and group interventions. The therapeutic relationship is very important to improved adherence.

*Keywords:* Early Diagnosis; Psychosis; First episode; Treatment

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Subjective cognitive impairment in people with early psychosis: Relationship with objective cognitive impairment and clinical symptoms

J.J. LIN<sup>1\*</sup>, A.C.Y. Tong<sup>1</sup>, W.C. Chang<sup>2</sup>, S.K.W. Chan<sup>2</sup>, E.H.M. Lee<sup>2</sup>, E.Y.H. Chen<sup>2</sup>

<sup>1</sup> The University of Hong Kong, School of Nursing, Hong Kong, Hong Kong S.A.R.; <sup>2</sup> The University of Hong Kong, Psychiatry, Hong Kong, Hong Kong S.A.R.

\* Corresponding author.

*Introduction.*– Subjective cognitive impairment (SCI) among individuals with early psychosis is under-recognized and under-studied. Yet, SCI is as important as objective impairment to be understood, since it assesses cognition difficulties in everyday, real-life situations from a personal perspective and is therefore an essence of individualized medicine.

*Objectives.*– This study aims to explore the associations between the objective and subjective measures of cognitive impairments and to identify factors contributing to SCI among people with early psychosis.

*Methods.*– Participants were 63 females (mean age=24.41 years old, SD=8.15) diagnosed with early psychosis within 5 years. They completed a battery of neuropsychological tests assessing on a range of cognitive functions. These included memory (HKLLT, Digit SPAN), attention (Letter Cancellation test), and executive functions (WAIS, STROOP). The Subjective cognitive impairment Scale (SCIS) was also used to assess their perceived cognitive decline. Psychotic symptoms (PANSS) and depression (CDS) were also assessed.

*Results.*– SCIS was not correlated with any of the objective cognitive tests results ( $P>0.05$ ). It was positively correlated with depression ( $r=0.55$ ,  $P<0.001$ ) and positive symptoms ( $r=0.49$ ,  $P<0.001$ ). A hierarchical multiple regression model reveals that positive symptoms and depression together explained 31.3% of the total variance in SCIS and only depression significantly predicted subjective cognitive impairment in our participants ( $\beta=0.4$ ,  $P<0.01$ ).

*Conclusions.*– Subjective feeling of cognitive impairment may be a result of catastrophization associated with depression secondary to the psychosis. Treatments should not only focus on symptomatic remission and cognitive training, but also place emphasize on improving affects of individuals with early psychosis.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Psychosis in temporal lobe epilepsy: A case report

H. Maatallah\*, A. Amina, A. Faten, K. Amira, E.H. Zouheir  
Razi Hospital, F, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Psychotic syndromes are frequently found in people with epilepsy, with prevalence rates ranging from 4% to 7% of all people with epilepsy; this is up to 15 times higher than the 0.4% prevalence in the general population. The rate increases to 11% when temporal lobe epilepsy (TLE) is investigated alone, suggesting a greater prevalence of psychosis in those whose seizures originate in the temporal lobes.

**Methods.**– We describe a case of Temporal Lobe Epilepsy TLE discovered in patient with acute psychosis and discuss the association between epilepsy and psychosis.

**Case report.**– A 35-year-old Tunisian man was admitted to an inpatient psychiatric unit for management of acute psychotic symptoms: delusional ideas, auditory and visual hallucinations. He had a prior diagnosis of schizophrenia and was on Risperidone 4 mg per day but no improvement with prescribed medication in the 12 weeks before admission.

Upon admission, necessary investigations were performed including CT scan and EEG. His CT was normal but EEG was grossly abnormal. Neurology consultation was sought and a sleep deprived EEG and MRI was ordered. Meanwhile, carbamazepine was commenced in view of the change in diagnosis to that of temporal lobe epilepsy. The patient responded very well to this regime and improved in all spheres. He was finally discharged with follow-up appointments with both neurology and psychiatry clinic.

**Conclusion.**– This case highlights the importance of remaining open-minded in patients with refractory psychosis.

These cases suggest that despite the association between acute psychosis and seizures, in particular TLE, a routine EEG may provide additional benefits to the clinician.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Neurodevelopmental influences in psychosis: A Case of left cerebral hemiatrophy and a psychotic episode

S. Malta Vacas\*, M. Constante, M.J. Heitor  
Hospital Beatriz Ângelo, Psychiatry and Mental Health, Lisboa, Portugal

\* Corresponding author.

Dyke-Davidoff- Masson syndrome (DDMS) is a radiologically defined characteristic childhood syndrome, which consists of unilateral hemispheric atrophy accompanied by ipsilateral calvarial thickening and overgrowth of sinuses. This rare syndrome includes two forms comprising: the congenital form, which may result from congenital malformations, infections or vascular etiology and the acquired form related to perinatal birth trauma, hypoxia and intracranial hemorrhage, or postnatal prolonged febrile convulsions, trauma, vascular insult or intracranial infections. The clinical symptomatology usually starts in early childhood and mainly includes contralateral motor impairment, facial asymmetry, epilepsy and intellectual dysfunction. Psychiatric manifestations are uncommon and have rarely been reported

We report a 41-year-old male who presented with left cerebral hemiatrophy and psychotic episode. We discuss the relevance of left-sided neurodevelopmental cerebral atrophy in the context of disrupted neural development of brain lateralization, plasticity, and

evidence regarding left hemisphere dysfunction in schizophrenia and other psychotic disorders.

Overall, this rare case of DDMS manifesting with a psychotic episode expands the available sparse evidence concerning the neuropsychiatric aspect of cerebral hemiatrophy and adds to the evidence that this condition may present with psychotic abnormalities particularly when left hemiatrophy is present. As a disorder of neural development confined to a unilateral cerebral hemisphere, DDMS is especially interesting in the context of lateralization of brain functions associated with neuropsychiatric disorders and neurodevelopmental models of schizophrenia. The influence of abnormalities in neural connectivity, changes in plasticity following early hemispheric damage and functional reorganization of neural networks contributing to the pathogenesis of psychotic disorders remain to be elucidated.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

Timisoara, Romania; <sup>4</sup> PhD Candidate, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, Timisoara, Romania

\* Corresponding author.

**Introduction.**– Temporal epilepsy is a form of partial epilepsy characterized by complex partial seizures. Studies show that patients with temporal epilepsy tend to have an increased incidence of secondary psychosis. Nevertheless, there are cases in which epilepsy and psychosis coexist as distinct disorders.

**Objectives.**– To disclose a clinical case where epilepsy is comorbid with paranoid schizophrenia.

**Methods.**– Psychiatric assessments (psychiatric interview, PANNS scale, SCL-90 scale).

**Results.**– A 17-year-old Romanian male, living in a rural area, with complex organic pathology (mental retardation, macrocephaly, epilepsy with partial seizures and previous intracranial hypertension). The patient was admitted for psychomotor agitation, delusions regarding eye change: "my mother switched her eyes with mine, then in another city, at the market, switched hers, which were mine, with the devil; now my eyes belong to the devil"; auditory and visual hallucinations: "God appeared to me and told me that I am Jesus"; mystical delusions secondary to the visual and auditory hallucinations, bizarre behaviour (even when awake, the patient stayed with his eyes closed). Blood tests within normal limits. After assessment of symptoms, he was diagnosed with paranoid schizophrenia according to ICD-10 criteria and received treatment with antipsychotics and mood stabilizers.

**Conclusions.**– The particularity of this case stems from the association between epilepsy with bizarre schizophreniform psychosis, in a young man with complex organic structure and the presence of mystic delusions (which can occur in both epilepsy, as well as in functional psychoses).

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0810

### Impact of clozapine prescription on global functioning

S. Maroua<sup>\*</sup>, U. Ouali, Y. Zgueb, R. Jomli, F. Nacef  
Razi Hospital, Psychiatry A, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Clozapine's superiority in treating resistant symptoms has been recognized since its introduction. Indeed, this antipsychotic has transformed the outcomes of many handicapping psychiatric disorders). Later, the positive effect of this drug on quality of life has been proven at 12 months of treatment. Besides, little is known about clozapine's effect on global functioning.

**Objectives.**– To compare the global functioning of patients before and after treatment with clozapine.

**Methods.**– This is a retrospective and cross-sectional study conducted in 2015 in male outpatients with schizophrenia, bipolar and schizoaffective disorders treated with clozapine. Data related to social functioning as well as psychometric data: Global assessment of functioning scale (GAF), Positive and Negative Syndrome scale (PANSS) and the clinical global impressions scale (CGI) were recorded.

**Results.**– Forty two men were included in this study. The mean age of the sample was  $36.9 \pm 7.31$  years.

A significant increase in GAF scores was recorded at 6 months of clozapine ( $P=0.002$ ). When comparing PANSS and CGI scores before clozapine initiation and at the time of the study in 2015, an important improvement was noted ( $P=0.011$ ;  $P=0.000$ ). Furthermore, family relationships were improved ( $P=0.016$ ). However, there was no significant increase in the number of friendships and no change in marital status in the patients.

**Conclusions.**– Our findings suggest a positive effect of clozapine on global functioning. More prospective studies are needed to confirm these results.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0811

### A vicious cycle: The potential pitfalls of misdiagnosing myasthenia gravis (MG) for antipsychotic-induced extra-pyramidal side effects (EPSE)

A. Mohandas<sup>\*</sup>, J. McCarthy, M. Gupta, S. Thomas, A. Swift  
Devon Partnership NHS Trust, Langdon Hospital, Exeter, United Kingdom

\* Corresponding author.

**Introduction.**– MG is an autoimmune neuromuscular disease weakening skeletal muscles and in severe cases can affect breathing. Antipsychotic medication can produce EPSE resembling symptoms of MG. If MG is misdiagnosed as EPSE then anticholinergic medication is frequently considered. Crucially, anticholinergic medication is contraindicated in MG and can in turn mimic worsening EPSE. MG alternatively should be treated with anticholinesterase inhibitors.

**Objective.**– This complex case-report highlights the complexity of diagnosing MG in a patient with paranoid schizophrenia suffering with what was thought to be EPSE caused by antipsychotic treatment.

**Methods.**– Symptoms included slurred speech, muscle weakness and dysphagia. Anticholinergic medication (procyclidine) was prescribed for a number of years in order to treat such symptoms. There was no improvement noted however procyclidine may have made these symptoms worse. A blood sample was taken to rule out MG, which was positive for Acetylcholine Receptor antibodies, which supported the diagnosis of MG. His MG was therefore

treated using IV immunoglobulin, plasmapheresis and an anticholinesterase inhibitor.

**Results.**– Zuclopenthixol alone has a marked anticholinergic effect. This in combination with anticholinergic treatment can significantly worsen MG symptoms. Zuclopenthixol was therefore switched to olanzapine, which has a relatively lower anticholinergic effect and fewer tendencies for EPSE. The symptoms of slurred speech, muscle weakness and dysphagia all improved. The symptoms of psychosis also improved.

**Conclusion.**– A differential diagnosis of neurological conditions should be considered when faced with complex symptoms suggestive of side effects related to antipsychotic treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0812

### Prevalence of depression and anxiety in patients with schizophrenia

S. Najjar<sup>\*</sup>, R. Naoui, M. Daoud, M. Chakroun, H. Najla, J. Aloulou, O. Amami

Hedi Chaker University Hospital, Psychiatrie B, Sfax, Tunisia

\* Corresponding author.

**Objective.**– Determine the prevalence of depression and anxiety in patients with schizophrenia.

**Methods.**– This is a descriptive cross-sectional study of 30 patients with schizophrenia at the outpatient department of psychiatry at the Hedi Chaker hospital in Sfax. The collection of the various socio-demographic and clinical data was done thanks to an anonymous self-questionnaire. The depressive and anxious symptomatology was evaluated using the HAD (Hospital Anxiety and Depression scale) scale translated into Arabic and validated in Tunisia. A score superior of 7 meant depression or anxiety.

**Results.**– The mean age in our sample was 39.3 years. Most were without a job (63.3%). The socio-economic level was average in 75%. The mean age of onset of the disease was 30.4 years. The number of hospitalizations ranged from one to 11 hospitalizations with an average of 4.77.

Depression was noted in 13,3% of patients, 30% had a suspicious depressive symptomatology and 56.7% didn't have a depressive symptomatology. Anxiety was noted in 23,3% of the patients while 40% had a suspicious symptomatology and 36,7% didn't have an anxious symptomatology.

**Conclusion.**– Our results underline the significant association, of depressive and anxious symptoms in a population of schizophrenic patients. This leads to the advantage of screening for an anxiety or depressive comorbidity in order to initiate the necessary treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Money for medication: Using financial incentives for improving medication adherence in patients with psychotic disorders; a multicentre, open-label, randomised controlled trial

E. Noordraven<sup>1\*</sup>, C. Mulder<sup>2</sup>, A. Bloemendaal<sup>3</sup>, A. Wierdsma<sup>2</sup>, P. Blanken<sup>4</sup>

<sup>1</sup> Center for Dual Diagnosis, Palier, Psychiatry, Amsterdam, The Netherlands; <sup>2</sup> Erasmus Medical Center, Psychiatry, Rotterdam, The Netherlands; <sup>3</sup> Center for Dual Diagnosis, Palier, Psychiatry, The Hague, The Netherlands; <sup>4</sup> Brijder Addiction Research Center, Parnassia, The Hague, The Netherlands

\* Corresponding author.

**Background.**– We aimed to assess the effectiveness of using financial incentives for improving adherence to antipsychotic depot medication in patients with psychotic disorders.

**Methods.**– A multicentre, open-label, randomised controlled trial at three mental health-care institutions in secondary psychiatric care services in the Netherlands. Eligible patients were aged 18–65 years, had been diagnosed with schizophrenia, had been prescribed antipsychotic depot medication, and were participating in outpatient treatment. Patients were randomly assigned to receive 12 months of either treatment as usual plus a financial reward for each depot of medication received (€30 per month; intervention group) or treatment as usual alone (control group). The primary outcome was the Medication Possession Ratio (MPR), during the 12-month intervention period. Patients were followed up for 6 months, during which time no monetary rewards were offered.

**Findings.**– Patients ( $n=169$ ) were allocated to the intervention ( $n=84$ ) or the control group ( $n=85$ ). Primary outcome data were available for 155 (92%) patients. At baseline, the mean MPR was 76.0% in the intervention group versus 77.9% in the control group. After 12 months, the mean MPR was higher in the intervention group (94.3%) than in the control group (80.3%), with an adjusted difference of 14.9% (95% CI 8.9–20.9%;  $P<0.0001$ ). This difference was maintained throughout the 6-month follow-up period: in the intervention group (86.6%) versus the control group (76.0%; adjusted difference 6.5%, 95% CI 2.0–10.9;  $P=0.047$ ).

**Interpretation** Financial incentives are an effective way of improving adherence to antipsychotic depot medication among patients with psychotic disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0814

### **Treatment resistant schizophrenia: A case report with long term hospitalization**

D. Ozbayrak Karapinar, B.R. Erim

*Abant İzzet Baysal University Medical Faculty, Psychiatry, Bolu, Turkey*

**Introduction.**– Schizophrenia is a common chronic mental disorder that affects 1% of the world's population. Although most of the patients respond to typical and atypical antipsychotics, a third of them don't respond to treatment well and they are considered treatment resistant patients.

**Objectives/Aims.**– In this case, we aimed to make a brief review on treatment resistant schizophrenia through a schizophrenia patient with long term hospitalization.

**Methods/Case.**– A 31 year old woman who had multiple hospital admissions with several diagnosis s was admitted to psychiatry unit with negativism, mutism irritability, insomnia, auditory hallucinations and socaial withdrawn behaviours. Her total PANSS score was 144. During four months of hospitalization period, she was given several combinations; paroxetine that she had used for 8 years, risperidone, olanzapine, essitalopram, aripiprazol and amisulpride. Electroconvulsive therapy was initiated because of the ongoing symptoms and her negativism. Due to the prolongation of the seizures, ECT was terminated at the fifth session. At the end of, we intent to start clozapine therapy but persisten leukopenia and pneumonia developed and it was cancelled.

**Results.**– Now, she is given amisulpride 1200 mg/day, olanzapine 30 mg/day, aripiprazol 30 mg/day and her PANSS score is 111 at the 137 th day of her hospitalization, and we decided to discharge her.

**Conclusions.**– When we rewieved the literature about the treatment resistant schizophrenia over the patient who still has the symptoms, it is concluded that the well being does not always develope.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Anhedonia in patients with schizophrenia and its relationships with negative symptoms and depression**

S. Patriarca\*, A. Mucci, C. Aiello, S. De Simone, P. Bucci, D. Molle, F. Brando, N. Merlotti, G. Silvana

*Università degli Studi della Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy*

\* Corresponding author.

**Introduction.**– Anhedonia has long been considered part of negative symptoms of schizophrenia, however some studies failed to confirm this evidence and suggest that anhedonia in schizophrenia may be more closely associated with depression than with negative symptoms, also in the acute phase of the illness.

**Objectives.**– To characterize trait anhedonia in patients with schizophrenia with respect to healthy controls and to explore the hypothesis that it may be more associated to depression than to negative symptoms.

**Methods.**– This study included 35 schizophrenic patients (SCZ) and 24 healthy controls (HC). Trait anhedonia was assessed by means of the Chapman Physical Anhedonia Scale and the Chapman Social Anhedonia Scale; consummatory and anticipatory anhedonia were assessed by means of the Temporal Experience of Pleasure Scale. For SCZ patients, the factor "Depression" was extracted from the Positive and Negative Syndrome Scale by the average of the items Anxiety (G2), Guilt feelings (G3) and Depression (G6). Avolition was measured by using the Schedule for the Deficit Syndrome.

**Results.**– SCZ showed, with respect to HC, a deficit in both consummatory and anticipatory pleasure and a greater severity on both social and physical anhedonia. In SCZ, trait social anhedonia was significantly predicted by depression, while neither social nor physical trait anhedonia were associated to Avolition.

**Conclusions.**– According to our findings, patient with schizophrenia have a deficit in consummatory as well as in anticipatory pleasure. Our data also support the hypothesis that anhedonia in schizophrenia is more related to depression than to negative symptoms.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0816

### **Gender dysphoria versus self-identity disorder produced by psychosis**

A.L. Pérez Morenilla<sup>1\*</sup>, P. Ortega Orihuela<sup>2</sup>

<sup>1</sup> *University Hospital Puerta del Mar- Cádiz, Psychiatry, INIBICA Instituto de Investigación e Innovación en Ciencias Biomédicas, Cádiz, Spain;* <sup>2</sup> *University Hospital of Puerto Real, Psychiatry, Cádiz, Spain*

\* Corresponding author.

Many psychiatric disorders share similar symptoms, sometimes it is difficult to perform a correct nosology or differentiate one disorder from another depending on the clinic.

We present the case of a 17-years-old man admitted to a Psychiatric Unit after an overdose of drugs. The patient was initially diagnosed with psychosis, presenting a delusional idea of harm and self-referentiality, stating that "he was recorded with cameras", that he "felt persecuted" and "somebody wanted to kill him".

Between his clinic, he also verbalized that “he would like to get rid of her body, become the opposite of his gender”, that “when he looked in the mirror he doesn’t recognize himself”, “he would like to be a woman” and “dress like she”, and that “inside his body, he had a woman”. He dressed in her mother’s clothes and at some point thought of cutting her genitals.

At a certain moment, a diagnosis of gender dysphoria superimposed on the psychotic disorder was considered, but it was finally discarded, when this symptomatology acquired a psychotic character, such as referring to “having a woman inside who gives him some orders”, as well as when referring auditory and kinesthetic hallucinations.

Therefore, in the field of psychiatry, there are sometimes limitations in making diagnoses, based exclusively on clinical criteria, which are sometimes shared by several diseases. It would be interesting future researches, in order to design exhaustive criteria for the classification of mental illnesses, which minimize the diagnostic ambivalence as much as possible.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0817

### **The relationship between level of cognitive impairment and treatment in patients with paranoid schizophrenia**

N. Petrova<sup>1\*</sup>, M. Dorofeikova<sup>2</sup>

<sup>1</sup> Saint Petersburg State University, Department of Psychiatry and Narcology, Saint-Petersburg, Russia; <sup>2</sup> Bekhterev Psychoneurological Research Institute, Department of Geriatric Psychiatry, Saint-Petersburg, Russia

\* Corresponding author.

Antipsychotic drugs are the main therapeutic approach in schizophrenia. Although some studies have shown that antipsychotics can improve cognitive functioning, more studies are required to determine their influence on it. 91 patients with paranoid schizophrenia (56% men, mean age 34.6 ± 9.9 years) at the stage of remission stabilization were assessed using Brief Assessment of Cognition in Schizophrenia (BACS), Rey-Osterrieth Complex Figure, PANSS, DAI.

Most often the patients received combined therapy with antipsychotics of different generations (51.3%). Antipsychotic polypharmacy was not a significant factor in determining cognitive functioning of patients, side effects or compliance. It has been shown that monotherapy with second generation antipsychotic was associated with more intact verbal fluency ( $r = 0.329$ ;  $P = 0.047$ ). Greater severity of motor disorders was found in patients taking traditional antipsychotics ( $37.9 \pm 15.6$  vs  $51.1 \pm 17.6$ ,  $P = 0.056$ ). Patients receiving only atypical antipsychotics were more accurate ( $84.8 \pm 25.6$  vs  $66.9 \pm 38.7$ ,  $P = 0.010$ ), demonstrated better working memory ( $35.3 \pm 11.3$  vs  $27.4 \pm 12.9$ ,  $P = 0.012$ ) and verbal fluency scores ( $38.7 \pm 11.4$  vs  $31.6 \pm 13.2$ ,  $P = 0.027$ ). The level of compliance was  $7.5 \pm 1.5$  points. When dividing patients into two groups (47.5% with 4 - 7 points, 52.5% with 8 - 10 points), it was found that more compliant patients were characterized by higher total BACS score ( $30.6 \pm 13.7$  vs  $18.8 \pm 18.3$ ,  $P = 0.071$ ), better planning abilities ( $48.2 \pm 24.3$  vs  $25.6 \pm 47.8$ ,  $P = 0.011$ ) and speech fluency ( $38.4 \pm 10.4$  vs  $31.2 \pm 10.5$ ,  $P = 0.066$ ). Thus, monotherapy with atypical antipsychotics was found to be preferable for sustaining cognitive functioning in patients with schizophrenia. Cognitive impairment is a factor of their adherence to therapy.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Clinical features of methamphetamine-induced psychosis in an emergency department of psychiatry: Description of 20 cases**

J.E. Pinzón Espinosa<sup>\*</sup>, C. Oliveras, G. Anmella, A. Gimenez, M. Vazquez

Hospital Clínic of Barcelona, Institute of Neurosciences, Barcelona, Spain

\* Corresponding author.

*Introduction.*– Over the past few years, methamphetamine-induced psychosis (MIP) has increased in Barcelona, accounting for a significant percentage of psychiatry visits in the emergency department (ED).

*Objectives.*– To describe the epidemiological and clinical features of MIP patients seen in a Psychiatry ED in Barcelona, Spain.

*Methods.*– Cross-sectional, retrospective study of patients seen between Jan 2016 and Nov 2017 at the Psychiatry ED at Hospital Clínic in Barcelona, with diagnosis of acute psychotic episode and recent methamphetamine use (self-report or laboratory confirmation). Patients with diagnosis of primary psychosis were excluded. Data was analysed with SPSS software (IBM, v.23).

*Results.*– Sample consists of 20 patients, 75% male, mean age of  $31.7 \pm 7.3$  years, and a history of substance use disorders (meth-/amphetamines, 40%; cocaine, 20%; GHB; 15%). Most had had a previous MIP episode (55%). Laboratory confirmation for MDMA was obtained in 80%. Most common concurrent drugs included cannabis (35%) and GHB (25%). The most frequent symptoms were anxiety (75%); delusions of persecution (65%), of reference (45%), and of grandiosity (15%); auditory (40%), visual (10%), and tactile hallucinations (10%); disorganized conduct (40%); and aggressiveness (40%). Half presented psychomotor agitation, but only 20% required physical restraint. Acutely, 70% were treated with antipsychotics, either alone or with a benzodiazepine. Mean time to discharge was  $18.6 \pm 13.3$  hours; 60% were referred to outpatient follow-up, while 20% were admitted. At discharge, only 45% were prescribed treatment (olanzapine, 35%).

*Conclusions.*– MIP presents with varied psychiatric symptomatology, including significant violence and aggressiveness. More studies are required on this condition in the Spanish population.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Clinical effectiveness of paliperidone palmitate intramuscular 3-monthly formulation in patients with schizophrenia: A case series**

A. Porras Segovia<sup>1\*</sup>, M. Guerrero<sup>1</sup>, C. Carrillo de Albornoz<sup>2</sup>, L. Gutiérrez-Rojas<sup>1</sup>

<sup>1</sup> University Hospital San Cecilio, Mental Health Services, Granada, Spain; <sup>2</sup> Hospital Comarcal de Baza, Mental Health Services, Granada, Spain

\* Corresponding author.

*Introduction.*– Insufficient treatment compliance is common among patients with schizophrenia and it is associated with an increased risk of relapse and a greater number of admissions to hospital.

In order to tackle this problem, several depot forms of atypical antipsychotic agents have been developed in the past few years, including 1-monthly formulations of olanzapine, aripiprazole and paliperidone. The recently approved new formulation of paliperidone palmitate is the first depot antipsychotic treatment in offering

a 3-month period of effectiveness. This advantage could be crucial in cases of severe non-compliance.

**Objectives.**– In order to explore the clinical effectiveness of paliperidone palmitate 3-monthly formulation, we present a case series of 11 patients with schizophrenia treated with this medication.

**Methods.**– We carried out a retrospective review of clinical files to explore the details of each one of the cases and to formulate Clinical Global Impression (CGI) scores.

**Results.**– Our sample consists on 10 patients diagnosed with schizophrenia who were treated with paliperidone palmitate 3-month formulation. 525 mg was the most frequently used dose. 9 of our patients remained clinically stable or improved after a period of 3 to 9 months after starting their treatment. The remaining patient, who suffered from resistant schizophrenia, continued to have positive psychotic symptoms despite the medication, with no significant worsening when compared with his previous treatment. Medication was generally well tolerated.

**Conclusions.**– Paliperidone Palmitate Intramuscular 3-Monthly Formulation was a clinically effective and well tolerated medication in the long-term treatment of our schizophrenic patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Treatment of clozapine-induced hypersalivation: A case series and review of the literature**

A. Porras Segovia<sup>1\*</sup>, C. Carillo de Albornoz<sup>2</sup>, M. Guerrero<sup>1</sup>

<sup>1</sup> University Hospital San Cecilio, Mental Health Services, Granada, Spain; <sup>2</sup> Hospital Comarcal de Baza, Mental Health Service, Granada, Spain

\* Corresponding author.

**Introduction.**– Clozapine is thought to be the most effective antipsychotic agent, with a remarkable capacity to improve positive, negative and cognitive symptoms.

However, its potential to induce neutropenia has limited its use to treatment-resistant schizophrenia. Other adverse effects, such as sialorrhea, sedation and constipation, although less severe, can have a significant impact on tolerability.

**Objectives.**– Our aim is to review the existing evidence about Clozapine-induced hypersalivation and to report two cases of patients suffering from this side effect.

**Results.**– Sialorrhea affects between 31.0 and 97.4% of patients treated with Clozapine. It usually appears early after treatment.

Although there is no consensus regarding the mechanism by which clozapine causes sialorrhea, it is postulated that this antipsychotic agent antagonizes a number of receptors, which ultimately results in sialorrhea. One of this receptor is A1, whose stimulation causes vasoconstriction in the salivary glands, which causes the excessive production of saliva by an increase of the blood flow.

Clozapine is also an agonist of M4, which promotes excessive secretion of saliva.

We report two cases of patients diagnosed with treatment-resistant schizophrenia, who received Clozapine and suffered from sialorrhea as a side effect. We treated both cases with an anticholinergic agent (scopolamine), which greatly improved the sialorrhea without causing additional adverse effects.

**Conclusions.**– Clozapine is a useful antipsychotic agent which can greatly improve the quality of life of patients suffering from schizophrenia. The use of anticholinergic medication to tackle one of its side effects could increase the tolerability of the antipsychotic medication, which may, in turn, improve treatment compliance and satisfaction.

### **Causes of antipsychotic change in patients with schizophrenia**

M.D.L.C. Ramirez Dominguez<sup>\*</sup>, I. Perez Eguagarai, G.R. Alfonso, R.G. Eduardo

Psychiatrist, Psychiatrist, Aljaraque, Spain

\* Corresponding author.

**Introduction.**– With the arrival in recent years of atypical injectable antipsychotics long acting (LAI) a paradigm shift is being proposed in the treatment of schizophrenia for several reasons and among others, why with oral treatments there are frequent relapses due to the abandonment of treatment, with fatal consequences such as increased hospital admissions, and increased polytherapy

**Objective.**– To analyze the causes of change from oral antipsychotic treatment to injectable treatments in patients with schizophrenia in the province of Huelva, Spain.

**Result.**– A preliminary analysis of the data indicates that the most difficult cause is the therapeutic non-compliance, but there are other important causes that will affect the patient and the therapeutic processes that will be analysed in depth.

**Conclusions.**– Long acting injectable antipsychotics are an alternative to other oral therapies, which ensure proper administration, reduce hospitalizations, stay in hospital and favor monotherapy

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Subclinical clozapine-induced myocarditis: The importance of using a screening protocol**

D. Rentero<sup>\*</sup>, I. Torio, M. Caballero, E.M. Sánchez-Morla, C. Pastor, M. Dompablo, R. Rodríguez-Jiménez, G. Rubio

Hospital Universitario 12 de Octubre, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Clozapine-induced myocarditis is a rare but serious risk of clozapine use. Despite having incidence rates similar to, if not higher than, clozapine-induced neutropenia, there are no consensus protocols for monitoring the risk for its development. We present a case of a 44-year-old female with subclinical clozapine-induced myocarditis, which was detected with a modified protocol described in Ronaldson et al.

**Objectives.**– The use of early signs and symptoms of clozapine-induced myocarditis, such as the ones included in our protocol, may detect subclinical cases of clozapine-induced myocarditis.

**Results.**– Baseline troponin T, C-reactive protein and ECG showed no alterations, while the patient maintained abnormally high heart rate. On day 14, we detected a mild elevation in C-reactive protein with normal troponin T and without signs or symptoms consistent with infective illness or cardiac illness. With these results, we monitored troponin and C-reactive protein daily and both Troponin T and C-reactive protein showed a mild elevation (Troponin T > 200 and CRP > 50 mg/L). The ECG and Transthoracic Echocardiography were normal. At this point, we interrupted the treatment with clozapine. For the next days, Troponin T and PCR were normalized. Cardiac magnetic resonance imaging was performed on day 9 of clozapine cessation and resulted normal. The patient was asymptomatic at all times.

**Conclusions.**– Through the following case and subsequent overview of literature, we have attempted to emphasize the importance and

difficulty of the timely diagnosis of clozapine-induced myocarditis, being of interest to carry out a screening protocol to detect clinical and subclinical cases.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Paraphrenia: Kraepelin's Dark Horse – A historical review about a case report**

A. Ribeiro Marques<sup>1\*</sup>, A. Bonito Ferreira<sup>2</sup>, I. Souto Braz<sup>2</sup>, T. Duarte<sup>2</sup>, S. Paulino<sup>2</sup>, A. Rosa<sup>1</sup>, P. Cintra<sup>3</sup>

<sup>1</sup> Hospital Distrital de Santarém, Psychiatry Department, Lisboa, Portugal; <sup>2</sup> Hospital de Santa Maria, Psychiatry Department, Lisboa, Portugal; <sup>3</sup> Hospital de Cascais Dr. José de Almeida, Psychiatry Department, Cascais, Portugal

\* Corresponding author.

*Introduction.*– Kraepelin introduced the concept of paraphrenia and described it as a functional psychotic disorder different from dementia praecox. Paraphrenia is currently excluded from the main diagnostic classifications, but it still has a shadowy existence on the edge of our psychiatric nosology, being recognized by some but labeled as “atypical psychosis”, “schizoaffective disorder” or “delusional disorder” considering the lack of better diagnostic criteria. Kraepelin's described a disorder similar to modern day paranoid schizophrenia, with fantastic delusions and hallucinations, but with less cognitive deterioration and much better affective functioning. Personality was less deteriorated, volition was less impaired and behaviour was less disturbed. Patient's ability to communicate with others and demonstrate rapport and affective warmth remained fairly good.

*Objectives.*– To do a non-systematic literature review about the historical concept of paraphrenia and to present the case of a patient with systematized delusions and hallucinations but good affective and cognitive functions.

*Methods.*– Review of the literature on the topic and description of the clinical case.

*Results.*– One hundred eighty-one articles were found. According to their relevance, 12 articles and 3 books were chosen.

*Conclusions.*– It is possible to define and recognize paraphrenia in patients who meet the current criteria for schizophrenia but do not show the affective and cognitive decline that the strict definition of early dementia requires. The prognostic implications of these cases are completely different from those in which deterioration occurs. We suggest that further research would help to clarify these diagnostic categories, in benefit of the patients.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Toxoplasmic encephalitis in an immunocompetent host during childhood followed by schizophrenia 17 years later**

M.M. Roser<sup>\*</sup>, J. Clauss, M.A. Zimmermann, P. Vidailhet, F. Berna  
Hôpitaux Universitaires de Strasbourg, Psychiatry, Strasbourg, France

\* Corresponding author.

*Introduction.*– Many studies reported an association between toxoplasmosis and schizophrenia. The neurobiological changes induced by *Toxoplasma gondii* in rodents and the links with the actual conception of the neurobiology of schizophrenia could be seducing.

However studies, or even case reports, demonstrating the anteriority of a toxoplasmic infection to a schizophrenia still missing.

*Material and methods.*– We examined the case of a patient with ultrasensitive schizophrenia who presented a toxoplasmic encephalitis during his childhood.

*Results.*– The 9 years old patient presented in 1973 acute psychotic symptoms after a few days of fever. Toxoplasmic encephalitis was diagnosed by seroconversion and a complete recovery was observed under antitoxoplasmic treatment. During 17 years after this infection, the patient did not present any psychotic features and developed later, in 1990 as he was 26 years old, chronic psychotic symptoms. There was no toxoplasmic seroconversion found in 1990. These symptoms always resisted to antipsychotics drugs (PANSS score = 96 with 12 items  $\geq 4$  under clozapine). Moreover, all EEG registered between 1973 and 2013 showed an irregular activity with intermittent delta or theta activity in the frontal derivations. The MRI, performed in 2013 at the age of 50, showed a moderate diffuse cortical atrophy with predominance in temporal lobes. MMSE score was 29/30 in 2013. The patient was immunocompetent, in particular HIV negative.

*Conclusion.*– Cerebral toxoplasmosis is a very rare presentation of *Toxoplasma gondii* infection in immunocompetent hosts. This case is the first case reported of a toxoplasmic infection preceding schizophrenia.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0825

### **Use of Transcranial Direct Stimulation (TDCS) in treatment of negative symptoms of schizophrenia**

M. Pontillo, F. Costanzo, R. Averna, O. Santonastaso<sup>\*</sup>, M.C. Tata, D. Menghini, S. Vicari  
IRCSS Bambino Gesù, Neuroscience- Child Neuropsychiatry Unit, Rome, Italy

\* Corresponding author.

*Introduction.*– Schizophrenia (SCZ) is a debilitating disease that affecting approximately 1% of the population. Most patients with schizophrenia have severe social, role and global functional impairment and poor quality of life. Negative symptoms are among the major determinants of this functional impairment and a significant proportion of patients with negative symptoms will continue to experience these symptoms despite antipsychotic medications. For example, negative symptoms like amotivation and affective flattening remain some of the most vexing challenges for effective treatment and improvement in outcome.

*Methods.*– This is a selective review of the literature published between 2011 and 2017 on use of TDCS in treatment of negative symptoms of schizophrenia. We included only studies where schizophrenia and negative symptoms were assessed using any psychometrically validated scale (e.g. SIPS/SOPS or CAARMS). Studies of participants with neurological conditions were excluded, as were those that did not report any symptom outcome variables.

*Results.*– Only five studies are included. Two studies showed a decrease of negative symptoms. In a case study, results showed a substantial reduction of positive and negative symptoms. The other studies did not showed any therapeutic effects of tDCS in the severity of positive and negative symptoms compared to controls.

*Discussion.*– Our findings are controversial and suggest that there is a need for further studies on the use of transcranial direct stimulation. Indeed, it should be considered a new complementary treatment option for reduction of negative symptoms in schizophrenia.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Psychosocial treatments: What patients say they need and what clinical psychologists can offer**

N. Semenova<sup>1</sup>\*, E. Kryukova<sup>2</sup>, N. Karabasheva<sup>2</sup>

<sup>1</sup> *Moscow Research Institute of Psychiatry MoH RF, Outpatient Psychiatry, Moscow, Russia;* <sup>2</sup> *Psychiatric Hospital No 3 Named after VA Hilyarovsky, Pathopsychology Laboratory, Moscow, Russia*

\* Corresponding author.

*Introduction.*– There is a growing body of evidence on the efficacy of psychological interventions for schizophrenia (Pilling S. et al., 2002).

*Objectives.*– This study examines the psychosocial treatment-related beliefs and perceived needs of patients, and proposes ways that clinical psychologists can help meet these needs.

*Methods.*– We constructed a concise mixed-method survey to assess patients' confidence and attitudes about psychosocial treatment, and perceived needs for additional support. An initial form of the survey was trialed on a small group of patients; suggestions for changes were included on the final version of the survey. Forced-choice and open-ended survey questions provided quantitative and qualitative data from  $n=12$  patients who were in the midst of implementing a psychosocial treatment in a large psychiatric hospital in Moscow.

*Results.*– The majority of patients perceived benefits (87 percent) as well as drawbacks (93 percent). Qualitative responses indicated that patients supported the idea of psychosocial treatment, but were ambivalent about implementing these practices. Patients' strongest need was for additional training.

*Conclusions.*– We conclude with suggestions based on our findings for how clinical psychologists can best support patients to implement more inclusive practices. Specifically, we suggest that clinical psychologists need to be more visible and proactive in supporting patients, and can positively influence greater inclusion by: (1) offering more psychosocial treatment options; (2) disseminating research that shows clinical benefits of psychosocial treatment; (3) developing realistic learning plans; and (4) listening to and advocating for patients.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0827

### **The role of aripiprazol on functional recovery of a patient with schizophrenia.– A Case Report**

A.S. Sequeira\*, R. Caetano Silva

*Centro Hospitalar de Lisboa Ocidental, Psychiatry and Mental Health Department, Lisboa, Portugal*

\* Corresponding author.

*Introduction.*– In schizophrenia-spectrum disorders a balance between symptom remission and functional recovery should be achieved. First-generation antipsychotics (FGA) are effective in positive symptoms control but may worsen negative and cognitive symptoms.

*Objectives.*– To report the case of a patient with schizophrenia difficult to manage due to symptom resistance and impaired psychosocial functioning, that achieved functional recovery after a switch from zuclopenthixol to aripiprazol.

*Methodology.*– We present the patient's clinical history, diagnostic investigation, therapeutic approach and clinical evolution. A research was performed in the "Pub Med" database with the terms "schizophrenia", "zuclopenthixol", "aripiprazol", "functional recovery".

*Results.*– We report the case of a 23 year-old man admitted to a psychiatry community team for reference and persecutory delusions, anhedonia, avolition, insomnia, social retirement and functional impairment. Symptoms began two years before. He was first medicated with olanzapine 10 mg/day with no response, then paliperidone 150 mg IM for 2 months with partial response and then zuclopenthixol 200 mg (each two weeks) with psychotic symptom remission. Although, one year later, he maintained marked social functioning impairment and complained of avolition, anhedonia and fatigue. He integrated a rehabilitative structure but couldn't engage in the proposed activities. A switch to aripiprazol 400 mg IM monthly was made with maintenance of psychotic symptom remission and improvement in social functioning. He was able to conclude a one-year internship in a rehabilitative structure with success.

*Conclusions.*– We propose that a switch from FGA to aripiprazol can have a positive impact on psychosocial functioning of patients with schizophrenia.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Pathology of the psychic sphere in patients with epilepsy, revealed by psychiatrist of the regional consultative center of the Subarctic Territory**

L. Shapovalova<sup>1</sup>\*, K. Shapovalov<sup>2</sup>

<sup>1</sup> *State Autonomous Health Agency of the Republic of Komi "Consultative and Diagnostic Center of the Republic of Komi", Diagnostic department, Syktyvkar, Russia;* <sup>2</sup> *State Education Agency of Additional Professional Education of Republic of Komi "Komi Republican Institute for Development of Education", Chair of Additional Education, Syktyvkar, Russia*

\* Corresponding author.

*Introduction.*– Epilepsy is a global problem. In the structure of the overall incidence, it ranks third (after diabetes mellitus), and in the structure of neurologic morbidity - 19.0%.

*Objectives.*– The pathology of the mental sphere was analysed in 1312 patients with epilepsy examined by the outpatient psychiatrist of the regional consultative center of the subarctic territory

*Methods.*– Analytical, statistical

*Results.*– In the structure of the pathology of the mental sphere in epileptic patients, the first three ranked places are occupied by (F00-F09): F06.7. Light cognitive disorders -  $26.4 \pm 1.2\%$ ; F07 Personality disorders  $23.4 \pm 1.2\%$ ; F06.6 Organic emotionally labile (asthenic) disorders  $19.9 \pm 1.1\%$ . They account for up to 69.7% of all types of nosological forms detected annually. Then follows: F06.4 Organic anxiety disorders -  $12.1 \pm 0.9\%$ ; F06.362 Nonpsychotic depressive disorders -  $10.5 \pm 0.7\%$ . Less common diagnoses are: F04 Organic amnesic syndrome -  $3.9 \pm 0.5\%$ ; F01 Dementia -  $3.8 \pm 0.5\%$ .

*Conclusions.*– The revealed mental pathology in patients with epilepsy allows the psychiatrist to correct its unfavorable course, reduce the negative effect of epileptic seizures on the brain, the frequency of mental changes and the potential danger of seizures for patients and others. This allows you to solve the problems of epilepsy patients concerning work, car driving, family relationships and offspring.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0829

### **Are the negative SCH symptoms more severe with longer duration of illness?**

R. Softic<sup>1\*</sup>, E. Becirovic<sup>2</sup>, A. Sutovic<sup>2</sup>, E. Avdibegovic<sup>2</sup>, M. Mirkovic Hajdukovic<sup>2</sup>, E. Osmanovic<sup>3</sup>

<sup>1</sup> Clinical Center University of Sarajevo, Department of Psychiatry, Sarajevo, Bosnia - Herzegovina; <sup>2</sup> University Clinical Center Tuzla, Department of psychiatry, Tuzla, Bosnia - Herzegovina; <sup>3</sup> Heart Center, Invasive cardiology, Tuzla, Bosnia - Herzegovina

\* Corresponding author.

*Background.*– Despite the fact that negative symptoms are among the central manifestations of schizophrenia, they are less known aspect of illness. Negative symptoms referes to loss of function, and they are associated with poor outcome. It is considered that they are more prominent with longer duration of illness.

*Aim.*– To determine negative symptoms in patients with schizophrenia and compare it with duration of illness.

*Subjects and Methods.*– A cross-sectional study was conducted on 60 consecutive outpatients with schizophrenia. Two groups were formed regarding the duration of illness ( $\leq 2$  years, and  $>3$  years). The negative symptoms were established with Brief negative symptoms assessment - BNSA.

*Results.*– Average score of negative symptoms in the group with shorter duration of illness was  $8.37 \pm 2.94$ , and in the group with longer duration was  $10.73 \pm 2.86$ . Independent Samples Test was significant  $P=0.003$ ,  $t=-2.367$ , and therefore difference of scores on BNSA within groups were significant. Moderate size effect was found ( $d 0.69$ ).

*Conclusion.*– Negative symptoms of schizophrenia are more severe with longer duration of illness.

*Keywords:* Schizophrenia; Negative symptoms; Duration of illness

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The article gives an in-depth discussion on hebephrenic schizophrenia and aberrant decussation of the pyramidal tracts of the spinal chord**

H. Solomons

University of the Witwatersrand, Psychiatry, 30 Viljoen st, South Africa

Hebephrenic schizophrenia appears to be associated with aberrant decussation of the pyramidal tracts of the spinal cord.

Schizophrenia is a multiperson personality disorder characterised by auditory and visual hallucinations.

Patients with hebephrenic schizophrenia have been found to have aberrant decussation of the pyramidal tracts of the spinal chord.

Hebephrenic schizophrenics suffer from delusional disorders and often suffer from suicidal ideation.

With the DSM classification hebephrenic Schizophrenia is now classified as a DSM IV disorder.

Aberrant conduction disorders result in mood disorders characterised by thought disorders and altered serotonin and noradrenalin levels.

This may well be a genetic manifestation of hebephrenic schizophrenia but the primary abnormality appears to be aberrant decussation of the pyramidal tracts in the spinal chord !

Mood disorders are frequent and patients are unkempt and disheveled.

Frequently they cannot keep a job and spend the day ruminating and staring at inanimate objects.

Their actions are directly opposed to catatonic schizophrenics with multiple schizoaffective disorders pervading their every thought.

The pyramidal tracts decussate in an abnormal fashion and hebephrenics frequently cannot account for themselves. They cannot formulate a sentence and they confabulate making them difficult to follow.

They have guttural utterances and may stammer and stutter.

Suicidal ideation pervades their every thought and they tend to overdress in cold situations.

Their appearance is slack and they lack motivation.

Delusional disorders and grandiose thoughts are the norm.

They have psychomotor poverty and have difficulty in expressing their emotions.

This is all related to abnormal decussation of the pyramidal tracts of the spinal cord!

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

Major morphological abnormalities in schizophrenia converge on the anterior insula (AI) and anterior cingulate cortex (ACC). The study aimed to determine impaired cellular metabolism in left (LAI); right (RAI) anterior insula and pregenual ACC (pgACC) and longitudinal morphological CNS changes in first-episode schizophrenia spectrum patients (FES). During one MRI session, 1H-MRS at 3T was performed in the AI and pgACC on the largest sample of FES examined by MRS to date and healthy controls (HC). Additionally, longitudinal VBM was analysed in FES between baseline and one year after first scan. Concurrently, resting state functional connectivity analysis of pgACC region was performed in patients. FES showed significantly increased Cho in AI in favour of RAI, and reduced NAA in pgACC in comparison to HC. During the course of illness, GM pathology was detected within brain areas that precisely overlap with functional connectivity network of pgACC. The findings are explained in terms of recently proven intrinsic network-based pathophysiology observed in neurodegeneration in general. Incipient microscopic pathology typically starts within small neuronal populations positioned in central nodes of the brain's network architecture in those disorders. Further in the course, progression of pathology subsequently follows a pathological system model that is best characterized by a cascading network failure (CNF). Our results suggest CNF in schizophrenia as well. During the course of illness, the GM reduction shows spatiotemporal progression in a topographically predicted manner selectively through functional connections of pgACC. The study was supported by the Ministry of Health Czech Republic, grant number 16-32696A

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

*Introduction.*– In a comprehensive phenotype determination research we have built our work on the knowledge that mental disorders are accompanied by specific anomalies of the linguistic and cognitive functions.

*Objectives.*– A detailed differential analysis of the linguistic functions' disorders between the acute and compensated states of four patients with bipolar type schizoaffective disorder, bipolar disorder and schizophrenia.

*Methods.*– Clinical assessment was made using PANSS, SANS, YMRS, and MADRS scales. Neuropsychological mapping was done using WCST, Miyake-, Stroop-, VPT, Digit Span (forward/backward), Non-word repetition, Listening Span, ToM False Belief, MMSE, and Clock-drawing tests. For linguistic mapping we tested temporal features of spontaneous speech phonemic fluency, semantic fluency, action naming fluency, discourse organization, narrative intelligence and identity. The intra- and interindividual comparisons were based on qualitative and quantitative analyses.

*Results.*– Cognitive assessments and fluency tasks demonstrated statistically similar performances in both phases (probably due to the small number of elements), although subjects performed better in the remission phase. We found more remarkable differences in some of the temporal features (articulation and speech tempo, hesitation rate) of schizophrenic subject. We observed differences in the narratives the patients have produced: (switching of) perspective, integration, and causality were significantly poorer in the acute phases for all four patients; organization, coherence, recursion, and eventfulness were occasionally more organized and more detailed.

*Conclusion.*– Our findings suggest that in the acute phase phonemic aspects, semantic fluency, some narrative features and mentalization were impaired, regardless of the diagnosis.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Vitamin D supplement therapy among hospitalized patients with psychosis spectrum disorder: Clinical and therapeutic correlates**

C. Niolu<sup>1</sup>, A. Talamo, E. Caporusso, F. Di Michele, P. Brogna, A. D'argenio, A. Paterniti, A. Facchi, V. Infante, D. Liberato, D. Miri Lavasani, A. Pomilio, L. Tomassini, A. Siracusanò  
Tor Vergata Hospital, Department of Systems Medicine, Roma, Italy

\* Corresponding author.

*Introduction.*– Vitamin-D plays an important role in calcium homeostasis, bone metabolism as well as in several metabolic-processes, immune responses, and regulating neurotropic, neuroprotective processes, neurotransmission and synaptic plasticity. Recent studies have shown vitamin-D deficiency in patients with psychiatric disorders as well as hypovitaminosis-D as risk factor for schizophrenia.

*Objective.*– We compared Vitamin-D-low-level psychosis-spectrum-disorder patients with and without Vitamin-D-supplement-therapy (VitDTx vs. Tx) by symptom-severity, length of hospitalization (LOS) and psychopharmacological-treatment.

*Methods.*– After written informed consent was obtained, we included 19-patients (VitDTx  $n=8$  [Women  $n=5$ , 62%; Mean-age 40.7 SD12.4] vs. Tx  $n=11$  [Women  $n=4$ , 36%; Mean-age 35.9 SD13.2]) diagnosed with psychosis-spectrum-disorder and low-level-Vit-D in the study. They were consecutively hospitalized (January-June2017) at the Acute-Psychiatric-Unit "Policlinico Tor Vergata "Hospital, Rome, Italy. The Brief Psychiatric Rating Scale (BPRS) and the Positive and Negative Symptoms Scale (PANSS) were used to evaluate symptom-severity. Calcitriol 0.5mcg qd-po was given as Vitamin-D-supplement-therapy.

*Results.*– VitDTx-patients had LOS of 13days vs. Tx-patients 16days; the admission BPRS-score of VitDTx-patients was 58.5vs.68 of Tx-patients; the discharge BPRS-score of VitDTx-patients was 36vs.42 of Tx-patients; the admission PANSS-score of VitDTx-patients was 89.5vs.94 of Tx-patients; the discharge PANSS-score of VitDTx-patients was 53vs.61 of Tx-patients; the discharge CPZEq dose of VitDTx-patients was 425vs.279 of Tx-patients. Moreover, we found the discharge LiEq-dose of VitDTx-patients was 883vs.1219 of Tx-patients (all  $P>0.05$ ).

*Conclusions.*– VitDTx vs. Tx-groups were not significantly different, most likely, because of small sample size. However, this is one of few studies evaluating inpatients with psychosis, Vitamin-D-supplement-therapy and clinical-therapeutic correlates. Further, insight into the role of vitamin-D, in psychosis, might help to shed light on the underlying pathophysiology and aid the design of better treatment strategies (i.e. controlled trials and longitudinal studies) for the twenty-first-century.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Gender differences in first episode psychosis patients**

T. Teodoro<sup>1,2,3\*</sup>, T. Filipe<sup>1</sup>, M. Teles Martins<sup>1</sup>, I. Pinto<sup>1</sup>, M.J. Avelino<sup>1</sup>, S. Garcia<sup>1</sup>, R. Mateiro<sup>1</sup>, J. Salgado<sup>1,2</sup>

<sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry Department, Lisbon, Portugal; <sup>2</sup> NOVA Medical School/Faculdade de Ciências Médicas, Clinical Medicine Department, Lisbon, Portugal; <sup>3</sup> CEDOC - Chronic Diseases Research Center, Integrated Pathophysiological Mechanisms, Lisbon, Portugal

\* Corresponding author.

*Introduction.*– The clinical heterogeneity of psychotic disorders is well established in literature. Gender differences in schizophrenia and first episode psychosis have been the subject of several studies but further understanding of such differences could be an important contribution to an increasingly personalized approach to patients especially in the earlier stages of psychotic disorders.

*Objectives.*– Characterize gender differences in a group of inpatients admitted to a First Episode Psychosis Unit.

*Methods.*– 71 patients admitted to our service between 2016 and 2017 were included in this study (41 males; 29 females). Sociodemographic data, duration of untreated psychosis, substance use,

duration of admission, family history and other clinical data were collected from records. Statistical analysis was performed using SPSS version 25. A significance level of  $P < 0.05$  was used.

**Results.**– There was a statistically significant gender difference in average age (Male average age 26,63; Max. 51; Min. 14; SD 9/Female average age 40,52; Max. 72; Min. 20; SD 15;  $P < 0.001$ ); marital status (Single males 78%/Single females 41%;  $P = 0,04$ ); tobacco use (Males 61%/Females 10%;  $P < 0.001$ ); cannabis use (Males 76%/Females 21%;  $P < 0.001$ ); cocaine use (Males 20%/Females 3%;  $P = 0,04$ ). In the remaining variables there weren't statistically significant differences between genders. Olanzapine and risperidone were the most frequently selected oral antipsychotic drugs as initial treatment in both genders.

**Conclusion.**– Our results are consistent with some of the available data from other studies although significant differences were noted. Further studies exploring differences between clinical profiles of first episode psychosis patients are important to improve the care provided to these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Current prescription practices of antipsychotics in the treatment of psychotic disorders in a psychiatric hospital of Nancy**

J. Tournebise<sup>1\*</sup>, D. Dobre<sup>2</sup>, V. Gibaja<sup>1</sup>, G. Didon<sup>1</sup>, J.P. Kahn<sup>3</sup>

<sup>1</sup> Nancy University Medical Center, CEIP-Addictovigilance - French Addictovigilance Network, Nancy, France; <sup>2</sup> Centre Psychothérapique de Nancy, Medical Information Department, Nancy, France; <sup>3</sup> Nancy University Medical Center, CEIP-Addictovigilance - French Addictovigilance Network - Université de Lorraine, Nancy, France

\* Corresponding author.

**Introduction.**– The prescription of antipsychotics, and in particular, second-generation antipsychotics (SGAs), has substantially increased in recent years. Despite treatment guidelines usually recommending that SGAs are preferable and should be used as monotherapy, available literature revealed frequent use of first-generation antipsychotics (FGAs), polypharmacy, and use of antipsychotics at lower than recommended doses. Minimal data exist regarding antipsychotic use in French psychiatric hospitals.

**Objectives.**– The aim of this study was to assess antipsychotic prescribing practices in the treatment of psychotic disorders and to compare them with guidelines.

**Methods.**– Retrospective cohort study utilizing the hospital database of Centre Psychothérapique de Nancy from 01/01/2015 through 12/31/2015. Only patients with diagnosis for psychotic disorders and with at least one antipsychotic prescription were included.

**Results.**– 204 patients (92 inpatients and 112 outpatients) were included. The majority of patients were men (65.2%,  $45.7 \pm 15.3$  years). In inpatients, the FGAs (58.8%) were the most prescribed and 62.5% were treated with antipsychotics in combination with other antidepressant medications. Multiple antipsychotics were present in 66.3% of prescriptions.

Although the majority of outpatients (56.3%) received at least one SGA, 43.8% were prescribed more than one antipsychotic and 70 (62.5%) patients were prescribed antidepressant agents in addition to antipsychotics. Multiple antipsychotics were present in 26.8% of prescriptions.

The use of antipsychotics at lower than recommended doses was also observed in inpatients (23%) and outpatients (29%).

**Conclusion.**– Current clinical practice differs from guideline recommendations. Patients frequently received FGAs in combination

therapy and at doses below the recommended guidelines for the management of psychotic disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Examination of “Anomalous World Experience” (EAW), “Subjective Attention Error Evaluation” (ESEA) and “Frankfurt Complaints Questionnaire” (FCQ) in schizophrenia: Conceptual correspondence**

M. Vargas<sup>1,2\*</sup>, N. Jimeno Bulnes<sup>3</sup>, I. Legascue de Larrañaga<sup>2</sup>, R. Molina<sup>4</sup>

<sup>1</sup> Complejo Asistencial de Zamora, Psychiatry, Valladolid, Spain; <sup>2</sup> GINCS, Psychiatry, Segovia, Spain; <sup>3</sup> Universidad de Valladolid, Psychiatry, Valladolid, Spain; <sup>4</sup> Fundación Alcorcón. Universidad Rey Juan Carlos, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Examination of Anomalous World Experience (EAW) [1] is a new instrument for the semi-structured evaluation of schizophrenia subjective experiences. Subjective Attention Error Evaluation (Spanish “Evaluación Subjetiva de Errores Atencionales” (ESEA)) [2] explores subjective anomalous schizophrenic experiences assuming a neurocognitive disorder of the attention cognitive control. EAW and ESEA are both based on phenomenology. EAW lists 75 specific items, grouped in six domains: Space and objects, time and events, other persons, language, atmosphere, and existential orientation. ESEA is composed by thirteen items grouped in three factors: Subjective deficits, perceptive intrusions and cognitive-motor automatisms. Frankfurt Complaints Questionnaire (FCQ) [3] is a self-applied instrument composed of 98 items and six complementary coping strategies. EAW, ESEA and FCQ share basic symptoms theory.

**Objectives.**– To propose a conceptual equivalence framework between EAW, ESEA and FCQ.

**Methods.**– Four expert psychiatrists in basic symptoms theory were asked to determine conceptual equivalences between the items of the three instruments. The criteria for doing that were the respective manuals and their clinical experience. Responses were blinded between them. In a second moment, discrepancies were reaching a consensual agreement.

**Results.**– A table of equivalences is presented.

**Conclusions.**– EAW, ESEA and FCQ are complementary instruments in the phenomenological evaluation of schizophrenia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Role of cognitive control on reward and loss anticipation: An electrophysiological evaluation in schizophrenia**

A. Vignapiano<sup>1</sup>, A. Mucci, E. Merlotti, G.M. Giordano, A. Amodio, P. Bucci, S. Galderisi

University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

\* Corresponding author.

*Introduction.*– Cognitive and motivational impairments are core clinical features of schizophrenia and have been reported among predictors of real-life functioning. A crucial aspect of cognitive deficit is the impairment of cognitive control, or the ability to flexibly adjust behaviour in accordance with one's intentions and goals. The role of the anterior N2 component of event-related potentials (ERPs), as a correlate of motivational-based cognitive control, has been assessed in many study, but never explored in subjects with schizophrenia (SCZ).

*Aims.*– We investigated the effects of reward and loss avoidance anticipation on N2 in a group of SCZ and one healthy controls (HC), in order to explore whether reward- and avoidance-based motivation has a different impact on this ERP component in the two groups.

*Method.*– ERPs were recorded during the execution of the Monetary Incentive Delay task in 34 SCZ stabilized on second-generation antipsychotics and 22 HC. Neurocognition, negative domains (avolition/apathy and expressive deficit), positive and disorganization dimensions were also assessed in SCZ.

*Results.*– No group differences were observed in N2 amplitude or latency. In the HC group, N2 amplitude was significantly larger for anticipation of large punishment than reward and for all incentive conditions than neutral one; while in SCZ it didn't discriminate motivational relevance. N2 amplitude was not correlated with psychopathological dimensions and cognitive deficits in SCZ.

*Conclusion.*– Our data evidenced an impact of salience-based motivation on cognitive control only in HC. Findings observed in SCZ suggest that the discrimination of motivational value is impaired, independently of psychopathology and cognitive deficits.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Illness causal beliefs in a population of french close relatives of persons experiencing schizophrenia and spectrum disorders**

M. Villani<sup>1\*</sup>, V. Kovess - Masféty<sup>2</sup>

<sup>1</sup> Fondation Pierre Deniker, Recherche, Paris, France; <sup>2</sup> Fondation Pierre Deniker, Recherche, Rennes, France

\* Corresponding author.

*Introduction.*– Parents' illness causal beliefs influence their care behaviour and, in turn, outcomes in their relative experiencing schizophrenia or schizophrenia spectrum disorders. Yet, in France, the evaluation of the Psychiatry and mental health plan 2011-2015 showed that associations were very disappointed by the slow progress in families integration in mental health care. How well informed are French close relatives taking care of a person experiencing schizophrenia about probable causes of the illness? What is their own opinion?

*Objective.*– Our objective is to describe and explore illness causal beliefs of close relatives of persons experiencing schizophrenia.

*Methods.*– We used a semi-structured interview assessing close relatives' level of information about the illness, as well as the Causal item of the Brief Illness Perception Questionnaire.

*Results.*– Our sample is constituted of 27 close relatives of persons experiencing schizophrenia. Our results show that, even if 76,64% had had communication of the diagnosis of their relative, probable causes had been explained to only 42,3% of them. In order to find more information, 48,36% had followed psychoeducation trainings. Genetic was ranked by a majority in our sample as the first probable cause of the illness, shortly followed by substance abuse. Among the other possible causes, trauma and a stressful family environment were the most frequently cited.

*Conclusions.*– After having discussed associations with education, level of information, and psycho-education, we conclude that; being one of the factors influencing type of care behaviour, close relatives' illness causal beliefs should require more attention from health professionals.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0839

### **Differences in illness perceptions in french persons experiencing schizophrenia or schizophrenia spectrum disorders and their close relatives**

M. Villani<sup>1,2\*</sup>, V. Kovess - Masféty<sup>1,2,3</sup>

<sup>1</sup> Fondation Pierre Deniker, Recherche, Paris, France; <sup>2</sup> Université Paris Descartes, Laboratoire Psychopathologie et processus de santé-Ea4057, Boulogne - Billancourt, France; <sup>3</sup> EHESP, Professor, Rennes, France

*Introduction.*– Discrepant illness perceptions between persons experiencing schizophrenia or schizophrenia spectrum disorders and their close relatives are related to greater anxiety, depression and lower self-esteem in the first, and greater distress in the second. On the contrary, it was established that family psycho-education reduces relapse rate in persons experiencing schizophrenia, and depression symptoms in parents.

*Objective.*– In this context, our objective is to compare illness perceptions of French persons experiencing schizophrenia and close relatives, and to explore the determinants of discrepancies.

*Methods.*– We used a semi-structured interview and a widely used standardized measure assessing negative perceptions about physical or mental illness, the Brief Illness Perception Questionnaire, in its French validated version.

*Results.*– Our results show significant discrepant perceptions of illness between persons experiencing schizophrenia and their close relatives, in particular in terms of emotional and practical consequences on the person experiencing schizophrenia, personal control of the latter on the course of the illness, probable duration of illness, and faith in treatment efficiency.

*Conclusion.*– After having discussed determinants of these differences, we conclude that discrepancies of illness perceptions between persons experiencing schizophrenia and their close relatives should be assessed at onset and then on a regular basis. Further research would be needed to confirm our results and explore how these discrepancies can best be addressed.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Supported employment and functional outcome in serious mental illness—a review

V. Viveiros<sup>1</sup>, T. Vinhas de Sousa<sup>2</sup>, C. Costa<sup>1</sup>, D. Pereira<sup>1</sup><sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal; <sup>2</sup> Hospital Prisional São João de Deus, Psychiatry, Lisbon, Portugal

\* Corresponding author.

The high rates of unemployment and underemployment among individuals with psychiatric disabilities represent a strong negative impact on quality of life and on the further course of the disease. It also constitutes an impact on mental health costs. For these reasons, there is an increasing interest on understanding the importance of supported employment in the outcome of patients with serious mental illness.

The authors carried out a literature search, with the aim of investigating the barriers to employment for people with serious mental illness (individual, environmental and program factors) and the functional outcome of the individual placement in an evidence-based employment. Overall, the current review is consistent with earlier papers, although here was emphasized that efforts should also be directed towards new populations in order to understand the impact of supported employment in bipolar and schizoaffective disorders.

### Comparison of effectiveness of antipsychotics in schizophrenia in South Asian population: Second-generation versus the first-generation

U. Zubair<sup>1</sup>, A. Ali<sup>2</sup>, R. Taj<sup>1</sup><sup>1</sup> PIMS- SZAMBU, Psychiatry, Islamabad, Pakistan; <sup>2</sup> Poonch Medical College Rawalkot AJK, Psychiatry, Rawalakot, Pakistan

\* Corresponding author.

**Introduction.**— Antipsychotic medications are the first line treatment for schizophrenia. Two group of drugs are generally used, 1<sup>st</sup> and the 2<sup>nd</sup> generation. Despite many trials there is still a debate regarding superiority of one group depending upon the efficacy and side effect profile.

**Objective.**— To compare the efficacy of the 1<sup>st</sup> & 2<sup>nd</sup> generation antipsychotics for the treatment of schizophrenia.

**Methods.**— This RCT was conducted at in/out patient department of Psychiatry at a tertiary care hospital of Pakistan over the period of six months. All the patients of schizophrenia between 18-50 years of age were included in the study. Each patient was assessed with the Simpson-Angus Scale (SAS) for the EPS and the Positive and Negative Syndrome Scale (PANSS) for the schizophrenia at the baseline, 06 weeks and 12 weeks after starting the designated medication.

**Results.**— The overall response of 1<sup>st</sup> Generation & 2<sup>nd</sup> Generation antipsychotics was 51(140) 36% and 135 (210) 64% respectively (P-value = 0.00024). 63 (45%) patients who were taking 1<sup>st</sup> Generation Antipsychotics had relapse of the disease as compared to the 29(13.7%) patients who were taking the 2<sup>nd</sup> Generation antipsychotics. Dryness of mouth, sedation and EPS were the common side effects with the 1<sup>st</sup> generation antipsychotics while dryness

of mouth, cardiac arrhythmias, and sexual dysfunction were the common side effects with the 2<sup>nd</sup> generation antipsychotics.

**Conclusion.**— This study concluded that the 2<sup>nd</sup> generation antipsychotics were superior to the 1<sup>st</sup> generation antipsychotics among the patients of schizophrenia in terms of the success rate, relapse rate and the tolerability.

### Spiritual intelligence in gender identity disorder patients and control group

S. Arya<sup>1</sup>, M.R. Najrzadegan<sup>1</sup>, H. Taghizadeh Aboozar<sup>2</sup><sup>1</sup> Iran University of Medical Sciences, Mental Health Research Center, Tehran, Iran; <sup>2</sup> Kish International Branch, Islamic Azad University, Kish, Iran

\* Corresponding author.

**Introduction.**— Spiritual intelligence influences mental health disorder patients like gender identity disorder (GID). According to our religious country, Iran, we have insufficient documentation on gender identity disorder patients that are necessary for their treatment. **Objectives.**— To compare spiritual intelligence in Gender identity disorder patients and control group.

**Methods.**— This cross-sectional study was conducted on 30 gender identity disorder patients and 30 age-matched controls that were ruled out axis I and axis II disorders. Spiritual intelligence is assessed by the King Questionnaire 2008 (The spiritual intelligence self-report inventory- SISRI 24) in 4 subscales: Critical Existential Thinking (CET), Personal Meaning Production (PMP), Transcendental Awareness (TA) and Conscious State Expansion (CSE). Data were analysed by t-test.

**Results.**— The results show that the mean spiritual intelligence was significantly lower in gender identity disorder patients ( $P=0.012$ ). Controls had significantly higher scores in the fields of critical existential thinking and transcendental awareness than patients with Gender Identity Disorder ( $P=0.022$  and  $P=0.004$ , respectively). However, in personal meaning production and conscious state expansion, the differences between two groups were not significant ( $P=0.061$  and  $P=0.125$ , respectively).

**Conclusion.**— Gender identity disorder seems to be associated with lower spiritual intelligence. Due to religious restrictions in Middle Eastern countries, further investigations are needed for evaluating the efficacy of spiritual intervention in the treatment of these patients—especially in reducing their guilt feelings.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

### Structure of affective disorders and sexual dysfunctions

T. Butkova<sup>1</sup>, N. Kibrik

Moscow Research Institute of Psychiatry, Sexology, Moscow, Russia

\* Corresponding author.

**Relevance.**— The structure and severity of affective disorders, mainly in the form of depressive disorders, affect the nature of sexual dysfunctions, which manifest themselves either as a reduction of

sexual activity, or as a complete lack of libido. Affective disorders in the context of sexological dysfunction often lead to suicidal attempts, and also change the clinical picture of the manifestation of the underlying disease.

**Objective.**– the importance of early diagnosis and adequate therapy of psychophysiological disorders in the structure of affective disorders increases.

**Materials and methods.**– Clinical methods, which included the study of somatic status, include gynecological in women and urological in men, the mental status examination.

**Results and discussion.**– were examined in 109 patients, aged 18 to 50 years old. The findings suggest that with anxiety-phobic disorders accompanied by fear and the desire to avoid a traumatic situation, due to the expectation of sexual failure, social isolation is formed with erotic fantasies and autoeroticism. Of special interest are asthenic disorders, which mainly influence the parameters of sexual manifestations, resulting in the weakening of erection or change of the duration of sexual intercourse and also coloring orgasmic sensations. Psychologically emotional reactions of anger, resentment, misunderstanding and loneliness that arise in conflict families accompanied by family and sexual disharmony sexual disorders associated with sexual disorder and abstinence.

**Conclusion.**– The positive effect of the treatment was based on the improvement of sexual dysfunctions in the form of: Increased libido, restoration of erection, ejaculation, acuity of orgasmic sensations, against the background the with drawal of anxiety, improvement in mood, memory, attention, fatigue, anxiety, fear, depression, reduction of neurotic symptoms

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Hypolibidemiya in patients with chronic dermatoses**

N. Dobaeva<sup>1</sup>\*, N. Kibrik<sup>2</sup>

<sup>1</sup> Russian society of psychiatrists, Department of Sexopathology of Moscow scientific-research Institute of Psychiatry., Moscow, Russia; <sup>2</sup> EPA, Department of Sexopathology of Moscow scientific-research institute of psychiatry., Moscow, Russia

\* Corresponding author.

**Introduction.**– Assessment of the effects of chronic dermatoses on sexual function is a topical issue. Underestimation of the psychosomatic and sexological status of these patients significantly decreases of treatment.

**Study objective.**– Identification of clinical variants of sexual dysfunction in patients with chronic skin diseases using investigations commonly employed in sexological practice.

**Materials and methods.**– The study enrolled 98 patients suffering from psoriasis and neurodermatitis, aged 18 to 40 years, who underwent clinical-psychopathological, psychological, and sexological evaluations, DLQI and the SCORAD.

**Results and discussion.**– Hypoactive sexual desire disorders was observed in 33 subjects (33.7%): 19 of them male (57.6%) and 14 female (42.4%). These patients had decreased libido, lack of confidence in their sex appeal, depressed moods, and asthenia. There were changes in sexual dysfunction, which were manifested by ejaculation and erection disturbances in men. Decreased libido was observed afterwards, as affective and neurotic disorders set in. In female patients of this group, decreased libido was characterized by the absence of any wish to have sex, deterioration of sexual reactions associated with intercourse, and reduction of sexual tension, coital anorgasmia. Psychiatric disorders were detected in this study group: 51.5% of these patients had a combined anxiety and depres-

sion disorder (F41.2), while dysthymia (F34.1) and hypochondriasis (F45.2) were practically equally common in 48.5% of them.

**Conclusions.**– Obtained data helped formulate a differentiated approach to the psychopharmacological, psychotherapeutic, and sexological correction of mental disorders and sexual disturbances that the described patient population has to receive along with dermatological treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0845

### **Socjodemographic profile of transsexual patients in Poland**

M. Zajackowska, M. Filip, P. Galecki\*, A. Orzechowska  
Medical University of Lodz, Department of Adult Psychiatry, Łódź, Poland

\* Corresponding author.

**Introduction.**– Broadening and popularizing knowledge about the determinants of transsexuality in medical and non-medical communities play an important role in shaping the positive attitudes, tolerance and respect towards persons suffering from this condition and also enables them to receive a proper medical and psychological help. Patients would also benefit from improved diagnostic, therapeutic and legal processes related to the gender change in Poland.

**Objectives.**– The aim of the study is sociodemographic characteristics of the group affected by transsexuality in Poland.

**Methods.**– Study includes a retrospective analysis of medical record of patients (in the period from 2009-2015) aged 18 and above, both sexes, with definitive transsexual diagnosis (ICD 10-F64), treated in the Mental Health Clinic and the Pathology of Intimacy Clinic in Lodz. One group of approximately 136 participants and no control group was created. The obtained data was analysed statistically.

**Results.**– Of the 136 participants in the study, 30 were diagnosed with transgender type - MtF (22.05%) and 106 - FtM (77.94%). The age range in the study was wide. The oldest person was 53 years old, the youngest was 17 years old (M=25.57, SD=7.89). The study also included the number of years of treatment (attendance at the clinic) - maximum 24 years, minimum less than 1 year (M=5.34, SD=4.58).

**Conclusions.**– Gathering and analysis of sociodemographic data is important for elucidating the transsexual patient's profile. It facilitates better understanding, timely recognition and choice of appropriate treatment for these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0846

### **Effectiveness of cognitive behavioral techniques on the coital anorgasmia induced by idiosyncratic masturbatory syndrome; a male case report**

S.D. Mohammadi  
Qom University of Medical Sciences, Kamkar Arabia Hospital, Qom, Iran

**Introduction.**– Although formal psychiatric classifications of mental disorders such as DSM and ICD have not recognized masturbation as a pathological type of sexual outlet, however some atypical kinds of practicing it called idiosyncratic may later cause coital sexual dysfunctions such as anorgasmia, delayed orgasm and impotency for men.

**Objectives.**– Main aim was experiencing of coital orgasm for the patient.

**Method.**– Cases were 5 men between 25–33 years, newly married, referring to Novid Psychiatric Clinic (Shiraz City– Iran) with the chief complain of not experiencing orgasm during coitus. Ten to twenty years of prone-position masturbating and 5–15 years of using porn and porn fantasies to being excited sexually was recorded. A course of 20 sessions of CBT during 6 months was executed encompassed psych-educational sessions, assigning periodical abstinence distances, changing masturbation to more vaginal-like procedures such as hand masturbation, gradual sensitization to partners' body/vagina and sexual coitus and restoring and reconditioning of penis to less harsh stimulations.

**Results.**– The patients could replace prone-position masturbation with other ways of stimulation after 2–3 months of treatment while it last another 2–4 months to be quite competent with getting orgasm during intercourse and changing many distorted cognitions about sex remained from porn using.

**Conclusions.**– While mental health experts and even sex therapist do not consider masturbation as a pathological way of sexual outlet, more individuals particularly men come to clinics due to dysfunctions resulted from unusual ways of masturbation, in recent years. Role of pornography in producing these symptoms is obvious, also. **Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Sexual dysfunction as an important factor in treatment abandonment in patients taking antidepressants: A case series**

G. Pardo de Santayana

Hospital Universitario Marques De Valdecilla, Psychiatry, Santander, Spain

**Introduction.**– Sexual dysfunction is an important reason for treatment abandonment in patients that are taking antidepressants. Frequently, sexual dysfunction is not detected by the medical team because patients will not share with their doctors this kind of information out of embarrassment.

**Aim.**– Studying the prevalence of sexual dysfunction in patients in treatment with antidepressants.

**Methods.**– This is a descriptive study of a sample consisting of 35 patients who attended our psychiatric consultation from March to August 2017. Patients were between 18 and 65 years old and in treatment only with one antidepressant. We compared the prevalence of patients who claimed spontaneously to have sexual dysfunction, in relation to the amount of patients that admitted having it only when actively asked about this matter. The presence of sexual dysfunction was assessed using the PRSexDQ-SALSex.

**Results.**– Out of the 35 patients in treatment with antidepressants, 19 reported sexual dysfunction (54.2%) when asked. Only 6 of them (17.1% of the total sample and 31.5% of those with sexual dysfunction) reported sexual dysfunction spontaneously.

**Conclusions.**– It is essential for all doctors and psychiatrist in particular to ask their patients in treatment with antidepressants if they are having sexual dysfunction because an important percentage of them will have some level of dysfunction and only a minority of them will report it spontaneously.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0848

### **Vortioxetine as a treatment alternative in patients with sexual dysfunction induce by other antidepressants: A case series**

G. Pardo de Santayana

Hospital Universitario Marques De Valdecilla, Psychiatry, Santander, Spain

**Introduction.**– Sexual dysfunction is a frequent secondary effect of antidepressants and can have an important impact on the patient's relationships, quality of life and adherence to treatment. The prevalence of sexual dysfunction associated with antidepressants varies greatly between different studies, making it complicated to estimate the accurate number of patients that suffer it. Vortioxetine is one of the antidepressants with lower percentage of antidepressant-associated sexual dysfunction.

**Aim.**– Studying whether Vortioxetine is a good alternative in patients with antidepressant-associated sexual dysfunction.

**Methods.**– This is a descriptive study that pretends to assess the effect in sexual function of switching to Vortioxetine in patients with antidepressant-associated sexual dysfunction. The sample consisted of 6 patients (4 women and 2 men) that came to our psychiatric consultation from March to August 2017. Patients were between 18 and 65 years old and in treatment with only one antidepressant. The presence of sexual dysfunction was assessed using the PRSexDQ-SALSex.

**Results.**– Out of the 6 patients, 5 reported to have felt an improvement in their sexual function with a mean of 1.2 points in the PRSexDQ-SALSex. The sixth patient abandoned prematurely the treatment due to the appearance of side effects (pruritus). No other relevant side effects were detected.

**Conclusions.**– Vortioxetine appears to be a good alternative in patients in treatment with antidepressants that suffer from sexual dysfunction due its lower percentage of antidepressant-associated sexual dysfunction.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0849

### **Cosmopolitanism of Gay BDSM culture: Cultural study of U.S and Poland**

D. Sendler<sup>1\*</sup>, M. Lew-Starowicz<sup>2</sup>

<sup>1</sup> Felnett Health Research Foundation, Laboratory of Forensic Sexology- Legal Medicine- and Digital Ethnography, Staten Island, USA; <sup>2</sup> Institute of Psychiatry and Neurology, III Department of Psychiatry, Warsaw, Poland

\* Corresponding author.

**Introduction.**– This study investigates cross-cultural mechanisms of BDSM play in gay men residing in New York and Warsaw.

**Methods.**– A mixed-methods approach was applied, combining qualitative and quantitative methods. In the first part, we identified digital kink discussion communities on the Internet by selectively searching the Internet, using DEVONagent Pro. After conducting qualitative analysis of discussion boards where people talked about BDSM play, we advertised survey study, which was completed by a third of individuals.

**Results.**– We identify three novel themes explaining gay BDSM sexuality in New York vs. Warsaw: Sex travelers, pro-master culture, and consent. Sex travelers group described individuals who frequently travel for work, while recruiting people for sex. Pro-master culture refers to dominant man over the age of 40, who own playrooms, and provide sex services for a fee. Consent theme describes

the existence of “50:50,” or novice switch group, where boundaries of consent are often broken as these men are still inexperienced in kinky play. All of these results point out to one important consideration – STD prevention among kinky sex mates. The primary way by which dominant sex masters ensure safe sex practices is by screening potential sex partners, ensuring that they understand their role in the game, and take additional care with novice, “50:50” mates who are inexperienced in BDSM.

**Conclusions.**– These findings have important implications for understanding normativity of kinky sexual behaviours, and the defining features of consent in gay BDSM partnerships.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Neuronal mechanisms and treatment of hypo- and hyper sexuality/symposium of EPA section sexual medicine and mental health**

M. Waldinger

University of Utrecht, Department of Pharmaceutical Sciences, Utrecht, The Netherlands

Complaints of hyposexuality are part of psychiatric disorders (depression, schizophrenia), psychoactive medication (antidepressants, antipsychotics) and SSRI-induced irreversible sexual dysfunction (Post SSRI Sexual Dysfunction). On the other hand, patients with complaints of hypersexuality or as are currently termed Compulsive sexual behaviours (CSB), e.g. problematic pornography use, excessive masturbation, and paid sexual services, are also often referred to the psychiatrist. Although sexual psychopharmacological research in rodents has increased our knowledge of the neurobiology and neuropharmacology of sexual functioning, the methodology and design of clinical psychiatric research of sexual dysfunction in psychiatric disorders has remained at a low level. In addition, the occurrence of irreversible SSRI-induced hyposexuality, resembling chemical castration in males and females, remains mysterious and is difficult to investigate. Moreover, CSB and its underlying neural mechanisms appear under-investigated. At the current symposium the clinical syndromes of hypo- and hypersexuality are presented. Based on already published or in-press articles of the presenters, underlying neuronal mechanisms of these disorders will be critically presented and evaluated.

### **Beliefs about sleep loss predict depression and anxiety in patients with primary insomnia after adjusting for subjective and objective sleep**

S. Khrushchev<sup>1\*</sup>, E. Rasskazova<sup>2</sup>, A. Tkhostov<sup>3</sup>

<sup>1</sup> National Research Center for Hematology, Laboratory studying Mental and Neurological Disorders in Hematology, Moscow, Russia; <sup>2</sup> Lomonosov Moscow State University/Mental Health Research Center, Associate Professor- Senior Researcher, Moscow, Russia; <sup>3</sup> Lomonosov Moscow State University, The Head of the Clinical Psychology Department, Moscow, Russia

\* Corresponding author.

**Introduction.**– Symptoms of anxiety and depression are common in chronic insomnia and could depend not only on sleep disturbances but on cognitive and emotional factors.

**Objectives.**– The aim was to reveal cognitive predictors of anxiety and depression in primary insomnia beyond sleep quality.

**Methods.**– 62 patients with chronic primary insomnia filled checklists of reasons and ways of coping with insomnia, Hospital scale of anxiety and depression, glasgow content of thoughts inventory, dysfunctional beliefs about sleep scale and insomnia severity index. Objective sleep was registered using 1-night polysomnography.

**Results.**– Both depression and anxiety were unrelated to objective sleep ( $-.19 < r < .19$ ). According to hierarchical stepwise regressions, anxiety but not depression in patients with chronic insomnia are related to poorer subjective sleep ( $\beta = .41, P < .05$ ). Adjusted for subjective sleep, depression is higher in patients attributing their illness to psychological and behavioural ( $\beta = .47, P < .05$ ) but not situational ( $\beta = -.32, P < .05$ ) reasons and believing in importance of active coping with illness ( $\beta = .38, P < .05$ ). Anxiety is higher in those reporting secondary reasons of insomnia (like fear not to fall asleep).

**Conclusions.**– Treating depression and anxiety in chronic insomnia demands addressing subjective appraisal of sleep and reasons of insomnia. Intrinsic locus of control regarding reasons could be a factor of depression while fears secondary to lack of sleep predict general anxiety in patients with chronic insomnia.

\* Corresponding author.

**Introduction.**– Despite extensive studies of cognitive and behavioural factors of insomnia (Perlis et al., 2011), less is known about their interactions in illness perpetuation.

**Objectives.**– In Russia disturbances of sleep hygiene and self-restrictive behaviour are typical for more than 70% and 40% patients respectively, making important to reveal major and interaction

effects of beliefs, thoughts and behaviour in sleep in patients with primary insomnia.

**Methods.**– 37 patients with primary chronic insomnia (12 males, 16–65 years old) were interviewed about sleep hygiene and self-restrictive behaviour and filled Glasgow Content of Thoughts Inventory, Dysfunctional Beliefs about Sleep Scale and Insomnia Severity Index. Objective sleep was registered using polysomnography.

**Results.**– According to moderation analysis, disturbance of sleep hygiene, dysfunctional beliefs and thoughts before sleep are all related to poorer subjective sleep ( $\beta = .26-.45, P < .05, R^2 = 43.9\%$ ) but the effect of beliefs is stronger in patients without disturbance of sleep hygiene ( $\beta = -.30, P < .05, \Delta R^2 = 7.3\%$ ). The effect of thoughts is stronger in patients with self-restrictive behaviour ( $\beta = .32, P < .05, \Delta R^2 = 9.1\%$ ). More thoughts are related to longer delta-sleep latency ( $\beta = .47, P < .05$ ) especially for those with disordered sleep hygiene ( $\beta = .40, P < .05$ ) and with shorter REM-sleep latency ( $\beta = -.43, P < .05$ ).

**Conclusions.**– In primary insomnia self-restrictive behaviour could amplify negative effect of cognitions just before sleep while an effect of beliefs increases in patients with appropriate sleep hygiene.

The reported study was funded by RFBR according to the research project No. 17-29-02169

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The efficacy of Positive Airway Pressure (PAP) therapy on executive function and sleep quality in patients with Obstructive Sleep Apnea Syndrome (OSA)**

M.R. Najarzadegan<sup>1</sup>, S. Arya<sup>2</sup>

<sup>1</sup> Iran University of Medical Sciences, Mental Health Research Center, Isfahan, Iran; <sup>2</sup> Iran University of Medical Sciences, Mental Health Research Center, Tehran, Iran

**Introduction.**– Patients with obstructive sleep apnea have problems in their quality of life like higher risk for occupational and car accidents and some psychiatric disorders such as depression.

**Objectives.**– To determine the efficacy of airway positive airway (PAP) therapy on quality of life, cognition, problem solving, planning, reaction time and impulsivity in OSA patients.

**Methods.**– This cohort study was performed on 60 patients with moderate to severe obstructive sleep apnea, whom was divided in 2 groups with 30 patients, based on using PAP therapy. To assess the working memory, we used the *n*-back test and Wisconsin Card Sorting Test (WCST) for executive function, London Tower for planning and problem solving, Iowa gambling test (IGT) for impulsivity and Continuous Performance Test (CPT) for attention. Patients' sleep quality was also measured by the Pittsburgh Sleep Quality Index. The intervention group was evaluated before the PAP therapy and 10 weeks after.

**Results.**– The performance of participants using PAP was significantly higher in the London Tower test ( $P = 0.036$ ). Also, the results of WCST show that the total number of attempts in the PAP group were significantly lower ( $P = 0.008$ ). On the other hand, the results of the sleep quality were difference between the two groups after the PAP therapy ( $P = 0.001$ ).

**Conclusion.**– Short-term use of PAP is associated with limited improvements in some aspects of executive function. For example, working memory did not change in PAP group but planning and problem solving became better.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **A projective and psychosemantic study of emotional reactions in patients with different forms of essential hypertension in stressful situations**

E. Pervichko

Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia

**Introduction.**– A half-century of research has been performed in an effort to clarify the psychosomatic nature of essential hypertension (EH).

**Objectives.**– To inquire into the specifics of emotional reactions of patients with different forms of EH in stressful situations.

**Methods.**– A study was undertaken with our modified version of Rosenzweig Picture-Frustration Test

85 HW patients (average age is  $45.9 \pm 2.8$ ), 85 patients with 'classical' EH (average age is  $47.4 \pm 4.5$  years) and 82 healthy subjects (average age is  $44.9 \pm 3.1$ ) took part in the study.

**Results.**– The categorial structure of emotional experiences of HW patients show the most significant differences ( $P < .05$ ) from the 'classical' EH patients and normotensive persons on the representation of emotions of the "anger" ( $32.4 \pm 4.8$  vs  $23.5 \pm 4.6$  vs  $16.5 \pm 4.0$ ) and "contempt" ( $17.0 \pm 4.8$  vs  $8.1 \pm 2.1$  vs  $6.6\% \pm 2.8$ ) modalities.

Verbalized reactions of HW patients differ from answers of representatives of other groups through frequency of obstacle-dominant responses ( $41.4 \pm 3.29$  vs  $35.8 \pm 4.55$  vs  $26.9 \pm 3.37$ ;  $P < .05$ ).

Nonverbalized reactions of HW patients significantly differ from answers of patients with "classical" EH and healthy subjects: there are significantly more extrapunitive answers at them ( $69.6 \pm 5.39$  vs  $53.5 \pm 2.03$  vs  $45.3 \pm 4.49$ ;  $P < .05$ ); whereas intropunitive and impunitive answers are significantly less represented in them ( $P < .05$ ), than in other groups. There are significant differences ( $P < .05$ ) between subjects with HW and "classical" EH patients on the representation frequency of obstacle-dominant ( $43.9 \pm 2.53$  vs  $38.9 \pm 4.44$ ) and ego-defensive responses ( $44.3 \pm 3.27$  vs  $40.9 \pm 3.18$ ).

**Conclusions.**– HW patients significantly more frequently than representatives of other groups are more prone to repression of their sthenic negative emotions.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Perceived stress, anxiety and depression among medical Tunisian students**

N. Messedi, N. Smaoui\*, M. Chakroun, F. Charfeddine, L. Aribi, O. Amami

Hedi Chaker University Hospital, Department of Psychiatry B- Hedi Chaker University Hospital- Sfax- Tunisia, sfax, Tunisia

\* Corresponding author.

**Introduction.**– University life is stressful for the students. Many studies have demonstrated high levels of stress and depression among medical students.

**Objectives.**– To assess levels of perceived stress, anxiety and depression among medical Tunisian students and to establish the relationship between these parameters.

**Methods.**– A cross-sectional and analytical study among a sample of 100 students of Sfax's medicine faculty, in Tunisia, during the month of January 2017.

The Perceived Stress Scale (PSS-10): to evaluate the levels of perceived stress.

The Hospital Anxiety and Depression Scale (HADS): to assess the symptoms of anxiety and depression.

**Results.**– The average age of the participants was a  $22.94 \pm 2.7$  year and the sex ratio was 0.7. The majority of students were single (78%) and living in urban area (86%). They were smokers in 30% and alcohol users in 14% of case. The notions of repeating and absenteeism were found in 16% and 57% respectively. High levels of perceived stress (PSS score  $\geq 27$ ) were found in 56% of students and the mean PSS score was  $27.21 \pm 6$ . According to the HADS, depressive symptoms were present among 35% of them and anxious symptoms in 49%. There were correlations between high levels of perceived stress and depression ( $P < 0.001$ ), smoking ( $P = 0.01$ ), repeating ( $P = 0.001$ ) and absenteeism ( $P = 0.03$ ).

**Conclusions.**– This study highlights high levels of stress, depression and anxiety among our students. It is essential to take into account the psychological difficulties encountered by medical students given the possible repercussions on their well-being and on their academic success.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **“Smart Pills”: The pressure of a work changing society?**

C. Teles

*Psychiatric Resident, Psychiatry Service of Portimão- Centro Hospitalar do Algarve, Quarteira, Portugal*

**Introduction.**– A “smart pill” is a drug that increases the cognitive ability of anyone taking it, whether the user is cognitively impaired or normal. There is an increasing use of these drugs as a “lifestyle”, rather than for medical reasons, with the aim to better an already healthy cognitive functioning.

**Objectives.**– To characterize the use of “smart pills” by healthy people, describing its epidemiological and etiological issues.

**Methods.**– Research on Pub Med using the terms “smart pill”, “cognitive enhancement” and “healthy people”. There were only considered systematic reviews and meta-analysis from the last 5 years.

**Results.**– The prevalence of “smart pills” use by healthy individuals in order to increase performance ranges from around 10 to 15% in academic populations and 6.7% in work environments.

Besides students, people who are worried about their jobs, working at the limit of their capabilities, or in fields where small mistakes can have serious consequences seem to be particularly prone to using cognitive enhancers.

The main purposes for using these pharmacological helpers are enhancement in higher pressure situations (examinations, giving a presentation, important negotiations), to work and attainment of goals become easier, to competitive edge and cope with a pressure to succeed and requirements for sleep become less.

**Conclusions.**– Cognitive abilities in particular are becoming progressively more important for work performance and successful competition in a global environment. Therefore, an increasing number of healthy people are reported to use “smart drugs” to maintain or improve work performance.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Trajectories of sleep problems from childhood to adolescence: Relationship with emotional and behavioral problems, joint development with dysregulation profile**

B. Wang

*University Medical Center Göttingen, Department of Child and Adolescent Psychiatry and Psychotherapy, Göttingen, Germany*

**Objectives.**– Little is known about the developmental course of general sleep problems (Gregory and Sadeh, 2016). This also holds true for the bidirectional relationship between sleep problems and emotional as well as behavioural difficulties.

**Methods.**– Data were drawn from Western Australian Pregnancy Cohort Study. Sleep problems were assessed at ages 5, 8, 10, and 14, respectively. Emotional/behavioural difficulties were assessed at ages 5 and 17 years.

**Results.**– Growth mixture modeling identified two classes of sleep problem trajectories: the majority of children and adolescents were Normal Sleepers with few sleep problems and a small group of children and adolescents were Troubled Sleepers with persistent higher levels of sleep problems. Baseline attention problems, aggressive behaviour and the interaction between gender and anxiety/depression were significantly predictive of elevated risk of being Troubled Sleepers. There were significant differences at the level of later attention problems and aggressive behaviour between Normal Sleepers and Troubled Sleepers.

**Conclusions.**– Findings from this study provide empirical evidence for the heterogeneity of sleep problems and their development, and emphasize the importance of understanding sleep problems and their relationship to children and adolescents’ mental health.

**Follow-up study.**– The development of sleep problems and dysregulation profile was captured by joint trajectory models, showing that the majority of adolescents (92.3%) followed the same trajectory class for sleep problems and dysregulation profile. These results revealed a strong overlap between the course of sleep problems and dysregulation profile.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **High levels of norepinephrine-dopamine reuptake inhibitor bupropion suppresses chronic NMDA-antagonist dextromethorphan abuse in a U.S. combat veteran with PTSD**

N. Agrawal

*ETSU Quillen College of Medicine, Psychiatry and Behavioral Sciences, Johnson City, USA*

Dextromethorphan (DXM) abuse has been increasing among adolescents and young adults. Here we report the chronic 10-year abuse of DXM in a U.S. combat veteran with PTSD and MDD. The patient also carries a history of polysubstance abuse, before setting on his drug of choice of DXM up to 2400 mg per day, which stabilized his PTSD symptoms. The patient reports 11 psychiatric hospitalizations, over 10 suicide attempts, one TBI in the military

and multiple trials of a number of commonly used psychotropics. When the patient was seen, he was started on a trial of bupropion SA 12 Hr 150 mg PO BID. Instead of taking the medication as prescribed, the patient reported using 150 mg every 3 hours, with daily dose of 1200 mg per day. We report a first case of a veteran with PTSD achieving symptomatic relief of PTSD and a first case report of high dosages of wellbutrin curbing chronic DXM abuse. The patient reported no side effects, including seizures and QTc prolongation. Patient reports achieving similar euphoric, dissociative feelings to that of DXM. This case report suggests the role of atypical dosages of commonly used NDRI anti-depressants for treating addiction and PTSD. At higher dosages, bupropion is reported to take on effects similar to dissociative glutamatergic antagonists, such as ketamine. This may suggest the role of dopaminergic agonists influencing a common pharmacological pathway connecting to glutamatergic receptors and further lead to the supportive role of novel, atypical therapeutics for patients with PTSD, with polysubstance abuse.

### **The characteristics of drug abusers attending detox hospital in oman and pattern of health care services utilization**

A. Al Madhani<sup>1\*</sup>, N. Al Wahaibi<sup>2</sup>, A. Al Lawati<sup>3</sup>, F. Al Ruqeishy<sup>4</sup>, A. Al Khatri<sup>5</sup>, Y. Al-Farsi<sup>6</sup>, F. Al Hinai<sup>7</sup>, S. Al-Adawi<sup>8</sup>

<sup>1</sup> Oman Medical Speciality Board, Psychiatry, Muscat, Oman; <sup>2</sup> Wadi Kabir Health Centre, Directorate General of Health Services, Muscat Governorate, Oman; <sup>3</sup> Ruwi Health Centre, Directorate General of Health Services, Muscat Governorate, Oman; <sup>4</sup> Muscat Health Centre, Directorate General of Health Services, Muscat Governorate, Oman; <sup>5</sup> Al Masarrah Hospital, Directorate General of Health Services, Muscat, Oman; <sup>6</sup> Sultan Qaboos University- College of Medicine and Health Sciences, Department of Family Medicine and Public Health, Muscat, Oman; <sup>7</sup> Muttrah health center, Directorate of Health Services, Muscat, Oman; <sup>8</sup> College of Medicine and Health Sciences- Sultan Qaboos University, Department of Behavioral Medicine, Muscat, Oman

\* Corresponding author.

*Background.*– It is indicated that Oman is witnessing an increase in issues pertinent to alcohol and drug abuse.

*Aim.*– The aim of this study was to identify the characteristics of drug abusers attending detox hospitals in Oman and their pattern of health care services utilization.

*Methodology.*– A cross sectional study was conducted in a tertiary care center for alcohol and drug abuse. The participants seeking consultation for alcohol and drug abusers were selected by the systematic random method. A six-part questionnaire was designed to solicit socio-demographic background and clinical data, healthcare utilization and its barriers.

*Results.*– Among 293 alcohol and substance abusers, 99% were males. The most common age of onset for alcohol and drug problems was shown to be between the ages of 15 to 19 years old. Variables such as peer pressure were seen to be integral in leading to first exposure incidences with alcohol and drug problems. The majority of attendees were poly-drug abusers and many of them were making use of intravenous drugs. In a majority of cases, cannabis and alcohol were the first substances being consumed. Hepatitis C and psychiatric disorders were found to be common EVMorbidities. Those dependent on cannabis and benzodiazepines were the most to perceive 'improvement' upon receiving healthcare.

*Conclusion.*– To our knowledge, this is the first study that explored socio-demographic background, clinical data, health care utilization and its barriers and 'improvement' perception among alcohol and drug abusers attending drug detox units in Oman.

*Keywords:* Alcohol and substance misuse; Utilization of health care services; Oman

### **Prevalence of tobacco smoking among psychiatric outpatients attending a tertiary care hospital in Oman: A cross-sectional study**

K. Alrissi<sup>1\*</sup>, M. Almqbali<sup>1</sup>, H. Alsinawi<sup>2</sup>, W. Alalmaei Asiri<sup>3</sup>

<sup>1</sup> Oman Medical Speciality Board, Psychiatry, Muscat, Oman; <sup>2</sup> Sultan Qaboos University Hospital, Behavioral Medicine, Muscat, Oman; <sup>3</sup> King Khalid University Hospital, Psychiatry, Riyadh, Saudi Arabia

\* Corresponding author.

*Objective.*– tobacco smoking is the single most avoidable cause of morbidity and mortality around the world. Patients with psychiatric disorders tend to smoke tobacco at a higher rate than the general population, with significant adverse health consequences. This study aims to determine the prevalence rate of tobacco smoking among psychiatric outpatients attending a tertiary care hospital, Sultan Qaboos University Hospital, Muscat, Oman.

*Methods.*– a cross-sectional study was conducted among psychiatric outpatients attending a psychiatric clinic from April to December 2017. A data collection sheet was designed to document the patients' demographic, history of smoking, previous hospitalizations and the number of and specific psychotropics used during treatment. Degree of dependence on tobacco smoking was measured using the Fagerstorm test for nicotine dependence.

*Results.*– a total of 272 patients were included in this study (54% male). The overall rate of smoking among psychiatric patients was 13.6%. Patients with schizophrenia had the highest rate of smoking (22.2%), followed by bipolar disorder (13.15%) and anxiety disorders (11.1%). Patients who smoked tobacco were more likely to be admitted in the psychiatric ward than no-smokers ( $P < 0.05$ ).

*Conclusion.*– tobacco smoking is common among psychiatric patients, a finding consistent with similar studies conducted in different parts of the world. Assessment of smoking status and its associated adverse health impacts among patients with mental disorders is of paramount importance.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Substance and alcohol abuse in Iranian drivers**

N. Amanat<sup>1\*</sup>, S. Bahrampour<sup>1</sup>, H.R. Khankeh<sup>2</sup>

<sup>1</sup> University of Social Welfare and Rehabilitation Sciences, Health in Emergency and Disaster, tehran, Iran; <sup>2</sup> Karolinska Institute, Department of Clinical Science and Education, Stockholm, Sweden

\* Corresponding author.

Car accidents are one of the major health problems in Iran. However, assessment of effective factors in crash incidence and severity can include as primary step in developing prevention strategies. Substance abuse is one of them.

This study was review of substance abuse and car accident researches that doing in Iranian Context.

This study is a systematic review article. All of searches did with keywords such as traffic accident, crash, vehicular accident, motor vehicle collision, addict, substance abuse, driver and Iran in databases such as Web of Science, Pub Med, ProQuest and SID. All descriptive and intervention studies in the period 2000 to 2017 were studied. 1267 articles found in the early stages, 10 researches were enrolled in the study.

Results of this research discussed in some sections such as epidemiologic studies, risk factors in crashes, indirect effects of Substance abuse in health of drivers and effect of Substance and alcohol abuse in risky and aggressive behaviours. Other results shown risk of car accidents increase in substance and alcohol abuse drivers. Despite that, alcohol drinking is forbidden in Iran, therefore alcohol abuse assesses rarely in Iranian researches. In other hand, screening tests for Substance abuse haven't enough sensitivity for diagnose of drug abuser.

Substance and alcohol abuse increased in Iran. Also, the role of drug abuse in drivers especially in public vehicles drivers to car accidents is important. So, this study recommendation is doing screening tests frequently and abandon of Substance and alcohol abuse drivers.

### **Drug abusers psychopathology in relation to perceived parental bonding**

M. Antoniolì\*, A. Nivoli, G. Ricci, L. Floris, L. Folini, E. Antoniolì, L. Loretto

*Institute of Psychiatry, Psychiatry, Sassari, Italy*

\* Corresponding author.

*Introduction.* – Parental bonding styles predict psychopathological traits in general population, as well as in clinical samples of drug abuse patients.

*Objective.* – The aim of our study was to evaluate how perceived parental bonding correlates to psychopathological traits in a sample of patients with substance abuse disorder (SUD).

*Methods.* – 144 patients from a rehabilitation community in Sardinia were recruited. Data were collected through the Parental Bonding Instrument and Millon-Clinical-Multiaxial-Inventory (MCMI-III). Student t test, ANOVA, Pearson Chi Square and Fischer's exact test were performed.

*Results.* – Paternal "optimal bonding" was inversely associated with drug dependence, major depressive disorder, borderline personality disorder and somatoform disorder, with a modest effect also on antisocial and sadistic personality disorder and dysthymic disorder. Paternal "neglectful parenting" was directly correlated with borderline personality and mildly with antisocial sadistic personality and somatoform disorder. Maternal "affectionate constraint" and maternal "neglectful parenting" directly correlated with paranoid personality disorder. Maternal "neglectful parenting" also directly associated with the presence of anxiety disorders. Moreover, we noted how paternal overprotection scores alone were directly associated with masochistic personality and delusional disorder.

*Conclusions.* – This is one of the few studies that take into consideration in-patients with SUDs. Taken together, these results show how perceived "bad parenting" styles are linked to higher psychopathological traits in drug abuse patients, in line with previous research. Moreover we noted how perceived paternal "optimal bonding" was inversely associated to both Axis I and Axis II disorders. This study confirms the role of perceived parenting in the development of psychopathology of drug abuse patients.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Hazards of phenibut intoxication: A "new" internet drug**

M. Arts<sup>1\*</sup>, S. Petrykiv<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> *Mental Health Western Northern Brabant, Geriatric Psychiatry and Neuropsychiatry, Halsteren, The Netherlands;* <sup>2</sup> *University of Groningen- University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands;* <sup>3</sup> *Mental Health Care-Friesland GGZ-Friesland, Department of Geriatric Psychiatry, Leeuwarden, The Netherlands;* <sup>4</sup> *Leonardo Scientific Research Institute, Department of Geriatric Psychiatry and Neuropsychiatry, Groningen, The Netherlands*

\* Corresponding author.

*Introduction.* – Phenibut ( $\beta$ -phenyl- $\gamma$ -aminobutyric acid) is a GABA agonist that was developed during the 1960s in the Soviet Union for the treatment of several conditions including asthenia, insomnia, anxiety, depression, alcohol withdrawal, posttraumatic stress disorder, as well as for preoperative sedation. Nowadays, this drug is available through online stores as a dietary supplement.

*Objectives & Aims.* – We describe the case of a patient who suffered life-threatening symptoms after intoxication with phenibut.

*Methods.* – A case study is presented and discussed, followed by a literature review.

*Results.* – A 24-year-old man with a history of substance abuse, and depression was found in comatous condition in the street. At the emergency department, vital signs showed hypotension, bradycardia, and hypothermia. Electrocardiogram and CT-brain scan were normal. Routine laboratory testing showed no abnormalities, with the exception of hypernatremia (152 mmol/L). After 8,5 hours the patient returned to a normal level of consciousness. The patient seemed to have ingested phenibut at a dose of 3.5 g/day orally over a period of 5 days. After ceasing phenibut use he had no further symptoms or residual damage.

*Conclusions.* – One should not underestimate the hazards of phenibut intoxication. Both in the United States and in Europe, phenibut is becoming increasingly popular under (young) adults. Physicians should be aware of the hazards of this drug and know that its use can rapidly lead to dependence or tolerance. Baclofen can usually be administered for the treatment of phenibut intoxication.

### **Experience in the application of group psychoanalytic psychotherapy in the clinic of addictive pathology**

I. Belokrylov\*, A. Bryukhin, V. Karnozov

Peoples' Friendship University of Russia RUDN University,

Department of Psychiatry and Medical Psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– The need for psychotherapy for patients with addiction to psychoactive substances is an axiom. Data on the effectiveness of the application of psychoanalytic psychotherapy to these patients are contradictory, while in Russia this method is among the most developing.

**Objectives.**– Evaluation of the effectiveness of psychoanalytic psychotherapy (group analysis) in the treatment of patients with alcoholism.

**Methods.**– Patients with alcoholism (F10.2) who underwent inpatient treatment (No = 220, 164 men, 56 women, mean age  $39.5 \pm 4.3$  years, average duration of illness  $5.6 \pm 3.5$  years); the sample was randomized into 2 identical groups. Patients of the main group participated in-group analysis sessions (90 minutes), 2 times a week for 1 month, in the control group - in the same volume and rhythm with patients, psycho-evacuation sessions with elements of behavioural therapy were conducted. Efficacy was measured by the degree of change in the clinical picture, the quality of life and the duration of remission.

**Results.**– By the degree of reduction of clinical symptoms of dependence, the groups compared did not differ. On the quality of life after treatment and the duration of remission, the patients of the main group showed significantly better results than the control group (remission ratio  $\geq 1$  year 55/32%,  $P < 0.05$ ).

**Conclusions.**– The method of group analysis can be effectively used in the complex treatment of alcohol dependence.

The publication was prepared with the support of the "RUDN University Program 5-100

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

vulnerability to psychosis- faculty of medicine of Monastir-

University of Monastir- Tunisia, Psychiatry, Monastir, Tunisia

\* Corresponding author.

**Introduction.**– the fact that Cannabis use can lead to psychotic symptoms has been recognized years ago. Moreover, when the patient is using cannabis, the distinction between a primary psychotic disorder and a cannabis-induced psychosis seems to be critical for the prognosis.

**Objective.**– was to identify main factors associated to cannabis-induced disorders.

**Methods.**– A retrospective study for a period of twelve years, from January 2002 to December 2013. The study sample was composed of patients hospitalized in the psychiatric department, who reported cannabis-use, and those whose blood and urinary toxicological screening have shown cannabis use.

**Results.**– The sample was composed of 75 patients. Overall, 53 (70.66%) were diagnosed as having a primary psychosis, and 22 (29.33%) were diagnosed as having cannabis-induced psychosis. Significant differences were observed in two domains, concerning family and clinical features. The multivariate data analysis using logistic regression has shown four predictors as being greater in the cannabis-induced psychosis group. The first factor was the age below 25 years old. Subjects in the induced psychosis group were younger, having a median age of 25.1 years compared with 32.1 years for subjects in the cannabis-induced psychosis. The second factor was the marital status. Single or separated subjects were developing more cannabis-induced disorders [OR], 2.5; 95% Confidence Interval (CI), 0.69-8.96 the Pearson's correlation factor (p), 0.09)

The third factor was family history of psychiatric disorders ([OR], 2.6; 95% CI, 1.14-5.9).

**Conclusion.**– Differences between substance-induced and comorbide substance-use disorders permit identification of predictors of a substance-induced psychosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Tobacco dependence among people with mental illness: A facility-based cross sectional study from Southwest Ethiopia**

M. Daba<sup>1\*</sup>, Z. Molla<sup>2</sup>, L. Dube<sup>3</sup>, W. Krahl<sup>4</sup>

<sup>1</sup> Jimma University, Psychiatry, Jimma, Ethiopia; <sup>2</sup> Tseda Nursing

College, Nursing, Bahirdar, Ethiopia; <sup>3</sup> Jimma University,

Epidemiology, Jimma, Ethiopia; <sup>4</sup> Isar Amper Klinikum, Forensic

Psychiatry, Munich, Ethiopia

\* Corresponding author.

**Background.**– Tobacco smoking among people with mental illness is significantly higher than in the general population. Tobacco smoking has negative effects on physical, mental and financial well-being of people with mental illness but little is known about tobacco dependence among mental health service users in sub-Saharan African countries, including Ethiopia. Therefore, this study attempted to assess the prevalence of tobacco dependence and associated factors among mental health service users at Jimma University teaching hospital.

**Method.**– A cross-sectional study was conducted among 305 male and 117 female mental health service users at Jimma University teaching Hospital in 2014. The Fagerstrom Test for Nicotine Dependence (FTND) was used to assess tobacco dependence. Logistic regression analysis was used for bivariate and multivariate analysis.

**Results.**– The prevalence of current tobacco dependence among the study participants was 18.5%. There was a significant association between tobacco dependence and alcohol use disorder (AOR 4.14, 95% CI = 1.54, 11.11), daily khat chewing (AOR 13.51, 95% CI = 4.27, 42.74), chewing khat 2-3 times per week (AOR 5.09, 95% CI = 1.37, 18.95), chewing khat once a week (AOR 4.31, 95% CI = 1.04, 17.78), having friends who smoke tobacco (AOR 4.88, 95% CI = 2.12, 11.25) and being diagnosed with schizophrenia compared to a diagnosis of major depression (AOR 5.26, 95% CI = 2.07, 13.37). However, daily attendance at a place of worship (AOR 0.46, 95% CI = 0.22, 0.95) was associated negatively with tobacco dependence.

**Conclusion.**– There is a pressing need to increase availability of psychological and pharmacological interventions to reduce tobacco dependence and tobacco-related medical illness in this vulnerable group.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

**Objective.**– The aim of the present study was to evaluate relationship of BPD with history of suicide attempt, while controlling the severity of psychopathology in a sample of patients with opioid use disorder.

**Method.**– Participants included 232 patients with opioid use disorder. The study was conducted in Bakirkoy Training and Research Hospital for Psychiatry, Neurology and Neurosurgery, Alcohol and Drug Research, Treatment and Training Center in Istanbul between September 2014 and April 2015. Participants were evaluated with the Symptom Checklist-90-R (SCL-90-R) [3,4] and BPD was assessed with the Structured Clinical Interview for DSM-III-R Personality Disorders (SCID-II).

**Results.**– Age, duration of education, marital and employment status did not differ between those with the history of suicide attempt ( $n=56$ , 24.1%) and those without ( $n=176$ , 75.9%). Severity of psychopathology ( $16.60 \pm 6.44$  vs  $13.39 \pm 7.48$ ,  $t=-2.795$ ) and borderline personality symptoms ( $3.32 \pm 2.94$  vs  $1.73 \pm 1.89$ ,  $t=-3.798$ ,  $P<0.001$ ) were higher among those with the suicide attempt history than those without (respectively). The presence of BPD diagnosis was 7.54 times higher (95% C.I = 3.65–15.60) among those with the history of suicide attempt ( $n=25$ , 44.6%) than those without ( $n=17$ , 9.7%, Chi-square = 35.07,  $P<0.001$ ). In a logistic regression model the presence of BPD, together with the severity of psychopathology, particularly Obsessive-compulsive dimension score predicted the presence of suicide attempt history.

**Conclusion.**– These findings suggest that the presence of BPD is related with suicide attempt history, together with the severity of psychopathology, particularly Obsessive-compulsive dimension, among patients with opioid use disorder.

### **Results of neuropsychological diagnostics of patients with alcohol and drug dependence; experience of the Russian Federation**

E. Fadeeva<sup>1\*</sup>, K. Vyshinskiy<sup>2</sup>

<sup>1</sup> Head of Department Preventive Care of Addiction Disorders, National Medical Research Centre for Psychiatry and Narcology n.a. V. Serbsky Russian Federation Ministry of Health, Moscow, Russia; <sup>2</sup> National Medical Research Centre for Psychiatry and Narcology n.a. V. Serbsky-Russian Federation Ministry of Health, Epidemiology, Moscow, Russia

\* Corresponding author.

Currently in the Russian Federation dynamic development of medical science is taking place, including introduction of new methods of diagnosis, treatment and rehabilitation into practice. Neuropsychological diagnosis is an innovative method that increases effectiveness of medical care for patients with alcohol and drug dependence. Domestic and foreign studies indicate morpho-functional disorders of frontal cortex, subcortical disorders, and interhemispheric interaction in patients with alcohol and drug dependence. However, nowadays neuropsychological diagnostics and neuropsychological rehabilitation have not been introduced into systemic practice of treatment and rehabilitation of patients with alcohol and drug dependence, based on the principles of restoring disturbed higher mental functions and motivational sphere. The purpose of this study was to highlight results of neuropsychological diagnosis of higher mental functions in patients with alcohol and drug dependence. Diagnostic tool used was “Neuropsychological study scheme”

**Results.**– Pilot study using methods of neuropsychological analysis was carried out among 72 patients with alcohol and drug dependence. Analysis has shown statistical correlations between the following five variables: ICD-10 diagnosis, disturbances of figural diagnosis and posture praxis, Hed test and reciprocal coordination. Significance of difference with the control group for these indicators was  $\leq 0.01$ .

The use of neuropsychological diagnosis and neuropsychological rehabilitation methods, make it possible to increase duration of remission and restore cognitive and motivational component of personality among patients with alcohol and drug dependence syndrome.

### **Abuse of Over The Counter (OTC) medicines**

A. Nenasteva

National Medical Research Centre for Psychiatry and Narcology n.a. V. Serbsky Russian Federation Ministry of Health, Department clinical research of Addiction Disorders, Moscow, Russia

In the recent years, numerous countries including Russia experienced an increase in abuse of OTC medicines to derive narcotics. OTC medicines are easily accessible in pharmacies without a need for a prescription and can be used to “cook” drugs. The latter include: substance prepared by using phenylpropanolamine, holidialitics drugs, pregabalin. The OTC drug market is constantly injected by new types medicines; easy access and low cost lead to increase in abuse. OTC medicine ingredient modifications and enhancements distort clinical picture and complicate diagnostics. Currently, National Research Center of Addiction is conducting a clinical research on manifestations of OTC medicine ingredient use in “cooking” drugs and their impact on social consequences.

**Objective.**– To observe the development of substance abuse, derived from medicines, medical and social impact of its use.

**Materials and methods.**– Study is being conducted by observing 50 of pregabalin consumers' ages 21 to 32 years. Research methods: clinical, psychopathological, statistical.

The severity of withdrawals were measured using scales by assessing the severity of opioid withdrawals COWS, Montgomery-Asberg Depression Rating Scale was used to study the intensity of affective disorders.

**Results.**– Pregabalin abuse by the patients with opioid dependence and is predominantly replacing character. Patients are beginning

to take it for the relief of symptoms of opioid withdrawals. There is an increase dosage of the drug, at which point patients euphoria followed by a sedative effect, similar to heroin intoxication. If you remove the pregabalin, patients experience similar to the SLA condition with prevalence of affective disorders and algic syndrome. *Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Pavlovian-instrumental transfer in the course of alcohol use disorder**

M. Garbusow<sup>1\*</sup>, C. Sommer<sup>2</sup>, S. Nebe<sup>2</sup>, M. Sebold<sup>1</sup>, S. Kuitunen-Paul<sup>3</sup>, H.U. Wittchen<sup>3</sup>, M. Smolka<sup>2</sup>, U. Zimmermann<sup>2</sup>, M. Rapp<sup>4</sup>, Q. Huys<sup>5</sup>, F. Schlagenhaut<sup>1</sup>, A. Heinz<sup>1</sup>

<sup>1</sup> Charité - Universitätsmedizin Berlin, Klinik für Psychiatrie und Psychotherapie, Berlin, Germany; <sup>2</sup> Technische Universität Dresden, Department of Psychiatry and Psychotherapy, Dresden, Germany; <sup>3</sup> Technische Universität Dresden, Institute of Clinical Psychology and Psychotherapy, Dresden, Germany; <sup>4</sup> University of Potsdam, Social and Preventive Medicine- Area of Excellence Cognitive Sciences, Potsdam, Germany; <sup>5</sup> University of Zürich, Translational Neuromodeling Unit- Department of Biomedical Engineering- Swiss Federal Institute of Technology ETH, Zürich, Switzerland

\* Corresponding author.

*Introduction.* – Pavlovian cues have impact on ongoing behaviour, theoretically formalized as Pavlovian-to-instrumental transfer (PIT) effect. Animal studies showed enhanced PIT in addicted animals and neural correlates in nucleus accumbens (NAcc) and amygdala. PIT experiments are rare in social drinkers and alcohol-dependent patients. Therefore, we will present behavioural and neural data from our research group “Learning in alcohol dependence” (LeAD).

*Objectives.* – To examine PIT’s relevance to understand behavioural and neural mechanisms over the course of AUD.

*Methods.* – We recruited two samples: 1) 18-year old high vs. low risk social drinkers, 2) alcohol-dependent patients after detoxification and matched controls. Patients were followed up to assess relapse status. We conducted a PIT task during fMRI to measure the effect of experimentally trained Pavlovian conditioned cues and of alcohol-related cues on instrumental approach behaviour.

*Results.* – Behaviourally, nondrug-related PIT was enhanced both in high compared to low risk social drinkers, and in alcohol-dependent patients compared to controls. These effects were associated with a stronger activation in amygdala (sample 1) and nucleus accumbens (sample 2), with the latter being predictive for relapse in alcohol dependent patients. Moreover, abstainers showed reduced responses towards alcohol-related background cues compared to relapsers and controls, accompanied by a stronger activation in the NAcc in abstainers only.

*Conclusions.* – PIT associated neural activations are in line with the incentive salience theory of addiction and point to potential risk and resilience factors to develop or maintain AUD. Therefore, our data underline the importance of contextual cues in influencing behaviour and may stimulate preventative and therapeutical programs.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

\* Corresponding author.

The diagnosis of pathological gambling is currently based on clinical and subjective assessments. Novel tools for the objective identification of the risk of developing pathological behaviour are needed. Pathological gamblers are known to be deficient in decision-making under ambiguity and show motivational dysregulation. To identify the neural correlates specific to this disorder, we have been using specific laboratory tests and electroencephalography (EEG) to target decision-making under ambiguity and motivational dysregulation. For this purpose, in a first step we validated the use of EEG to assess 20 healthy volunteers who performed the Iowa Gambling Task (IGT) and the Effort Expenditure for Reward Task (EEfRT). We found heterogeneity in the results of the IGT, with some successful study participants and others who failed to develop an optimal strategy. Furthermore, we found a positive correlation between the performances of EEfRT and IGT, indicating that the level of motivation affects decision-making under conditions of uncertainty. The cerebral activity of participants showed that the amplitude of the P300 was positively correlated with the motivational level. After validating the EEG investigation, in the second step we enrolled volunteers with recreational gambling behaviour and with pathological gambling behaviour. The comparison of results obtain for both populations might determine if pathological gambling involves a specific decision-making ability and motivational level and if the P300 wave might be a biomarker of risk for pathological gambling. We will present and discuss the results of the second stage of our study during the Congress.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Prevalence of inpatients with acute psychotic episode due to cannabis abuse: 4 Years study**

J. Gomez-Trigo<sup>\*</sup>, J.M. Portes, M. Pérez, C. Blanco, L. Del Río, M. Arrojo, E. Paz, M. Páramo

Hospital Provincial de Conxo, Servicio de Psiquiatría, Santiago de Compostela, Spain

\* Corresponding author.

Increase in cannabis use in Spanish population, is one of the conclusions of the last study of Spanish Ministry of Health, about use and abuse of legal and illegal drugs. The relationship with psychotic pathology, make it necessary to know sociodemographic characteristics of risk consumers, in order to avoid relapses. The present study tries to find risk factors among patients’ environment, and it focus special attention on prevalence evolution of psychotic break due to cannabis abuse.

*Objectives.* – The purpose of this study is to know the prevalence of psychotic breaks that require psychiatric hospitalization. 69 patients’ data were collected, from acute psychiatric ward with discharge diagnosis of harmful use, dependence syndrome and/or psychotic disorder due to use of cannabinoids (according ICD-10),

from 2013 until September 2017. 35 variables were studied with statistic program R-Commander.

**Results.**– Prevalence increased more than double from January 2016 to September 2017. From total 76 inpatients, 84.1% were male. Mean age was 31.87 years. Family psychiatric history was found in 54.5% and 14.49% had family history of addiction disease. Single-ness seemed to be a risk factor (79.4%), as well as low adhesion to the treatment (60.9%) with statistical differences between gender (68.4% men vs. 25.0% women, abandoned pharmacological treatment,  $P=0,022$ ).

**Conclusions.**– Prior studies suggest than gender and marital status as factor risk of psychiatric complication due cannabis abuse. Single men showed more risk of psychotic break in our sample, with a possible connection between gender and abandonment of treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Long-term use of benzodiazepines in psychiatric patients

F. Guerhazi\*, S. Omri, M. Maalej, A. Feki, N. Charfi, J. Ben Thabet, L. Zouari, M. Maalej

Hedi Chaker University Hospital, Psychiatry C, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Benzodiazepines (BZD) represent some of the most frequently prescribed tranquilizers in the world. The problem of drawing a line between misuse and therapeutical long-term use of BZD has become especially apparent lately with highlighted discussions about the development of dependence during long-term use of therapeutic dosages.

**Objectives.**– To determine the sociodemographic and clinical profile of chronic BZD users and to investigate the reasons for the extension of use.

**Methods.**– A retrospective study including 30 medical files over a period of 3 months from September to December 2016. Patients included had taken BZD for more than 3 months and followed-up in outpatient psychiatry unit at Hedi Chaker university hospital, Sfax, Tunisia.

Data collection was conducted using a standardized questionnaire for sociodemographic, clinical, therapeutic and BZD use characteristics.

**Results.**– The average age of patients was 42 years, with a sex ratio was 1.14. The majority of them were married (60%) and unemployed (53.3%). The level of education did not extend beyond primary school in 40% of cases.

The most prescribed BZD was lorazepam (80%). The mean dose of BZD (Lorazepam) consumed was 3.87 per day. Patients claim increasing doses in 17%.

The most frequent psychiatric disorders were mood disorders (50%) followed by schizophrenia (20%).

The major reason for the extension of use was rebound effect (43.3%).

**Conclusion.**– We need make more effort to comply with recommendations regarding the prescription of BZD in order to avoid their impairment and misuses. Effective alternatives (psychotherapy, antidepressants. . .) could be used.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Relationship of smartphone addiction with social network service and alexithymia

A. Algül, İ. Gündoğmuş\*, A. Karagöz

GATA Haydarpaşa Training Hospital, Psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Smartphones, which is taking up an indispensable in daily life, have been causing some problems about excessive use of it. The concept of smartphone addiction was emerged while research to understand its excessive use and find out smartphone's role in our lives. The aim of this research was assess whether smartphone addiction was related to social network usage and alexithymia scores among university students.

**Method.**– A group of 935 students aged between 18 and 45 years (509 girls, 426 boys) were recruited from different universities in Istanbul. Smartphone addictions, alexithymia and social network services were assessed using the Smartphone Addiction Scale Short Version, Toronto Alexithymia Scale-20 Items, and Sociodemographic form.

**Results.**– Results showed that smartphone addiction were related remarkably with alexithymia and social network usage style. In addition, significant correlations exist between alexithymia, and smartphone usage severity.

**Discussion.**– To our best knowledge, this is the first study that evaluated interrelationships among alexithymia, social network usage and smartphone addictions in Turkish sample of university students. The results put forth that have linked smartphone addiction with social network and alexithymia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### 5-HT2A T102 C Polymorphism and alcohol use disorder (relationship with impulsivity, aggression and craving)

E. Hanci Yenigun<sup>1\*</sup>, A.C. Sengul<sup>2</sup>, M.C. Balci Sengul<sup>3</sup>, S. Zeybek<sup>4</sup>, H. Senol<sup>5</sup>, K. Karakulah<sup>6</sup>, B. Albuz<sup>4</sup>, E. Tepeli<sup>4</sup>

<sup>1</sup> Haydarpaşa Sultan Abdulhamid Han Training and Research Hospital, Psychiatry, Istanbul, Turkey; <sup>2</sup> Likya Hospital, Psychiatry, Antalya, Turkey; <sup>3</sup> Private Practice, Psychiatry, Denizli, Turkey; <sup>4</sup> Pamukkale University, Medical Genetics, Denizli, Turkey; <sup>5</sup> Pamukkale University, Medical Statistics, Denizli, Turkey; <sup>6</sup> Ordu Unye State Hospital, Psychiatry, Ordu, Turkey

\* Corresponding author.

**Introduction.**– The underlying neurobiological, behavioural and genetical mechanisms of Alcohol Use Disorder (AUD) is complex and effective treatment options still remain obscure and limited. Previous studies found serotonergic dysfunction is associated with AUD.

**Objectives.**– In this study we investigated the relationship between impulsivity, aggression, craving and 5HT2A(HTR2A) T102 C gene polymorphism in patients diagnosed with AUD. **Methods.**– Our study included 100 patients diagnosed with AUD and 100 healthy volunteers in the age between 18–75. We applied the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID-I), socio-demographic data form, Barratt Impulsivity Scale (BIS), Buss Perry Aggression Scale (BPAS) to the all the participants, and also AUDIT and Penn Alcoholism Craving Scale (PACS) to the group of patients. HTR2A polymorphisms were analysed with Real-time PCR.

**Results/Conclusions.**– There was a significant correlation between the time period of being diagnosed with AUD and impulsivity. But

there was no difference in the distribution of genotypes between the controls and the patients. The BIS and PACS scores had a significant correlation in patients with TT genotype, even it is a weak correlation but we could not find that association in the other genotypes. This may be another dimension of craving in alcoholism. To our knowledge this is the first study found this result. Also there was an association between BIS (total and subscale) scores and the time passed after being diagnosed with AUD in patients with CC genotype. This supports the former studies suggesting the role of impulsivity of C allele in 5HT2A T102 C polymorphism in patients with AUD.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

**Alcohol use disorder and blackout: What about the role of impulsivity and 5HT2A?**

E. Hanci Yenigun<sup>1\*</sup>, A.C. Sengul<sup>2</sup>, M.C. Balci Sengul<sup>3</sup>, S. Zeybek<sup>4</sup>, H. Senol<sup>5</sup>, K. Karakulah<sup>6</sup>, B. Albuz<sup>4</sup>

<sup>1</sup> Haydarpasa Sultan Abdulhamid Han Training and Research Hospital, Psychiatry, Istanbul, Turkey; <sup>2</sup> Likya Hospital, Psychiatry, Antalya, Turkey; <sup>3</sup> Private Practice, Psychiatry, Denizli, Turkey; <sup>4</sup> Pamukkale University, Medical Genetics, Denizli, Turkey; <sup>5</sup> Pamukkale University, Medical Statistics, Denizli, Turkey; <sup>6</sup> Unye State Hospital, Psychiatry, Ordu, Turkey

\* Corresponding author.

*Introduction.*– It is known that patients diagnosed with alcohol use disorder are more impulsive. 5HT2A T102 C gene polymorphism has been found to be related with impulsivity in patients diagnosed with Alcohol Use Disorder. Researchers have suggested that some dimensions of the impulsivity may also be related to blackouts.

*Objectives.*– In this study we investigated the role of impulsivity and 5HT2A T102 C polymorphism in alcohol-induced blackout.

*Methods.*– Our study included 100 patients diagnosed with AUD in the age between 18–75. We applied the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID-I), socio-demographic data form, Barratt Impulsivity Scale (BIS) and also AUDIT to the all the participants. HTR2A polymorphisms were analysed with Real-time PCR.

*Results.*– 66 participants reported blackouts. There was no association between 5HT2A T102 C polymorphism and having a blackout. A statistically significant relationship was found between having blackouts and barratt impulsivity scale’s total, nonplanning and motor scale scores ( $P < 0.05$ ).

*Conclusions.*– Revealing out blackout risk factors may help the clinician to understand its neurobiological etiology and will open new doors for treatment options. Also impulsivity is one of the risk factors for both alcohol use disorder and its related complications. Enlightening the complex nature of the impulsivity will guide physicians. Also it may help to subtype alcohol use disorder, which is known to be a heterogeneous group, and it may contribute to the steps to be taken in the way of clarifying its etiology.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

**Trends and risk markers of emergency department visits with alcohol intoxication among students in a public university—a longitudinal data linkage study**

C. Holstege<sup>1\*</sup>, D.A. Ngo<sup>2</sup>, S. Redge<sup>1</sup>, N. Ait-Daoud<sup>3</sup>

<sup>1</sup> University of Virginia, Emergency Medicine, Charlottesville, USA; <sup>2</sup> University of Virginia, Student Health and Emergency Medicine, Charlottesville, USA; <sup>3</sup> University of Virginia, Psychiatry and Neurobehavioural Sciences, Charlottesville, USA

\* Corresponding author.

*Introduction.*– Available studies of alcohol intoxication in hospital emergency departments (ED) are cross-sectional and no studies have identified student characteristics associated with this risky drinking behaviour.

*Objectives.*– This study examined trends in the incidence and the demographic, organizational, academic, and clinical risk markers of student ED visits with alcohol intoxication in a public university.

*Methods.*– University admission data of 177,128 students aged 15–49 enrolled from 2009/10 to 2014/15 academic years was linked to ED visits with alcohol intoxication in the university-affiliated hospital identified using ICD-9 codes within one year following enrollment. Incidence rate per 10,000 person-years was calculated. Multi-variable Cox proportional hazard regression was performed.

Figure 2.

LAI	$\bar{x} \pm SD$	Range
Paliperidone dose	62.8±33.4	12.5–200.0
Paliperidone TDM	24.8±14.0	0.20–96.0
Haloperidol dose	93.6±29.2	37.5–300.0
Haloperidol TDM	24.8±14.1	0.20–96.0
Risperidone dose	36.8±11.1	12.5–50.0

### **The Impact of education on knowledge and attitude of medical students about the abuse of prescription drugs in Iran**

G. Abolfazl<sup>1</sup>, A. Kheradmand<sup>2\*</sup>, N. Mahdi<sup>3</sup>, A. Alireza<sup>3</sup>

<sup>1</sup> Zanjan University of medical sciences, Zanjan Social Determinants of Health Research Center, Zanjan, Iran; <sup>2</sup> Shahid Beheshti University of Medical Sciences, Taleghani Hospital, Tehran, Iran; <sup>3</sup> Zanjan University of medical sciences, Medical School, Zanjan, Iran

\* Corresponding author.

**Introduction.**– The abuse of prescription drugs is considered as an important challenge for societies. Regarding many factors contributing to this challenge and its negative impact especially on young and educated people, there is an attempt in this paper to survey the impact of education on knowledge and attitude of medical students about the abuse of prescription drugs.

**Methods.**– This was a quasi-experimental study, which was conducted on medical students. Two groups of 53 medical students were selected as participants for both intervention group and control group. These participants were studied using the researcher-made questionnaires about knowledge and attitude toward the abuse of prescription drugs.

**Results.**– Education plays a significant role in both raising the students' awareness and changing their attitude about the abuse of prescription drugs. The age variable had a significant relationship with pre-training knowledge. The female participants had less pre-training knowledge about drug abuse so that it was not observed after intervention.

**Conclusions.**– It is suggested that education can be considered as a strategy to prevent drug abuse and reduce the demand for drug abuse by raising the awareness and amending the attitudes as well as promoting the anti-consumption culture.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Evaluating the relapse after ambulatory detoxification of patient with alcohol dependence**

L. Linhares<sup>1</sup>, J. Crawford, S. Carmenates, T. Duarte, C. Urbano, S. Pombo, F. Ismail

Centro Hospitalar Lisboa Norte, Department of Psychiatry, Lisboa, Portugal

\* Corresponding author.

Patients with alcohol dependence may require detoxification to prevent alcohol withdrawal syndrome. In the less severe cases,

detoxification can take place in the ambulatory setting and comprises a period of 15 working days.

In order to evaluate the outcome after ambulatory detoxification, patients were reassessed in a longitudinal evaluation that lasted about 3 months. To evaluate the relapse during the 12-week period, the patients were divided into two groups: abstinence and relapse. The relapse was defined as any consumption of alcohol after a period of abstinence.

The aim of the present study is to evaluate which factors may influence the relapse in the initial stages after ambulatory detoxification.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Smoking cessation, a service embedded within an addictions service in Singapore**

L. Low

Institute of Mental Health, National Addictions Management Service, Singapore, Singapore

**Introduction.**– The National Addictions Management Service (NAMS) has two satellite clinics located within the heartlands that seek to provide treatment of addictions. At one satellite clinic, we piloted a new smoking cessation service that combines both pharmacological and counseling approaches to help patients with nicotine dependence. This approach is in-line with current management guidelines.

**Methods.**– The smoking cessation service was started in our satellite clinic in February 2017 and patients were encouraged to be seen by both the doctor and the addictions counselor at the first and subsequent visits. Fagerstrom test of nicotine dependence (FTND) was done at the initial visit to quantify severity of nicotine dependence. We present the data for the first 6 months of this service (till 31<sup>st</sup> July 2017).

**Results.**– There were 10 referrals for smoking cessation in the first 6 months. 8 patients were male and 2 female. The age ranged from 19 years to 61 years of age. 4 patients (40%) had comorbid psychiatric illnesses. 7 patients had high dependence, 2 had moderate dependence and 1 had low dependence to nicotine as per FTND. 4 patients were started on Bupropion, 2 patients on Varenicline, 2 patients on dual NRTs, 1 on Naltrexone and 1 was not started on any pharmacological treatment. As of 31<sup>st</sup> July 40% of our patients had reduced their cigarette smoking by 50% or more or had abstained from smoking.

**Conclusion.**– This nascent smoking cessation service located in the heartlands has seen promising results and we will continue to monitor treatment outcomes.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The drugs phenomenon from the perspective of nursing students: Patterns of consumption, attitudes and beliefs**

L. Magalhães<sup>1\*</sup>, T. Verônica Cardoso Vernaglia<sup>2</sup>, S. Vieira das Chagas<sup>3</sup>

<sup>1</sup> Federal University of Rio de Janeiro - IPUB, PROJAD, Rio de Janeiro, Brazil; <sup>2</sup> Federal University of State of Rio de Janeiro, Nursing Medical Surgical, Rio de Janeiro, Brazil; <sup>3</sup> Public Ministry of State of Rio de Janeiro, CAO Citizenship, Rio de Janeiro, Brazil

\* Corresponding author.

**Introduction.**– Drug use has become a concern that affects society worldwide, posing an important threat to health, well-being and social development.

**Objective.**– To describe and analyze patterns of consumption of drug use and abuse among first and fifth year undergraduate nursing students and to investigate their attitudes and beliefs regarding drugs and users.

**Method.**– A quantitative, descriptive and analytical cross-sectional study with 160 students from the Universidade Federal do Estado do Rio de Janeiro, who answered the instruments: ASSIST and NEADA FACULTY SURVEY. Statistical analyzes were performed with a significance level of  $P < 0,05$ .

**Results.**– Alcohol was the most prevalent drug in the last three months, in the first and fifth years, respectively (69,4% and 80,0%). Students believe they have adequate basic education about drugs, however, they present a prejudiced view and negative attitudes toward users.

**Conclusion.**– The pattern of drug use among students and the lack of preparation to care users reinforce the need to review and reformulate contents and practices on the subject.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Problem video game playing scale portuguese version**

H. Espírito Santo<sup>1,2</sup>, J. Tomázio<sup>3</sup>, I. Massano Cardoso<sup>3\*</sup>, F. Daniel<sup>1,4</sup>  
<sup>1</sup> Miguel Torga Institute, Departamento de Investigação & Desenvolvimento, Coimbra, Portugal; <sup>2</sup> Universidade Coimbra, Centro de Investigação do Núcleo de Estudos e Intervenção Cognitivo-Comportamental, Coimbra, Portugal; <sup>3</sup> Instituto Superior Miguel Torga, Departamento de Investigação & Desenvolvimento, Coimbra, Portugal; <sup>4</sup> Universidade Coimbra, ceisuc, Coimbra, Portugal  
 \* Corresponding author.

**Background.**– DSM-5 proposed Internet Gaming Disorder as a condition for future research. Given the existence of one available assessment instrument - the Problem Video Game Playing scale (PVP) - it is relevant and timely to verify its psychometric properties in Portuguese adults.

**Objectives.**– To reexamine the psychometric properties of PVP in Portuguese adult gamers.

**Method.**– One hundred and eleven adult gamers completed an online evaluation comprising PVP, type and number of games played, and presence of other dependencies, namely substance abuse.

**Results.**– Removing two of the items, PVP reliability values were similar to previous studies (Cronbach's  $\alpha = .66$ ). A one-factor structure analysis was confirmed through a principal components analysis (KMO = .73; Bartlett's Test of Sphericity:  $P < .001$ ) explaining 33.6%, of the variance. Statistically significant associations between the PVP and other measures supported the construct validity.

**Conclusions.**– Results confirm that problematic video gaming can be measured reliably and validly through the Portuguese version of PVP. It is proposed to test PVP using a wider national sample and to analyze it with clinical samples to determine a cutoff value.

### **Women addictions in montenegro**

N. Matkovic<sup>\*</sup>, M. Roganovic, B. Cizmovic, R. Perisic, M. Vukotic  
 Special Psychiatric Hospital, Special Psychiatric Hospital, Kotor, Montenegro

\* Corresponding author.

Researches in Europe have shown that in whole population there are 3 to 5% women addicted to alcohol, while the number of women addicted to drugs is higher, rising up to 20%.

In Special hospital for psychiatry in Dobrota, Kotor, from 2012 to 2017, 56 female patients were treated for psychoactive substances addiction. 42 of them were female drug addicts (90% heroin addicts), and 14 were alcohol addicts. Addictions in females are a socio-medical problem, which constantly increases in our environment.

Woman's organism is less tolerant to alcohol and psychoactive substances because of monthly hormonal changes and less water quantities, and this that leads to faster physical decay and developing liver diseases. There is also fetal alcohol syndrome, which occurs in children whose mothers consumed alcohol while pregnant. Heroin can slow down the growth of the baby, as well as development of baby's brain. Also, this can cause problems with breathing after baby's birth. One of the most serious problems is that using heroin causes in babies are symptoms of addiction, so these babies need to be monitored after birth and receive special care in hospitals. Disorders of heart rhythm are often, high blood pressure, and damages on body.

**Conclusion.**– The number of addicts in women in Montenegro constantly increases and consequences are immense. Not just for the addicts and their families, but for the society as well. Since there is no department for treating women as an addict in Montenegro, this results in special problem that needs to be resolved.

### **The role of pharmacotherapy on smoking cessation**

S.F. Nascimento<sup>1\*</sup>, M. Bernardo<sup>2</sup>, S. Viveiros<sup>3</sup>, A. Alves<sup>3</sup>, J. Pereira<sup>3</sup>, E. Freire<sup>3</sup>, A. Lopes<sup>3</sup>, I. Carvalho<sup>3</sup>

<sup>1</sup> Department of Psychiatry and Mental Health, University Hospital Center of Algarve, Vila Nova de Gaia, Portugal; <sup>2</sup> Department of Psychiatry and Mental Health, Hospital Garcia Orta, Almada, Portugal; <sup>3</sup> Department of Psychiatry and Mental Health, Hospital Center of Oporto, Oporto, Portugal

\* Corresponding author.

**Introduction.**– There are currently several effective pharmacological options that are approved to help with smoking cessation. However, many patients are reluctant to use drugs to quit smoking, relying on their motivation and being open only to a psychotherapeutic approach.

**Objectives.**– To access the efficacy of the pharmacological approach and compare the impact of different medications on smoking cessation.

**Methods.**– A retrospective analysis was conducted using data from the patients that attended smoking cessation consults provided by the liaison psychiatry service of a central hospital, between 2006 and 2016. The data concerned demographic parameters, smoking habits as well as the results from the Richmond Motivation Test. Data concerning medications and their results was also collected.

**Results.**– Of the 1248 patients evaluated, 330 (25,9%) were medicated, 71 were on polypharmacy, ranging from two to four different types of drugs. However, we did not find a statistical signifi-

cance between the patients who quit smoking and the number of drugs prescribed. From the various drugs prescribed and evaluated, only varenicline was found to have a statistically significant effect ( $P=0,003$ ) on smoking cessation. If a patient was medicated with varenicline, there was 1,27 x odd of being successful, in comparison to a patient who was not being treated with that drug.

**Conclusion.**– The use of prescribed drugs, particularly varenicline, can play an important role in smoking cessation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Sleep diseases related to cocaine abuse: A case review**

C. Noval Canga<sup>1</sup>\*, R. Hernández Antón<sup>2</sup>, S. Gómez Sánchez<sup>1</sup>, A. Alonso Sánchez<sup>2</sup>, A. Álvarez Astorga<sup>2</sup>, N. Uribe Vilorio<sup>2</sup>, S. Cepedello Pérez<sup>2</sup>, L. Rodríguez Andrés<sup>2</sup>

<sup>1</sup> Hospital Clínico Universitario Valladolid, Psychiatry, Valladolid, Spain; <sup>2</sup> Hospital Clínico Universitario, Psychiatry, Valladolid, Spain

\* Corresponding author.

**Objectives.**– Detail the main characteristics in sleep diseases on drug users, mainly in patients during de first period of a detox program.

**Methods.**– We present a case review of patients admitted in a Hospital Detox Unit in order to participate in a cocaine detox program. We have collected data in cocaine users during March and April 2017.

**Results.**– We have shown 6 different clinical cases. The age average is about 35 years old (between 25 and 45 years old), mostly male in a 3:1 proportion. The 100% of those patients had reported sleep diseases during a detox program (specifically during the first 2 weeks). The main characteristics we have reported were: nightmares that the patients felt like real, with a very explicit content and many of them related to cocaine abuse. All the patients remembered a great among of the drug during the dream and also violence episodes during the nightmare. We have also reported that most of the cases (4/6 of them) referred very detailed scenes in the moment they were going to start cocaine use, this use was disrupted by an early awakening, unleashing moderate anxiety and also a lot of cocaine craving.

**Conclusions.**– According to the bibliography review made, there is different opinion about those patients forecast related to sleep diseases mentioned before. Some authors suggest a good long-term forecast, other authors suggest that those dreams increase craving after the dream, as well as an early relapse.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Benzodiazepine use in opioid consumers**

C. Oliveira<sup>1</sup>\*, C. Vieira<sup>2</sup>

<sup>1</sup> Hospital Prof. Dr. Fernando Fonseca, Psychiatry, Lisboa, Portugal; <sup>2</sup> Hospital Prof. Dr. Fernando Fonseca, Psychiatry, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– Benzodiazepines (BZD) is anxiolytic, sedative and hypnotic psychotropic drugs and are indicated for the treatment of anxiety and insomnia when symptoms are pathological and should not be used in the symptomatic treatment of mild to moderate anxiety or insomnia. Benzodiazepine therapy should be restricted in time, given the considerable increase in the risk of habituation, tolerance and dependence, after one month of use.

**Methods.**– We present a non-systematic review of benzodiazepine consumption by opioid addicts

**Results.**– The estimated prevalence for the EVconsumption of BZD and opioids, heroin, methadone and buprenorphine, is 51% -70%. Multiple studies report an increase in the risks and complications for this population, emphasizing a higher mortality and morbidity due to overdose, a greater degradation of mental state and physical health and a potentiation of cognitive dysfunction with a significant increase in the risk of injury in the substitution programs with opioid agonists. It is also found that BZD users: require treatment with higher daily doses of methadone; more frequently consume other substances (e.g. alcohol, cannabinoids and cocaine); engage in more risk behaviours; have higher rates of HIV infection; present poorer adherence and response to opioid substitution treatment. All of these lead to a worse psychosocial and rehabilitative prognosis.

**Conclusions.**– Given the high prevalence of this phenomenon in opioid users, the negative impact it has on individual and public health, as well as the scarcity of information available, a better characterization and understanding of this phenomenon is much needed

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0888

### **Psychosis in a young man induced by abusive nitrous oxide consumption: A case report**

S. Petrykiv<sup>1</sup>\*, M. Arts<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> University of Groningen- University Medical Centre Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands; <sup>2</sup> Mental Health Care - Western North Brabant, Department of Geriatric Psychiatry and Neuropsychiatry, Bergen op Zoom, The Netherlands; <sup>3</sup> Mental Health Care Friesland, Department of Geriatric Psychiatry, Leeuwarden, The Netherlands; <sup>4</sup> Leonardo Scientific Research Institute, Department of Geriatric Psychiatry and Neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

**Introduction.**– Besides its use in anesthesia, nitrous oxide (N<sub>2</sub>O) has a long history as a recreational drug, which incessantly gains popularity among young people. To date, few cases report N<sub>2</sub>O induced psychotic states, which illustrates the unmet need in the field of the symptoms recognition, mechanisms of toxicity and treatment of patients consuming N<sub>2</sub>O. Current case report provides insights into N<sub>2</sub>O toxidrome and raises awareness of its irreversible short-term neural damage.

**Objectives & Aims.**– Case report of a patient with N<sub>2</sub>O poisoning who developed a paranoid psychosis after 1-month daily habit of inhaling “laughing gas”, followed by a literature review on psychotic symptoms evoked by N<sub>2</sub>O, mechanism of its action and therapy.

**Methods.**– An English-language literature search was conducted using Pub Med, EMBASE searching for case reports and observational studies reporting psychotic symptoms in patients with N<sub>2</sub>O poisoning.

**Results.**– A 25-year old man developed paranoid psychosis with a 2-day history of symmetrical numbness in his legs and difficulty with walking. The patient’s current use of N<sub>2</sub>O fulfilled the DSM-IV-TR criteria of substance dependence, in absence of any other substance abuse. He was treated with daily intramuscular B<sub>12</sub> injections (1 g/d), physiotherapy, and methionine tablets (1 g/d). Shortly thereafter, symptom regression was observed and after 7 days he was able to walk without support again.

**Conclusion.**– We suggest that excluding N<sub>2</sub>O toxicity in patients with recognized substance-related disorders and a new neurolog-

ical deficit is compulsory, as untreated for months, the damage to the nervous system is at risk of becoming irreversible.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0889

### **Cannabis abuse and the risk of psychosis: A brief review of the clinical evidence**

S. Petrykiv<sup>1</sup>, M. Arts<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup>University of Groningen- University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands; <sup>2</sup>Mental Health Care - West North Brabant GGZ-WNB, Department of Geriatric Psychiatry and Neuropsychiatry, Bergen op Zoom, The Netherlands; <sup>3</sup>Mental Health Care Friesland GGZ-Friesland, Department of Geriatric Psychiatry, Leeuwarden, The Netherlands; <sup>4</sup>Leonardo Scientific Research Institute, Department of Geriatric Psychiatry and Neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

*Introduction.* – Psychotic disorders are determined by multiple genetic and environmental factors. The changing of legal status of cannabis is likely to contribute to the increasing rates of cannabis use worldwide and subsequently translate into sizeable public health implications. It is still speculated whether cannabis use may be a cause of psychosis and precipitate schizophrenia, and the causal nature of this association is unclear. Therefore, educational campaigns informing the public about cannabinoids use and its hazards are urgently needed.

*Objectives & Aims.* – Review of longitudinal studies on cannabis use and its contribution to the development of psychotic disorders.

*Methods.* – An English-language literature search was conducted using Pub Med, EMBASE searching for studies reporting cannabis abuse and occurrence of psychotic symptoms.

*Results.* – Epidemiological studies suggest that cannabis use during adolescence confers an increased risk for developing psychotic symptoms later in life. Around one in 10 regular cannabis users develops dependence. Cannabis abuse in adolescence approximately doubles the risks of psychoses in adulthood and has appreciable causal impact on future risk for schizophrenia. Of people with schizophrenia, more than 11% were reported to have cannabis abuse.

*Conclusion.* – Cannabis use is likely to worsen the burden of psychosis. However, further studies are needed to explain this association since psychotic disorders take years to evolve and it remains difficult to measure both the explanatory and the response variable and their complex relationship.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Psychiatric adverse drug reaction tramadol-related in a young man**

V. Prisco<sup>1</sup>, T. Iannaccone<sup>2</sup>, L. Vecchione<sup>3</sup>, G. Di Grezia<sup>4</sup>

<sup>1</sup>AOR S. Carlo, SPDC Villa D'Agri ASL Potenza, Potenza, Italy; <sup>2</sup>University of Salerno, Department of Pharmacology, Salerno, Italy; <sup>3</sup>Pellegrini Hospital A.S.L. Napoli 1, Maxillofacial surgery Department, Naples, Italy; <sup>4</sup>University of Naples Luigi Vanvitelli, Department of Radiology, Naples, Italy

\* Corresponding author.

Drug craving is the most typical reported symptom in about 90 percent of subjects in treatment with tramadol; on the contrary, atypical symptoms, occurring in 10 percent of these

patients, include unusual psychiatric adverse reaction. A 27 years-old patient was admitted in psychiatric department because he showed an increasing state of psychomotor agitation associated with aggressiveness. The patient was taking cloridrato tramadol from about 2 weeks, without medical monitoring (dosage and times are no referred) because of increasing knee pain, and then withdrawn, without medical consultation. Toxicological and laboratory tests did not show alterations, except for an increase in white blood cells (19600 cells/mm<sup>3</sup>; normal range 4500-10000 cells/mm<sup>3</sup>). He was treated with chlorphenamine, delorazepam and promazine, because of uncontrollable psychotic agitation, dysperceptive phenomena (visual hallucinations), but he had not previous psychiatric disorders history. Once hospitalized, psychiatric symptoms improved and white blood cell values came back to normal. Furthermore, neurological and psychiatric examinations resulted negative and brain computed tomography (CT) scan showed no organic abnormalities. At the light of the above, the diagnosis of psychotic symptoms occurred during tramadol withdrawal is the most probable hypothesis. In the literature, few cases of psychotic episodes related to opioid withdrawal are described, and among them, only in four cases tramadol were implicated, and only in old men.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **A (drinking) game of thrones: A comparative study of traditional and more modern drinking games**

J. Richards<sup>1</sup>, S. De Souza<sup>2</sup>

<sup>1</sup>University of Bristol, Health Sciences, Bristol, United Kingdom; <sup>2</sup>Somerset Partnership NHS Foundation Trust, Old Age Psychiatry, Taunton, United Kingdom

\* Corresponding author.

*Introduction.* – Drinking games encourage excessive binge drinking amongst participants, exposing participants at a range of short and long-term risks. Previous studies suggest that communal consumption games lead to lower intake, compared to skill or chance games. Our study looks to establish if more modern media-based drinking games (communal consumption games) encourage a higher intake, compared to traditional drinking games.

*Objectives.* – To examine, using an experimental design, whether students participating in 'modern', media-based drinking games consume greater quantities of alcohol, than those participating in more 'traditional' targeted and chance games (i.e. 20 +1, high or low).

*Methods.* – Participants ( $n=5$ ) completed in two drinking games' 20 + 1', and 'high or low'. The quantity of alcohol that would theoretically consumed to each individual throughout each game was calculated. The rate of volume consumed was compared a media-based drinking game, which involved an observer watching an episode selected from random, from the 'Game of Thrones' series, then noting when drinks would have been consumed per the rules of play.

*Results.* – Paired comparisons suggested the number of units ingested during the media-based drinking game ( $M=21.00$ ,  $SD=7.94$ ), was significantly higher than that of '20 + 1' ( $M=2.59$ ,  $SD=1.26$ ). It was also greater than the 'High or Low' DG ( $M=16.92$ ,  $SD=2.60$ )

*Conclusion.* – Consistent with previous studies, our data indicates there is variation in total consumption in units, depending on the game type. However, contrasting to other evidence, media-based communal consumption games result in greater consumption, than chance or target-based and skilled drinking games.

### **Sexual dysfunction in patients with alcohol dependence**

D. Pereira\*, M. Mendes, S. Nascimento, R. Fernandes, M. Moreno, J. Teixeira

*Centro Hospitalar Psiquiátrico de Lisboa, Psychiatry, Lisbon, Portugal*

\* Corresponding author.

*Introduction.*– Sexual dysfunction (SD) is a serious health problem and it is often reported by patients seeking treatment for alcohol problems. This situation deteriorates quality of life and leads to marked distress and interpersonal difficulties.

*Objectives.*– This review attempts to characterize the relationship between sexual dysfunction and alcohol dependence.

*Methods.*– A Pub Med search was performed in August 2017 using the search keywords “Sexual Dysfunction”, “Alcohol Dependence” and “Alcohol Consumption”.

*Results.*– The rates of SD in alcohol dependent patients can range from 40 to 95,2%. Also, it often leads to treatment nonadherence and sexual or marital disharmony. Low sexual desire, orgasm related problems and dyspareunia were the most common SDs reported among women. Erectile dysfunction, premature ejaculation and decreased sexual desire were the main issues reported by men. Initiation of alcohol use at earlier age, longer duration of alcohol consumption, longer duration of alcohol dependence, and severe dependence appeared to be significant predictors of developing sexual dysfunction among these patients. Alcohol use is an independent risk factor for low sexual function.

*Conclusion.*– This review suggests that long-term use of alcohol is associated with SD in almost all domains of sexual functioning. Increased clinicians' awareness for this problem is needed, as approaching this issues not only may improve quality of life, but also increase treatment compliance and lower the risk of relapse There is a limited number of studies evaluating this relationship and those available suffer from many limitations, hence the need for better and more solid studies.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Pathological narcissism and gambling addiction: The mediating role of impulsivity**

G. Rogier<sup>1\*</sup>, P. Velotti<sup>2</sup>

<sup>1</sup> *La Sapienza, Dynamic and Clinical Psychology, Rome, Italy;* <sup>2</sup>

*Università of Genoa, Educational Sciences- Psychology Unit, Genoa, Italy*

\* Corresponding author.

*Introduction.*– Clinical literature often depicted addicted gamblers as individuals with high levels of narcissism traits (Lesieur & Rosenthal, 1991). Moreover, Narcissistic Personality Disorder (NPD) frequently EVoccurs with Gambling Addiction (GA) (APA, 2013). However, few studies investigated narcissism features in addicted gamblers and exclusively measured the grandiose aspect of narcissism (Lahey et al., 2008; MacLaren & Best, 2013). In addition, impulsivity has been showed to be a central aspect of both GA and NPD. To date, there is a paucity of study investigating the link between narcissism and GA exploring the role played by impulsivity in such relationship.

*Objective.*– To investigate the associations between both vulnerable and grandiose narcissism in GA and to examine the role of impulsivity in such relationships.

*Method.*– We administered to a sample of 55 addicted gamblers and to a sample of 70 healthy controls self-report questionnaires including the South Oaks Gambling Screen (Lesieur & Blume, 1987), the Pathological Narcissism Inventory (Pincus et al., 2009) and the Impulsive Behavior Scale Short Form (Whiteside & Lynam).

*Results.*– We found that that addicted gamblers scored higher on several PNI and UPPS dimensions. Specific dimensions of Pathological Narcissism and Impulsivity significantly predicted the severity of GA. Positive Urgency fully mediated the relationship between Grandiose Narcissism and severity of GA.

*Conclusions.*– Both Grandiose and Vulnerable Narcissism seem to play an important role in GA. Moreover, such association might be explained by a difficulty to act rashly under the influence of intense positive emotions.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0894

### **The subjective experience of gambling addiction: A thematic analysis of interviews with addicted gamblers**

G. Rogier<sup>1\*</sup>, A. Caputo<sup>1</sup>, V. Langher<sup>1</sup>, P. Velotti<sup>2</sup>

<sup>1</sup> *La Sapienza, Dynamic and Clinical Psychology, Rome, Italy;* <sup>2</sup>

*University of Genoa, Educational Sciences- Psychology Unit, Genoa, Italy*

\* Corresponding author.

*Introduction.*– Gambling Addiction (GA) is now considered a worldwide mental health issue (Calado and Griffiths, 2016). A numbers of empirical studies investigated GA throughout the exclusive use of quantitative methods albeit few studies explored personal narratives of addicted gamblers. Furthermore, most of these studies investigated specific constructs in population of non-addicted gamblers or did not explore the relationship between narrative of GA and the whole gambler life's story.

*Objective.*– To explore the subjective experience of GA in a sample of 11 addicted gamblers.

*Method.*– We administered to eleven addicted gamblers the Psychiatric Illness Interview for Gambling Addiction (PIIGA, Velotti, Rogier, Lysaker, 2017). Thematic analysis of elementary contexts and correspondence analysis were carried out using the T-Lab software.

*Results.*– Five main clusters emerged from the thematic analysis of interviews. Moreover, correspondence analysis identified four factors organizing the relationships between such clusters. Findings shed light on several central aspects of the subjective experience of GA as, for example, dissociative mechanisms, materialism and experiential avoidance. Moreover, a concrete style of thinking and obsessive traits characterized the narratives of addicted gamblers. Finally, negative interpersonal and social impacts of the disorder emerged as well as difficulties related to treatment.

*Conclusions.*– Subjective experiences of GA seem to support evidences brought by empirical literature. Moreover, specific aspects of psychological functioning of addicted gamblers emerged, underlying the proficiency of qualitative methods in the investigation of GA. Finally, awareness of the disorder might have a key role in the treatment process, suggesting interesting clinical indications.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Smoking cessation in severe mental disorder patients: The 3 A's intervention at community mental health. Longitudinal follow-up to 12 months

S.S. Sanchez Rus<sup>1\*</sup>, M. Ortigosa Luque<sup>1</sup>, M.D. Sin Cabrero<sup>1</sup>, G.M. Ruiz Martinez<sup>2</sup>, C. Coca Cruz<sup>2</sup>

<sup>1</sup> Psychiatrist, Complejo Hospitalario de Jaen, Jaen, Spain; <sup>2</sup> MIR Psiquiatria, Complejo Hospitalario Jaen, Jaen, Spain

\* Corresponding author.

**Introduction.**– Smoking is a serious health problem for people with mental illness and especially for severe mental disorder patients. It is necessary to explore the possibilities of brief intervention in the context of community care that may act on the level of motivation for change.

**Objectives.**– Assess the effectiveness of the 3 A's intervention (Ask, Advise and Assess) in a sample of severe mental disorder patients after 12 months.

**Methods.**– 28 patients diagnosed with severe mental disorder (according DSM-5 criteria) that were psychopathologically stabilized (defined by the positive and negative scale) and attended in the Community care centers of Jaén, Andalusia (Spain). Patients who consumed in the last month qualified for the level of motivation for change (measured by URICA scale); before and after conducting a brief intervention of no more than 30 minutes in total, divided in three contacts during a month, two face to face and one phone contact. We evaluated the results in the smokers at baseline and after 12 months of the intervention.

**Results.**– After 12 months of follow-up, a 6,5% was abstinent, a 17,1% tried to abandoned the consumer at least once during the follow-up an average 8 days (2-30). A 30,5% discontinued the study.

**Conclusions.**– This is the first paper that evaluate the 3 A's intervention in severe mental disorder with 12 months of follow up. The results of abstinence after were similar to those obtained in patients with schizophrenia using the same intervention (5%)

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0896

### Opioid use disorder individuals on methadone maintenance treatment versus those not on methadone treatment: A Naturalistic cross-sectional comparative study of cognitive performance

K. Sant<sup>\*</sup>, A. Dimech, A. Camilleri

Mount Carmel Hospital, Psychiatry, Attard, Malta

\* Corresponding author.

**Introduction.**– Studies of cognitive functioning in drug addiction have shown consistent impairments. Attempts at highlighting neurocognitive recovery of opioid dependent (OD) individuals stabilised on methadone, have resulted in contradictory conclusions. This study attempts to test the hypothesis that methadone enhances cognitive recovery in OD individuals when compared to their untreated counterparts.

**Objectives.**– To compare the cognitive function of OD on methadone maintenance treatment (MMT) to those who are not on methadone treatment (NOMT), relative to healthy controls (HC). We examined whether comorbid cocaine dependence, methadone dose, duration of dependency/abstinence, were correlated with cognitive function

and whether any psychiatric treatment enhances cognitive stability.

**Methods.**– The Montreal Cognitive Assessment was administered to three groups of participants: 22 MMT, 21 NOMT and 22 HC. The cognitive domains tested include Executive Function/Visuospatial Skills/Naming/Attention/Language/Abstraction/Delayed Recall/Orientation.

**Results.**– Visuospatial Skills/Executive Function were improved in MMT but not NOMT individuals. The Language domain appears to be impaired in both MMT and NOMT with a negative correlation to the duration of dependency. NOMT were impaired in all other aspects of cognition apart from Naming/Orientation when compared to HC. MMT did not significantly differ in the other areas of cognition when compared to HC. No correlation was observed between comorbid cocaine dependence/methadone dose and cognitive function.

**Conclusions.**– Methadone treatment appears to be associated with an improvement in cognitive function in OD individuals. MMT may facilitate public health by augmenting cognitive performance in former OD individuals, thus, ensuring compliance to their treatment plan with fewer relapse rates and mitigation of risky behaviours.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Insight, readiness to change, and motivation were not correlated in alcohol-dependent in patients

M. Slepecky<sup>1\*</sup>, V. Stanislav<sup>2</sup>, A. Kotianova<sup>1</sup>, M. Kotian<sup>1</sup>, M. Zatkova<sup>1</sup>, M. Martinove<sup>2</sup>, J. Prasko<sup>1</sup>

<sup>1</sup> Faculty of Social Science and Health Care- Constantine the Philosopher University in Nitra, Department of Psychology Sciences, Nitra, Slovak Republic; <sup>2</sup> OLUP Predna Hora- Muranska Huta- Predna Hora 126- 049 01 Muran, OLUP Predna Hora, Muran, Slovak Republic

\* Corresponding author.

Substance-related disorders are the global problem. Poland, the Czech Republic, and the Slovak Republic are countries with high alcohol consumption.

**Aim.**– The purpose of the study was to examine the readiness to change at the beginning and the end of inpatient short (six weeks) and long (12 weeks) therapeutic program in the Slovak Republic, Poland, and the Czech Republic, and look for the relationship between readiness to change, insight, and motivation in alcohol-dependent persons.

**Methods.**– We studied a sample of 380 alcohol-dependent inpatients (282 men and 98 women) by Alcohol Use Disorders Identification Test (AUDIT), The Stages of Change Readiness and Treatment Eagerness Scale (SOCRATES), Readiness to Change Questionnaire (RCQ), and Demographic Questionnaire.

**Results.**– The single patients declare a higher severity of alcohol dependence than married or divorced ones. At the beginning of the treatment, the majority of patients declared the motivation stage of action (68.5%) or preparation (26.3%). At the end of the treatment, married patients showed higher Readiness to Change in domain Taking steps. The single patients displayed the decrease of domain Ambivalence. The duration of the completed therapeutic program may not be crucial for readiness to change.

**Conclusions.**– In the sample the intention and motivation to alcohol treatment seem to be high at the beginning of the treatment, but recognition of the alcohol problems were low in highly dependent patients. Marital status was connected with an increased active component for readiness to change. The passive component (decreasing the ambivalence) was observed in the single patients.

### **Addiction to Benzodiazepines: Between reality and practice?**

B. Tefahi

*Faculty of Medicine- University 2 Batna, El Madher-Batna Psychiatric Hospital, Batna, Algeria*

Benzodiazepine addiction is a disorder characterized by a recurring process including repeated intoxication followed by the progressive establishment of addiction with withdrawal symptoms and a compulsive need to consume or craving. This phenomenon is often due to the availability of its substances, the non-respect of the recommendations of their prescription and the existence of psychopathological disorders. Their treatment requires the setting up of comprehensive management combining drug, psychotherapeutic and socio-educational approaches.

We will illustrate our intervention by a literature review based on the Pub Med data, taking as a criterion for inclusion the young subjects dependent on benzodiazepines between 2013 and 2017 and as Keywords: “Drug abuse”, “Benzodiazepine”, “Dependence”, “Craving”, “Psychopathology”, “Neurobiology”, “Treatment” to elucidate all the neurobiological parameters that explain the link between addiction and personal and social vulnerability.

*Keywords:* Addiction; Benzodiazepines; Craving; Vulnerability.

EV0899

### **MODAFINIL: The possibility to have a better brain?**

C. Teles

*Psychiatric Resident, Psychiatry Service of Portimão- Centro Hospitalar do Algarve, Quarteira, Portugal*

*Introduction.*– Modafinil is a wakefulness-promoting agent licensed for the treatment of excessive daytime sleepiness associated with narcolepsy, sleep apnoea and shift-work sleep disorder. In addition, it is thought to be used widely off-prescription for cognitive enhancement.

*Objectives.*– To summarize the extensively literature regarding the effects of modafinil in cognitive, emotional and motivational functions when used by healthy people.

*Methods.*– Research on Pub Med using the terms “modafinil” and “cognitive enhancement”. There were only considered systematic reviews and meta-analysis from the last 5 years.

*Results.*– When simple psychometric assessment is considered, modafinil intake appears to enhance only executive functions (planning, decision-making). When more complex tasks are considered, modafinil appears to enhance attention, higher executive functions, and learning and memory.

These effects seem to be modest in healthy individuals. However, in individuals whose baseline performance is poorest, the enhancement might be more significant. Benefit may be optimal for those who are sleep deprived and then only in single doses.

The side effects are slight.– insomnia, headache, gastrointestinal complains (nausea, abdominal pain) and dry mouth. It appears that modafinil exerts minimal effects on mood–if anything improving it. Also, it might lead to an overrating of the actual cognitive performance.

*Conclusions.*– Modafinil is one of the most promising and highly investigated neuroenhancers to date. Nevertheless, some concerns

remain to clarify such as modafinil’s long-term safety and efficacy, potential for misuse, and influence on the developing brain. Likewise, its use as a cognitive enhancer, raise important social and ethical questions.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

According to available data from Worldwide report about drugs by United Nations office on drugs and crime (UNODC) almost 29 million people are addicted to drugs. Last year 27 million people were registered as addicts, 12 million of them as “injecting narcotics users”, while 14% of them lives with HIV. General influence of drug use is defeating. Five percent of adult population, around 250 million people aged from 15 to 64, has used at least one type of drugs in 2014. According to World Health Organization there are 170-200 million people infected with hepatitis C virus (HCV). Each year 3-4 million people are registered as newly infected with hepatitis virus, while 250.000 dies of consequences of HCV infection.

Out of 530 patients in 2012, twelve patients were positive for hepatitis C, which is 29%. In 2013 there were 24 patients (24%) positive for hepatitis C, while in 2014 the number of patients positive for virus was 21 (17%). In 2015 there were 19 positive patients (14,5%) and in 2016, 14 patients tested positive for hepatitis C virus (13%). Infections with hepatitis B and C are common between active and former injecting narcotics users. History of injecting narcotics is the most frequent risk factor in Europe and on our area, especially for infections with hepatitis C virus. Injecting narcotics users, particularly those who come from a social margin, are not just vulnerable to infections by blood transmissible viruses but are also vulnerable to other infections.

### **Emotional distress and smoking in health professionals**

M. Turki<sup>1</sup>, R. Ennaoui, N. Cheffi, N. Halouani, J. Aloulou, O. Amami  
*Hedi Chaker university hospital, psychiatry “B” department, Sfax, Tunisia*

\* Corresponding author.

*Introduction.*– Smoking is a problem of growing concern, since it has a serious impact on public health. It is associated with somatic and psychiatric morbidity, as well as increased rates of mortality.

*Aim.*– The current study aimed at assessing the relationship between smoking and anxiety and depression among health professionals.

*Methods.*– It was a cross-sectional, descriptive and analytic study. The sample consisted of 37 health professionals (20 doctors and 17 paramedics), practicing in Habib Bourguiba and Hedi Chaker

Hospitals in Sfax (Tunisia). Participants were invited to respond anonymously to a semi-structured questionnaire, after consent. We used the Fagerstöm Test For Nicotine Dependence (FTND) to screen for physical nicotine dependence. The Assessment of depressive and anxious symptoms was done through the Hospital Anxiety and Depression Scale (HADS).

**Results.**– The mean age of participants was 33.4 years, with a sex ratio of 2. Active smoking was reported by 62.1% of them. According to FTND, 65.2% of smokers scored as dependent (30.4% moderately to highly dependent). The prevalence of anxiety and depression in smokers was respectively 30.4% and 21.7%. Anxiety and depression were more frequent among smokers, without significant relationship. The FTND score was significantly higher in male smokers ( $P=0.043$ ), and in paramedical staff ( $P=0.008$ ). It was higher in depressed smokers but the relationship was not significant.

**Conclusion.**– Our study highlighted the psychological distress, which could accompany smoking. This relationship seems to be bi-directional. Thus, promotion of measures to prevent smoking among hospital staff, as well as the management of psychological distress is essential in order to improve well-being.

### Recommendations for the cognitive-behavioral therapy in technological addictions

O. Vasiliu

“Dr. Carol Davila” Central Military Hospital, Psychiatry, Bucharest, Romania

Technological addictions are a relatively recent cornered category of psychiatric disorders, which encompass, without being limited to, smartphone addiction, Internet gambling disorder, social networking sites addiction and problematic series watching. Although the existence of these conditions is disputed, it's worth mentioning that Internet gambling disorder has been included in the appendix of the DSM latest edition. Cognitive-behavioural therapy (CBT) has been associated with positive results in a large range of drug disorders, but data regarding its efficacy in behavioural addictions is still limited. In order to find out the current recommendations for the psychotherapy in technological addictions, existing data in the literature have been reviewed and systematized. After clustering of data for CBT applications in various technological addictions, three main directions have been identified: group therapy and family therapy; individual CBT based on the cognitive re-structuring; eclectic programs, which combine CBT with other forms of psychotherapy (self-help groups, psychodynamic therapy etc.). No high-quality randomized clinical trial focused on the evaluation of CBT efficacy in technological addictions has been found. It should be noted that case reports and case series for this pathology reported high rates of EVmorbidity with other addictions, personality disorders, depressive or anxiety disorders, so that configuring a complete image of the current situation of each patient should be the first step of any rationale therapy. In conclusion, CBT could be useful for technological and other behavioural addictions, and it should target not only de-structuring of the addictive behaviours and thought patterns, but also EVmorbid psychiatric conditions.

### Sociodemographic and clinical characteristics of patients with substance abuse in a University hospital psychiatric service

M. Yilmaz

Bulent Ecevit University, Psychiatry, Zonguldak, Turkey

In this study, it was aimed to investigate the sociodemographic and clinical characteristics of patients with drug abuse in the patients hospitalized in the closed psychiatric department of Bülent Ecevit University Medical Faculty Hospital. Bülent Ecevit University Medical Faculty Hospital When the medical records of the patients in the Closed Psychiatric Service were examined, it was learned that 15 patients had narratives of substance use 86.7% were male and 13.3% were female and the mean age was 19.06 ( $SS \pm 11.37$ ) and mean duration of substance use was 5.6 ( $SS \pm 10.87$ ) years. The educational status of the patients were 40% ( $n=6$ ) high school graduates, 33.3% ( $n=5$ ) high school students, 13.3% ( $n=2$ ) primary school graduates, 6.7% And 6.7% ( $n=1$ ) of university graduates. The items used by the patients were bonzai (73.3%), cannabis (66.7%), bally (13.3%) and ecstasy (13.3%). Simultaneous use of cigarettes and alcohol in 80% of patients, smoking in 13.3%, smoking and alcohol abuse in 6.7% were observed. It was learned that 73.3% ( $n=11$ ) of the patients started with the friendship environment and 26.7% ( $n=4$ ). It was observed that 73.3% ( $n=11$ ) of the patients did not come to the controls and 27.7% ( $n=4$ ) of the patients came to the controls after discharge. 60% ( $n=9$ ) of the patients were working and 40% ( $n=6$ ) were not involved in any work.

### Benzodiazepine dependence and personality disorders

O. Zikic<sup>1</sup>, G. Nikolic<sup>1</sup>, J. Kostić<sup>2</sup>, I. Binic<sup>1</sup>, S. Manojlovic<sup>3</sup>

<sup>1</sup> Faculty of Medicine- University of Nis, Department for Psychiatry, Nis, Serbia; <sup>2</sup> Clinic for Mental Health Protection- CC Nis, Department for adolescents, Nis, Serbia; <sup>3</sup> Clinic for Psychiatry- CC Nis, Department for psychoses, Nis, Serbia

\* Corresponding author.

**Introduction.**– The aim of our study was to determine whether there are differences in the intensity and frequency of indicators of benzodiazepine dependence in patients with and without personality disorder.

**Methods.**– The group consisted of 78 benzodiazepine users, which used the benzodiazepine as a monotherapy for at least 1 year at the time of screening. The group was divided into two subgroups: group of subjects with personality disorders and group of subjects without personality disorders. These two groups were mutually compared with respect to correlates of benzodiazepine dependence (problematic use of benzodiazepines, preoccupation with benzodiazepines, lack of compliance and withdrawal syndrome).

**Results.**– The intensity of problematic use was higher in subjects with schizotypal personality disorder and borderline personality disorder ( $P < 0,005$ ), while lower scores were found in subjects with narcissistic personality disorder ( $P < 0,005$ ). The intensity of preoccupation with benzodiazepines was elevated in the dependent, borderline, schizotypal and histrionic personality disorders ( $P < 0,005$ ). Lower level of compliance was associated with schizotypal and avoidant personality disorders ( $P < 0,005$ ). The intensity of withdrawal syndrome was associated with schizotypal, borderline and dependent personality disorders ( $P < 0,005$ )

**Conclusion.**– The study results suggested that the association with schizotypal, borderline, but also with dependent, avoidant and histrionic personality disorder is of particular importance for the intensity of benzodiazepine dependence and its indicators. Comorbidity with a narcissistic personality disorder had opposite effect, since the lower intensity of individual indicators was observed in these subjects in comparison to patients without it.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Cannabis Abuse: Prevalence and relationship with psychiatric morbidity among the heavy traffic vehicle drivers of Azad Jammu Kashmir**

U. Zubair<sup>1\*</sup>, A. Ali<sup>2</sup>

<sup>1</sup> PIMS- SZAMBU, Psychiatry, Islamabad, Pakistan; <sup>2</sup> Poonch Medical College Rawalkot AJK, Psychiatry, Rawalakot, Pakistan

\* Corresponding author.

**Introduction.**– Trend of cannabis use is on a rise and around 2.5% of the world population has been using this illicit drug. A recent survey reported an annual prevalence of 4% in Pakistan and 3.2% in Azad Jammu Kashmir (AJK). Cannabis abuse has been associated with various psychiatric conditions like anxiety, depression and psychotic illnesses.

**Objective.**– To determine the frequency of cannabis abuse and its relationship with psychiatric morbidity among the HTV drivers of AJK.

**Methods.**– The sample population comprised of 100 HTV drivers working in different parts of the AJK. Cannabis abuse was assessed using the Drug Abuse Screening Test (DAST-10). Psychiatric morbidity was assessed by using the General Health Questionnaire-12 (GHQ-12). Relationship of psychiatric morbidity and other socio-demographic factors was assessed with the cannabis use.

**Results.**– Out of 100 drivers screened through DAST-10, 70% had no signs of abuse while 30% had clinically significant level of abuse. After applying the logistic regression we found that persistent night shift driving, psychiatric morbidity, low education, tobacco smoking and contact with the sexual workers had significant association with the cannabis abuse.

**Conclusion.**– This study showed a high prevalence of cannabis abuse among the HTV drivers in AJK. Special attention should be paid to the drivers with the signs of psychiatric morbidity and tobacco smoking. Education standard should be made better and contact with the sexual workers should be discouraged.

**Keywords:** Cannabis abuse; HTV drivers; DAST-10; Psychiatric morbidity

## **Suicidology and suicide prevention**

EV0906

### **Relation between cognition and suicidality in patients with early stage schizophrenia**

I. Abad Acebedo\*, L. González Blanco, J. Rodríguez Revuelta, Á. Velasco Iglesias, L. García Álvarez, L. De La Fuente Tomás, L. Rubio Rodríguez, C. Moya Lacasa, M.P. García-Portilla González, P.A. Saiz Martínez, J. Bobes García  
Universidad de Oviedo - Facultad de Medicina y Ciencias de la Salud, psychiatry, Oviedo, Spain

\* Corresponding author.

**Introduction.**– Depression and suicidal behaviour are frequent in schizophrenia. Cognitive impairment is associated with history of suicidal attempts (SA) in affective disorders [1], but very little is published in schizophrenia. Furthermore, the existing publications don't use a consensual instrument and they found opposite results [2,3].

**Objective.**– To analyze differences in cognition performance between schizophrenia patients that have made/has not made a SA.

**Method.**– 72 young patients (18–45 years) with schizophrenia  $\leq$ 10 years evolution (average age=31.83, 61.1% – males). 14/72 has history of SA (19,44%). No significant differences between groups regarding age, gender, evolution years, education, antipsychotics dosis and others. Evaluation: PANSS, Personal and Social Performance Scale, Calgary Depression Scale (CDS), MATRICS Consensus Cognitive Battery.

**Results.**– No significant differences on cognitive function between groups except lower punctuation in the BACS test ( $t=-2.377$ ;  $P=0.02$ ) on the SA group in wich also we found a higher number of hospital admissions and higher punctuation on PANNS-P, PANNS-G, PANNS-total and CDS.

**Conclusion.**– On our sample, suicidal behaviour is associated with clinical severity. Regarding cognition, processing speed, measured with BACS test, seems to be firstly affected.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Case study of adolescent suicide risk factors. Suicide prevention outcome studies in juvenile detention facilities in Azerbaijan.**

N. Allahverdiyeva  
Ministry of Health of Azerbaijan, Department of Psychiatry, Baku, Azerbaijan

\* Corresponding author.

Following research and accidents, suicide is the second leading cause of death in adolescence. In addition to mentally ill juve-

niles, especially prisoners represent a high-risk group for suicidal behaviour and completed suicide.

**Introduction.**— According to Hagell, Coleman & Brooks (2013) refers to the “deliberate self-infliction of damage to body tissue” via self-mutilation or ingesting toxic substances. Caucasian youth (ages 10–19); died by suicide at a rate of 5.99 per 100,000 in 2014. This was the second highest youth rate across other races (Caucasian American Suicide Fact Sheet based on 2014 data 2016). Pilot survey of risky behaviour and more particularly suicidal ideation and behaviour at school level and crime adolescent. Case studies of risk factors or attempted suicide including 70 boys.

**Background.**— To assess the demographic, socioeconomic and mental health status of male arrivals in Azerbaijan jails and to analyze the time trends of these characteristics.

**Methods.**— The study was carried out in a prison for detained persons and short-term prisoners. Using a standardized questionnaire: C-SSRS, DAWBA, SDQ, PHQ-9, Wechsler Intelligence Scale (WAIS) scales. The information collected concerned: demographic data, level of education and professional status, reasons for detention or imprisonment, social and family background, lifestyle, medical and psychiatric history, suicide attempts and illicit use of drugs.

**Conclusion.**— The American Association of Suicidology (AAS) gives some general information about risk and protective factors that can help prevent Caucasian Suicide.

### Unconventional methods for preventing social suicide

S. Ambhaikar

Dali Medical University- China, Clinical Medicine, Raipur, India

Suicide has a major impact on society across the world and the cases are growing in number everyday. An estimated 1 million people worldwide take their lives by suicide every year and annual suicide fatalities could rise to 1.5 million by 2020. Suicide ranks among the 3 leading causes of death among those aged 15–44 years. Suicide attempts are up to 20 times more frequent than completed suicides. Clinical depression is a common cause. Depression often runs in families, suggesting that genetics can play a role, perhaps affecting chemical activity in the brain. Especially in teen the causes of suicide include exam results, love failures, lack of patience, nuclear family culture, peer pressure, competition, lack of self-confidence, etc. Substance abuse, severe physical disease or infirmities are also recognized causes, which may intensify depression, if not give rise to it. The countries of the Eastern Europe and East Asia have the highest suicide rate in the world. Those who have previously attempted suicide are at higher risk for future attempts. According to this research performed it is clear that psychological support is necessary for the depression patients. There are also cases, which are not depression but just an emotional outburst called sadness. Many people consider this as a depression and then lack of self believe and confidence leads to bad consequences like suicide. In this research we tried to merge neuropsychiatry with psychoneurology. Few therapies and healing methods, which deal with the neurotransmitters along with the Indian ancient therapies, show the positive results. Along with these behavioural therapies also showed outstanding results in depression patients. After going through these processes, outcomes were positive and hence suicide could be prevented.

### Suicide with intravenous kerosene: A case report in Bangladesh

S.M.Y. Arafat

Bangabandhu Sheikh Mujib Medical University, Psychiatry, Dhaka, Bangladesh

The mode and method of suicide varies due to multiple factors such as culture, religion, gender, belief, occupation, educational status, age and others. It usually depends on availability, victim’s knowledge on lethality and cultural influences. Here we report an adult Bangladeshi female medical graduate attempted suicide by infusing 10 cc kerosene, which is very uncommon in any cultural background in the world. A 30-year-old female, unmarried, medical graduate, admitted into the Intensive Care Unit (ICU) with the history of taking 10cc Kerosene intravenously. She also ingested Midazolam 7.5 mg 50 tablets and Amitriptyline 25 mg about 80–100 tablets at a time. She was suffering from Depression for the last 6 years and she consulted psychiatrists and psychotherapists multiple times but irregularly. She also used to take the anti-depressants irregularly. She was a very good achiever across her academic life but she had few friends and premorbidly she was anxious. She was maintaining an affair relationship with a boy for last 16 years. Before the day of attempted she came to know that her boy friend had got married. Being a medical graduate with a good functional status in a city choosing intravenous kerosene is quite unexplainable. However, prolong under treated depression, recent life stressors can play vital role to take the fatal decision.

**Disclosure of interest.**— The authors have not supplied their declaration of competing interest.

EV0910

### Overview of emergency department visits for suicidal behaviour from 2006 to 2016 in Baixo Alentejo, Portugal

P. Barbosa\*, S. Farinha-Silva, J. Brissos, M. Duarte-Mangas, J. Isaac, A. Matos-Pires, A. Silva, J. Coelho, F. Barrocas

ULSBA, Serviço de Psiquiatria, Beja, Portugal

\* Corresponding author.

**Introduction.**— The Observatório dos Comportamentos Suicidários is a team of health-care professionals from the Psychiatry Department (PD) and the Emergency Department (ED) at the Unidade Local de Saúde Baixo Alentejo (ULSBA). The team is committed to the study of Suicidal Behaviour in the region.

**Objective.**— Analyze sociodemographic data from patients who visited the ED for suicidal behaviour from 2006 to 2016.

**Methods.**— The sample includes visits to the ER assigned the following Manchester Triage System flowcharts: “Overdose or poisoning” and “Self-injury” ( $n = 2271$ ). The data analysis was performed in SPSS.

**Results.**— “Overdose or Poisoning” and “Self-injury” accounted for 0.4–0.5% of the ED admissions, on a 9:1 ratio. 68.8% were female and 63.7% were 20 to 49 years old. The analysis of variables such as admission time, day of the week, month, marital status and residency shows significant changes over the years

We highlight that the admissions for “Self-injury” did not increase in absolute value, but there was a gradual change in gender distribution: initially it was more observed in men, but since 2011 women present with auto-aggressive methods in higher number.

The geographic dispersion of individuals is not even and the age distribution varies by location. In certain municipalities suicidal behaviour is more common in younger people and in others it is more observed in the elderly.

**Conclusions.**– First impressions and the realization that suicidal behaviour demographics in Baixo Alentejo are changing show the importance of continuous evaluation over time, both for studying the behaviour itself and for developing preventive intervention strategies in the community.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Suicidal thoughts and behaviors among patients with skin diseases: Meta-analyses of the literature**

R. Calati<sup>1\*</sup>, P. Courtet<sup>2</sup>

<sup>1</sup> Inserm U 1061, Neuropsychiatry: Epidemiological and Clinical Research, Montpellier, France; <sup>2</sup> Department of Emergency Psychiatry and Post Acute Care- Lapeyronie Hospital- Centre Hospitalier Universitaire CHU Montpellier- France, Department of Emergency Psychiatry and Post Acute Care- Lapeyronie Hospital- Centre Hospitalier Universitaire CHU Montpellier- France, Montpellier, France

\* Corresponding author.

**Introduction.**– Skin diseases may severely impact on the individual quality of life and represent a psychosocial burden for the affected patients. They could be linked to suicidal thoughts and behaviours. In particular, skin disease patients reported higher rates of suicidal ideation in comparison to the general population.

**Objective.**– This meta-analysis aims to estimate the risk of suicidal thoughts and behaviours in patients with skin diseases.

**Methods.**– We searched MEDLINE and PsycINFO to identify articles published before October 2017, examining the association between suicide [ideation (SI), planning (SP), attempt (SA), death (SD)] and any form of diagnosed skin disease.

**Results.**– In preliminary analyses, 12 studies were included. Among skin diseases we were able to separately analyze atopic dermatitis (AD) and the broader category of eczema. Patients with AD had higher risk of SI compared to those without AD. In the case of eczema, results related to SI were not consistent.

**Conclusion.**– Within the treatment setting, the presence of suicidal thoughts and behaviours should be assessed in the AD patient, in particular in the presence of other features, such as severe pruritus and/or sleep problems.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Differential association between cytokines and cerebral activations during experience of social exclusion**

I. Conejero<sup>1\*</sup>, E. Olié<sup>2</sup>, E. Thouvenot<sup>3</sup>, F. Cyprien<sup>4</sup>, T. Mura<sup>5</sup>, N. Menjot De Champfleur<sup>6</sup>, S. Guillaume<sup>2</sup>, S. Finge<sup>7</sup>, P. Courtet<sup>2</sup>

<sup>1</sup> Nîmes University Hospital, Psychiatry, Nîmes, France; <sup>2</sup> Department of Emergency Psychiatry and Post-Acute Care- Hôpital Lapeyronie- CHU de Montpellier, Psychiatry, Montpellier, France; <sup>3</sup> Department of neurology- CHU de Nîmes, Neurology, Nîmes, France; <sup>4</sup> Inserm, Unit 1061, Montpellier, France; <sup>5</sup> CHU de Montpellier, CHU de Montpellier, Montpellier, France; <sup>6</sup> CHU de Montpellier, Neuroradiology, Montpellier, France; <sup>7</sup> CHU de Nîmes, Immunology, Nîmes, France

\* Corresponding author.

**Objective.**– To measure the association between cerebral activations during experimental social exclusion and levels of inflammatory markers in subjects, having a history of major depressive episode with or without suicidal act.

**Methods.**– 116 euthymic females divided into 3 groups: 45 having a history of depression and suicide attempt, 43 having a history of depression without suicide attempt and 28 healthy subjects. During fMRI, they performed Cyberball game, a validated social exclusion task. Blood levels of cytokines IL-1B, IL-6, TNF- $\alpha$  and IL-2 were measured prior to fMRI. Analyses were performed in regions of interest: insula, orbitofrontal cortex (OFC), and anterior cingulate cortex (ACC).

**Results.**– Baseline IL-1 Beta was negatively associated with R-OFC ( $P=0,01$ ), whereas baseline IL-2 was positively associated with R-ACC ( $P=0,02$ ); R-insula ( $P=0,002$ ) and R-OFC ( $P=0,004$ ). These associations remained significant after controlling on group, the type of mood disorder (unipolar or bipolar) and level of social distress.

**Conclusion.**– Baseline IL-1 and IL-2 blood levels show differential association with cerebral activations involved in perception of social exclusion, independently of suicidal behaviour or mood disorder history. Our results may help to better understand the role of basal inflammation in social stress and its link with pathophysiology of mood disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The case for zero suicide in healthcare**

D. Covington<sup>1\*</sup>, K. Hines<sup>2</sup>

<sup>1</sup> American Association of Suicidology, President-Elect, Phoenix, USA;

<sup>2</sup> The Kevin & Margaret Hines Foundation, Brain Health & Mental Wellness, Alpharetta, USA

\* Corresponding author.

Zero Suicide is a key concept of the 2012 National Strategy for Suicide Prevention, a priority of the National Action Alliance for Suicide Prevention (Action Alliance), a project of Education Development Center's Suicide Prevention Resource Center (SPRC), and supported by the Substance Abuse and Mental Health Services Administration (SAMHSA). The foundational belief of Zero Suicide is that suicide deaths for individuals under care within health and behavioural health systems are preventable. It presents both a bold goal and an aspirational challenge.

For health care systems, this approach represents a commitment: – To patient safety, the most fundamental responsibility of health care

– To the safety and support of clinical staff, who do the demanding work of treating and supporting suicidal patients

– The programmatic approach of Zero Suicide is based on the realization that suicidal individuals often fall through the cracks in a sometimes fragmented and distracted health care system. A systematic approach to quality improvement in these settings is both available and necessary.

– The challenge and implementation of Zero Suicide cannot be borne solely by the practitioners providing clinical care. Zero Suicide requires a system-wide approach to improve outcomes and close gaps.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Child and adolescent psychiatric clinic: Family-centered care for suicidal behaviour

D. Dovbysh<sup>1,2\*</sup>, M. Bebchuk<sup>2</sup>

<sup>1</sup> Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation, Department of Pedagogy and Medical Psychology- Faculty of Higher Nursing Education and Psycho Social Work, Moscow, Russia; <sup>2</sup> Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva- Moscow Department of Health Care, Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva- Moscow Department of Health Care, Moscow, Russia

\* Corresponding author.

**Introduction.**– There is an increasing number of children, who arrive at the mental health hospital in Moscow due to suicidal behaviour (2014 - 264, 2015 - 386, 2016 - 584). This tendency requires using family resources as the new approach in children healthcare.

**Objectives.**– Evaluation of parent's willingness to participate in child's treatment and their primary needs during child's hospitalization; development of the practical guidelines about family-oriented care for children with suicidal behaviour.

**Method.**– 341 families whose children were hospitalized in child mental health hospital (66% - by emergency services) and 58 child psychiatrists participated in our study from January to May 2017. Research includes the survey (in two options - for doctors and for parents) about the family needs and willingness of the parents to cooperate.

**Results.**– 92% of all families are interested in cooperation with health care providers, while the majority (94%) of psychiatrists stated that "child medical treatment" is the primary parent's need. 67% of parents are not satisfied with their communication with hospital staff and doctors; the unwillingness of doctors to admit parents as equal partners in the process of child treatment was named as the main barrier in effective communication. Health care providers, on the other hand, mark as the main barriers the lack of time and established over the decades treatment's tradition.

**Conclusions:** Readiness and willingness of parents to participate in the child's treatment during hospitalization demonstrate that training psychiatrists must be ready to use the rehabilitation potential of all family members.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Is Religiosity related to suicidal ideation among Tunisian college students after the January 14 Revolution?

F. Fekih-Romdhane<sup>1\*</sup>, R. Ben Rejeb<sup>2</sup>, R. Damak<sup>1</sup>, R. Ridha<sup>1</sup>, M. Cheour<sup>1</sup>

<sup>1</sup> University of Tunis El Manar- Faculty of Medicine of Tunis- Tunisia, Department of Psychiatry- Razi Hospital, Tunis, Tunisia; <sup>2</sup> University of Human and Social Sciences of Tunis, Department of Psychology, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– The founding act of the 2011 Tunisian revolution was a suicide. Since then, suicide risk rose significantly from 14% in 2005 to 22.7% in 2015. The highest suicide rates were in the 20–39 years age group, with an emergence of new methods of suicide, including self-immolation and suicide attacks.

Otherwise, Tunisia was known to be less religious than many Arab countries before the 2011 revolution, due essentially to the political control of and legal restrictions on religious activities. As a result of increased desire of the Tunisian people for religious freedom, and social and political changes that occurred during the seven last years, there was a rapidly increasing percentage of people who claimed some types of religious practice, with an unprecedented increase in radical Islamism.

**Objectives.**– This study aimed to explore whether religiosity relates to suicidal ideation, and whether associations persisted after controlling for psychosocial variables associated with suicide.

**Methods.**– Participants were 303 Tunisian college students who completed measures that assessed religiosity, hopelessness, depression, social support, and suicidal ideation.

**Results.**– After controlling for demographic variables and psychosocial factors, religiosity remained a significant predictor of suicidal ideation.

**Conclusions.**– Changes that Tunisian people have known in recent years pose new challenges to mental health professionals who need to better understand the main causes of their emergence, to implement intervention strategies that are effective. Our investigation highlighted religiosity as an important factor associated with lower levels of suicidal ideation among college students. These findings may prove especially beneficial to suicide prevention.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### An overview of non-suicidal self-injury among a sample of adult psychiatric patients

J. Fonseca<sup>\*</sup>, R. Rodrigues

Hospital Senhora da Oliveira, Psychiatry and Mental Health, Guimarães, Portugal

\* Corresponding author.

**Introduction.**– Non-suicidal self-injury (NSSI) is a repeatedly and non-social acceptable infliction of damage in one own body that implies its lesion in the absence of suicidal intent. This behaviour has been linked to early traumatic or loss experiences and to major mental disorders such as borderline personality disorder, eating disorders and post-traumatic stress disorders.

Among the methods described, the most common are skin cutting, head banging or hitting and burning. Other forms of self-injury include excessive scratching, taking supra therapeutic doses of prescribed medication or ingesting something harmful.

People who self-injure are usually trying to cope with intense and uncomfortable feelings, to resolve intra or interpersonal conflicts or to communicate something hard to express.

In recent years more attention has been given to this subject, but the literature is still scarce regarding this behaviour in the adult population.

**Objectives.**– The aim of this study is to analyze the characteristics of a sample of adult patients followed in a psychiatric outpatient clinic in Hospital Senhora da Oliveira in Guimarães, Portugal. We conducted an observational retrospective study of the patients observed in the crisis consultation of our outpatient clinic during the last year. We intend to describe the types, function and the epidemiology of self-injury in this population.

**Results.**– Data is still being collected and analysed. We intend to present a characterization of this behaviour and bring more attention to this topic that lacks more studies.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Non-suicidal self-injury and the Opioid system: Emotions, pain, and reward

F. Gomes<sup>1\*</sup>, B. Lourenço<sup>2</sup>, T. Teodoro<sup>3</sup><sup>1</sup> Centro Hospitalar Psiquiátrico de Lisboa, Clinic 1, Lisboa, Portugal; <sup>2</sup> Centro Hospitalar Psiquiátrico de Lisboa, Clinic 5, Lisbon, Portugal;<sup>3</sup> Centro Hospitalar Psiquiátrico de Lisboa, Clinic 1, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– Opioid system is involved in affective regulation, modulation of pain, and modulation of reward. Opioid system dysregulation has been proposed as one of possible mechanisms underlying non-suicidal self-injury (NSSI).

**Objectives.**– To review what is known regarding a possible role of the opioid system in NSSI.

**Methods.**– Non-systematic review searching Pub Med database for articles published from 2012 to 2017, using terms “self-injury”, “pain”, and “opioid”. 28 were selected, and 7 others from its references were also included.

**Results.**– In individuals with NSSI - namely, borderline personality disorder (BPD) cases -, pain attenuates negative emotions more intensely and selectively than in controls. Individuals with NSSI present a higher threshold and tolerance for pain. Besides pain modulation, also emotional regulation is postulated to be altered in individuals with NSSI, namely those with BPD. NSSI can be a maladaptive compensatory mechanism for a deficit in emotional regulation in BPD. Such effect seems to be mediated by brain structures responsible for affective and cognitive processing of pain, such as medial thalamus, anterior and mid-cingulate cortex, amygdala, anterior insular cortex.

NSSI provokes the release of  $\beta$ -endorphin and enkephalins, which may mediate a reduction in negative affect and/or an increase in positive affect. Individuals with NSSI may have lower resting levels of  $\beta$ -endorphin and enkephalins, generating an imbalance in the opioid system. Such imbalance may promote dysphoric and dissociative states, and also result in increased sensitivity of  $\mu$ -opioid receptors and increased analgesic and euphoric effects during NSSI.

**Conclusions.**– Future studies should include both biological and psychological variables, study non-BPD samples, and prospective studies.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Predictors of Suicidal ideation and prevention of autolytic attempts. Data collected in the HCUV

R. Hernández Antón<sup>1\*</sup>, J.M. Maderuelo<sup>2</sup>, E. Domínguez Álvarez<sup>3</sup>, M. Martín Alonso<sup>4</sup>, V. Molina Rodríguez<sup>5</sup>, P. Datta<sup>6</sup>, L. Gallardo Borge<sup>5</sup>, M. Hernández García<sup>5</sup>, M.V. Fernández<sup>2</sup>, J.A. Blanco Garrote<sup>5</sup>, R. González Collantes<sup>7</sup>, F. Uribe Ladrón de Cegama<sup>5</sup><sup>1</sup> MIR, Hospital Clínico Universitario Valladolid, Valladolid, Spain; <sup>2</sup> Instituto de Medicina Legal, Medicina Legal, Valladolid, Spain; <sup>3</sup> FEA Psiquiatría, Hospital Universitario de León, León, Spain; <sup>4</sup> MIR, Medicina Interna, Valladolid, Spain; <sup>5</sup> FEA Psiquiatría, Hospital Clínico Universitario de Valladolid, Valladolid, Spain; <sup>6</sup> Universidad Politécnica de Torino, Producción Industrial, Torino, Italy; <sup>7</sup> FEA Psiquiatría, Psiquiatría, Valladolid, Spain

\* Corresponding author.

**Introduction.**– Suicide is the act of deliberately taking away one's life. According to WHO, nearly 800,000 people commit suicide each year.

**Objectives:**

- To compare data from autolytic attempts in 2016/17 and in 1996/97 at the Hospital Clínico Universitario de Valladolid.
- To study if there is a relationship between consumed suicides and previous psychiatric care (income, ESM or ER) (if there were ideas of death, autolytic ideation and/or autolytic gestures).

- Influence of somatic diseases and economic crisis on suicide data and conflicting interpersonal in suicide attempts.

- Present prevention strategies

**Material and methods.**– Comparative descriptive data (age, gender, civil status, work situation, economic and legal, family and personal psychiatric antecedents, previous attempts), in cases of suicides and suicide attempts of both periods.

**Results:**

- Increased rate of suicide attempts of 45%.

- Distribution by sexes similar, although in 2016 a higher proportion was observed in males.

- The main methods of consummate suicide used in Valladolid are hanging (30%) and precipitation (28%).

- The percentage of women who self-injure (10 to 19 years) is significantly higher than that of men (29% women vs 4.5% men); the age of onset being less and less.

- 88.5% of the patients who underwent an autolytic gesture have a psychiatric diagnosis

- Interpersonal problems are the major stressors (53%).

**Conclusions:**

- Very important cause of mortality in the group of 15-24 years.

- Mortality in the general population has followed a decreasing trend; but suicide rates per 100,000 people have remained stable over the last decade.

- It is extremely important to carry out prevention strategies.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Stand up for life: Innovations and debates in stigma reduction and peer support in suicide prevention efforts

K. Hines<sup>1\*</sup>, D. Covington<sup>2</sup><sup>1</sup> The Kevin & Margaret Hines Foundation, Brain Health & Wellness, Alpharetta, USA; <sup>2</sup> American Association of Suicidology, President-Elect, Phoenix, USA

\* Corresponding author.

Suicide is a leading cause of death in the U.S. and public stigma is clearly associated with aversion to services that may reduce psychological distress/symptoms of mental illness and subsequently suicidal behaviour as well (Link, Phelan, 2002; Corrigan, Watson, 2004). Based on the work of Dr. Corrigan, the Center for Dignity, Recovery and Empowerment has developed structures, tools and evaluation instruments to guide effective stigma-reduction practice in the domain of mental health/mental illness. Most suicide prevention efforts center on a strategy of attempting to link at risk, people qualified with mental health resources. While this strategy makes sense, it will ultimately be ineffective if the culture surrounding the at-risk population is sending a louder message about stigma. We can have universally accessible, state-of-the-art care, but if the core beliefs held are about shame, these resources will not be used. This course is designed to teach new approaches to stigma reduction, such as the Center for Dignity, Recovery and Empowerment's "Coming Out Proud" program and the "Hope Group" (suicide attempt survivors support group) and will facilitate a "tensions in stigma reduction" debate on such questions:

- Should we or how should we use of word "stigma"?

- Do suicide prevention gatekeeper models break down barriers or build them?

- How do we best engage people with lived experience of suicide who 'come out' and disclose?
- How do we best bring Suicide Attempt Survivors and Suicide Loss Survivors together?
- What are best practices in suicide attempt survivor support groups?

### **Suicidal conduct and bipolar disorder type II**

A. Kachouchi\*, S. Salim, I. Adali, F. Manoudi, F. Asri  
University Hospital Mohammed VI, Department Of Psychiatry,  
Marrakech, Morocco

\* Corresponding author.

*Introduction.* – Suicide attempts are a very serious complication of bipolar disorder. 20% to 56% of patients with bipolar disorder will attempt suicide in their lifetime and 10% to 15% will die by suicide. Through three clinical cases of bipolar disorder type II, we aim to put the point on this problem.

*Method.* – Clinical cases.

*Results.* – First case: A 32-year-old unmarried woman, living with her parents, who was referred by a regional hospital emergency department for attempted suicide by drug poisoning. Second case: A 34-year-old divorced woman, a life-long painter, with toxic antecedents, with a history of attempted suicide, who went to the emergency room for another suicide attempt by drug poisoning. Third case: A 26-year-old married woman with two children, housewife, former training with a history of attempted suicide, who went to the emergency room accompanied by her husband for a new phlebotomy suicide attempt.

*Conclusion.* – The prevention of suicidal behaviour is essential and requires early diagnosis of the disorder, and a careful and repeated evaluation of the suicidal risk.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

<sup>5</sup> The Agha Khan University, Human Development Programme, Karachi, Pakistan;

<sup>6</sup> Harvey House Social Enterprises Lancashire, Harvey House Social Enterprises Lancashire, Lancashire, United Kingdom;

<sup>7</sup> Queens University, Center for addiction and mental health, Toronto, Canada

\* Corresponding author.

*Background.* – Self-harm is the most important predictor for future suicide attempt and there are 10-20 self-harm acts for every suicide.

Suicide and attempted suicide are illegal acts, and are socially as well as religiously condemned therefore there is no official data on suicide from Pakistan, a South Asian Islamic country. There is evidence that mental health care of patients who attempt self-harm can be improved by understanding self-harm and by safeguarding opportunities for dialogue.

*Objectives.* – To explore the experience of self-harm in Pakistan and also the experiences of participation in a culturally adapted intervention trial.

*Method:* Semi-structured in-depth interviews were conducted with 19 participants. All interviews were recorded, transcribed verbatim and analysed using the stages of a framework analysis; familiarisation, identification of a theoretical framework, indexing, charting and mapping and interpretation.

*Results.* – Three key themes were emerged “(1) precipitating factors for self harm (with four sub-themes; disturbed family relationships and domestic violence, isolation, gender roles and poverty), (2) traditional methods of conceptualizing mental illness (with two sub-themes; role of devils/possessions, faith healers), (3) effects of culturally adapted intervention (with two sub-themes; positive impact on emotional well-being, privileging pharmacological models instead of psychological).

*Conclusion.* – There are various psychosocial factors that can contribute to self-harm behaviour in low-income countries. Interventions that are culturally adapted and tailored according to need of population can lead to improvement in psychological well being of that population.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

<sup>2</sup> Pakistan Institute of Living and Learning, Research, Karachi, Pakistan;

<sup>3</sup> Harvey House Social Enterprises Lancashire, Harvey House Social Enterprises Lancashire, Lancashire, United Kingdom;

<sup>4</sup> Dow University of Health Sciences, Psychiatry, Karachi, Pakistan

\* Corresponding author.

*Background.* – The risk for suicide is significantly high among depressed women during the perinatal period, and suicide has been reported to be a leading cause of death in this depressed population. Suicidal ideation, a risk factor for completed suicide is more common than attempts or completed suicides, with thoughts of self-harm during the perinatal period ranging from 5 to 14%.

*Objectives.* – To find out the prevalence of suicidal ideation in mothers using both the self-report and trained interviewer administered measures.

*Methods.* – This is a secondary analysis of a larger study in which 600 mothers were recruited from low resource areas of Karachi. Out of these mothers, 338 were depressed on Edinburgh Postnatal Depression Scale (EPDS) and 262 were non-depressed. Clinical Interview Schedule-Revised (CISR) was administered to confirm the diagnosis of depression.

*Results.* – The prevalence of suicidal ideation using EPDS was 11.83% in depressed and 3.82% non-depressed mothers. On CISR, 14.63% depressed and 1.2% non-depressed mothers reported suicidal ideation.

**Conclusion.**– The rates of suicidal ideation are high in low-income mothers in urban Pakistan. EPDS appears to be a useful instrument to screen both for depression and high-risk mothers with suicidal ideation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Aircraft-assisted pilot suicides in the United States before and after the 24.3.2015 accident in the French Alps - Evidence on International Copycat Phenomenon?**

T. Laukkala<sup>1</sup>, J. Kuoppala<sup>2</sup>, R. Bor<sup>3</sup>, A. Sajantila<sup>4</sup>, B. Budowle<sup>5</sup>, P. Navathe<sup>6</sup>, A. Vuorio<sup>7</sup>

<sup>1</sup> Kela, the Social Security Institution, Helsinki, Finland;

<sup>2</sup> Siinto, Helsinki, Helsinki, Finland;

<sup>3</sup> Royal Free Hospital, Centre for Aviation Psychology, London, United Kingdom;

<sup>4</sup> University of Helsinki, Department of Forensic Medicine, Helsinki, Finland;

<sup>5</sup> Center for Human Identification- University of North Texas Health Science Center, Center of Excellence in Genomic Medicine Research-King Abdulaziz University- Jeddah- Saudi Arabia, Fort Worth, USA;

<sup>6</sup> Maitland Hospital, Maitland, Maitland, Australia;

<sup>7</sup> University of Helsinki, Mehiläinen Airport Health Centre, Vantaa, Finland

\* Corresponding author.

**Introduction.**– Aircraft-assisted pilot suicide, such as the Germanwings flight, is an extremely rare but serious phenomenon. These suicides were searched from the U.S. National Transport Safety Board (NTSB) database five years before and two years after the deliberate flight into the French Alps (24.3.2015) to assess possible changes.

**Objectives.**– The aim of this study was to assess whether there is evidence of changes in pilot aircraft-assisted suicide risks in the U.S. after the 24.3.2015 accident.

**Methods.**– The NTSB database search (13.9.2017) included only fatal aviation accidents in U.S., with accident investigation finalized and the cause of accidents assessed as a pilot suicide. The relative risk (RR) of the aircraft-assisted pilot suicides in all fatal accidents was calculated to compare the period 2 years after with 5 years before the accident in the French Alps.

**Results.**– During two years (25.3.2015- 24.3.2017) after the incident, 3 out of 453 (0.66%) fatal accidents were aircraft-assisted suicides compared with 6 out of 1292 (0.46%) during five years (24.3.2010-23.3.2015) before, the relative risk being 1.43 (95% CI 0.54-3.78).

**Conclusions.**– An increase in the aircraft-assisted suicide risk was not observed in our statistical analysis. Thus, a copycat phenomenon, which would contribute to an increased risk, has not occurred during this time span. Limitations of this study include the fact that manner of death assessments are based solely on data included in accident investigations. Moreover, pilots in general are resilient and criteria for fitness to fly tend to select against high-risk individuals.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Essence of suicidal article highlighted the social determinants that contribute to risks of suicidal behavior**

M. Mammadova\*, M. Mammadova

Ministry of Justice, Main Medical Department- Psychiatric department, Baku, Azerbaijan

\* Corresponding author.

The problem of suicide, bearing interdisciplinary in nature, is located at the intersection of problematic fields of sociology, philosophy, psychology, psychiatry. There are social determinants that contribute to the risk of suicidal behaviour which include 3 groups of problems subjects depending on the level of suicidal risk: The first group consists of teenagers having 1-2 signs of suicidal risk, the second group - with 3 signs of suicide risk, the third group - 4 signs of suicidal risk. In the study, adolescents with deviant (addictive, delinquent and criminal) behaviour undergoing rehabilitation in narcological clinic, it was found the predominance of reactive aggression over proactive. Revealed such personal predictors of self-destructive behaviour as a demonstrative, affectivity, low self-esteem and a sense their own inadequacy, social pessimism, lack of sustained goals in the future, problems in interpersonal relationships, including with loved ones relatives, as well as the presence of signs of social maladjustment. Currently, it seems to us that all prison staff must be trained on recognizing the signs of mental illness as part of suicide prevention. Inmates with a higher propensity for suicide, including those who already have made a suicide attempt in the past, needs around the clock are being monitored or contained in the premises, equipped with video surveillance systems, allowing to control their actions. The Ministry of justice is doing everything possible to prevent suicides in prison institutions, taking measures such as early detection of suicidal prisoners with the help of scientific and rational methods, particularly psychoanalysis and counseling psychologist.

### **Self-Harm research UK: Development of an online research platform**

A. Marchant\*, K. Lloyd, A. John

Institute of life science, College of Medicine, Swansea, United Kingdom

\* Corresponding author.

**Introduction.**– Self-harm is a growing public health issue. Current research is largely based on populations presenting to Emergency Departments leaving a large number of vulnerable individuals unrepresented. The nature of the online world has led to a substantial research interest into the nature and influence of internet use in those who self-harm.

**Objectives.**– This study aims to assess the feasibility of a web-based platform for self-harm research. This platform will aim to bring together: questionnaire data; routinely collected healthcare data and uploads to a databank of online material.

**Methods.**– An online platform for self-harm research has been developed. This platform functions as a questionnaire delivery platform and as a place for individuals to upload sources of advice/information from the Internet. These uploads will form a databank of media sources that can undergo further assessment. Participants will be given the option to sign up to the UK's first population based linked research register and to consent to having their data linked with routinely collected healthcare data.

**Results.**– Work with the platform is in its preliminary stages. It is hoped that results will assist in identifying vulnerable groups

missed by traditional research. Such results will assist in the development of future service provision and support.

**Conclusions.**– If successful this project would demonstrate the utility of an online platform for self-harm research. It may also result in a register of individuals who self-harm that can be contacted for future research and a databank of media sources that can undergo further study.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Descriptive analysis of personality traits in outpatients with previous suicidal behaviours**

R. Navarro Pablo<sup>1</sup>\*, O. Santamaria Gómez<sup>1</sup>, F. Gotor Sánchez Luengo<sup>1</sup>, B.O. Plasencia García de Diego<sup>2</sup>, S.L. Romero Guillena<sup>3</sup>

<sup>1</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Seville, Spain;

<sup>2</sup> De la Merced Osuna Hospital, Department of Psychiatry, Seville, Spain;

<sup>3</sup> U.G.C Salud Mental Virgen Macarena Hospital, Department of Psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– Suicide is an important public health problem and the result of a serious complication of psychiatric disorders. Suicidal behaviours are epidemiologically and clinically related to Personality Disorders.

**Objectives.**– Describe the sociodemographic and personality traits of a sample of outpatients with a previous history of suicidal behaviours.

**Methods.**– Cross-sectional observational study. Sociodemographic and clinical data were collected during 6 months (July to December 2016). A personality assessment was performed using the Salamanca Questionnaire on Personality Disorders. Those patients suffering from Dementia or mental retardation were excluded.

**Results.**– Twenty-four patients participated in the study, 75% were women. The mean age was 46.3 (SD = 8.66). 75% were women. The mean of previous suicidal attempts was 3.37. Half of the patients had a previous diagnosis of Personality Disorder and 93.75% scored positive values for different personality disorders.

The highest scores were: Histrionic (M = 3.56, SD = 1.54); Anxiety (M = 3, SD = 1.86), Emotional instability limit type (M = 3.37 SD = 1.07) and Dependent (M = 3; SD = 2). The least frequent scores were: Antisocial (M = 0.56) and Narcissistic (M = 0.87).

The most frequent traits were: intense variable emotions, excessive care for appearance, frequent feelings of boredom and emptiness, frequent thoughts of lack of role in life, nervousness and fear of ridicule.

**Conclusions.**– These data showed profiles with multiple anomalous personality traits and corroborate how personality difficulties could lead suicidal behaviour. Extended research is needed to identify potential personality risk markers.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0927

### **Suicide: A systematic check-up**

M.D.L.C. Ramirez Dominguez\*, L. Hernandez Gonzalez, M. Nuñez Caro

Psychiatrist, Psychiatrist, Aljaraque, Spain

\* Corresponding author.

**Introduction.**– Suicide is always a tragedy for the individual, his family and friends and the communities of which it is part. In terms of

population, suicide is also a major public health problem, which involves more than 34,500 deaths annually in the United States and a million or more is estimated worldwide.

**Objectives.**– There are good and bad news regarding existing trends in the advancing age and suicide over time in the United States, where the overall suicide rate declined slowly but steadily from 1985 to 2000, after which it started to increase again marginal mode.

**Results.**– To design interventions to reduce morbidity and mortality related to suicide, we need to understand its causes. Establish causation in a complex outcome, multietiological, rare and dire consequences: such as suicide is a daunting task. However, identifying risk factors and protective can guide preventive measures.

**Conclusion.**– The importance of depression as a pathogenic factor in the suicide of the advanced stage of life makes their detection and effective treatment are paramount. The multidisciplinary care provided by primary care professionals who have the support of mental health experts has produced promising results as indicated preventive intervention, although its effect in reducing suicide in elderly men is yet to be determined

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0928

### **Population drinking and gender gap in suicide mortality in Russia**

Y. Razvodovsky

Grodno State Medical University, Pathological Physiology, Grodno, Belarus

**Introduction.**– Across most countries, suicide rates are significantly higher for men compared to women, while women typically have higher rate of suicidal attempts. The gender difference in the suicide rates is particularly large in the Eastern European countries. There is suggestive evidence of a crucial role of alcohol in explanation of this phenomenon.

**Objectives.**– In present study we will test the hypothesis of the close aggregate level link between alcohol consumption and gender difference in suicide mortality rates in Russia using data on sex-specific suicide rates and alcohol consumption per capita between 1965 and 2015.

**Methods.**– Time-series analytical modeling techniques (ARIMA) were used to examine the relation between the gender gap in suicide mortality and trends in alcohol consumption per capita.

**Results.**– According to the results of time-series analysis, alcohol consumption is a statistically significant factor associated with gender gap in suicide mortality in Russia, implying that a 1-litre increase in consumption per capita is associated with an increase in the difference between male and female suicide mortality rates by 8.3%. The results of the analysis also suggest that 66% of the difference in suicide mortality between males and females in Russia could be attributed to alcohol.

**Conclusions.**– The outcomes of this study provide indirect support for the hypothesis that alcohol is a major contributor to the high gender gap in suicide mortality and its dramatic fluctuations in Russia during the last few decades.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Sociodemographic and clinical characteristics of patients with suicidal behavior or ideation in the Northern area of Tenerife**

A. Sánchez-Pavesi<sup>1</sup>, R. Calles, L. Navarro, M. Alcántara, L. Povedano, Y. Morant, I. Ximénez de Embún, M.R. Cejas<sup>\*</sup>  
Hospital Universitario de Canarias, Psychiatry, San Cristóbal de La Laguna, Spain

\* Corresponding author.

More than 800,000 people committed suicide in 2015; 3,602 in Spain. In Canary Islands, 190 died, 94 of which committed suicide in Tenerife.

Currently, there is no suicide prevention program in this province. We consider imperative to initiate a protocol, and to this end, we elaborate a study that reflects the current situation.

Through a database software, sociodemographic, clinical and discharge data were collected from 98 patients who attended the Hospital Universitario de Canarias between April first and December thirty-first 2016.

Patients were mostly women, middle-aged, with children, unemployed, living with their own family. 75% were discharged in less than 4 days, while 8% required hospitalization. 34% had suicidal ideation. 83% of the attempts were made by prescription drug overdose. 53% had made previous attempts. As for the data regarding discharge, more than 80% received some anti-depressant and anxiolytic drug. 90% were referred to their Mental Health Unit, reaching 30% in the first month.

The data analysed shows characteristics similar to those observed in the rest of studies that deal with this topic. It is worth noting the short period of hospitalization of the majority of patients. In addition, although the vast majority is referred to its Mental Health Unit, only 30% reaches in the first month.

The absence of a protocol to care for patients with suicidal risk means that they do not have adequate follow-up after discharge. Therefore, it is necessary to establish in an early manner this protocol, already existing in other provinces and whose results are widely recognized.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0930

### **Suicide risk factors in outpatients with suicide behaviour in a community mental health unit**

O. Santamaria<sup>1\*</sup>, R. Navarro<sup>1</sup>, B.O. Plasencia<sup>2</sup>, F. Gotor<sup>1</sup>, S.L. Romero<sup>3</sup>

<sup>1</sup> Nuestra Señora de Valme University Hospital, Psychiatry, Seville, Spain;

<sup>2</sup> La Merced Hospital, Psychiatry, Osuna Seville, Spain;

<sup>3</sup> Virgen Macarena University Hospital, Psychiatry, Seville, Spain

\* Corresponding author.

*Introduction.*– To minimize the chance of suicide, it is absolutely necessary to have a cross approach.

The actions must be considered at the following stages: a) prevention; b) detection; c) diagnosis; e) treatment; and f) follow-up treatment of mental health disorders.

Over the last years, the approach has been more about the prevention of the suicide pattern.

One of the most important actions to do this, is the evaluation of the suicide risk through psychometrics tools and clinical interview.

*Objective.*– To analyze the presence and frequency of suicide risk factors in an outpatient sample.

*Methods.*– A descriptive epidemiological study that analysed the medical histories of 29 patients, who has been evaluated using the Sad Persons Scale in a Community Mental Health Unit. These patients are in treatment because they have committed previous suicide attempts.

The scale give one point for each item: sex, age, depression, previous attempt, etanol abuse, rational thinking loss, social support lacking, organized plan, no spouse, sickness.

*Results.*– The percentage of each suicide factor is presented in the graphics below.

*Conclusions.*– The risk is evaluated in this case by “Sad Persons” scale, which does not substitute the psychopathological evaluation and other risk factors. Among the results, there are two indications: a) Signs of depression on his various forms, is considered the most important suicide cause, b) Absence of a partner (i.e. husband or wife) adds to a social risk factor.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0931

### **To find the silent message–nurses experiences of the non-verbal communication preceding a suicide**

T. Sellin<sup>1\*</sup>, P. Rytterström<sup>2</sup>, M. Lindeborg<sup>3</sup>, S. Korhonen<sup>3</sup>

<sup>1</sup> University Health Care Research Center, Faculty of Medicine and Health, Örebro, Sweden;

<sup>2</sup> Department of Social and Welfare Studies, Linköping University, Linköping, Sweden;

<sup>3</sup> Psychiatric Specialist Care, Region Örebro County, Örebro, Sweden

\* Corresponding author.

*Introduction.*– Suicidal individuals often communicate their suicidal intent, but not necessary verbally. It requires sensitivity to recognize the silent and indirect messages of suicide plans that otherwise may pass unnoticed. Psychiatric nurses have a central role in the care of patients with suicidal behaviour or thoughts. By sharing nurses' experiences, essential knowledge about suicidal communication can emerge.

*Objectives.*– The aim of this study was to explore nurses' experience of non-verbal messages by the patients preceding suicide.

*Method.*– A qualitative design with a phenomenological hermeneutical approach was used. Seven nurses working in psychiatric specialist care were interviewed about their experience of the studied phenomenon.

*Results.*– Experiences of silent suicidal communication are presented in three themes and ten sub-themes. The nurses experienced a multi-faceted change in the patient just before the suicide. The identified changes were to improve rapidly, to put up a disguise, and to be unreceptive of further treatment or encouragement. The nurses also described patients' painful awareness of life conditions and how they lose hope and confidence in future, with feelings of being powerless without ability to influence the situation. They finally decided to capitulate. The last period in life was characterized by an increased preoccupation of thoughts about death and making an end. This was shown in practical preparations, in expressing gratitude to people, and by bidding farewell.

*Conclusion.*– Nurses in psychiatric care can perceive and interpret nonverbal messages from patients who are suicidal. This knowledge might be used as a complement to a structural suicide risk assessment.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0932

### Depression and suicide thoughts among medical students

M. Iorga<sup>1</sup>, S. Socolov<sup>2</sup>, T. Pantilimonescu<sup>3</sup>, M.I. Gavrilesco<sup>3</sup><sup>1</sup> University of Medicine and Pharmacy “Grigore T. Popa”, Behavioral Sciences, Iasi, Romania;<sup>2</sup> “Gr. T. Popa” University of Medicine and Pharmacy, General Medicine, Iasi, Romania;<sup>3</sup> University of Medicine and Pharmacy “Grigore T. Popa”, General Medicine, Iasi, Romania

\* Corresponding author.

**Introduction.**– Recent evidence show that medical students are at high risk for depression and suicidal ideation caused by stress and burnout, comparing to general population.

**Objectives.**– The aim of this study is to investigate and compare the overall prevalence of depressive symptoms among medical students from 1st and 6th year of study.

**Methods.**– A number of 202 medical students took part in this study (98 freshman students and 104 enrolled in 6th year of study). Students were asked to fill a questionnaire with socio-demographic data and to answer to the items of Beck Depression Inventory in order to evaluate the level of depression. The statistical analysis of data was done using SPSS Statistics v23.0.0 for MAC.OSX and for the comparative analyses we used Independent Samples T-Test.

**Results.**– The overall depression score was lower:  $t(198)=4.010$ ,  $P=0.000$  for the 6th year students ( $M=6.81 \pm 7.47$ ) compared to the 1st year medical students ( $M=10.97 \pm 7.17$ ). Seniors ( $M=0.03 \pm 0.23$ ) had less self-punitive thoughts ( $t(197)=2.235$ ,  $P=0.027$ ) compared to freshman students ( $M=0.15 \pm 70.46$ ).

**Conclusions.**– Our results show that 1st year students are more depressed than seniors and the prevalence of suicidal thoughts among freshman students is higher. Strategies for preventing and treating depression among medical students, especially for those in the pre-clinical years are needed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

Results published by WHO show that suicide is one of three leading causes of death among people aged between 15 and 34 years old.

**Objective.**– To study patterns in formation of suicidal behaviour among females.

**Methodology.**– 30 women who attempted suicide within last three days were examined in Medical Centre No. 1 in Baku, Azerbaijan. Each patient was interviewed, and his or her response was used to fill in a questionnaire. Thereafter, the responses were analysed using Beck depression inventory and Zung depression scale.

**Results.**– Most of the subjects had mild or more severe depression (BDI–82.3%, Zung depression scale–82.4%).

The subjects were divided into groups based on their age, marital status, social status and education level. A negative correlation between education level and size of the respective group was observed.

Interviews with the married women suggested that:

– (i) Their inability to get divorced due to fear of social stigma was an important factor driving them to suicide.

– (ii) Most of the suicide initiatives were intended not to result in death, but to serve as a means for self-defence or influencing another person to achieve a goal. BAP’s depression phase and symptoms of Conversion Disorder were observed in the former and latter cases, respectively.

**Conclusion.**– The research identified level of education, presence of conflicts in family, fear of social stigma to be important factors in determining likelihood of women attempting suicide. It is suggested that these conclusions can be used to create gender-differentiated methods for preventing suicide specifically aimed at women.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Constructivist strategies in cognitive-behavioural therapy for managing suicidal ideation and hopelessness: A case study

C. Silva, C. Varanda<sup>\*</sup>

Universidade Paulista, Institute of Human Sciences, Santos, Brazil

\* Corresponding author.

Suicide is currently a global public health problem and is one of the leading causes of mortality. Based on the literature it is also known that in most cases, some disease or mental disorder is amongst the contributing factors to suicidal behaviour. Likewise, the subject who manifests a suicidal intent tends to express beliefs of hopelessness and few perspectives about the future. The aim of this study was to describe the contributions of constructivist strategies in cognitive-behavioural therapy (CBT) to manage suicidal ideation and hopelessness and to point out the related cognitive triad. The case report describes the psychotherapeutic care of a 28-year-old patient with depressive symptoms. In the diagnostic assessment, the ICD-10 and DSM-V criteria were used, as well as the Beck inventories for depression, hopelessness and suicidal ideation. The treatment plan proposed the exploration of sensory pathways for questioning beliefs using constructivist techniques such as subjectivation and objectification. Referral for psychiatric follow-up, cognitive-behavioural techniques such as psychoeducation of depression and cognitive model, search for social support, problem solving, cognitive restructuring and strategies for relapse prevention were used. As results, there were reductions in Beck’s inventory scores, reduction of distorted thoughts, remission of depressive symptoms, and improvement in biopsychosocial functioning. It is suggested, therefore, that the strategies of the two approaches complement each other to offer the possibility of remeaning experiences in the management of hopelessness, as well as in the expansion of behavioural repertoire and beliefs to face the desire to die.

## Training in psychiatry

EV0935

### French psychiatry residency training reform: Will the phoenix raise from the ashes?

A. Fontaine<sup>1\*</sup>, A. Pelluet<sup>2</sup>, R. Sayous<sup>3</sup>, C. Henry Dit Guillaumin<sup>4</sup><sup>1</sup> University of Lille- Lille's University Hospital- Department of Psychiatry- F-59000, General psychiatry, Lille, France;<sup>2</sup> Grenoble University Hospital, Psychiatry, Grenoble, France;<sup>3</sup> Lyon University Hospital, Psychiatry, Lyon, France;<sup>4</sup> Montpellier's University Hospital, General Psychiatry, Montpellier, France

\* Corresponding author.

**Introduction.**– Since 2009, France has been working on a profound remodelling of residency training, including psychiatry. The French psychiatry residents' association (AFFEP) has been actively working on this reform from the very beginning, alongside with the National College of Psychiatry Professors (CNUP), and the French Junior Doctor Union.

**Method.**– We will present the reform and the changes it brings, on the positive and negative sides.

**Results.**– The French residents who have started residency training in November 2017 are benefiting from a brand new system. Their curriculum is divided in 3 stages, with gradual autonomy, and their knowledge and experience acquisition synthesised in a progressive portfolio. Child and adolescent subspecialty training (CAP) is upgraded so that residents can complete the six rotations needed for the European recognition. A new subspecialty of old age psychiatry has been created, broadening the training in this field. So far, very few residents have had the opportunity to realise rotations in old age psychiatry. Even though the reform is promising, some issues remain unsolved. Training in forensic psychiatry has to be developed to face the society demands; making it a subspecialty is essential but not accepted by the government yet. The proportion of residents choosing CAP and the ways to improve it is also a hot topic.

**Conclusion.**– This reform is a major shift in French psychiatry residency that will profoundly modify the training of future psychiatrists and the field itself. Yet, there are some points that remain to be clarified.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### BPS working group on recovered memories and extreme abuse surveys

R.H. Kurz

Outstanding Achievements, Research, Long Ditton, United Kingdom

**Introduction.**– This paper revisits results of a BPS survey where 15% of practitioners had encountered Satanic Ritual Abuse (SRA) disclosures and the Extreme Abuse Survey where Satanists were the most frequently identified offender group.

**Objectives.**– The presentation reviews evidence of SRA gathered through survey formats.

**Aims.**– This presentation educates mental health professionals about SRA and the associated dissociative disorder symptoms that are frequently overlooked or misdiagnosed in clinical practice.

**Methods.**– Key results of the two surveys regarding SRA were reviewed.

**Results.**– In the May 1995 issue of *The Psychologist* Andrews et al reported on 'The recovery of memories in clinical practice' soon

after their BPS Working Party on Recovered Memories report had been published. In their survey 13% of 1083 respondents' ever worked with client reporting SRA and had believed them'. Curiously neither the article nor the report made any attempt to define or describe SRA.

The 307 page report on the Extreme Abuse Survey conducted in 2007 can be downloaded from [endritualabuse.org](http://endritualabuse.org), the website of US Clinical Psychologist Dr Ellen Lacter. It features results of surveys with survivors, professionals and carers of child survivors of extreme abuse outlining dozens of extreme abuse varieties including 'impregnation' to breed babies and 'Human Sacrifice Murder'. **Conclusion.**– Given that SRA was encountered by a substantial proportion of practitioners and seemingly covers heinous crimes it appears opportune to conduct a replication of the BPS Survey with a branched administration of the Extreme Abuse Survey for those who have encountered disclosures of SRA.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Helping students learn useful clinical skills–reconsidering the pedagogy of the mental status exam

E. Lenouvel<sup>1,2\*</sup>, J. Lipiec<sup>3</sup><sup>1</sup> Réseau Santé Mentale, Outpatient Psychiatry, Bienne, Switzerland;<sup>2</sup> Karolinska Institutet, Learning- Informatics- Management- and Education, Stockholm, Sweden;<sup>3</sup> Fondation de Nant, Outpatient Addiction Psychiatry, Montreux, Switzerland

\* Corresponding author.

**Introduction.**– The psychiatric mental status exam (MSE) is a structured assessment of behavioural and cognitive functioning. It requires observational skills and subtle discrimination to discern the often difficult to describe traits that characterize a psychiatric disorder. Its use and interpretation is a fundamental skill medical students and medical practitioners must have, to establish well founded diagnoses and evaluate treatment progress. This is particularly important due to the high prevalence and chronology of psychiatric disorders. In comparison to other clinical skills, little is known about how the MSE is taught.

**Objective.**– To investigate currently available publications regarding MSE pedagogy through a thorough literature review, and to extract teaching/learning activities (TLAs) from those publications. **Methods.**– Relevant articles in Pub Med, ERIC, and Psycinfo databases were manually searched. Mental Status Exam, Mental Status Examination alone and combined with scholarship, education, teaching, learning, and pedagogy. Exclusion criteria were no mention of the MSE or omission of discussion on teaching methodology.

**Results.**– 8 relevant articles were retained, and 6 TLAs were identified: Didactic lectures (the most common and traditional TLA), videotaped interviews, simulated patients, virtual patients, tutorial groups, and student roll play following lectures.

**Conclusions.**– In attempting to establish an MSE course these TLAs can be considered. The choice of which TLAs to implement in a training program depends on an institutions' available resources. Further published research and discussion on this topic will help build evidence for effective teaching methods, which will hopefully translate into more effective psychiatric evaluations in the next generation of medical professionals.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### On an integrative psychiatry in education

M.C. Michailov<sup>1</sup>\*, E. Neu<sup>1</sup>, C. Lütge<sup>2</sup>, U. Welscher<sup>1</sup>, H.W. Bauer<sup>3</sup>, A. Hofstetter<sup>4</sup>, E.R. Weissenbacher<sup>5</sup>, M. Schratz<sup>6</sup>, G. Weber<sup>7</sup>

<sup>1</sup> Inst. Umweltmedizin c/o ICSD e.V., PharmaEVPhysiology, Munich, Germany;

<sup>2</sup> Techn. Univ. München, Inst. Ethics Dir., Munich, Germany;

<sup>3</sup> Univ. München and Free Univ. Berlin, Med. Fak., Munich, Germany;

<sup>4</sup> Univ. München, Klinikum Grosshadern Dir. a.D., Munich, Germany;

<sup>5</sup> Univ. München Med. Fak., Premium Med. Clinic Dir., Munich, Germany;

<sup>6</sup> Univ. Innsbruck, School Education Dean, Innsbruck, Austria;

<sup>7</sup> Univ. Lxbg. and Vienna, Fac. Psychology Dean, Vienna, Austria

\* Corresponding author.

**Introduction.**– Objectives: Psychiatry is interdisciplinary science and of fundamental importance for enormous problems of humanity. Creation of an integrative psychiatry in context of a multidimensional&holistic medicine, founded by HIPPOCRATES-GALENUS-HUA T'UA-PARACELSUS is necessary to counteract disastrous human situation.

**Methods.**– Related to medical-philosophy.

**Results.**– Theoretical approaches about discussion for an integrative psychiatry. During Opening-Ceremony of 18thWorld-Congress Psychosomatic-Medicine (ICPM 2005 Kobe) were present their majesties Emperor&Empress of Japan, Prime&Ministers for Science-Education-others&prominent scientists. Emperor AKIHITO honored congress by strategical ideas, available also for all anthropological-health sciences, “total symptoms of mind&body, seeking ways of holistic care ... it is extremely important for patients, my hope contributes to the progress of medical science and people's happiness in the entire world”.

Yujiro IKEMI/Ex-President of ICPM opened new dimension not only in psychosomatics&psychiatry, but also in general-medicine&psychology by integration of oriental somatopsychic theory&self-regulation practices (Yoga/Qigong/Zen-meditation/etc.) with occidental psychosomatics (Th.von UEXKÜLL). Psychiatric-societies/EPA/WPA, continental/national (American-Asian-European-etc.) could found Committees preparing proposals for creation of an integrative psychiatry incl. harmonious participation of medical-philosophy (epistemology-ethics-aesthetics), psychology, psychosomatics, psycho-physiology/pharmacology in education&research. Also support of round-table-discussions in this matter during congresses (involving scientists/politicians) giving recommendations to UNSEVWHO-EU-governments is recommendable.

ON AN INTERNATIONAL ACADEMY FOR PSYCHIATRY (IAP), similar to European-Acad Neurology/EAN founded 2015 in Berlin, could be promoted creation of an integrative-psychiatry incl. oriental-holistic traditional medicine-philosophy-psychology counteracting enormous dominance of occidental-one.

**Conclusion.**– New kind of education/research/practice in psychiatry by interdisciplinary fundamentals in context of philosophy-psychology-informatics to experimental/clinical psychiatry could open new dimension in psychiatry (therapy/prophylaxis) in context of UNO-Agenda21 for better health/ecology/economy on global level.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The effect professors have on students

A. Rokach<sup>1</sup>

<sup>1</sup> Center for Academic Studies, Psychology, Petach-Tikva, Israel

\* Corresponding author.

Good practices in education have a positive impact on students' development and engagement. Student-faculty interaction is a meaningful and important factor in students' academic and social success in university. Those teacher-student interactions are particularly significant when they occur informally, increase students motivation, they remain engaged in class activities, and are actively involved in the learning process, and such an interaction has been identified as a primary agent of college culture, and has an important influence on the attitudes, interests, and values of college students. Research has explored Teacher -Student Relationship and identified two main dimensions of this type of relationship: the affective dimension, which includes honesty, trust and respect and which describes the bond built between students and teachers forming the basis for secure and affective positively experienced relationships, and the support dimension, including respectful approach, trustworthiness, safe atmosphere, and fairness which describes the support that must be provided through TSR for students' success at university. Faculty may interact with students formally in class, informally out of class, or it could take on a more intense flavor in a tutorial style classroom, where a faculty member may meet with a small number of students for up to an hour. The poster concludes with various ways in which faculty can enhance students' growth, dedication to the program, and success in academic work.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0940

### Scientific research as an integral part of the work of a psychiatrist leading an outpatient consultation in the regional diagnostic center of the Subarctic territory

K. Shapovalov<sup>1</sup>\*, L. Shapovalova<sup>2</sup>

<sup>1</sup> State Education Agency of Additional Professional Education of Republic of Komi “Komi Republican Institute for Development of Education”, Chair of Additional Education, Syktyvkar, Russia;

<sup>2</sup> State Autonomous Health Agency of the Republic of Komi “Consultative and Diagnostic Center of the Republic of Komi”, Diagnostic department, Syktyvkar, Russia

\* Corresponding author.

**Introduction.**– The work of practicing psychiatrist leading consultative outpatient, is associated with constant analysis of identified symptoms of diseases, results of diagnostic examinations and clinical analyzes. He carries out educational activities to prevent using of toxic substances by population.

**Objectives.**– It was analysed 87 scientific and 143 methodical works, including 1 monograph and 8 manuals (Two of them Ministry of Education of Russia awarded the neck of textbooks for students of higher educational institutions), carried out by psychiatrist of regional consultative center of the subarctic territory.

**Methods.**– Historical, analytical

**Results.**– Scientific interests of psychiatrist include following problems: Mental morbidity of population of circumpolar regions; Public health; Social Medicine; Didactics of fundamentals of life safety, healthy lifestyle and health preserving technologies in higher and secondary vocational schools.

Five information letters were developed, which deal with the differential and diagnostic criteria of the syndromes of latent depression. For doctors and nurses, lectures are given: 1) What you need to know about depression. Depression and somatic diseases. 2) Anxiety in general somatic practice. 3) Mental disorders in craniocerebral trauma. 4) Cognitive impairment in old age. 5) Gerontology. Accelerated aging of the population. The main factors of mortality and morbidity in Russia. 6) Somatoform disorders, psychosomatic diseases, somatopsychic disorders. 7) Features of the psyche of an elderly person.

**Conclusions.**– Scientific and methodical work is spent on correct formation of a contingent of patients directed on reception to psychiatrist and the psychotherapist of the regional advisory center by general practitioners of city polyclinics and the central regional hospitals.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Configurations of clinical discussions, modulated according to the common patient stereotypes, and so constructed among supervisors and residents in a Brazilian university psychiatric outpatient service**

E.R. Turato\*, M.E.F. Bremberger

UNICAMP - State University of Campinas, Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

\* Corresponding author.

Clinical supervisions are impregnated by subjective aspects, in addition to clinical objectivity of the cases. In psychiatric discussions, emotional aspects tend to be more characteristically modulated according to different diagnostic and therapeutic demands in the 'madness' approach. Usual behavioural types of patients construct respective types of supervision discourse.

**Objective.**– To categorize types of discourse that are configured in clinical discussions among supervisors and residents, considering psychological stereotypes of adult patients, from audio recordings that occurred after medical consultations.

**Method.**– Qualitative design. Data collection through audio recordings of clinical discussions, at the General Hospital of the State University of Campinas, State of São Paulo, with 17 medical professionals - 03 supervisors and 14 residents, after consent form. Free-floating readings of the transcribed speeches, consisting of 66 sessions, 947 minutes. Data interpreted by content analysis. Categories validated at the Laboratory of Clinical-Qualitative Research.

**Results.**– 04 categories are emerged: (1) medical team configures a "defensive posture", due to patients that cause emotional overloads for presenting demands of multiple natures; (2) "impotent posture" towards called "difficult" patients, considering the proposed therapeutic schema, but with problematic adherences; (3) clinicians become a "exciting team" because patients are scientifically challenging due to rarity or clinical richness; (4) an "intriguing team" configuration, because patients are marked by unusual situations, provoking human curiosity and perplexities.

**Conclusions.**– Peculiarities of often-discussed clinical cases lead to narratives that build their own configurations, as a usual way of dealing with those peculiarities. Awareness of such configurations may be useful for professors in self-criticism.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Students with specific learning difficulties in undergraduate medical education: Are attempts at equality working?**

J. Underwood

Cardiff University School of Medicine, MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff, United Kingdom

**Background.**– Specific Learning Difficulties (SpLDs), such as dyslexia, are explicitly discussed within Equality Act 2010, which ensures provision of assistance and prevents discrimination [1]. Despite this, evidence suggests that students with SpLDs are under-represented in medicine compared to other disciplines.

**Methodology.**– This study systematically reviews literature on SpLDs in undergraduate medical education following the PRISMA guidelines. Nine studies were included which examined medical undergraduates, with 8 included from wider clinical education.

**Discussion.**– Studies report prevalence of learning difficulties in medical students between 1.5–3% [2]. Stigma was highlighted to be a major factor, resulting in reluctance to report difficulties or disclose diagnoses [2,3]. Few papers assess the adaptive or assistive methods used, but where discussed were generic to higher education [3].

Two studies examine the results of students with SpLDs, the most quantitative measure of equality of education. Both find that students with SpLDs when properly identified achieve academic parity. There is disagreement over whether assessment method results in disadvantage with a gap in the literature [4,5].

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Study psychological mechanisms of procrastination for sample of students in Qatar university

B. Abu hamdah\*, T. Bellaj

*Qatar University, Social Sciences, Doha, Qatar*

\* Corresponding author.

Because of the increasing interest in procrastination since it is considered a complicated psychological process, which contains many interactions between the cognitive and the non-cognitive psychological conditions. This study aims to study how procrastination is related to Impulsive, the ability to seduction and irrational thoughts. The current study was done on a sample of 120 students from Qatar University (36 males and 84 females). Several scales were applied on the targeted sample, for example the Pure Procrastination Scale, the Irrational Procrastination Scale, the Susceptibility to Temptation Scale, the Individualism and Collectivism Scale and Impulsive Behavior Scale. The results of this study agreed with the validity and persistence of the PPS  $\alpha = 87$  which generally indicates the internal consistency of the PPS scale. Whereas the findings did not show a significant correlation between procrastination and the cultural orientations, we found a statistically significant relationship between procrastination and impulsivity, the susceptibility to temptation and the irrational thoughts of procrastination, which proved the importance of non-cognitive processes in shaping the procrastination that interacts necessarily with cognitive processes in its determination.

*Keywords:* Procrastination; Susceptibility to Temptation; Irrational thoughts; Impulsive behaviour; Cultural orientation)

### Therapy engagement among women with substance use disorders: A cultural perspective

H. Ahluwalia<sup>1\*</sup>, P. Chand<sup>2</sup>, L.N. Suman<sup>1</sup>

<sup>1</sup> *National Institute of Mental Health and NeuroSciencesNIMHANS, Clinical Psychology, Bangalore, India;*

<sup>2</sup> *National Institute of Mental Health and NeuroSciencesNIMHANS, Psychiatry, Bangalore, India*

\* Corresponding author.

*Introduction.*– Several barriers affect adherence and outcomes in the treatment of women with substance use disorders (wSUDs). Low socioeconomic status and ethnic minority status are associated with higher rates of attrition. Potential reasons for not returning to treatment include feeling better, being satisfied with treatment, and wanting to problem solve independently. These findings have been from community studies from the West and little is known

of the potential challenges and strengths in collectivistic lower and middle-income countries.

*Objectives.*– The current study aims to examine the unique cultural components that facilitate and inhibit treatment in a tertiary care facility in India

*Methods.*– Ten women with a diagnosis of substance use disorder were purposively sampled from a de-addiction centre in South India and were offered a cognitive behaviour therapy program. The barriers faced in treatment were recorded in sessions and by a feedback form. Their cultural strengths were also recorded.

*Results.*– A qualitative analysis revealed that availability of a support system, and non- abandonment of family, were strengths in this population. A majority of family engaged in treatment. Challenges faced included loneliness (often heightened by culturally sanctioned enmeshment), overinvolvement of the family and lack of autonomy of the patient, external locus of control and religious inclinations.

*Conclusions.*– Intervention program must be tailored to overcome barriers and harness strengths to engage larger number of people more efficiently. The judicious use of the family in the psychotherapeutic process may have unique influence on therapy outcomes in collectivistic cultures.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### High doses of cholecalciferol decreases anxiety in menopausal women treated with hormonal replacement therapy

J. Fedotova<sup>1,2\*</sup>, T. Dudnichenko<sup>3</sup>

<sup>1</sup> *I.P. Pavlov Institute of Physiology RASci, Department of Neuroendocrinology, Saint-Petersburg, Russia;*

<sup>2</sup> *ITMO University, Chemistry and Molecular biology, St. Petersburg, Russia;*

<sup>3</sup> *North-Western State Medical University named after I.I. Mechnikov, Department of Obstetrics and Gynecology named after S.N. Davydov, St. Petersburg, Russia*

\* Corresponding author.

Women's transition into reproductive senescence is marked by reductions in ovarian function and output, referred to as menopause. This stage is characterized by a dramatic development of affective-related disorders and different psychoemotional pathologies.

This study evaluated the effect of cholecalciferol supplementation in high doses (60000-100000 IU, per os) alone or in a combination with standard hormonal menopausal therapy (HRT) on anxiety scores and hormonal status for menopausal women. The women treated with cholecalciferol in 80000 IU and 100000IU doses alone or in a combination with HRT had greater reduction in anxiety scores than the control group. The cholecalciferol groups of women had significantly higher 25-hydroxyvitamin D<sub>3</sub> concentrations and estradiol levels in comparison to the control group. The present trials showed that consuming 100000 and 80000 IU vitamin D<sub>3</sub> daily were effective in decreasing anxiety levels. Furthermore, this is the first clinical study to show a beneficial effect of chronic vitamin D<sub>3</sub> in high doses administration on anxiety score in menopausal women. It can be supposed that vitamin D<sub>3</sub> supplementation may be necessary in menopausal women. This work promotes more effective creating of the novel therapeutic targets and strategies for anxiety-related state treatment in menopausal women.

The reported study was funded by Russian Science Foundation (RSF) accordingly to the research project No 16-15-10053.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Perinatal mental health and substance use**

S. Fink\*, P. Korenis

Bronx-Lebanon Hospital-Mt Sinai Health System, psychiatry, Bronx, USA

\* Corresponding author.

Depressive disorder with peripartum or postpartum onset occurs during pregnancy or within four weeks of delivery. According to the Diagnostic Statistical Manual 5(DSM5) it actually occurs in half the cases while peripartum. It is highly associated with substance use, anxiety and panic attacks and is associated with high rates of reoccurrence. Peripartum mood episodes can present with psychosis most commonly infanticide. Psychosis usually occurs with history of bipolar type 1 or Major Depressive Disorder or previous postpartum depressive disorder (PPD). Current literature reports three million cases of postpartum depression reported annually. During pregnancy, suicide occurred on average at 5 months. Suicide during the postpartum period, tended to occur at 7.5 months after birth. Substance use disorders is a significant comorbid concern and might be overlooked by an unsuspected clinical. With the increasing growing body of literature describing the occurrence of PPD, researchers also note that PPD screening may reduce depressive symptoms in women and reduce the prevalence of depression. While screening instruments can identify pregnant and postpartum women who need further evaluation and may need treatment, there exists little consensus on which screening tool to use and how to educate practitioners about screening.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Non pharmacological treatment in the “together“- pre-, peri-, and postnatal mental disorders prevention and treatment program in Saint John hospital in Budapest, Hungary**

É. Hegedüs<sup>1</sup>, T. Németh<sup>2</sup>, V. Thory<sup>3</sup>, E. Babus<sup>3</sup>, I. Danis<sup>4</sup>, T. Kurimay<sup>1</sup><sup>1</sup> Saint John Hospital, Department of psychiatry and psychiatric rehabilitation, Budapest, Hungary;<sup>2</sup> Géza Halász Medical Center, private practice, Budapest, Hungary;<sup>3</sup> Saint John Hospital, pediatric department, Budapest, Hungary;<sup>4</sup> Semmelweis University, Institute of mental health, Budapest, Hungary

\* Corresponding author.

The first Hungarian Mother-Baby unit was established in 2005 in Budapest.

*Objectives.*– To identify some qualitative indicators for using non-pharmacological interventions combined with pharmacological ones.

*Methods.*– Besides treating the psychiatric disorders of mothers - the therapeutic focus has been shifted to the relationship between mentally ill mothers and their children.

23,3% of the cases were diagnosed with Schizophrenia Spectrum Disorders, 30% suffered in Major Affective disorders, including BD (13,6%). Diagnoses of 35% were in the spectrum of Anxiety Disorders, including Adjustment Disorder. 11,7% of the patients had organic and personality disorders.

We use a complex therapy -pharmacotherapy (if it's unavoidable) and non-pharmacological therapy, including supportive-educative therapeutic interventions, family therapy, behaviour therapy, group therapies and integrated parent-infant consultations, video-feedback).

*Results.*– Since 2007, more than 260 mothers and 5 fathers have taken part in our program. 55% of the patients participated as inpatient, and 45% were treated as outpatient. The number of admitted patient increases continuously. 19,4% of the patients was in prenatal period (pregnancy), while 80,6% was in post-natal period.

One of our main indicators for Baby-Mother-(Father) Program is the numbers of children successfully stayed in their family. Since the program started only 6 children (2,5%) were taken to the care of social services, the others could stay within the family networks.

*Conclusion.*– Is that this kind of complex therapy in our program offers fast recovery from mental disorders of the mother and the strengthening of maternal roles and mother-infant attachment. Further qualitative research also needs.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Denial of pregnancy**

G. Hızlı Sayar<sup>1</sup>\*, B. Bostancı<sup>2</sup>, O. Omay<sup>3</sup><sup>1</sup> Uskudar University, Clinical Psychology, Istanbul, Turkey;<sup>2</sup> Üsküdar University, Clinical Psychology, Istanbul, Turkey;<sup>3</sup> La Teppe Medical Center, Perinatal Psychiatry, Tain-l'Hermitage, France

\* Corresponding author.

“Pregnancy denial “refers to the condition in which a woman cannot recognize that she is pregnant before 20 weeks of pregnancy. The condition may be best defined as unperceived pregnancy. At 20 weeks of pregnancy, it is detected in 1 of 475 women, but the incidence is still very high at the time of delivery: 1 in 2500(1). Unperceived pregnancy can cause complications both for the mother and the newborn, including the lack of antenatal care, unassisted delivery, neglect of the newborn or even infanticide (2). Roughly 4 of every 10 women with an unperceived pregnancy reported that they have seen a doctor with symptoms such as nausea or abdominal pain, yet they haven't been diagnosed as pregnant. It is necessary for the health community and the society to gain awareness of this frequent condition in order to prevent it where possible, or accompany the women, families and babies concerned in an appropriate way. In this poster study, the news of the past few years from various media channels which were thought to be related to pregnancy denial were compiled to raise awareness. Acute dissociative reaction to spontaneous delivery in a case of total denial of pregnancy: Diagnostic and forensic aspects. Vedat Şar, Nazan Aydın, Onno van der Hart, A. ### Unequal gender-power relations, sociocultural dynamics and hiv risk vulnerability among young girls from North West Province

A. Lentoor

Medunsa, School of Medicine- Clinical Psychology Department, Pretoria, South Africa

**Introduction.**– South Africa remains the epicentre of the HIV/AIDS pandemic. Sexual coercion or violence is prevalent and felt by many women. This is located within entrenched and intricate gendered notions around masculinity and power that is socio-culturally sanctioned and justified

**Objectives.**– This study is aimed at describing the psychosocial factors that continue to place young women at risk for HIV.

**Methods.**– Face to face, semi-structured interviews were conducted with participants ( $n=12$ ) recruited from the Bojanala district using purposive venue-based sampling. Data were analysed using constant comparative method of analysis based on principles of grounded theory.

**Results.**– Unequal gender-power relations between men and women are mirrored in violence or the threat of violence against women in sexual relationships. The threat or fear of violence from their male partners impels women to engage in risky sex as preferable to immediate physical harm. Such threat further reduces women's ability to negotiate safe sexual practices. The use of alcohol also seemed to play a major role in the participants' HIV-vulnerability. The findings suggest that women are more likely to be subjected to sexual coercion or violence while intoxicated or when the partners are intoxicated; and engage in unwanted, unconsented and unprotected sex. Poverty shapes a platform where young girls exchange sexual favours in order to obtain certain goods. This is reflected in the dynamics of inter-generational sexual relationships

**Conclusions.**– The finding echoes the urgent need to design specific interventions that target psychosocial, economic and contextual factors that continue to put individuals at risk for HIV-infection.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Puerperal psychosis

L. Asensio Aguerri<sup>1</sup>, B. Mata Saenz<sup>2</sup>, E. Segura Escobar<sup>2</sup>, L. Nuevo Fernández<sup>2</sup>, C. Rodriguez<sup>2</sup>, V. Muñoz Martínez<sup>2</sup>, L. Beato Fernández<sup>2</sup>

<sup>1</sup> Psychiatrist, Hospital General de Ciudad Real., Sevilla, Spain;

<sup>2</sup> Psychiatrist, Hospital General de Ciudad Real., Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– Most postpartum psychoses are affective psychoses. The frequency is one to two cases per 1000 births in the general population. The risk increases in women with a personal history of mood disorders, especially bipolar disorder. The debut is in 40% of cases in the first week postpartum with a high frequency peak in the 10th day.

**Objectives.**– The objective is to provide a bibliographic review of the clinical, evolution and treatment of postpartum psychosis.

**Methods.**– A systematic review from the literature has been carried out by Pub Med/Medline, Cochrane, and Dialnet

**Results.**– To women who previously have had postpartum psychosis, there is a high risk of having another episode (> 25%). Hormonal changes, as well as alterations in sleep, influence in the onset of the psychosis. The clinic can be summed up in insomnia, variations in mood, like mania or depression, delusions and hallucinations. The treatment should include psychoeducation, which is

essential. The pharmacotherapy is necessary in the acute episode. The medication options include atypical antipsychotic agents and mood stabilizer. The electroconvulsive therapy is also a good option.

**Conclusions.**– The correct and rapid diagnosis of postpartum psychosis is essential to expedite an appropriate treatment, prevention of future episodes, full recovery for the mother and reduction of risk to the mother and her children.

**Keywords:** Postpartum psychosis; Organic psychosis; and Pregnancy

### Perinatal anxiety screening: Worth it?

K. Lieb\*, S. Reinstein

Montefiore Medical Center, Psychiatry, Bronx, USA

\* Corresponding author.

**Background.**– Screening for peripartum depression has long been standard of care. There is little research on anxiety screening during pregnancy, and whether adding anxiety screening would increase diagnosis and treatment of women suffering from mood disorders around pregnancy.

**Methods.**– Current practice at our busy urban clinic is to screen with PHQ2 at all prenatal visits. We prospectively tracked screenings done for 3 months, and then added a GAD-2 validated 2-question anxiety scale to this assessment. Our primary study outcome was the referral rate to mental health professionals; secondary outcomes included maternal and neonatal obstetric and medical outcomes.

**Results.**– A total of 100 women underwent PHQ-2 screening only, and 125 women underwent both PHQ-2 and GAD-2 screening. More action was taken during pregnancy with the GAD2 + PHQ2 than with PHQ alone (OR 1.75, CI 0.76-4/97); this became statistically significant when controlling for history of mental health diagnosis (OR 14.9, CI 5.6-39.7), history of substance abuse (OR 26.7, CI 4.6-155.0), or BMI (OR 1.07, CI 1.1-1.14). Postpartum PHQ2 screen positive rates were not statistically different between the groups. Positive GAD-2 screening was significantly more common in patients with a history of substance abuse (OR 43, CI 2.6-698.5).

**Conclusion/implications.**– Screening for anxiety along with depression during the perinatal period increases detection patients who may benefit from referrals to mental health care practitioners, and may be an important tool in combating peripartum mental health disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Premenstrual dysphoric disorder: A case report

E. Mancha<sup>1</sup>, M.J. Leñero Navarrete<sup>2</sup>, Y. D' Hiver Cantalejo<sup>3</sup>, H. Saiz García<sup>4</sup>

<sup>1</sup> Servicio Navarro de Salud, CSM Ansoain, Pamplona, Spain;

<sup>2</sup> Sacyl, Hospital Universitario Río Hortega, Valladolid, Spain;

<sup>3</sup> Sescam, Hospital Universitario de Guadalajara, Guadalajara, Spain;

<sup>4</sup> Servicio Navarro de Salud, Complejo Hospitalario de Navarra, Pamplona, Spain

\* Corresponding author.

**Objectives.**– Study a clinical entity called premenstrual dysphoric disorder (PMDD) consisting of the presence of irritability, crying, demotivation, anergy, apathy, feeling of sadness, isolation and

difficulty for social relationships, intense anxiety, difficulty in concentration, increase in appetite, maintenance insomnia, headaches and muscle aches. Symptoms appear about 7-15 days before menstruation and persist throughout the menstrual cycle, disappearing later.

**Methods.**– Analyze the case of a 25-year-old woman who, at age 14, began with clinical signs of dizziness and headache, and was assessed by neurology with normal results, also cerebral MRI. No history in Mental Health. She is referred by her general doctor, because for years she has recurrent episodes of emotional decay with emotional lability that makes her incapable of normal activities. It lasts 1 or 2 weeks with recovery ad integrum. It relates to the premenstrual period.

**Results.**– The diagnosis of premenstrual dysphoric disorder (PMDD) is issued. It is explained hygienic-dietetic measures that must be carried out to reduce the symptoms: avoid alcohol consumption, daily physical exercise, try an adequate rest as well as maintain a balanced diet. He is proposed to start treatment with SSRIs that he refuses, given the intermittency of the clinic.

**Conclusions.**– Some contraceptives, such as chlormadinone acetate associated with ethinylestradiol, have proven effective in reducing the intensity of these symptoms; however, in the literature paradoxical effects are described in some patients. Antidepressants, vitamins and nutritional supplements such as calcium and magnesium, analgesics and diuretics may also be used.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Assessing fear of childbirth and its predictors among Hungarian pregnant women: A new approach

V. MoghaddamHosseini<sup>1</sup>, A. Makai<sup>2</sup>, K. Varga<sup>3</sup>, C. Ördögh<sup>3</sup>, Á. Várnagy<sup>4</sup>

<sup>1</sup>Doctoral School of Health Sciences–, Msc- PhD student- Doctoral School of Health Sciences- Faculty of Health Sciences- University of Pécs- Hungary, Pécs, Hungary; <sup>2</sup>Doctoral School of Health Sciences–, Doctoral School of Health Sciences- Faculty of Health Sciences- University of Pécs, Pécs, Hungary; <sup>3</sup>Eötvös Loránd University- Faculty of Education and Psychology, Affective Psychology Department, Budapest, Hungary; <sup>4</sup>Faculty of Medicine- University of Pécs, Department of Obstetrics and Gynecology, Pecs, Hungary

\* Corresponding author.

**Background.**– To assess fear of childbirth, all Researchers have used the total score of Wijma Delivery Expectancy/Experience Questionnaire (WDEQ-A) in different cultures despite of being multidimensional.

**Objective.**– Our aim was to assess fear of childbirth and determine predictors based on WDEQ-A subscales among Hungarian pregnant women.

**Method.**– this cross-sectional study was conducted on 423 healthy pregnant women at the third trimester attending NST laboratory. A socio-demographic and obstetrics characteristics checklist, the Hungarian version of WDEQ-A, Beck Depression Inventory-Short Form and Beck Anxiety Inventory were completed. Analysis was performed using descriptive statistics and multivariate linear regression.

**Results.**– among four subscales, the highest and lowest mean scores allocated to the Fear and Moment of birth, respectively in both groups of nulliparous and multiparous. By parity, nulliparous obtained significantly higher mean score in Isolation ( $P=0.017$ ) and Lack of positive emotion ( $P=0.013$ ) than multiparous. In nulliparous, significant predictors included anxiety for all four subscales, economic hardship for Moment of birth, being housewife

for Fear, and wanted pregnancy for Lack of positive emotion. In multiparous, Isolation was predicted by being married, depression, and negative birth experience, Lack of positive emotion by anxiety, previous normal vaginal delivery, and elective cesarean section, Moment of birth by anxiety, and Fear by being housewife and anxiety.

**Conclusion.**– assessing fear of childbirth using WDEQ-A, revealed different mean scores and predisposing factors for each subscale by parity. This should be explored relative to its constituent factors for a more accurate and detailed insight to be achieved.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Specialist perinatal mental health–development of a national model of care in a small country

D.M. Wrigley

Health Service Executive, Mental Health Division, Dublin 8, Ireland

**Introduction.**– Perinatal mental health disorders are those, which complicate pregnancy (antenatal) and the first postnatal year. The Irish Health Service's Mental Health Division (MHD) prioritised the development of a Specialist Perinatal Mental Health model of care in 2016.

**Objectives.**– To design a plan in line with Table 1, for the development and operation of:

- i) The three components of specialist perinatal mental health services
  - Specialist liaison psychiatry service to maternity units/hospitals
  - Specialist perinatal mental health teams
  - Specialist inpatient mother and baby units
- ii) The interface of this specialist service with secondary care mental health services.

Table 1 Rates of Perinatal Psychiatric Disorder per thousand maternities.

Postpartum psychosis	2/1000
Chronic serious mental illness	2/1000
Severe depressive illness	30/1000
Mild-moderate depressive illness and anxiety states	100-150/1000
Post-traumatic stress disorder	30/1000
Adjustment disorders and distress (JCP-MH 2012)	150-300/1000

**Methods.**– A national working group was established. The members were multidisciplinary with service user representation. Each discipline presented on their areas of expertise.

These presentations/submissions included:

- Literature review
- Overview of specialist perinatal mental health services
- Service user and Obstetrician perspectives

**Results.**– Hub and Spoke model of care identified as well as an overall perinatal mental health clinical pathway to ensure women with milder mental health problems will be both identified and receive appropriate help from skilled staff at primary care and within maternity services.

**Conclusion.**– Implementation of the National Model of Care in six hub sites

Supported training of staff in implementing the Model of Care

Overall clinical pathway identified for women with milder mental health problems

Core clinical outcome dataset identified

**Comparative analysis of personality profile characteristics, coping strategies and psychological defence mechanisms of naive middle-age women and men with uncomplicated essential hypertension**

E. Pervichko<sup>1\*</sup>, Y. Zinchenko<sup>1</sup>, T. Ostroumova<sup>2</sup>, V. Tarabancheva<sup>1</sup>, O. Ostroumova<sup>3</sup>, V. Parfenov<sup>2</sup>

<sup>1</sup> Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia;

<sup>2</sup> I.M. Sechenov First Moscow State Medical University, Department of Neurology, Moscow, Russia;

<sup>3</sup> A.I. Yevdokimov Moscow State University of Medicine and Dentistry, Department of Faculty Therapy and Professional Diseases, Moscow, Russia

\* Corresponding author.

*Introduction.*– Since F. Alexander's work essential hypertension (EH) is traditionally referred to psychosomatic diseases. However, there is a lack of data on gender differences in this area.

*Objectives.*– To conduct a comparative analysis of the personality profile characteristics, psychological defence mechanisms and coping strategies of middle-age women and men with EH.

*Methods.*– The study involved 22 naive middle-age women (average age is  $53.3 \pm 5.8$ ) and 27 men (average age is  $50.1 \pm 7.0$ ) with uncomplicated EAH, stage 1-2. Participants performed the following assessment: Sixteen Personality Factor Questionnaire (16PF), Life Style Index (LSI), Ways of Coping Questionnaire (WCQ), Cognitive Emotion Regulation Questionnaire (CERQ).

*Results.*– Women with EH differ from EH men by higher rates of factors: A (Warmth) ( $5,66 \pm 2,2$  vs  $4,45 \pm 1,7$ ;  $P=0,04$ ) and I (Sensitivity) ( $6,66 \pm 1,7$  vs  $3,95 \pm 1,6$   $P=0,00$ ), and lower rates of factor C (Emotional Stability) ( $5,09 \pm 1,6$  vs  $6,35 \pm 1,5$ ;  $P=0,02$ ) in 16PF test. Women are statistically significant less likely to use repression ( $20,69 \pm 7,3$  vs  $32,00 \pm 5,4$ ;  $P=0,01$ ), but more often reactive formation ( $32,27 \pm 11,2$  vs  $15,63 \pm 7,5$ ;  $P=0,00$ ) in LSI test. They are more likely to seek social support ( $12,92 \pm 3,3$  vs  $10,47 \pm 3,5$ ;  $P=0,02$ ), less often blame others in resolving problem situations ( $8,86 \pm 3,2$  vs  $11,12 \pm 3,6$ ;  $P=0,02$ ) in WCQ. However, women less often use a positive reappraisal ( $13,36 \pm 2,9$  vs  $15,18 \pm 2,7$ ;  $P=0,04$ ) as an effective strategy of regulating emotions in CERQ test.

*Conclusion.*– The results prove the presence of gender differences in cohort of naive middle-age EAH patients and justify the need for differentiated approach to treatment and psychological support for these patients.

**Effectiveness of logo therapy on marital intimacy and satisfaction and life expectancy among women**

M. Pirmoradi<sup>1\*</sup>, E. Ebrahimi<sup>2</sup>, F. Asadi Bedmeshki<sup>3</sup>

<sup>1</sup> Iran University Of Medical Sciences, Clinical Psychology, Tehran, Iran;

<sup>2</sup> Islamic Azad University- Tonekabon Branch-, Psychology, Tonekaboon, Iran;

<sup>3</sup> Sobh Sadegh, Psychology, Tehran, Iran

\* Corresponding author.

*Introduction.*– Marriage is an important developmental level of life. The relationship between marital intimacy and marital satisfaction and life expectancy is effectiveness in successful marriage.

On the other hand in unsuccessful life logo therapy is effectiveness. Logo therapy is defined as treatment of a condition, illness, or maladjustment.

*Objective.*– The aim of the study was to investigate the effectiveness of logo therapy on marital intimacy & satisfaction and life expectancy among married staff women of Tajrish Shohada Hospital.

*Method.*– This study is an experimental study with pretest-posttest and control group. The population of this study was all the married women employees of Shohada hospital ( $n=150$ ) and 108 people were selected randomly. They were completed of questionnaires including: marital intimacy, satisfaction and life expectancy. The sixty subjects were selected referring to cut-off point of the intimacy of couples, marital satisfaction and life expectancy. Thirty subjects assigned randomly in experimental and control groups, separately. The logo therapy training for experimental group and control group did not. Both groups were assessed after completion of logo therapy training in post-test assessment time. The research data were analysed by covariance analysis (MANCOVA).

*Result.*– The finding showed that there is significant relationship between logo therapy treatment planning skills training and the variables of marital intimacy and satisfaction in life expectancy among married women employees.

*Conclusion.*– The logo therapy is good method for impact on marital intimacy & satisfaction and life expectancy.

*Keywords:* Logo therapy training; Intimacy; Marital satisfaction; Life expectancy

**Neuroleptic malignant syndrome in Pregnancy**

A. Pirtovsek Savs, M. Derganc

University Psychiatric Clinic Ljubljana, CKP, Ljubljana, Slovenia

*Introduction.*– Neuroleptic malignant syndrome is a potentially life-threatening neurologic emergency associated with the use of antipsychotic drugs. It poses a special problem if it happens in pregnancy as in the case presented.

*Case report.*– 35-year old woman with a history of schizoaffective disorder was admitted to our clinic in the first trimester of pregnancy. She was agitated and had imperative acoustic hallucinations. She discontinued antipsychotic treatment when she became pregnant. Upon admission she was so agitated that she had to be restrained. She received haloperidol. Four days after admission she developed fever and muscle rigidity and she became mutactic. Her blood pressure and pulse were high. Her creatinine kinase, myoglobin and leukocyte levels were elevated. She was transferred to

the neurology clinic because of malignant neuroleptic syndrome. She was treated with bromocriptine, dantrolene and diazepam. Neuroleptic malignant syndrome subsided after three weeks but psychotic symptoms remained. She was treated with quetiapine and olanzapine with no success. Psychosis was so intense that she needed to be restrained again. Finally we decided to switch to clozapine. After three months she achieved moderate remission. She was treated with clozapine until the end of pregnancy. She gave birth to a healthy child.

*Conclusion.*– Despite the fact that neuroleptic malignant syndrome in pregnancy is a very rare condition it should not be overlooked. Once diagnosed, it can be treated successfully. In the presented case it was treated in the way that did not affect the newborn child.

### **Silence and secrets: Understanding dissociation in Indian settings**

D. Prasad<sup>1</sup>, S. Dutta<sup>2</sup>, H. Naidu<sup>2</sup>

<sup>1</sup> Nur Manzil Psychiatric Centre, Child and Adolescence Guidance Clinic, Lucknow, India;

<sup>2</sup> Nur Manzil Psychiatric Centre, Department of Psychiatry, Lucknow, India

\* Corresponding author.

*Introduction.*– Conflict is present in all families irrespective of class, creed or geographical locations in India. Deep rooted family traditions within cultural contexts, values, virtues and parental core beliefs form the embedded layers in conflicts. Within the similar cultural framework, each family has its unique psychodynamic structure, style of adaptation and communication. Dissociation, an interesting mental condition, filled with intrigue arises from within the intricacies of familial relationships. Often the same is engulfed from conflicting elements from the external world.

*Aim and Objectives:* To examine the varying dynamics playing in the backdrop of dissociation.

*Methods.*– We hereby present 4 case vignettes with chief complaints of falling unconscious, irritability, reduced work interest and depressive cognitions. Detailed interview and ventilation-laden sessions led to the better understanding of medley of conflicts.

*Results.*– Element of failed efforts to withstand loneliness, perceived notions of right and wrong, inability to handle estranged parental ties and financial constraints set the stage for dissociation. Unrealistic expectation, secure-insecure attachment style, controlling tendency and self-harm behaviour escalated the already escalating distress and agony.

*Conclusion.*– Need for efforts to inculcate healthy family virtues of wholeness, responsibility within parents, cohesiveness and tolerance for acceptance and expression of other's feelings is required. Recognition of stressors and conflict resolution are the primary goals for management of dissociative disorders.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The perfect storm of trauma: A qualitative study into the experiences of women who have experienced birth trauma and subsequently accessed residential parenting services**

H. Priddis<sup>1</sup>, H. Dahlen, H. Keedle

Western Sydney University, School of Nursing and Midwifery, Sydney, Australia

\* Corresponding author.

*Introduction.*– There appears to be a chasm between idealised motherhood and reality, and for women who experience birth trauma this can be more extreme and impact on mental health. Australia is unique in providing residential parenting services (RPS) to support women with parenting needs such as sleep or feeding difficulties. Women who attend RPS have higher rates of intervention in birth and poor perinatal mental health but it is unknown how birth trauma may impact on early parenting.

*Objectives.*– The objective of this study was to explore the early parenting experiences of women who have accessed RPS in Australia and consider their birth was traumatic.

*Methods.*– In-depth interviews were conducted with eight women who identified as experiencing birth related trauma and accessed RPS in the early parenting period. Data were analysed using thematic analysis.

*Results.*– One overarching theme was identified: “The Perfect Storm of Trauma” which identified that women who access RPS are more likely to have entered pregnancy with pre-existing vulnerabilities including mental illness such as depression, generalised anxiety disorders and eating disorders, and experienced a culmination of traumatic events during labour, birth, and in the early parenting period. Four subthemes were identified: “Bringing Baggage to Birth”, “Trauma through a Thousand Cuts”, “Thrown into the Pressure Cooker”, and “Trying to work it all out”.

*Conclusions.*– How women are cared for during their labour, birth and postnatal period impacts on how they manage early parenthood. Support is crucial for women, including practical parenting support, and emotional support by health professionals and peers.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Premenstrual dysphoric disorder: A multidisciplinary approach**

H. Saiz Garcia<sup>1</sup>\*, V. Pereira<sup>2</sup>, M.Á. Álvarez de Mon<sup>2</sup>, L. Montes<sup>1</sup>, Á.S. Rosero<sup>1</sup>, E. Mancha<sup>1</sup>

<sup>1</sup> Complejo Hospitalario de Navarra, Psychiatry, Pamplona, Spain;

<sup>2</sup> Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

\* Corresponding author.

*Introduction.*– Premenstrual dysphoric disorder (PMDD) is a disease with a prevalence of about 3–8%, with important clinical, biological and biosocial implications. PMDD is characterized by its symptoms and cyclicity. Neurosteroids may contribute to its typical gender physiopathology. It affects woman during their reproductive years. A wide variety of symptoms can be identified in this disease: somatic symptoms, psychological symptoms or mixed somatic and psychological symptoms. Typical onset is one week before menstruation.

*Methodology.*– A review was conducted aiming to clarify the biological mechanisms and the best interdisciplinary treatment for the premenstrual dysphoric disorder. The literature search was conducted in Pub Med data reviewing articles dating between 2003 and 2017.

**Results.**– 1. There are many and interdisciplinary treatment options for the premenstrual dysphoric disorder. Some of these options are cognitive behavioural therapy, psychotropics agents, hormone-based treatments, diuretics and, in some cases, surgery. 2. First-line treatment for PMDD is pharmacotherapy with SSRIs. This treatment can be used only in the luteal phase or during the entire month. 3. There is limited evidence for the treatment of PMDD with combined oral contraceptives containing drospiridone plus ethinyl estradiol. Also levonogestrel can be used. 4. Cognitive-behavioural therapy brings in to the patient coping skills to afford this disease.

**Conclusions.**– PMDD is a common disorder with a high prevalence, with high implication in the clinical practice. PMDD treatment has to be individualized in order to achieve a good response. This treatment can be psychological or pharmacotherapy, depending of the symptoms of each patient.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Patients with schizophrenia and the gender of the clinician: Daring to ask questions**

N. Semenova<sup>1</sup>, S. Shport<sup>2</sup>, O. Karpenko<sup>3</sup>

<sup>1</sup> Moscow Research Institute of Psychiatry MoH RF, Outpatient Psychiatry, Moscow, Russia;

<sup>2</sup> The Serbsky Federal Research Center for Psychiatry and Narcology, Administration, Moscow, Russia;

<sup>3</sup> Psychiatric Hospital No 1 named after NA Alekseev, First Episode Division, Moscow, Russia

\* Corresponding author.

**Introduction.**– Gender differences in schizophrenia are described in almost all aspects of the illness.

**Objectives.**– The purpose of this cross-sectional study was to measure the level of apathy in schizophrenia and its relation to gender issues; to investigate to which extent clinicians were able to estimate their patient's perspective on motivation for engaging in treatment, to which extent they agreed on the patient's motivation. The data were collected within the prospective "Motivation and Psychosocial Treatment" study.

**Methods.**– The present study assessed motivation as rated by clinicians ( $n = 35$ ) and patients with schizophrenia ( $n = 138$ ) using two versions of the Apathy Evaluation Scale (AES)–clinician, and self-rated.

**Results.**– It was found that the agreement on the level of motivation between patients and clinicians was moderate. The mean level of apathy of patients with schizophrenia, as rated by clinician (AES-C), was significantly higher than that of self-rated scores (AES-S). In our study, a tendency to gender differences was not shown: statistically significant differences could not be confirmed between men and women, in both clinicians and patients groups.

**Conclusions.**– It is concluded that patients with schizophrenia and their clinicians have different perceptions on the patient's motivation, regardless of the gender issues. Nevertheless, the findings imply that the match between clinician and patient gender is important in schizophrenia to ensure effective mental health interventions. It is our intention to discuss why the clinician's gender may be so important when working with the (largely) male psychiatrically disordered population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0963

### **Mental healthy of family member of sever suicidal patient**

C. Shu-Chin

MacKay Memorial Hospital, Suicide Prevention Center, Taipei City, Taiwan R.O.C.

**Introduction.**– It is a very stressful thing to take care of suicidal people, especially while their suicide attempts are repeated happened or suicide ideation is frequently high. Family members usually are inevitable person to take care for them, but there are very less study discussing about this issue.

**Objectives.**– This project tried to understand the mental health state of sever suicidal patient's family members.

**Methods.**– This is a descriptive study. 18 family members of sever suicidal patient recruited from suicide prevention center in a general hospital, aged 32-67; include 12 mothers, 4 fathers, one wife and one husband. 17 participants live with suicidal client.

They filed questionnaires to assess their mental states, include depression (Patient Health Questionnaire-9, PHQ-9), anxiety (Beck Anxiety Inventory, BAI), burden to take care decreased (Caregiver Burden Scales, CBS) and quality of life (short Form version of the Quality of Life Enjoyment and Satisfaction Questionnaire, QLESQ).

**Results.**– Despite they did not suffer MDD or anxiety disorder. Their quality of life is worse as MDD patient, their burden even worse than cancer patients' family, especially "spirit burden" and "physical and psychological burden". The scores of BAI shows their anxiety state is moderate, eight of them are suffer from sever anxiety.

**Conclusion.**– The result implied that family member needs some kind of help, some researcher designed skills group to help with those family members. Since this project only recruited 17 participants, bigger sample size project is needed. Different relationship might have different impact also needs future study.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Maria - portrait of a Brazilian pregnant woman awaiting zika test results and her psychological expectations: Case report from a university obstetric public service**

E.R. Turato\*, D.D. Lima, E.M. Amaral, F.G.C. Surita, H.M.B.P.M. Milanez, G.J. Lajos

UNICAMP - State University of Campinas, Medical Psychology and Psychiatry - Laboratory of Clinical-Qualitative Research, Campinas, Brazil

\* Corresponding author.

The discovery of the vertical transmission of Zika virus in Brazil and its negative consequences for the fetus has sounded an alarm. This revelation startled the health system and the population, especially pregnant women, who started to live under the risk of infection and transmission during a period of supposed uncontrolled epidemic.

**Objective.**– To report an experience of one of these women, here called Maria, and to pay attention to magnitude of a problem that also affects non-infected people and includes, besides biological, social and psychological concerns.

**Method.**– Qualitative design. Observations made at the arbovirosis outpatient service of university hospital for women's and newborn health care. Data were collected through an in-depth interview.

**Results.**– Despite all the media fuss about the epidemic, Maria showed she did not have adequate information about the symptoms of ZIKV infection. She speaks about her anxiety for test results and uncertainty concerning the course of her life if she is diagnosed

with ZIKV. Negative consequences of this process add to the physical severity of the disease and may affect the relationship with the baby, partner, and rest of the family for a long time, irrespective of the severity of the morbidity.

*Conclusion.*– Maria could be the spokeswoman for many Brazilian pregnant women who experience the anguish of being under the risk of having contracted ZIKV. However, the greatest adversity for many “Marias” is to be part of a vulnerable population from poor settings, who suffer physically and psychologically the consequences of economic and gender inequalities.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0965

### **Psychological practice with transsexual individuals: A study case in Brazil**

C. Campelo Novaes, J. Oliveira, P. Sinigaglia, C. Varanda\*

*Universidade Paulista, Institute of Human Sciences, Santos, Brazil*

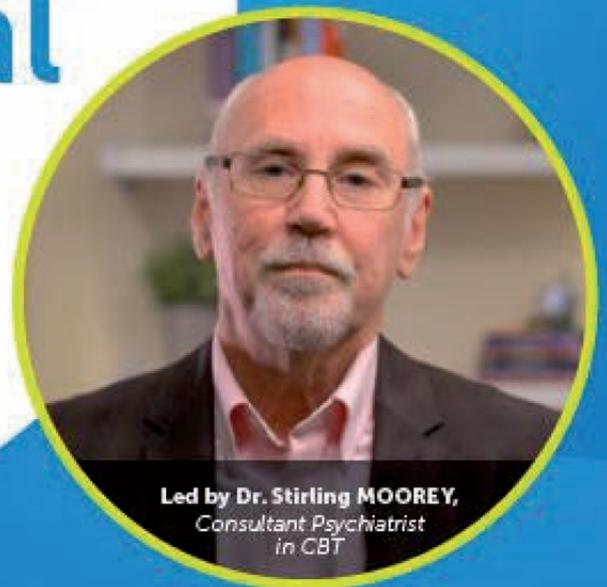

\* Corresponding author.

Discussing transsexuality is different than discussing the sexuality itself, it implies taking the personal, professional and social

identity into account. Psychology has therefore to be ethically committed with the construction of this gender identity. This is a qualitative research, which used a semi-structured interview with a private practice clinical psychologist who has great experience with transsexual individuals. The aim was to discuss how the work of a psychologist is performed in supporting those individuals when dealing with the multiple variables involved in their social, work, family and private lives providing an example of care model based on extensive professional experience. According to the results, psychology is being disconnected of the medical practice, which is mainly about pathologization; and even if psychologists still need International Classification of Diseases due to judicial necessity, enabling transsexuals to access their rights, such as social name, hormonal transition and surgery, psychologists should have a different approach to manage this issue, acknowledging the role of making informed choices and the value of harm reduction approaches. Psychology commitment is related to social construction, which is connected to matters of prejudice, stereotypes, and the possibility to face them. Also, orientation about transsexuality targeting family members may help with familiar acceptance.
