**Person-centered psychiatry**

G. Stanghellini

University “G. d’Annunzio” – Chieti Italy and University “D. Portales” – Santiago Chile, Department of Psychological– Humanistic and Territorial Sciences, Chieti, Italy

Most of our current, supposedly humanitarian or dialogic therapeutic practices are based on the ideal of establishing some form of consensus between patients and carers. Yet consensus is a woolly kind of dialogic value. While it looks for agreement and harmony, it implicitly holds that some values are better than others and builds on the metaphysical belief that conflict of values is just a stage on the way to sharing universal values. In this vein, conflicts of values are signs of imperfection, rather a constitutive part of human life. This unrealistic idea promotes pseudo-dialogic practices that downplay the person’s subjectivity and surreptitiously endorse one-sided values. Examples of this are social rehabilitation (which endorses prevailing social values), or potentially intolerant techniques to enhance compliance (which endorse the distinction illness/health based on the clinician’s values)—both taking for granted that “good” values are on the side of the clinician. Coexistence with mental sufferers and with the values each of them embodies is better practice. This practice is produced in dialogue, which is contact across a distance. It aims to acknowledge, understand, and respect different ways of life, enlighten our ethical conflicts, honor conflicting values—and ultimately negotiate reciprocal recognition.

Person-centered practice is much more than assessing operationalized symptoms and eliminating them, or reducing their intensity through some kind of therapeutic technique. Rather, it is a *quest for meaning and reciprocal recognition*. It seeks for meaning, order, and value within and throughout ordinary experience and the patient’s everyday life. It is a meeting of forms of life—the patient’s and the clinician’s—each with its system of relevance and meaning structure, stemming from different and sometimes conflicting values. It is the occasion to initiate a shared project of reciprocal understanding between the vulnerable person and the mental health carer.

**Why eating disorders being in adolescence**

J. Treasure

Institute of Psychiatry, Eating Disorders, London, United Kingdom

Over 30 years ago it was found that involving the family reduced relapse following inpatient treatment in adolescents with a short duration of illness (less than 3 years). This has been replicated, and has since been used as a standalone treatment, with various family permutations (separated parent/individual, multifamily therapy). The treatment is cost effective. For example the length of inpatient stay can be reduced if family therapy is added. Furthermore elements of the intervention have been delivered in self-help forms, sharing skills and information for carers. However 20–30% of cases fail to respond. In particular those who have been ill for over 3 years do not benefit. Non responders may be identified early in the course of treatment. Therefore work to develop new interventions to manage this group of patients is in progress.

Both family therapy and guided CBT are of benefit for binge eating disorder and bulimia nervosa but the evidence base is smaller. In this lecture I will review past evidence and consider new approaches.

ATE0003

### Dealing with migrants' mental health needs

L. Küey  
 Istanbul Bilgi University, Department of Psychology, ISTANBUL, Turkey

The discussions in this “Meet the expert session” will mainly focus on the following topics: Terminology (migration, migrants, forced displacement, refugees, asylum seekers, IDPs and etc.); Current dimensions of forced displacement and migration; Historical perspective on migration; Mental health consequences; Role of psychiatrists and mental health workers.

*Disclosure of interest.* – The author declares that he has no competing interest.

ATE0004

### The WPA program for strengthening the contribution of psychiatrists in situations of conflict and emergency

H. Herrman  
 Orygen- The National Centre of Excellence in Youth Mental Health, Centre for Youth Mental Health, Parkville, Australia

The WPA Action Plan 2017–2020 sets out a collaborative strategy for expanding the contribution of psychiatry to improved mental health for people across the globe. It is based on consultation within the WPA and with potential partner organisations including EPA as well as the work that has preceded it. It builds on the capacity of organised psychiatry to promote mental health and improve equitable access and quality of mental health care. In doing so, the plan provides a targeted strategy for reaching people—particularly young people—who face adversity and disadvantage.

This intent is translated into action through a strategic framework based on three dimensions: (1) Strengthening the contribution of psychiatrists to reducing distress, illness and suicidal behaviour among young people under extreme stress including those affected by conflict and emergencies; and people living with long-standing mental illnesses and their caregivers. (2) Enabling activities—supporting psychiatrists to promote mental health and improve care capacity. These activities include: service development; awareness raising and advocacy; education, publications and research; all conceived as gender- and culturally-sensitive. (3) Partnerships and collaboration—expanding the reach and effectiveness of partnerships with both service providers and service beneficiaries.

*Disclosure of interest.* – The author declares that he has no competing interest.

ATE0005

### Caring for people with intellectual disabilities

K. Courtenay<sup>1</sup>, B. Perera<sup>2</sup>  
<sup>1</sup> UCL, Division of Psychiatry, London, United Kingdom; <sup>2</sup> Barnet Enfield Haringey Mental Health NHS Trust, Psychiatry of Intellectual Disability, London, United Kingdom

Intellectual Disability (ID) has a prevalence of up to 3% in the general population. The prevalence of mental disorders in people with ID is high compared with people without ID for example, Schizophrenia prevalence rate is 3%. In addition, the rates of physical disorders for example, diabetes and epilepsy is higher too that can lead to great health inequalities when compared with the general population. Assessing mental disorders in people with ID can be challenging because of communication difficulties, the co-existence of neurodevelopmental disorders or other neurological disorders. An understanding of the presentation of mental disorders in people with ID is essential to making accurate diagnoses and offering treatment.

The purpose of the Ask-the-Expert session is to assist colleagues with limited experience in working with people with ID to manage the complexities involved in assessing and managing mental disorders in this group of people. Participants are encouraged to present relevant cases in the session to the panel who will seek to provide more insights in to assessing and managing mental disorders in ID.  
*Disclosure of interest.* – The authors declare that they has no competing interest.

### Planning ahead for acute mental health crises: Methods and outcomes

C. Henderson  
 King's College London, Health Service and Population Research, London, United Kingdom

The term ‘advance statements’ covers a range of interventions which vary with respect to their basis in legislation and the manner in which health professionals are involved in their creation. Advance directives lie at one end of this range because their content is determined solely by the patient. They have not been shown to have an effect on rates of involuntary hospitalisation. The most likely reason for this is that they are enacted only when the holder is deemed to have lost capacity to make treatment decisions. Routine care plans lie at the other, paternalistic, end of the crisis planning spectrum, as they may be produced without any patient/consumer involvement, although by consensus this is not seen as good practice. Joint crisis plans (JCP) lie toward the centre of this spectrum, as an application of shared decision making. To achieve this, JCPs require an external facilitator, namely an independent third party, to complete the crisis plan. The facilitator, a mental health professional independent of the treatment team, aims to engage the service user and treating mental health professionals in writing the JCP.

The results of a randomized controlled trial of JCPs for people with psychotic or bipolar illness showed reduced use of involuntary hospitalization associated with their use and reported positive views of the plans by service users and mental health professionals, when compared with routine care plans. The larger CRIMSON multi-site trial found a positive effect on service user-rated therapeutic relationships, but no reduction in compulsory admission rate. There was clear evidence that the JCP process had not been fully imple-

mented by many members of staff, because of attitudinal barriers to sharing clinical decision making powers with patients. Increasingly such implementation barriers are being recognised as critical brake on healthcare improvement. Implementation science may therefore be of use for translating the findings of the first trial into routine patient benefit

*Disclosure of interest.*– I was the PI for the first trial of Joint Crisis Plans and a coapplicant on the CRIMSON trial

ATE0007

### **Changes in the classification of sexuality, sexual health, and gender identity for ICD-11**

G. Reed

*World Health Organization, Department of Mental Health and Substance Abuse, Geneva, Switzerland*

In forthcoming Eleventh Revision of WHO's International Classification of Diseases and Related Health Problems (ICD-11), there have been substantial changes related to the classification of conditions

related to sexuality and gender identity previously conceptualized as mental disorders. Changes have implemented based on advances in research and clinical practice, and major shifts in social attitudes and in relevant policies, laws, and human rights standards. Gender identity disorders in ICD-10 have been reconceptualized as 'gender incongruence', and moved to out of the classification of mental disorders to a new chapter on Conditions Related to Sexual Health. All categories specifically related to sexual orientation have been deleted. The proposed classification of paraphilic disorders distinguishes between conditions that are relevant to public health and clinical psychopathology and those that merely reflect private behaviour. Yet, some areas of controversy remain. This Ask the Experts session will provide an opportunity to discuss the main changes, the rationale and evidence considered, and important differences from ICD-10 and DSM-5, as well as to consider the clinical, legal and policy implications of these changes in Europe and around the world.

*Disclosure of interest.*– The author declares that he has no competing interest.

## 26th European Congress of Psychiatry

### Core Symposium: New Perspectives in Negative Symptoms: A Transnosographic Approach to Diagnosis and Treatment

CS0001

#### Treatment of negative symptoms across diagnostic categories: Achievements and challenges

S. Kaiser

Geneva University Hospitals, Adult Psychiatry Division, Geneva, Switzerland

Negative symptoms can be observed in a variety of neuropsychiatric disorders and are not specific to a diagnostic category. The dimensional approach aims at developing specific treatments for negative symptoms independent of categorical diagnoses. Although there is no clear evidence for transdiagnostic treatments so far, this approach has stimulated the discussion on potential target mechanisms. Here we provide a selective review of pharmacological and psychosocial treatment approaches targeting negative symptoms in at least two diagnostic groups of patients.

Pharmacological treatments include modulators of the monoaminergic systems. Antidepressants have been employed in different disorders, but they have only limited effects against negative symptoms without concurrent depression. Stimulants have proven to be effective against negative symptoms in neurological disorders, but clear evidence for efficacy in schizophrenia and affective disorders is lacking. Newer approaches including the use of memantine and anti-inflammatory drugs will be briefly discussed.

Psychosocial treatments have rarely targeted negative symptoms as primary outcome. Nevertheless, cognitive behaviour therapy seems to be a valid treatment option for negative symptoms, but will also have to take into account the diagnostic context. Cognitive impairment has been linked to negative symptoms and recent studies suggest a positive effect of cognitive remediation that is not restricted to patients with schizophrenia. Finally, an increasing number of studies shows a beneficial effect of physical exercise on negative symptoms, although these symptoms have rarely been defined as the primary outcome.

Future development of transdiagnostic treatment approaches should aim at a better integration of pharmacological and psychosocial treatment approaches. A truly dimensional approach to

the treatment of negative symptoms will eventually require transdiagnostic treatment studies, which employ the same treatment protocol across diagnostic categories.

*Disclosure of interest.*– SK receives royalties for cognitive test and training software from Schuhfried (Austria).

### Core Symposium: Brain Mechanisms of Resilience to Mood and Psychotic Disorders

CS0002

#### Brain volume abnormalities in different types of first degree relatives of schizophrenia and bipolar disorder: An ENIGMA study

N. Van Haren<sup>1,\*</sup>, S. de Zwarte<sup>1</sup>, C. Ching<sup>2</sup>, O. Andreassen<sup>3</sup>, T. van Erp<sup>4</sup>, J. Turner<sup>5</sup>, P. Thompson<sup>2</sup>, R. Brouwer<sup>1</sup>, for the ENIGMA Relatives Working Group<sup>2</sup>

<sup>1</sup> Brain Center Rudolf Magnus – UMC Utrecht, Psychiatry, Utrecht, The Netherlands; <sup>2</sup> Keck School of Medicine of University of Southern California, Imaging Genetics Center, Los Angeles, USA; <sup>3</sup> Institute of Clinical Medicine-University of Oslo, NORMENT – KG Jebsen Centre, Oslo, Norway; <sup>4</sup> University of California, Department of Psychiatry and Human Behavior, Irvine, USA; <sup>5</sup> Georgia State University, Psychology Department & Neuroscience Institute, Atlanta, USA

\* Corresponding author.

*Background.*– First-degree relatives of schizophrenia (SZ) and bipolar disorder (BD) patients show brain abnormalities. Through the ENIGMA consortium, we compare different types of SZ or BD first-degree relatives (i.e. co-twins, siblings, offspring, parents) to healthy controls (HC) on global and subcortical brain measures.

*Methods.*– To date, 6235 individuals (of which 1177 SZ relatives and 868 BD relatives) from 27 independent studies were included. MRI scans were processed with FreeSurfer. Linear mixed model analyses were performed comparing each type of relative to HC, while taking family relatedness into account. Cohen's *d* effect sizes were obtained at each site and then pooled using an inverse variance-weighted random-effects meta-analysis for all relatives combined.

*Results.*– First-degree relatives of BD patients had a significantly larger intracranial volume (ICV) than controls (Cohen's *d* = 0.16), which was not the case for SZ relatives (*d* = –0.03). See figures. Fur-

thermore, first-degree relatives of BD patients showed significantly larger volumes of cortical and cerebellum GM ( $d=0.14$ ,  $d=0.12$ ), total surface area ( $d=0.14$ ), and lateral ventricle volume ( $d=0.13$ ) as compared with controls, which no longer reached significance after correction for ICV. After ICV correction only a smaller thalamus volume ( $d=-0.13$ ) was found in BD relatives.

First-degree relatives of SZ patients showed significantly smaller volumes of the total brain ( $d=-0.11$ ), cerebral WM (Cohen's  $d=-0.09$ ), cerebellar GM ( $d=d0.10$ ) and WM ( $d=-0.09$ ), mean cortical thickness ( $d=-0.14$ ), accumbens ( $d=-0.09$ ), putamen ( $d=-0.09$ ) and thalamus ( $d=-0.12$ ), and a larger third ventricle volume ( $d=0.13$ ) relative to controls. After correction for ICV, the pattern of findings for SZ relatives remained largely similar or effect sizes increased, and additionally included a smaller cortical GM volume ( $d=-0.13$ ).

**Conclusions.**– The main finding is that BD relatives have a larger ICV as compared with controls, which was not the case in SZ relatives. In contrast, smaller global and subcortical brain volumes were present in SZ relatives. This may implicate that the familial risk for SZ and BD differentially associates with structural brain measures, possibly reflecting different neurodevelopmental pathways. We are currently expanding the analyses to investigate whether having a DSM diagnosis other than SZ or BD in the relatives explains the differences in intracranial and other brain volumes, and whether there are differences between the different types of relatives.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

CS0003

### **Polygenic risk profile score increases schizophrenia liability mostly through cognition pathways: Mathematical causation models with latent cognition and polygenic risk**

T. Touloupoulou<sup>1,\*</sup>, X. Zhang<sup>2</sup>, R. Straub<sup>3</sup>, D. Dickinson<sup>4</sup>, K. Berman<sup>4</sup>, P. Sham<sup>2</sup>, D. Weinberger<sup>3</sup>

<sup>1</sup> Bilkent University, Psychology, Ankara, Turkey; <sup>2</sup> The University of Hong Kong, Department of Psychiatry, Hong Kong Special Administrative Region; <sup>3</sup> Johns Hopkins University, Lieber Institute of Brain Development, Baltimore, USA; <sup>4</sup> National Institutes of Mental Health, Psychosis, Bethesda, USA

\* Corresponding author.

**Objective.**– Cognition shares substantial genetic variance with schizophrenia, with recent evidence from cross diagnosis genome-wide association study (GWAS) data and from statistical modeling of twin data suggesting direct causality from the former to the latter. However, it is not clear how much of the genetic component of schizophrenia is mediated through cognition. Thus, we included in causation models direct measurements of the genetic risk (e.g. schizophrenia polygenic risk scores) to quantify the genetic component of schizophrenia that is mediated by cognition and captured by the polygenic risk score.

**Method.**– Data were from 1313 members of 1078 families, and included 416 schizophrenia patients, 290 unaffected siblings, and 607 controls. Polygenic risk scores (PRS) were based on the latest data from the schizophrenia working group of the Psychiatric Genomics Consortium (PGC) and represented the sum of genotypic scores for all common genetic variants associated with schizophrenia at p-value thresholded to 0.05 (i.e. PRS6). Cognition (L-COG) was extracted through common pathway models and captured the common variance across measurements in six cognitive domains: processing speed, verbal memory, visual memory, span, working memory, and executive function.

**Results.**– Of the genetic component of schizophrenia, 2.71% was through PRS pathways mediated by L-COG, 3.93% by PRS covariation pathways that included L-COG, and 26.87% by L-COG pathways not captured by the PRS. The remaining variance in schizophrenia liability was through pathways other than cognition and PRS.

**Conclusions.**– Cognition pathways captured by the PRS score mediated a significant part of genetic risk for schizophrenia. However, the evidence suggests that other cognition pathways not captured by PRS mediate an even greater part. We anticipate that when schizophrenia PRS include all possible variants associated with risk, more than 25% of the variants' cumulative effect will first influence variation in cognition.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Core Symposium: Forcibly Displaced People and Mental Health in Europe: Challenges and Needs**

CS0004

### **Dimensions of the problem and the psychosocial context**

L. Küey

Istanbul Bilgi University, Department of Psychology, Istanbul, Turkey

Warfare, armed conflicts, persecution and human rights violations, in different parts of the world have led to an humanitarian disaster: forced displacement of millions of people, especially in the last decade. There has been an increase in the number of refugees by about 1/3 over the last 10 years, over half of whom were under the age of 18. Hence, this is not only a disaster of today but will have serious impact on our future.

Forcibly displaced people are under threat in all areas of attachment, mastery, and survival. Almost all attachments are left behind, degree of mastery is decreased; the nutrition of the self and the self-image are devastated. Basic needs for survival maintained mostly in the mercy of others. Refugees fleeing with few possessions leading to neighbouring or more developed countries face many life-threatening risks before, during and after displacement, and they have nowhere to return. A refugee is a person who has lost the past for an unknown future. Experiences of loss and danger are imprinted in their selves.

There is increasing evidence that about 60% of refugees and asylum seekers residing in Europe suffer from mental disorders in the short/medium term. In the long term, evidence suggests that mental disorders tend to be highly prevalent in war refugees even many years after resettlement. This increased risk may not only be a consequence of exposure to wartime trauma but may also be influenced by post-migration socio-economic factors.

This presentation aims to review the current situation of the forcibly displaced people (refugees and asylum seekers) living in Europe. The dimensions of the problem and the psychosocial context in which the mental health problems develop will be further discussed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

CS0005

### **Mental health situation of forcibly displaced people**

M. Schouler-Ocak

*Psychiatric University Clinic of Charité at St. Hedwig Hospital, Psychiatry and Psychotherapy, Berlin, Germany*

It is well known that migration is one of the risk factors for developing mental disorders, and that traumatized migrants, in particular, may face psychological distress and even serious psychiatric illness as they have been exposed to adverse conditions before, during and after migration. Prior to migration, migrants may have been exposed to deprivation, persecution, violence, imprisonment, human rights violation, including sexual harassment, even torture. Particularly, it is recognized that the transition phase which often includes a temporary residence can also be perceived as very stressful as well as the post migratory phase in the new host country. Data from studies on risk for psychosis show that stress factors in the post migratory stage over all have more impact on mental health than those in the pre-migratory stage.

Furthermore, it is well known that the loss of loved ones/caregivers and/or livelihood, the destruction of property, deprivation, persecution, insecure living conditions, war, torture, imprisonment, terrorist attacks, abuse and sexualized violence have high impact on the mental health situation of refugees and asylum seekers. Experiences, e.g. defencelessness and disorientation, conditions of cold or heat, hunger and thirst, lack of medical care, robbery, assault and discrimination during the process of flight are often. Additionally, many women may be subjected to different kinds of sexual assaults and violations.

In this talk data from representative studies on the mental health situation of forcible displaced people will be presented and discussed.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

## **Core Symposium: Setting Priorities for Mental Health Research in Europe**

CS0006

### **The ROAMER project: A roadmap for mental health research in Europe**

J.M. Haro

*Parc Sanitari Sant Joan de Deu, CIBERSAM, Barcelona, Spain*

Developing priorities for mental health research across Europe: methods, priorities and developing impacts.

Mental disorders represent potentially the greatest health burden to Europe – not only for directly affected individuals, but also for caregivers and wider society. This burden has increased during the last decades and the predictions are that this increase has not finished. However, funding for research to mitigate these effects lags far behind the cost to society. This is despite the fact that the return to society from mental health research is similar to the return from other areas such as cancer or cardiovascular diseases. These linked presentations describe the ROAMER project, funded by the European Commission, which established a comprehensive, coordinated mental health research agenda for Europe and the world that might reduce these costs and burdens.

This paper leads on from the description of Consortium and a comparison of methods for achieving consensus by Professor Josep Maria Abad Haro, the ROAMER consortium lead. This presentation concentrates on how each work package produced their list

of priorities and how these led to consensus on the gaps in current research and priorities for future research. These priorities were integrated and revised through surveys and consensus decision-making by more than 1000 scientists and affected stakeholders including individuals with mental health problems and their families, healthcare workers as well as policymakers and funders to produce 6 high-level priorities for mental health research in Europe which if answered would have substantial impact in the next five to 10 years.

In a further joint presentation Professors Wykes and Haro will describe how these priorities have been adopted in Europe and the UK and the management of this process as an example of moving research priorities into policy and then into funding.

Finally, Professors Wykes and Haro will discuss the current European scenario in mental health research and the impact of the ROAMER project.

*Disclosure of interest.* – Josep Maria Haro has received honoraria for participating in advisory boards or giving educational lectures from Eli Lilly and Co., Lundbeck and Otsuka.

CS0007

### **Priorities for mental health research in Europe: A survey among National Stakeholders' Associations within the ROAMER project**

A. Fiorillo

*University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy*

Discontent towards our profession is increasingly reported by patients with mental disorders and their relatives. Criticisms by patients are mainly related to the existing divergences between the goals of clinicians and those of users and carers. Recent arguments suggest that opinions of people who use mental health services are fundamental to set priorities in mental health research field.

Within the ROAMER project, funded by the European Commission, an online survey was carried out with the European associations of all stakeholders involved in mental health (psychiatrists, other mental health professionals, users and carers, psychiatric trainees) with the aim to identify the priority areas for mental health research.

One hundred and eight associations/organizations compiled the questionnaire. The most frequently reported research priorities were early detection and management of mental disorders, quality of mental health services, prevention of mental disorders, rehabilitation and social inclusion, new medications for mental disorders, and stigma and discrimination. These results seem to support the recent argument that some rebalancing in favour of psychosocial and health service studies may be needed in psychiatric research.

The stakeholders' views are being progressively considered in the process of developing clinical guidelines, public health recommendations and research protocols. In particular, users' and carers' direct involvement in research development can lead to a "better" quality of the research itself.

### Defining research priorities for mental health: An integrated and comprehensive ROADMAP

T. Wykes

King's College London, Psychology, London, United Kingdom

Developing priorities for mental health research across Europe: methods, priorities and developing impacts.

Mental disorders represent potentially the greatest health burden to Europe – not only for directly affected individuals, but also for caregivers and wider society. They incur substantial economic costs through direct (and indirect) healthcare and welfare spending, and via productivity losses – all of which significantly affect European development. Funding for research to mitigate these effects lags far behind the cost to society. These linked presentations describe the ROAMER project which established a comprehensive, coordinated mental health research agenda for Europe and the world that might reduce these costs and burdens.

This paper leads on from the description of Consortium and a comparison of methods for achieving consensus by Professor Josep Maria Abad Haro, the ROAMER consortium lead. This presentation concentrates on how each work package produced their list of priorities and how these led to consensus on the gaps in current research and priorities for future research. These priorities were integrated and revised through surveys and consensus decision-making by more than 1000 scientists and affected stakeholders including individuals with mental health problems and their families, healthcare workers as well as policymakers and funders to produce 6 high-level priorities for mental health research in Europe which if answered would have substantial impact in the next five to ten years.

In a further joint presentation Professors Wykes and Haro will describe how these priorities have been adopted in Europe and the UK and the management of this process as an example of moving research priorities into policy and then into funding.

Finally, Professors Wykes and Haro will discuss the current European scenario in mental health research and the impact of the ROAMER project.

### Core Symposium: Cyberbullying, Cybersuicide and Novel Psychoactive Substances: Mental Health Needs in Young People

CS0009

#### Cyberbullying: A new challenge for mental health care

A. Fiorillo

University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

Internet has facilitated communication and dissemination of information worldwide, at little or no cost. Internet and related technologies are not inherently "good" or "bad", but they are rather tools that can be used for a variety of purposes, with a variety of consequences. There is no doubt that the Internet and related technologies are posing new challenges to mental health professionals, such as the development of new forms of psychopathologies, including cyberbullying and cybersuicide.

Cyberbullying is a repeated hostile or aggressive behaviour against others, performed by an individual or a group of individuals using

electronic or digital media. This activity can take many different forms, including email, blogs, chat rooms, and text messaging.

Cyberbullying is different from "traditional" bullying, since it is not based on physical direct violence, the perpetrator remains anonymous and the violent behaviour can happen anywhere and at any time.

Although prevalence rates vary considerably across countries from 1% to 60%, a significant association between cyber victimization and depressive disorders and suicidality has been observed. In a recent study carried out in an Italian sample of students from secondary schools, we found that 30% of participants reported to have been victimized and 6% of them suffered from cyber victimization. The long-term consequences of being cyber victimized are not yet completely understood, but it seems that these traumatic events are pathoplastic for the development of mental disorders during adulthood.

A better identification of the new forms of Internet-related mental disorders in young adults, including a clinical and therapeutic characterization, is needed.

CS0010

#### Youth space and youth mental health

M. Birchwood

University of Warwick, Mental Health, Coventry, United Kingdom

*Background.* – Services to young people in the city of Birmingham have been transformed from a traditional CAMHS-AMS framework to a 0–25 framework with an early intervention ethos. This includes collaboration with schools in the early detection of emerging mental health problems, including the subject of this presentation: emergent eating disorders. It is known that long duration of untreated eating disorders, leads to a low recovery rate such that those with an eating disorder over 10 years duration have a very low chance of LT recovery. This study aims to identify the earliest stages of emergent eating disorders in adolescence and to predict early transition.

*Research questions.* – (1) What is the period prevalence of partial or full ED in 13/14 year olds? (2) How many incident cases are there? (3) Can we predict transition to these incident cases?

*Method.* – Over 600 school students age 13–14 years were followed-up for 2 years in 4 6-monthly waves, using computer aided data collection. We used the Eating Disorder Examination (self-report) EDE-Q (Fairburn, Cooper, and O'Connor, 2008), a widely used validated measure together with measures of affective dysregulation, self-esteem and BMI.

*Results.* – The two year period prevalence of partial ED syndromes in 13/14 year olds was 15%. During this period 8% transitioned to de novo partial ED syndromes. The best predictor of transition was raised level of eating/weight concerns on EDQ. Within the EDQ, moderate or severe dieting raises risk of transition to ED by factor of 10 and 23 respectively. Using a ROC curve it was found that and EDQ value of >2.9 best predicted transition.

*Conclusion.* – Using relatively non-intrusive screening in schools the earliest stages of eating disorders could be identified including those with prodromal features including moderate or severe dieting. The results justify an early intervention approach to screening and early intervention as a realistic method of preventing the early entrenchment of eating disorders in young people. We are now developing an early intervention trial.

## Core Symposium: Revision of the International Classification of Diseases – State of the art in ICD-11 Field Studies

---

CS0011

### Current developments in overall ICD-revision on mental, behavioural or neurodevelopmental disorders

G. Reed

World Health Organization, Department of Mental Health and Substance Abuse, Geneva, Switzerland

In June 2018, the World Health Organization (WHO) will have released the ICD-11 for implementation by WHO member states. The Clinical Descriptions and Diagnostic Guidelines (CDDG) developed by the WHO Department of Mental Health and Substance Abuse, the diagnostic manual designed for use by mental health professionals in clinical settings, will also be published near the same time published. This session will present an overview of the extensive programme of international and multilingual field studies that have been used to test major innovations in the new system. The initial focus of the field studies was large international surveys of psychiatrists' and psychologists' views of mental disorders classification and the features that would make it maximally useful. This was followed by formative field studies of the structure of clinicians' conceptualization of mental disorders. A systematic program of case-controlled field studies was then implemented using experimental methodologies to evaluate the specific impact of proposed changes to the diagnostic guidelines on clinicians' diagnostic decision-making. Case-controlled field studies were implemented over the internet with members of the Global Clinical Practice Network, consisting of more than 14,000 psychiatrists and other health professionals from more than 150 countries who agreed to participate in field studies related to the ICD-11. Finally, ecological implementation field studies focusing on the reliability and clinical utility of the diagnostic guidelines for ICD-11 mental and behavioural disorders have been implemented in clinical settings in 17 countries, including every WHO region.

Overall, results of the case-controlled field studies indicated significant improvements in the consistency of clinical judgments and clinical utility of the proposed diagnostic guidelines for ICD-11 as compared to ICD-10. Results for specific aspects of the guidelines that did not perform as expected were used as a basis for making improvements in the guidelines. Preliminary data from clinic-based field studies indicate very high reliability and clinical utility for the ICD-11 guidelines across global settings.

### ICD-11 and the future of diagnosis in psychiatry

M. Maj

University of Naples SUN, Department of Psychiatry, Naples, Italy

The ICD-11 chapter on mental disorders will be the only one in the new diagnostic system – along with those on sleep-wake disorders and conditions related to sexual health, which were part of it in the previous editions of the classification – whose title will not contain the term “disease”. As a matter of fact, at the current state of development of our discipline, we are not assuming anymore that all the conditions we are dealing with are discrete disease entities. What we know is that they are patterns of reported experiences and observed behaviours which derive their clinical

utility from their ability to allow non-trivial inferences about further course and response to treatment. Indeed, clinical utility has been the organizing principle underlying the ICD-11 chapter on mental disorders and the main focus of the relevant field studies. Are current ICD-11 categories the most clinically useful tools to describe the “patterns” that are the subject of our discipline? This is the key question about the future of psychiatric diagnosis. The two main alternatives to the ICD-11 approach that can be identified at the present are: (a) the one assuming that the domain of psychopathology can be more efficiently described in terms of dimensions; and (b) the one assuming that the neurobiological underpinnings of psychopathology should be the major drivers of psychiatric classification. These two alternatives are currently exemplified by the projects named Hierarchical Taxonomy Of Psychopathology (HiTOP) and Research Domain Criteria (RDoC). Both these approaches, in order to emerge in the future as real alternatives to the ICD-11 classification, will have first of all to prove being at least equally clinically useful, which means equally applicable in ordinary clinical practice, with an acceptable degree of inter-clinician reliability, and at least equally able to guide the choice of treatment and predict outcomes. This will have to be documented in different clinical settings and in the hands of different relevant categories of health professionals. However, a different, much more likely, scenario is that those projects will not turn up to be a basis for a reclassification of psychopathology, but that elements of them will be gradually incorporated in the clinical characterization of individual cases, a step which should always follow that of classification, and which is indeed the other, even more decisive, element of diagnosis intended in its proper meaning. Several pieces of evidence suggest that this is indeed what we are going to witness in the years to come.

## Core Symposium: ADHD and Addiction, Towards a Consensus

---

CS0013

### Epidemiology of ADHD and SUD

M. Clerici<sup>1,2,\*</sup>, E. di Giacomo<sup>1,2,3</sup>, F. Colmegna<sup>3</sup>

<sup>1</sup> Università degli Studi di Milano-Bicocca, DCMT, Milano, Italy; <sup>2</sup> PhD Program in Neuroscience, Doctorate School of the University of Milano-Bicocca, Milano-Bicocca, Italy; <sup>3</sup> ASST Monza MB, Psychiatric Department, Monza, Italy

\* Corresponding author.

Attention-deficit/hyperactivity disorder (ADHD) has been primarily considered, for a long time, a childhood condition. Despite it, recent data suggest that symptoms of ADHD continue into adulthood in up to 50% of people diagnosed as affected by ADHD during their childhood. Accurate diagnosis of ADHD in adults is challenging and requires attention to early development and symptoms of inattention, distractibility, impulsivity and emotional lability. Currently, it does not exist a “gold standard” for its diagnosis, and we demonstrated a low reliability of screening test such as the Brown ADD Scales in populations at risk (e.g. acute psychiatric inpatients and parents of children affected by ADHD). Moreover, diagnosis is further complicated by the overlap between the symptoms of adult ADHD and the symptoms of other common psychiatric conditions such as depression and substance abuse. While stimulants are a common treatment for adult patients with ADHD, they are often used as a self-treatment, especially in patients who lack of a correct diagnosis and treatment. Antidepressants may also be effec-

tive, while cognitive-behavioural skills training and psychotherapy are useful if adjuncts to pharmacotherapy. Addiction thus embodies a key point in differential diagnosis as well as it might be considered an adverse effect of a long duration of untreated illness. As a consequence, it should be accurately checked and weighted during the diagnostic process.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

CS0014

### **International statement on ADHD in patients with SUD**

C. Crunelle

*Universitair Ziekenhuis Brussel UZ Brussel, Psychiatry, Overijse, Belgium*

Adult attention deficit/hyperactivity disorder (ADHD) and substance use disorders (SUD) are often co-occurring, and are associated with early onset and more severe development of SUD and with reduced treatment effectiveness. Screening tools allow for a good recognition of possible ADHD in adults with SUD, and should be used routinely, followed by an ADHD diagnostic process initiated as soon as possible. Simultaneous and integrated treatment of ADHD and SUD, using a combination of pharmacological and psychotherapy, is recommended. Long-acting methylphenidate, extended-release amphetamines, and atomoxetine with up-titration to higher dosages may be considered in patients unresponsive to standard doses. This consensus statement includes evidence- and eminence-based recommendations developed to provide guidance in the screening, diagnosis and treatment of patient with ADHD-SUD comorbidity.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

CS0015

### **Treatment of ADHD in patients with SUDs: new evidences**

F. Matthys

*Professor Psychiatry and Medical Psychology-Head of Department, Psychiatry, Brussels, Belgium*

The treatment of ADHD in patients with SUD is a delicate matter. Previously caregivers thought SUD had to be under control firstly, but now we know that the treatment of ADHD is best integrated into the addiction treatment. Pharmacologically there are a number of options which, however, need to be adapted. Recent research shows that higher doses of stimulants may be needed.

In addition, psychotherapy is important and effective. This is more difficult to prove through a randomized trial. But there is evolution in that area too.

The existing programs for addiction must be adapted to the limitations of ADHD. Specific skills training is necessary and will be presented.

### **Cortisol secretion and specific methylation profiles: Biomarker of conversion to schizophrenia?**

O. Kebir\*, B. Chaumette, M.O. Krebs

*INSERM, Centre of Psychiatry & Neuroscience-U894, Paris, France*

\* Corresponding author.

The effect of stress on brain pathways could participate to the mechanisms underlying the onset of psychotic symptoms, both as a precipitating factor and as a marker of a predisposing vulnerability. This dysregulation fits into the gene × environment model: in subjects with genetic predispositions, stressful environmental factors can modify biological pathways implicated in psychiatric disorders, promoting the emergence of symptoms. However, many confounding factors obscure the literature, and further studies are needed in schizophrenic patients, ultra-high-risk (UHR) and first episode patients (FEP) to clarify the precise role of stress in psychotic transition.

The onset of psychosis is the consequence of complex interactions between genetic vulnerability to psychosis and response to environmental and/or maturational changes. Epigenetics is hypothesized to mediate the interplay between genes and environment leading to the onset of psychosis. We believe we performed the first longitudinal prospective study of genomic DNA methylation during psychotic transition in help-seeking young individuals referred to a specialized outpatient unit for early detection of psychosis and enrolled in a 1-year follow-up. We used Infinium HumanMethylation450 BeadChip array after bisulfite conversion and analysed longitudinal variations in methylation at 411,947 cytosine-phosphate-guanine (CpG) sites.

Here, we report findings from the first French cohort of young help-seekers (ICAAR) including UHR, FEP and non at-risk help seekers controls (HSC), followed by a meta-analysis of all available reports on salivary basal cortisol levels in early psychosis (UHR and FEP). We discuss the main methylomic findings from the same longitudinal cohort.

### **Neuropeptide concentrations and epigenetic profiles of patients who remitted from anorexia nervosa: Prognostic biomarkers?**

N. Ramoz<sup>1,\*</sup>, G. Dominique<sup>1</sup>, G. Sébastien<sup>2</sup>, C. Philippe<sup>2</sup>, C. Julia<sup>1</sup>, C. Boris<sup>1</sup>, G. Philip<sup>1,3</sup>

<sup>1</sup> INSERM U894, Center of Psychiatry and Neuroscience, Paris, France;

<sup>2</sup> Inserm U1061, Psychological Medicine and Psychiatry, Montpellier, France;

<sup>3</sup> Sainte-Anne Hospital, Clinic of Mental Health and

Encephale, Paris, France

\* Corresponding author.

*Introduction.* – Anorexia nervosa (AN) is the most severe disorder in terms of morbidity psychiatric illness with the highest mortality rate increased by 23-fold. Treatments have a limited effectiveness. Only one-third of the AN patients evolve to the remission. Deregulations of peripheral control of food intake, hunger signals (ghrelin and obestatin) and satiety signals (leptin and insulin), have been

reported. These differences could be a consequence or risk factors of the disease due to genetic or epigenetic factors, such as DNA methylation. They could represent useful biomarkers to prognostic the evolution of the disorder to the remission.

*Objectives.*– We are currently investigating genotyping of polymorphisms and DNA methylation of candidate genes, and we have measured the concentration levels of the neuropeptides encoded by these genes in current AN patients, subjects in remission and healthy control women. Our goal is to replicate the differences of concentration levels between AN, remitters and controls, and to identify in link the differences of genetic variants or in the levels of DNA methylation that affect the gene expression, to characterize biomarkers of prognosis of AN.

*Methods.*– 100 anorexic patients, 50 remitters, and 200 control women were recruited at CMME (Sainte-Anne Hospital, Paris). They arrived at 8:30 am, fasting since the day before, to take a blood sample, in order to carry out genetic, epigenetic and physiologic

analyses. Dosage of ghrelin, obestatin, and leptin were done by EIA or RIA. Single nucleotide polymorphisms of candidate genes were genotyped by Taqman assay. DNA methylation levels were extracted from the data of the Infinium<sup>®</sup> Human Methylation chip.

*Results.*– We have confirmed that peripheral control mechanism of food intake is deregulated in AN patients compared to controls. We also report a significant intermediate concentration for remitters. No genetic association was observed. We have identified differentially methylated sites located among candidate genes. We are currently comparing methylated-sites and concentrations between remitters and AN patients to identify prognostic biomarkers.

*Conclusions.*– At least, leptin and ghrelin dosages might be prognostic biomarkers to remission of anorexia nervosa.

## 26th European Congress of Psychiatry

## Debate

**Debate: Assisted Suicide in Psychiatric Patients**

D0001

**Pro**

J. Vandenberghe

University Hospital Leuven – Psychiatric University Hospital UPC KU Leuven – University of Leuven – Belgium, Psychiatry, Leuven, Belgium

In Belgium, The Netherlands and Luxembourg, euthanasia or physician-assisted dying (PAS) is legally possible under certain conditions. In these legal frameworks, euthanasia is defined as ending the life of a patient through the administration of lethal medication by a physician at the patient's explicit request. In physician-assisted suicide, the only factual difference is that the medication is taken by the patient in the presence of the physician. PAS is only possible for intolerable suffering that cannot be relieved and is due to an incurable medical condition with no therapeutic perspective nor prospect of alleviation. Other legal conditions include an explicit, deliberate, well-considered and repeated request of a competent patient in the absence of external pressure. The physician who considers euthanasia has to consult an independent colleague. Non-terminal illnesses are not excluded, but extra legal criteria apply. The Federal Control and Evaluation Committee reviews and evaluates the euthanasia post factum.

Although the application of these legal criteria poses some problems if the medical condition is a psychiatric illness, I'll defend such a legislation for PAS based not primarily on autonomy, but on irremediable suffering. Furthermore, I'll plea to take lessons from the Belgian and Dutch euthanasia practice that arose from it, arguing for a committee based evaluation before the euthanasia in non-terminal illness, and for stricter legal criteria, guaranteeing more safeguards and due diligence. More legal checks and balances are needed to prevent patients from dying through euthanasia if not all therapeutic options and recovery-oriented approaches have been exhausted.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

**Con**

P. Courtet\*, C. Raffaella, E. Olié

CHU Lapeyronie, Emergency Psychiatry, Montpellier, France

\* Corresponding author.

The number of psychiatric patients requesting Euthanasia or Assisted Suicide (EAS) is constantly increasing in countries where this procedure is allowed.

Because mental disorders are among the most disabling illnesses, requests for EAS based on unbearable mental suffering caused by severe psychiatric disease may possibly increase. This raises the question: Should the management of patients with psychiatric disorders requesting EAS be considered for suicide prevention?

A systematic literature search allowed to analyse 25 studies from Netherlands and Belgium for the majority, and Switzerland, Germany, Canada, United States. The majority of patients requesting EAS were frequently suffering from both depression and personality disorders, in addition to a comorbid medical condition and other main suicide risk factors (previous history of suicidal act and social isolation). Frequently, evidence-based medical and psychosocial treatments currently are not provided to the majority of patients with psychiatric diseases who would benefit. Interestingly, among psychiatric patients requesting EAS, a considerable percentage no longer wished to die, postpone or withdrew their requests. In the case of patients who received EAS, the consultation with an independent psychiatrist was not an always followed procedure. In conclusion, we believe that the procedures to obtain EAS must be carefully revised, in particular constituting a committee including experts of mental health aimed at evaluating requests before EAS and not only after. Moreover, in the case of psychiatric patients, the waiting period should be longer and standardized treatments should have been formerly administered, particularly aiming at alleviating the enduring of pain suffered by these patients.

#### Patient controlled hospital admissions

C. Torgaard Thomsen<sup>1,\*</sup>, M. Eriksen Benros<sup>2</sup>, T. Maltesen<sup>3</sup>, L. Halling Hastrup<sup>4</sup>, P. Kragh Andersen<sup>3</sup>, D. Giacco<sup>5</sup>, M. Nordentoft<sup>2</sup>  
<sup>1</sup> Copenhagen University Hospital-Copenhagen-Denmark, Mental Health Centre Frederiksberg, Copenhagen, Denmark; <sup>2</sup> Copenhagen University Hospital-Copenhagen-Denmark, Mental Health Centre Copenhagen, Copenhagen, Denmark; <sup>3</sup> University of Copenhagen, Department of Biostatistics, Copenhagen, Denmark; <sup>4</sup> Psychiatric Research Unit-Region Zealand, Slagelse, Denmark; <sup>5</sup> Queen Mary University of London, Unit for Social and Community Psychiatry World Health Organisation Collaborating Centre for Mental Health Services Development, London, United Kingdom

\* Corresponding author.

**Background.**– Patient-controlled admission is a new treatment model in mental healthcare services that allows patients to self-refer to a designated hospital unit. This treatment model was developed to reduce coercion and improve clinical outcomes. The evidence is sparse and we therefore set out to study the effectiveness of patient-controlled admission in a large matched cohort.

**Methods.**– During 2013–2016, 422 patients in the PCA group were propensity score matched 1:5 with a control group ( $n = 2110$ ) that received treatment as usual (TAU). Patients were followed for at least one year using the intention to treat principle utilising nationwide registers. In a paired design, the outcomes of PCA patients during the year after signing a contract were compared to the year before.

**Results.**– No reduction in coercion (risk difference = 0.001; 95% CI = –0.038 to 0.040) or self-harming behaviour (mean difference = 0.005; 95% CI = –0.008 to 0.018) was observed in the PCA group compared with the TAU group. The PCA group had more inpatient bed days (mean difference = 28.4; 95% CI = 21.3–35.5) and more medication use ( $p < 0.0001$ ) than the TAU group. Before and after analyses showed reduction in coercion ( $p = 0.0001$ ) and inpatient bed days ( $p = 0.0003$ ).

**Conclusions.**– Implementing PCA did not reduce coercion, service use or self-harm behaviour when compared with TAU. Beneficial effects of PCA were observed only in the before and after PCA com-

parisons. Further research should investigate whether PCA affects other outcomes to better establish its clinical value.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

ECP0002

#### Integrated or functional model of care?

D. Giacco

Queen Mary University of London, Unit for Social and Community Psychiatry, London, United Kingdom

**Introduction.**– Mental health systems include hospital and community services. In systems based on personal continuity of care, the same psychiatrist treats a given patient in hospital and in the community, whilst in services based on specialisation, there are different psychiatrists who specialise to work in either hospital or community settings. Mental health policies in Europe and across the world inconsistently support one of these two alternative models without a systematic evidence base.

**Objectives.**– The COFI study is a natural experiment comparing outcomes, costs and experiences of care between personal continuity based and specialisation based systems of mental health care.

**Methods.**– COFI is one of the largest studies in mental health care having recruited and followed up more than 7000 patients with severe mental disorders. This study was carried in five European countries (Belgium, Germany, Italy, Poland and United Kingdom), in which both systems of mental health care co-exist. Different research methods were applied, including analyses of medical records, quantitative and qualitative interviews with patients and staff as well as analyses of costs and service use.

**Results.**– The final findings of the COFI study will be presented with regard to clinical effectiveness, preferences of patients and clinicians and costs associated with each system of mental health care.

**Conclusions.**– We hope that the presentation will generate a lively discussion with early career psychiatrists from different countries in order to reflect on how findings in the included countries can be extended to other national mental health care systems within and beyond Europe.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## ECP Symposium: Internet, Smart Phones and Mental Health Apps – What Is Their Role in Psychiatry?

ECP0003

### Using video-calls to combat loneliness in old age

S. Zamir<sup>1,\*</sup>, R. Jones<sup>1</sup>, A. Taylor<sup>1</sup>, C. Hennessy<sup>2</sup><sup>1</sup> University of Plymouth, Health and Human Science, Devon, United Kingdom; <sup>2</sup> University of Bournemouth, Health and Human Science, Devon, United Kingdom

\* Corresponding author.

Video-calls to reduce loneliness and social isolation within care environments for older people: an implementation study using collaborative action research.

*Introduction.*– Older people in care-settings may be lonely if families are unable to visit. Previous studies have demonstrated that video-calls can help reduce loneliness.

*Objectives.*– To identify how video-calls can be implemented for routine use in British care-settings.

*Methods.*– Two cycles of collaborative action research (CAR) with care staff as project collaborators, were piloted to implement video-calls across eight care-settings. Cycle one focused on video-calls with families using a 'Skype on Wheels' (SoW) device holding an iPad and handset connected to Skype or via Skype TV. Ethnographic field notes collected over 15 months were analysed using thematic analysis. This informed activities for cycle two that included video-calls with school pupils and inter-care home Skype quiz sessions. Mixed methods comprising interviews with older people and staff, pre-post surveys and interactive focus groups were employed over 10 months in cycle two.

*Results.*– In cycle one four care homes implemented SoW. Eight older people used SoW with staff assistance, and enjoyed using video-calls with distant family. However barriers to implementation included; staff turnover, risk aversion, SoW design, lack of family commitment and staff attitudes regarding technology. Cycle two addressed these barriers by seeking contacts with school pupils, other care homes, and getting residents to decorate SoW. Four care homes used SoW and Skype TV with 25 residents improving socialisation.

*Conclusions.*– Implementation of video-calls in care-settings to reduce loneliness would improve by first introducing inter-care home quizzes, intergenerational contact, and enabling residents to decorate and adopt the equipment before extending to contact with families.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

ECP0004

### Face-to-face or digitally? Patients preferences of being in contact with a volunteer

M. Pinto da Costa

*Hospital de Magalhães Lemos, Psychiatry Department of Porto, Porto, Portugal*

Volunteering can be used to address social isolation in patients with severe mental illness and evidence exists on its effectiveness. However, little is known about patients' preferences concerning the character of these relationships, and the format and goal of such volunteering.

A survey was conducted in community mental health teams in East London with patients with psychotic disorders. Questions covered socio-demographic characteristics, quality of life, loneliness and preferences on volunteering schemes. Binary logistic regressions were used to investigate potential predictors of interest to participate in a volunteering scheme face-to-face or digitally.

In this talk the findings from this study will be presented and discussed. From the 151 patients included in this study, more than half had not heard about these volunteering schemes, yet more than half were interested in taking part. A small percentage of patients did not use technology. Patients' interest in having face-to-face or digital volunteering varied based on their personal characteristics and predictors will be presented.

The variability in patients' preferences suggests that volunteering schemes should be offered in different formats (face-to-face and digitally) and with enough flexibility to incorporate individual preferences.

It is hoped that this talk will generate a lively discussion, gathering further understanding about the associations found between patients' personal characteristics and their preferences on the different formats to be in contact with volunteers.

This work presents research funded by the NIHR Programme Grants for Applied Research Programme (RP-PG-0611-20002).

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## ECP Training Workshop: Psychotherapy for Patients with Eating Disorders: What Works?

---

ECP0005

### Psychotherapy for patients with eating disorders: What works?

J. Treasure

*Institute of Psychiatry, Eating Disorders, London, United Kingdom*

The aim of this workshop is to examine the psychotherapy evidence base for people with eating disorders. There have been substantial advances in this area in the last 30–40 years. Nevertheless 9 years after presentation approximately 33% of cases of bulimia nervosa and 63% of anorexia nervosa remain ill. Effective early intervention may improve these outcomes. For example involving the family has been shown to be a cost effective strategy in adolescent cases of anorexia nervosa in particular. Several different permutations of family work are effective. There is less certainty about what works best for those who have failed to respond to this first step in treatment and for adult cases of anorexia nervosa.

A cost effective first step in the management of binge eating disorder and bulimia nervosa is guided CBT. However there is uncertainty about how to help the 30–50% who fail to respond to

this first step. Nevertheless new approaches are being tried and some are showing good potential.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **ECP Training Workshop: Prevention of Mental Health Disorders**

---

ECP0006

### **Prevention of suicide and self-harm behaviour**

M. Nordentoft

*Professor, Mental Health Center Copenhagen, Hellerup, Denmark*

Suicide is a major public health problem worldwide although rates of suicide vary substantially across nations. The highest rates are found in Russia and East European countries. The stress-diathesis model provides an understanding of suicide where stressors, both early-life and present stressors, interact with protective factors. This presentation summarises the existing evidence regarding societal and individual risk factors for suicide. At the societal level, risk factor such as economic crisis, social cohesiveness and media portrayal are mentioned. Individual risk factors include sociodemographic factors, physical and mental disorders, history of suicide attempt, and suicide risk in minority groups. The risk factors associated with the highest risk are mental disorders and history of suicide attempt. Population attributable risk fraction can guide preventive efforts, and calculations indicate that preventive efforts should be directed towards the excess risk associated with recent suicide attempt, mental disorders and social factors. For clinical practice identification of the above mentioned risk factors are less

useful, as the majority of people with the risk factors do not attempt suicide during a given time period, and therefore each risk factor has a very low predictive power. In clinical practice, we are most often still left trying to find the needle in a hay stack. We need more clinically relevant information in order to detect those who are at immediate high risk.

ECP0007

### **Prevention of substance misuse**

G. Dom

*Antwerp University UA-Belgium, Collaborative Antwerp Psychiatric Research Institute CAPRI, Boechout, Belgium*

As with many other psychiatric disorders substance abuse and addictive disorder initiate frequently within early adolescence and progress into adulthood. Different prevention strategies have been developed aiming both at reducing substance use at a population level and preventing the development of addictions in individuals. As to the first, so-called primary preventions have been developed targeting larger general populations in different settings (e.g. schools, workplaces). This also includes strategies using price settings and regulations to influence consumption patterns. A more recent, and possibly more promising approach, is the identification of individuals (or subgroups) of individuals that have a high risk of developing addictive disorders. Offering interventions, targeted on their specific vulnerabilities might be a more efficient approach in diminishing addiction risk. The results of the first longitudinal studies appear to be promising.

## Workshop

### Workshop: Asylum Seeker and Refugee Mental Health: Training Needs of Psychiatrists

W0001

#### Introduction

M. Schouler Oçak

Charité – Universitätsmedizin Berlin, Psychiatric University Clinic of Charité at St. Hedwig Hospital, Berlin, Germany

In the introduction of this workshop, it will be underlined, that according to the United Nations High Commissioners for Refugees (UNHCR), the worldwide numbers of asylum seekers and refugees show an upward trend, reaching 65 million and above. It is well known that migration is one of the risk factors for developing mental disorders, and that traumatized migrants in particular may face psychological distress and even serious psychiatric illness as they have been exposed to adverse conditions before, during and after migration. Prior to migration, migrants may have been exposed to deprivation, persecution, violence, imprisonment, human rights violation, including sexual harassment, even torture. Many studies report on the multiple and highly complex stressors with which refugees are often faced and which are at risk of having a lasting impact on their mental health. In line with growing globalisation and an increasing number of people on the move across national and international boundaries, it has become vast important that psychiatry and psychotherapy are aware of the different needs of the patients they are responsible for. Therefore, during times of global migration and an increasing number of ethnic minority migrants including refugees and asylum seekers, psychiatrists and psychotherapists may have a different cultural background than their patients. Thus, cultural psychiatry and psychotherapy is a matter of primary relevance and training of psychiatrists is needed. *Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Developing training for psychiatrists treating refugees: Some reflections

M. Hermans

Private practice, Child & Adolescent Psychiatry, MECHELEN, Belgium

Taking care of refugees as a psychiatrist is a challenging experience for many reasons. A refugee faces an episode in life confronting with many different transitions on all kind of levels. These include not only questions of language, but include also societal, cultural and religious aspects, among them concepts about psychic suffering.

The Section of psychiatry of the Union Européenne de Médecins Spécialistes (UEMS; [www.uems.eu](http://www.uems.eu)) developed in the past the *European Framework for Competencies in Psychiatry*. This document is based upon the CanMEDS criteria and describes these as metacompetencies, further developing into competencies and sub-competencies including ways these can be assessed. Very recently the Section also reviewed the *European Training Requirements for the Speciality of Psychiatry*.

It is evident that a professional treating refugees as patients must dispose of a large set of transcultural competencies while trying to address their needs. But also their own psychic health is exposed to some risks by listening to the traumatic stories of these patients. By the particularities of being a refugee scientific research seems to be rather difficult. This presentation will address some questions about ways scientific and professional associations, training institutes and universities might come to programs for training professionals involved in this kind of work.

European Framework for Competencies in Psychiatry <http://uemspychiatry.org/wp-content/uploads/2012/01/2009-Oct-EFCP.pdf>.

Charter on Training of Medical Specialists in the EU. Training Requirements for the Speciality of Psychiatry. <http://uemspychiatry.org/wp-content/uploads/2012/01/ETR-Psychiatry-201703.pdf>.

UEMS training requirements for the speciality of psychiatry: Annex on knowledge, skills and professionalism required for the care of refugees and asylum seekers. <http://uemspychiatry.org/wp-content/uploads/2013/09/2009-Oct-EFCP.pdf>.

### Forced displacement: A challenge for psychiatry residency programs

L. Küey

*Istanbul Bilgi University, Department of Psychology, Istanbul, Turkey*

Forced displacement of millions of people especially increasing in the last decade sets a major mental health challenge demanding the attention of psychiatrists and mental health workers. Its consequences on the mental health of refugees and asylum seekers also invite psychiatry to review current psychiatric training besides developing adequate mental health services and research.

People forcibly displaced to leave their homes and thus their psycho-social support systems are under threat in all areas of attachment, mastery, and survival. Refugees fleeing with few possessions leading to neighboring or more developed countries face many life threatening risks before, during and after displacement, and they have nowhere to return. Although, there is a marked variability in the content and quality of psychiatric training across Europe and the world, the current psychiatric residency and training programs could be improved to incorporate the unique mental health aspects of this humanitarian disaster.

Psychiatric residency and training programs should cover basic knowledge on the nosology/terminology and on the current dimensions of problems related to the forcibly displaced people (i.e., refugees, asylum seekers, IDPs, and etc.). Besides, mental health consequences of the physical and psychological traumas, including sexual abuses and human trafficking, related to the displacement process need to be emphasized. Considerable time should be spared to understand the mental health situation and prerequisites of specific risk groups (e.g., elderly, unaccompanied children, single mothering, people with disabilities) and resilient factors. Psychiatry training programs should also aim to develop the skills of the trainees on culturally sensitive clinical interview and assessment techniques for the forcibly displaced people and related human rights issues. Learning outcomes should be revised accordingly.

This presentation aims to highlight the importance of developing current psychiatry training programs to cover the necessary knowledge and skills that the future psychiatrists need in dealing with the mental health situation of forcibly displaced people (refugees and asylum seekers) living in Europe.

W0004

### Psychiatry across borders: Insights from EFPT's survey on training needs

I. Frankova

*Bogomolets National Medical University, Psychosomatic medicine and psychotherapy, Kyiv, Ukraine*

*Introduction.*– According to the United Nations High Commission for Refugee's (UNHCR) report, 65.5 million people were uprooted worldwide by conflicts in 2016. Forcibly displaced persons (FDPs) are more at risk for developing depression, anxiety, PTSD, psychosis, somatic disorders (Priebe et al., 2016). EPA called the European refugee crisis as one of the 21st century's biggest challenges, the WHO recommends specific training for mental health care professionals.

*Objectives.*– To survey European psychiatric trainees about their experience, knowledge of the FDPs mental health issues.

*Methods.*– An online questionnaire was designed collaboratively by the European Federation of Psychiatric Trainees (EFPT) Psychiatry Across Borders (PAB) Working Group, distributed via local networks among European trainees in 2017.

*Results.*– 407 respondents from 28 European countries answered the survey (64% female, 36% male, mean age 30 years old, SD: 4.6). 71% trainees had contact with FDPs in the last 12 months; 80% had encountered refugees as part of clinical work. The majority (75%) expressed a strong interest in the issue of FDPs' mental health, only 34.5% felt confident assessing and treating them. Specific training was provided to 16% of trainees, but only 25% felt it was adequate. Trainees rated transcultural competencies, PTSD and trauma management training, as the most necessary skills to confidently manage traumatised refugees.

*Conclusions.*– This survey shows a clear unmet need for specific training regarding refugee mental health for psychiatry trainees. Existing training may need improvement, for example, practical skills (interview with a translator). Trainees from almost all European countries are highly motivated to improve their knowledge.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Mental health needs in immigration removal centres

H. Grant-Peterkin

*Queen Mary University of London, Centre for Psychiatry, London, United Kingdom*

Each year up to 30,000 asylum seekers and migrants are detained in the UK in immigration removal centres (IRCs) or, post sentence, in prison while the Home Office makes decisions on their immigration status and/or arrangements for their removal or deportation. Whilst the UK is the only country in Europe who detains individuals indefinitely the phenomena of immigration detention in European wide and growing.

Such evidence that exists indicates that immigration detention can be harmful to mental health, especially for people with pre-existing mental health problems such as post-traumatic stress disorder. A systematic review of ten studies investigating the effect of immigration detention identified high levels of mental health problems among detainees. Time spent in detention was shown to be positively associated with the severity of mental health problems. In addition official inspectorates, international organisations, non-governmental organisations, and the law courts have repeatedly criticised both the immigration detention of mentally ill people and the conditions in which detainees are held. The needs of detainees are often not identified, and those in treatment often experience interruptions in care. No effective safeguards exist to prevent vulnerable people – for example, those who have been tortured-from being detained. In addition there is currently no process for identifying detainees who lack the mental capacity to participate in decision making relating to their immigration situation. Mental illness and distress are common among detainees.

This presentation will consist of three parts – an introduction to immigration detention worldwide (with a specific emphasis on the UK), followed by a brief review of the evidence relating to the impact of immigration detention on individuals with pre-existing mental health conditions and those without. The final part of the talk will cover the training and educational needs of psychiatrists who encounter individuals who have been detained and those who are seen in detention centres

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Reflections from the UK'S global health curriculum group

H. Ryland

*University of Oxford, Psychiatry, London, United Kingdom*

The Global Health Curriculum Group was commissioned by the Academy of Medical Royal Colleges to develop an educational framework for global health capabilities. This conceptualises the necessary skills in five categories: Diversity, human rights and ethics; environmental, social and economic determinants of health; global epidemiology; global health governance; and health systems and health professionals. In this workshop, these principles will be briefly presented and discussed in the context of the training psychiatrists need to respond to the needs of refugees and asylum seekers.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

W0007

### Introduction to the field of e-mental health and the eMEN Interreg project

O. Vlijter

*Arq Foundation, eHealth, Diemen, The Netherlands*

Mental illnesses present a huge and growing economic and social burden for society, accounting for 20% of the disease burden. Innovative and high-quality e-mental health plays an important role in tackling this societal challenge. However, the average use of e-mental health is still very low, with large differences between EU Member States. The reasons for this are complex but must be addressed in order to keep mental health care accessible and affordable.

The objective of this workshop is to give a brief overview of e-mental health implementation in the Netherlands, France, Germany, the UK, Ireland and Belgium, and to get a better understanding of the many implementation challenges: product quality (clinical effectiveness, costs effective evaluation, privacy, CE compliance, 'look & feel'); product development process (co-creation SMEs); awareness and acceptance; organisational priority; digital skills; confidence; high start-up costs; reimbursement; legal and policy framework; training and curricula; ICT infrastructure; 'blended care' implementation protocols; integration with integrated healthcare systems; definitions (transparency, reliability, validity, etc.).

eMEN is co-funded by the Interreg North West Europe programme, and has a total budget of €5.36 million (2016–2019). eMEN is led by Arq Foundation in the Netherlands and implemented with partners in Belgium, France, Germany, Ireland and the UK. It will undertake a unique combination of digital mental health activity in research, product development, policy and communications. The eMEN cooperation platform will further grow after the project phase.

Participants in this workshop are encouraged to give their opinion about the use and implementation of e-mental health.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

W0008

### eMen – Focus on transnational policy solutions

W. Gaebel

*LVR-Klinikum Düsseldorf – Kliniken der Heinrich-Heine-Universität Düsseldorf, Psychiatry and Psychotherapy, Düsseldorf, Germany*

The implementation of e-mental health is hindered by several challenges which must mainly be addressed on the policy level: lack of training curricula and acceptance, lack of funding and high start-up costs for eHealth developers, lack of interoperability, quality and safety (standards), as well as lack of legal clarity with regards to accountability and data use and overall, lack of e-mental health implementation strategies. Moreover, there is a great variance in development of e-mental health between North West European (NWE) countries with respect to access, speed or reliability of internet services. The eMEN work package "Transnational policy solution for e-mental health implementation" aims to develop and actively promote effective and workable policy solutions for the NWE countries in order to enhance the uptake of e-mental health and hence, reduce unmet need and close the treatment gap. In order to develop applicable policy solutions, a collaboration between the European Psychiatric Association (EPA) and the LVR – Institute for Healthcare Research (LVR-IVF) has been agreed on and determined by an Agreement to Partnership.

The development of transnational policy recommendations can be seen as a series of interrelated actions. First, all relevant national and European policy documents that are dealing with e-mental health implementation as well as e-mental health projects and initiatives will be gathered, and the respective level of e-mental health development in the NWE countries will be analyzed. Subsequently, each participating country selects and interviews national and European experts in technology, policy, organization and legal issues.

On European level, relevant EU e(-mental)health policies and initiatives, such as the eHealth network, the Green paper on mHealth, the Joint Action on Mental health and wellbeing, have been taken into account. On the national level, several initiatives and projects on e-mental health have been identified, whereas policy documents addressing e-mental health are quite rare. Based on the literature review and the stakeholder interviews, differences in NWE countries in terms of driving factors, barriers and facilitators as well as implementation approaches (e.g. top-down vs. bottom-up) will be presented.

The gathered information builds the basis for the recommendations in the transnational policy solution which will address challenges, differences and similarities on the national and transnational level and will be actively promoted through meetings, seminars and conferences.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Environmental risk factors of attenuated psychosis in migrants and general population

A. Tortelli<sup>1,3</sup>, F. Schurhoff<sup>1</sup>, M. Leboyer<sup>1</sup>, R. Murray<sup>2</sup>, C. Morgan<sup>3</sup>, A. Szoke<sup>1</sup>

<sup>1</sup>INSERM, U955-15, Paris, France; <sup>2</sup>Institut of Psychiatry – Psychology and Neuroscience – King's COLLEGE LONDON, Psychosis Studies, London, United Kingdom; <sup>3</sup>Institut of Psychiatry – Psychology and Neuroscience – King's College London, Health Services and Population Research, London, United Kingdom.

\* Corresponding author.

(W03). – Attenuated psychosis in migrants and general population in a trans-national study.

*Scientific background/objectives.* – There is growing evidence that attenuated psychosis (schizotypy, psychotic experiences) and schizophrenia share common risk factors, such as childhood trauma, cannabis use, obstetric complications, and maternal viral infections (Barrantes-Vital and Kwapiil, 2015).

The association between psychosis and migration and/or ethnic minority status is well established and a variation of this risk across countries and ethnic groups has been observed (Bourque, van der Ven, & Malla, 2011; Cantor-Graae & Selten, 2005). However, only a few studies have explored migrant/ethnic status as a risk of schizotypy so far. We would like to explore this association in the light of these possible confounding factors. Moreover, these studies were conducted mainly among college students, which limit the generalizability of the results and using different methods/instruments, which make comparison between studies difficult (Zhang and Brenner, 2016).

**Objectives.**– To conduct a cross cultural study on attenuated psychosis dimensions in subjects from the general population using a homogeneous methodology.

To compare the impact of demographic and psycho-social risk factors on these dimensions across the different ethnic groups and different national contexts.

**Methods.**– We will analyse data from all non-psychotic subjects (i.e. controls and sibs) included in the EUGEI study, for which measures of attenuated psychosis (derived from CAPE and/or SIS) and birth place and ethnicity are available; and potential confounding data such as demographic data (gender, age, education, marital status), cannabis, socio-economic status.

**Results.**– Findings will be discussed in the light of the context of the psychosis continuum and associated risk factors.

**Conclusion.**– The context of EU-GEI allows for conducting a cross-cultural research and investigating the factors that influence attenuated psychosis dimensions in migrant and minority ethnic groups.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0010

### **Migration history and risk of psychosis in the EUGEI first episode psychosis study**

I. Tarricone<sup>1\*</sup>, M. Braca<sup>2</sup>, G. Bacoli<sup>1</sup>, D. Berardi<sup>1</sup>, M.R. Murray<sup>3</sup>, C. Morgan<sup>4</sup>

<sup>1</sup>Alma Mater Studiorum – University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; <sup>2</sup>Department of Mental Health and Pathological Addictions, Bologna Local Health Authority – Ausl di Bologna, Bologna, Italy; <sup>3</sup>Institute of Psychiatry – Psychology and Neuroscience King's College London, Department of Psychosis Studies, London, United Kingdom; <sup>4</sup>Institute of Psychiatry – Psychology and Neuroscience King's College London, Health Service and Population Research Department, London, United Kingdom.

\* Corresponding author.

**Introduction.**– The European Network of national schizophrenia networks studying Gene-Environment Interactions (EU-GEI) study – the largest international incidence study of psychotic disorders in 30 years – confirmed marked heterogeneity in risk of psychosis by person and place, including markers of area-level socioeconomic stability. Rates were elevated in minority groups (IRR: 1.6; 95%CI: 1.5–1.7).

**Aims.**– To present preliminary findings from the EUGEI European Network of National Schizophrenia Networks Studying Gene Environment Interactions study on the interaction between migration history and risk of psychosis.

**Methods.**– The EU-GEI study is an international multi-site incidence study. Setting: England (N=2 catchment areas), France (N=3), Italy (N=3), the Netherlands (N=2), Spain (N=6) and Brazil (N=1). The Bologna Migration History and Social Integration interview was administered to all first generation migrants (FGM).

**Results.**– 535 FGM with first episode psychosis (FEP) and 225 FGM controls were evaluated. FGM with FEP were more often unemployed and unsatisfied for family and friends' relationships in the pre-migration phase and moved from their country of origin more often for work reason compared to controls; in the post migration phase they received less social support from social services, acquired families and friends compared to healthy migrants. Cases are less satisfied in post migration phase for work, families and social relationships.

**Conclusion.**– The EUGEI study allows a deeper understanding on the relationship between the characteristics of the history of migration and the excess of FEP found among FGM in Europe. These preliminary results shape the scene for preventive interventions of the psychosis among migrants in Europe.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0011

### **Minority status and psychosis: A comparison of group density effects**

P. Schofield

Kings College London, Division of Health & Social Care Research, London, United Kingdom

**Introduction.**– It has been frequently observed that mental disorders, such as psychosis, are more common for people in some ethnic groups living in areas where their ethnic group is less well represented.

**Objectives.**– We set out to test the hypothesis that this 'ethnic density' effect reflects minority status generally by looking at three situations where individual characteristics differ from what is usual in a locality.

**Methods.**– Using data collected from the South East London Community Health study (N=1698) from 2008 to 2010 we looked at minority status (defined by: ethnicity, household status and occupational social class) and rates of psychotic experiences as well as common mental disorders and attempted suicide.

**Results.**– Being black in an area where this was (10%) less common was associated with higher rates of sub-clinical psychosis, odds ratio (OR) 1.34 (95% CI 1.07 to 1.67). Being single in an area where this was less common (10% less) was also associated with an increased risk of psychotic experiences (OR 2.18 95% CI 0.91 to 5.26). Minority status due to social class was associated with an increased risk of attempted suicide only (OR 1.33 95% CI 1.03 to 1.71). No association was observed between minority status and common mental disorders.

**Conclusions.**– The relation between social marginalisation and mental distress is most apparent when minority status is defined in terms of ethnicity. Similar although less consistent effects are also seen where individual household status and social class are incongruent with local norms.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0012

### **“Life is pleasant. Death is peaceful. It's the transition that's troublesome” (Isaac Asimov): The elderly and suicide**

P. Zeppegno

A. Avogadro University of Eastern Piedmont, Medicina Traslazionale, Novara, Italy

The reflection about old age, suicide, and assisted suicide should start with a reflection about the meaning of aging. As Carl Gustav

Jung wrote: “. . .the life of an older person is characterized by a contraction of forces, by the affirmation of what has been achieved, and by the curtailment of further growth”. Existing as an old person compels to individual to reflect: “. . .The fantasy of omnipotence is shattered by the arrival of youth: childhood dreams are broken and this requires that one adjusts to reality. . .in the second half of life. . .one’s man time is no longer rise and growth: here comes the unavoidable encounter with ‘the birth of death’” (Eugenio Torre, 2013).

Have opinions changed since Terentius’s statement that old age was a disease itself? Or is it consistent with the current research and interest about healthy ageing? The meaning of healthy ageing is another topic for discussion: healthy ageing and good ageing are not the same, just as the ‘solitary elderly’ is not the same of the ‘lonely elderly’, as described by Guido Ceronetti. Good ageing does not mean that one lives well in all the dimensions at once. The founder and master of the Psychiatry School in Novara, Eugenio Torre, in a recent conference about healthy ageing suggested that “To live well and to live healthy are not necessarily synonyms. Actually, sometimes they are opposite. And I am not thinking about an unrestrained hedonism, but rather to Norbert Bensaid’s words in his wonderful “La Lumière médicale. Les illusions de la prevention” . . .to remove our fear of death, they make us die of fear. . .”.

While it is widely acknowledged that old age has a greater risk of suicidal behaviour compared to other age classes, and several studies about this topic are available, there are a lot of questions which still have no answer in the field of euthanasia and assisted suicide in the elderly. Why is there the need for “assisted” suicide? Are there differences between those who ask for assisted suicide and those who commit suicide without assistance? How to conciliate, in the same country, assisted suicide and suicide prevention? What is the impact of legal euthanasia and physician assisted suicide on suicide rates? Does it represent an actual alternative to non assisted-suicide, or has the opportunity of assisted-suicide a different target population from the one of those who consider self-inflicted death?

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0013

### **Suicide prevention and prevention of assisted suicide in Switzerland**

G. Stoppe

*MentAge, Counsel – Practice – Research, Basel, Switzerland*

In most countries of the world, suicide rates are highest in the elderly population. The debate on preserving autonomy and dignity throughout the life span has also led to the demand to allow assisted suicide, which is possible in some countries. In Switzerland the numbers of people committing assisted suicide have increased dramatically in recent years. The average age of these people is 77 y. In order to prevent suicide a national plan for suicide prevention has been started with the focus on awareness, reduction of risk factors and promotion of models of good practice. During the last years there was some progress with regard to the prevention of falls and access to weapons. The prevention of suicide in the elderly focuses on access to diagnosis and therapy of depression, providing social integration and more. However, what should be done to prevent assisted suicide? Should it be prevented? The Swiss physicians and society are torn. It seems that the “risk factors” for assisted suicide differ from those for suicide. By use of a pragmatic approach to initiatives shall be presented. One is to contact people who have sought contact to private organisations for assisted suicide (EXIT) and have not yet plans to commit it in the very near future. The

second is a proposal to regulate the “process quality”, especially by law.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Assisted suicide and second opinion requests for euthanasia in elderly patients with concomitant psychiatric and somatic disorders. A case series**

C. Van der Feltz Cornelis

*Tilburg University, Tranzo, Tilburg, The Netherlands*

In the Netherlands, euthanasia is an accepted practice if the guideline is strictly followed. Also patients with mental disorders can file a request for euthanasia, and a guideline for this practice also exists, which recommends that euthanasia can only be possible if the patients suffers greatly, no relief of suffering is suspected, and a mental disorder exists that has been treated according to the relevant guideline for that disorder to the full extent without solace. However, recent research has shown that patients may receive such euthanasia without these requirements being met. Special clinics have been opened in the Netherlands that help patients with such a request and they ask second opinions to psychiatrists with the question if the condition could be treated or not. Current practice shows that even patients who could receive treatment, but who refuse that, may get euthanasia by such clinics, which has led to a lot of criticism. The advent of the new guideline for assisted suicide in the Netherlands has elicited a societal debate as well as a debate amongst psychiatrists who are divided between feeling that assisted suicide should be possible in desperate cases in order to avoid suicides; and psychiatrists who feel that patients should be able to count on their psychiatrist to provide them optimal treatment and being inclined to keep them alive. An overview will be provided and an illustrative case of a patient with combined somatic and mental disorder will be discussed.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Big data to track and treat? Proposing online therapy to problem gamblers: A randomized clinical trial**

A. Luquiens

*Hopital Paul Brousse, Addictologie, Villejuif, France*

*Background.*– Collaboration between academics and gambling service providers allows working on account-based gambling data. These massive data can help understanding the gambling disorder course, and developing new tracking tools to help gamblers before the impact of gambling grows out of control. We present two examples of the potential of such data, through an interventional study, and through the observation of the impact of a spontaneous responsible gambling measure. We present the results of an online randomized control trial and an exploration of self-exclusions motives and course of gambling after a self-exclusion. *Methods.*– In the first study, all active poker gamblers from a website were systematically offered screening and proposed to be included if Problem Gambling Severity Index (PGSI) score was  $\geq 5$ .

Problem gamblers were randomized into four groups: (1) waiting list (control group), (2) personalized normalized feedback on their gambling status by email, (3) an email containing a self-help book to be downloaded with a Cognitive Behavioral Therapy (CBT) program without guidance, and (4) the same CBT program emailed weekly by a trained psychologist with personalized guidance. Efficacy was assessed based on the change in PGSI between baseline and 6 weeks or 12 weeks and supported by player account-based gambling data automatically collected at the three time points. In the second study we included all poker gamblers who first self-excluded since the launch of a poker gambling website and reported a motive for self-exclusion ( $N = 1996$ ). We explored two groups: self-excluders who declared a motive linked to addiction and those who declared a commercial motive. We described and compared account-based gambling summary and session-data ( $N = 38206$  and  $14020$  respectively) in the previous month of both groups. We explored return to gambling and following self-exclusions.

**Results.**– In the first study, all groups met high attrition rates (83%), but the group with guidance had a significantly higher dropout rate than the other three groups, including the control group. Although all groups showed some improvement, no significant difference in efficacy between the groups was observed on the PGSI.

In the second study, we found that both groups of self-excluders were heavy gamblers. No between groups adjusted difference was found on summary gambling data, and sessions from both groups were poorly discriminated one from another with multiple machine learning models. 68.5% of gamblers were back on gambling after a first self-exclusion ( $N = 1368$ ), half within the first month. Gambling in the month of return was less heavy than before first self-exclusion, but rapidly increased and 60.1% self-excluded again ( $N = 822$ ).

**Conclusions.**– If very intrusive designs seem to be aversive, a currently available spontaneous responsible gambling tool, self-exclusion, seems to have a non persistent positive effect on gambling course for most gamblers. New intermediate responsible gambling tools, including tracking and proposal of guidance, could be developed to better protect problem gamblers.

**Disclosure of interest.**– Non funded collaboration with Winamax.

W0016

### **Development of a text-message brief contact intervention following a suicide attempt**

M. Larsen<sup>1,\*</sup>, F. Shand<sup>1</sup>, K. Morley<sup>2</sup>, P. Batterham<sup>3</sup>, B. Reda<sup>1</sup>, K. Petrie<sup>1</sup>, S. Berrouiguet<sup>4</sup>, P. Haber<sup>2</sup>, G. Carter<sup>5</sup>, H. Christensen<sup>1</sup>  
<sup>1</sup>University of New South Wales, Black Dog Institute, Sydney, Australia; <sup>2</sup>University of Sydney, Discipline of Addiction Medicine, Sydney, Australia; <sup>3</sup>Australian National University, Centre for Mental Health Research, Canberra, Australia; <sup>4</sup>Brest Medical University Hospital at Bohars, Adult Psychiatry, Brest, France; <sup>5</sup>University of Newcastle, Centre for Brain and Mental Health Research, Newcastle, Australia.

\* Corresponding author.

Suicide is a leading cause of death, particularly among young people. Continuity of care following discharge from hospital is critical, yet this is a time when individuals often lose contact with health-care services. A meta-analysis has shown that postcard-based brief contact interventions following a suicide attempt can reduce the number of repeat attempts, and text message interventions are currently being evaluated.

We sought to extend post-attempt caring contacts by designing a brief online intervention targeting proximal risk factors and the needs of this population during the post-attempt period. This

presentation details the development process and describes the realised RAFT (Reconnecting AFTER a suicide attempt) system.

To inform the design of the intervention, a lived experience design group was established. Participants were asked about their experiences of support following their suicide attempt, their needs during this time, and how these could be addressed in a brief contact ehealth intervention. The intervention design was also informed by consultation with lived experience panels external to the project, and a clinical design group.

Prompt outreach following discharge, initial distraction activities with low cognitive demands, and ongoing support over an extended period were identified as structural requirements of the intervention. Key content areas identified included coping with distressing feelings, safety planning, emotional regulation and acceptance, coping with suicidal thoughts, connecting with others/interpersonal relationships, and managing alcohol consumption.

The RAFT text message brief contact intervention combines SMS contacts with additional online brief therapeutic content targeting key risk factors. It has the potential to reduce the number of repeat suicidal episode and to provide accessible, acceptable, cost-effective support for individuals who may not otherwise seek face-to-face treatment. A pilot study to test the feasibility and acceptability of the RAFT intervention is underway.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Sleep inducers in elderly patients. What to prescribe?**

J. Bobes

University of Oviedo – Medical School, Psychiatry, Oviedo, Spain

Insomnia is a heterogeneous disorder characterized by difficulties in initiating or maintaining sleep, early awakening or non-restorative sleep accompanied by daytime consequences and interference with everyday functioning. In elderly, the estimated prevalence varies between 20 and 50%, and it is more frequent in women.

Benzodiazepine and nonbenzodiazepine receptor agonists are among the most commonly prescribed drugs along with sedative antidepressants (i.e., doxepin, mirtazapine, and trazodone) and antipsychotics (i.e., quetiapine) used as “off-label” medication. In the last years, one dual orexin receptor antagonist (suvorexant) and three melatonin agonists (prolonged-released melatonin, ramelteon, and tasimelteon) have demonstrated efficacy in managing insomnia and received approval by the EMA and/or FDA as hypnotic agents.

In this talk, I will address the reported efficacy and the potential adverse effects of the different medications employed for the treatment of chronic insomnia in the elderly, as well as, the recommendations made by the new updated Clinical Guidelines.

**Disclosure of interest.**– Julio Bobes has received research grants and served as consultant, advisor or speaker for the companies: AB-Biotics, Adamed, Almirall, AstraZeneca, Bristol-Myers Squibb, Ferrer, Glaxo-Smith-Kline, Hoffman La Roche, Janssen-Cilag, Lilly, Lundbeck, Merck, Novartis, Organon, Otsuka, Pfizer, Pierre-Fabre, Sanofi-Aventis, Servier, Shering-Plough and Shire, research funding from the Spanish Ministry of Economy and Competitiveness – Centro de Investigación Biomedica en Red area de Salud Mental (CIBERSAM) and Instituto de Salud Carlos III-, Spanish Ministry of Health, Social Services and Equality – Plan Nacional sobre Drogas – and the 7th Framework Program of the European Union.

## How to avoid irrational polypharmacy in elderly patients?

### Psychopharmacologist's view

M. Stuhec

Faculty of Pharmacy, Biopharmacy and Pharmacokinetics, Ljubljana, Slovenia

*Background.*— Our population is getting older and therefore more and more medications have been used in elderly patients. Almost 50% of elderly patients are treated with at least 5 different medications concomitantly, which can lead to serious drug-related problems and irrational polypharmacy. Nearly 50% of elderly patients take one or more medications that are not medically necessary. Research has clearly established a strong relationship between irrational polypharmacy and negative clinical consequences. These patients are often excluded from the treatment guidelines, although they represent a huge patient population. The best intervention for irrational polypharmacy reducing involves an inter-professional approach (a collaborative care approach) that often includes a clinical pharmacist.

*Aims.*— The main aim of this talk is to present impact of different interventions in irrational polypharmacy reducing including older ambulatory primary care, hospital, and nursing home patients. Firstly, different approved methods will be presented to avoid irrational polypharmacy in association with inappropriate prescribing in elderly (e.g. STOP/START, Beers and PRISCUS). Secondly, different possible mechanisms of rational psychopharmaceuticals and other medications prescribing will be presented to reduce irrational polypharmacy. In addition, antihypertensive drugs, proton pump inhibitors, antibiotics and some another groups will be discussed in term of irrational polypharmacy reducing. Lastly, a collaborative care approach including clinical pharmacist with clinical cases will be discussed. The participants will learn how to reduce irrational polypharmacy in elderly patients who need psychopharmacological treatment by using medication reviews and well planned drug prescriptions and collaborative care.

*Disclosure of interest.*— The authors have not supplied their declaration of competing interest.

## Drug discontinuation in elderly patients. When it is possible and rational in patients with mood disorders?

R. Heun<sup>1,\*</sup>, C. Hiemke<sup>2</sup>

<sup>1</sup>DHCFT, Psychiatry, Derby, United Kingdom; <sup>2</sup>Universitaet Mainz, Psychiatry, Mainz, Germany.

\* Corresponding author.

Depression is a frequent disorder in the elderly. Treatment with antidepressants is useful and common even though studies providing sufficient relevant evidence for the elderly patient population are rare. Most therapy recommendations are based on studies with younger samples. However, elderly depressed patients might be more difficult to treat as a result of physical and mental co-morbidities. In addition, elderly patients often receive multiple medications for various diseases. Drug-drug interactions are therefore most likely. Consequently, it has been recommended to describe lower doses of medications and to reduce these, if possible, and stop, as soon as possible. Sadly, scientific evidence for such clinical recommendations on how to and when to reduce or stop is very limited. More research to address these most urgent clinical gaps in scientific knowledge to help this population is required.

*Disclosure of interest.*— The authors have not supplied their declaration of competing interest.

## Psychopharmacological approach to mood disorders in the elderly. Realities and perspectives

M. Martín Carrasco

Clinica Psiquiatrica Padre Menni, Psychiatry, Pamplona, Spain

Mood disorders in the elderly are a significant, common, and growing problem that requires treatment. It has serious implications for the patient, family, and community. Identification followed by a thorough assessment can help guide the selection of an appropriate medication.

There are several factors to consider when selecting, adjusting, and changing drugs in the elderly. Treatment of mood disorders in the elderly is particularly challenging due to the relative scarcity of well-designed trials, atypical clinical presentations, presence of multiple comorbidities (i.e., cognitive impairment) and adverse effects (i.e. falls). While meta-analyses involving antidepressants, antipsychotics and mood stabilizers have generally shown modest treatment benefits in this population, clinicians treating geriatric patients must be especially mindful of issues regarding polypharmacy, drug metabolism, and adverse event profiles. Issues related to pharmacodynamics, safety, tolerability, and the unique features associated with the use of drugs in this population are further discussed.

Together, these strategies can help promote the safe use of psychoactive drugs in the elderly. Besides medications, other therapies might be considered include various forms of psychotherapy and neurostimulation, with electroconvulsive therapy still being the gold standard for severe or psychotic depression.

## Building national collaborations with senior psychiatrists: The Spanish experience

N. Gomez-Coronado

Hospital Virgen del Rocío, Psychiatry, Sevilla, Spain

National Trainees Associations (NTAs) represent the interests of psychiatric residents in their home countries. The European Federation of Psychiatric Trainees (EFPT) aims to unite their efforts at an international level. These organizations may help trainees to work more closely with senior psychiatrists, which in turn may be beneficial for both parts, and lead to a better psychiatric practice. The Spanish Society of Psychiatric Trainees (SERP), established in 2015, is one of the newest NTAs in Europe. In these two years, SERP has collected a valuable experience of cooperative work with senior psychiatric associations in Spain, which can serve as a model for trainees in other countries from Europe and beyond.

First of all, we started signing formal collaboration agreements, allowing trainees to obtain rights such as double affiliation to senior associations, scholarships and access to their newsletters and journals. Other relevant results have been the opening specific spaces and tracks for trainees in national scientific conferences, as well as co-authorship in academic publications.

More recently, SERP has been involved in national research projects on delirium and agitation management, in collaboration with senior associations.

These collaborations seek also to allow trainees to participate in the establishment of national policies regarding Mental Health and training in psychiatry.

How did we create these partnerships? Have been these collaborations beneficial for the trainees? What else can be done? These questions will be discussed during this talk.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Challenges of Psychiatric Trainees in Eastern Europe

T. Gondek<sup>1,\*</sup>, A.R. Szczegieliński<sup>2</sup>, P. Ryta<sup>3</sup>, M. Janusz<sup>1</sup>, M. Ciułkiewicz<sup>4</sup>

<sup>1</sup>Wrocław Medical University, Department of Psychiatry, Wrocław, Poland; <sup>2</sup>Medical University of Silesia in Katowice, Department and Clinic of Psychiatry and Psychotherapy, Katowice, Poland; <sup>3</sup>Lower Silesian Centre of Mental Health, Lower Silesian Centre of Mental Health, Wrocław, Poland; <sup>4</sup>Medical University of Silesia in Katowice, Medical University of Silesia in Katowice, Katowice, Poland.

\* Corresponding author.

Psychiatric Trainees in Eastern Europe often face different problems to those experienced by their colleagues from the other parts of the continent.

The low expenditure on health care systems and particularly on mental health care results in difficult working conditions and low salaries of psychiatric trainees in these countries. In some of the countries, the shift of the model of mental health care from an institution-based to a community-based care has not yet been completed and the trainees have often to perform their whole postgraduate training in large psychiatric hospitals, equipped with old facilities. The training curricula also often limit the possibilities of a more diversified development and force the trainees to organize themselves additional internships abroad to supplement their growth. The difficulties surrounding the training in Eastern Europe force them to also seek temporary or permanent migration to Western European countries to continue their work in significantly better conditions, which results in the brain drain effect and cause further problems in their respective countries.

Maintaining and Establishing a National Trainee Association (MENTA) Working Group, a part of the European Federation of Psychiatric Trainees (EFPT), has always been in support of the psychiatric trainees in European countries, with a particular focus on Eastern Europe. During the last years, the Working Group helped establish trainee associations in Poland and Rep. of Macedonia, as well as supported the associations in Czech Republic and Slovakia. Currently MENTA is trying build a trainee network in Bulgaria to create a similar organization in this country.

W0023

### Coordinating the efforts from trainees around Europe

C. Matei

Alexianer Hospital-Krefeld, Psychotraumatology, Düsseldorf, Germany

EFPT (the European Federation of Psychiatric Trainees) is a non-profit organization for European national psychiatric trainees. It is a federation of the National Trainees Associations from almost all European countries. In our era it is important that doctors from different countries share their experiences and develop common

research projects. This goes for motivated trainees too. EFPT pleads in favour of reducing the differences between training programs in the European countries and actively helps trainees by encouraging them to exchange opinions, information and compare their training programs. It enables many trainees to participate in exchange programs in other countries.

In 2016 EFPT has established the CET (Connecting European Trainees) program, designed to bring psychiatric trainees in Europe even closer. Thus we have created the EFPT NTA page, where one can find data such as the name of the NTA, of its president and of a delegate within the association, whom trainees will be able to contact when they have questions regarding, for example, training, research and exchange programs in this country. These contact persons will then be able to refer them to the most suitable doctor in their country. Thus communication between psychiatry trainees across Europe has become much easier.

Exchanging information between trainees mainly takes place through email, although social media platforms such as Facebook are also often used. Other social media platforms are also important for the communication between EFPT members and trainees.

The NTA Coordinator is a newer position in the EFPT organigram. The holder thereof is in charge of gathering the above-mentioned data and updating the page. He works closely with the IT Manager, the Chairman of the working group called MENTA (Maintaining and establishing a National Trainee Association) as well as the national delegates.

Our current objective is to create a page for each association. At this moment, more than half of the EFPT members have a page. The CET Program is an important part in bringing trainees of different background, nationality, culture, and training together.

### Crossing the bridge: Achievements of psychiatric trainees in Turkey

E. Sönmez

Caycuma State Hospital, Psychiatry, Zonguldak, Turkey

Trainees have played a major role since the first organisational attempts among psychiatric professionals were made during 1990s. Trainee Committee of Psychiatric Association of Turkey (TCPAT) has been formally established in 2013, which has been the culmination of long-term efforts of trainees in previous generations.

It now functions as a platform where hundreds of trainees are linked, can immediately react to each other's inquiries and provide peer support. Under the umbrella of TCPAT, local and international surveys regarding psychotherapy training, working and training conditions have been conducted and published, aiming to improve the existing status in each aspect. Several members of the committee participate as representatives in international early career psychiatrist associations. Moreover, for the last two years, national psychiatric trainee meetings are organized and this initiative was crowned by the EFPT Excellence Award in 2017.

In 2017, the European Forum of Psychiatric Trainees was hosted by TCPAT, for a second time after 2005. More than hundred delegates and observers from over 35 countries have been able to observe the local training scheme and examples of practice. These activities have enhanced trainees' feelings of autonomy, improved their leadership skills and capacity of working in teams and strengthened their professional identity.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

W0025

### Exploring training and working opportunities of substance abuse and dual disorders for early-career psychiatrists

C. Gomez<sup>1,\*</sup>, V. Pereira Sanchez<sup>2</sup>, E. López de Munáin<sup>3</sup><sup>1</sup>Hospital Virgen de la Victoria, Mental Health, Malaga, Spain;<sup>2</sup>Clinica Universitaria de Navarra, Psychiatry, Pamplona, Spain;<sup>3</sup>Hospital Universitario Ramon y Cajal, Psychiatry, Madrid, Spain.

\* Corresponding author.

**Introduction.**– Substance abuse and dual disorders (substance abuse+another psychiatric disorder) represent a challenge for early-career psychiatrists. An overview of training schemes around the world is important in order to encourage policies of improvement, and to strengthen international collaborations.

**Objective.**– To conduct a pilot survey comparing training schemes for psychiatric residents in substance abuse and dual disorders across countries from all over the world.

**Methods.**– National delegates from the countries included in the European Federation of Psychiatric Trainees (EFPT) and Young Psychiatrists' Network (YPN) were e-mailed with a 6-question survey about training and working opportunities for early-career psychiatrists in their countries regarding substance abuse and dual disorders. Questions asked for: length of psychiatric residency, specific training in substance abuse/dual disorders, specific training on adolescent populations, and facilities used for those disorders.

**Results.**– 60 countries were contacted, providing 13 responses: Nigeria, Iran, India, Azerbaijan, Turkey, Spain, Poland, Denmark, Czech Republic, Argentina, Mexico, Canada and USA. Great heterogeneity was found among training schemes. Only North American countries reported specific training on dual disorders and specific training in adolescent populations. Duration of training in substance abuse disorders is 1–4 years in North American countries and 1–7 months in the others. The most common kind of facilities are community-based centres, frequently coexisting with other public and private resources.

**Conclusion.**– Training in substance abuse and dual disorders seems heterogeneous around the world. North America counts with longer and more specific training programmes. A further survey, including more quantifiable data and countries, would provide policy-making results.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Developing and improving training in child and adolescent psychiatry in Europe

T. Gómez Alemany

Complex Hospitalari Salut Mental – Germanes Hospitalaries Benito Menni – CASM, Psychiatry, Barcelona, Spain

Efforts have been made, in Europe, in order to clarify the different training programs in the psychiatric field in terms of examinations, clinical rotations, psychotherapy and research, as well as whether if there is a specific program for Child and Adolescent Psychiatry as a speciality itself. Furthermore, some European associations have gone one step forward and have taken different actions seeking the unification of the training system throughout Europe.

In this workshop, detailed information is going to be presented regarding the differences in the Child and Adolescent Psychiatry residency throughout Europe according to the data pro-

vided by the European Federation of Psychiatric Trainees Annual Survey.

In addition, information about different free courses, international fellowships, grants and awards offered by worldwide psychiatric associations are going to be exposed, disclosing specific information about the application procedure and providing some tips and suggestions directed to trainees in order to be selected.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0027

### Implementing early detection and intervention services for psychosis in Europe: Obstacles and how to overcome them

A. Riecher-Rössler

University of Basel Psychiatric Clinics, Center for Gender Research and Early Detection, Basel, Switzerland

**Introduction.**– There is now enough evidence for establishing early detection and intervention services for psychosis and for the assessment of the at-risk mental state, including “staging” and staged interventions. However, such services are not available yet for all patients in the European countries.

**Objectives.**– With my talk I want to stimulate discussion on the lack of such services as well as on the potential obstacles to implementation.

**Methods.**– Overview.

**Results.**– Apart from a lack of services, many European countries also have no specific guidelines for early detection and intervention. Obstacles to further promote early detection and intervention might include traditional and faith-based paradigms in psychiatry which do not appreciate the chances of early detection and intervention. Besides a lack of devotion towards prevention, further obstacles might be a lack of clear policies/implementation plans by stakeholders, a lack of clear coordination between services, and a lack of training and supervision for the staff in this area, etc. In order to establish new services, we also need to involve consumers, their families, and carers in planning such services and encourage them to get involved in policy making towards this goal. And we need outreach campaigns directed to the public, at-risk populations, and professionals with the aim of education and fighting stigma.

**Conclusions.**– All patients of the European countries should have easy access to low-threshold early detection and intervention services with specialized staff oriented towards to patients' needs. It is our duty as professionals to fight for overcoming the mentioned obstacles.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0028

### Implementation of early detection services: Current status and perspectives in southeastern Europe

N. Maric Bojovic<sup>1,\*</sup>, S. Andric-Petrovic<sup>2</sup>, M. Rojnic Kuzman<sup>3</sup>, A. Riecher-Rössler<sup>4</sup><sup>1</sup>Faculty of Medicine University of Belgrade, Clinic for Psychiatry CCS, Beograd, Serbia; <sup>2</sup>Clinic for Psychiatry CCS, Dpt. for Research and Early Interventions in Psychiatry, Belgrade, Serbia; <sup>3</sup>Zagreb School of Medicine, Zagreb University Hospital Centre, Zagreb, Croatia;<sup>4</sup>University of Basel Psychiatric Hospital, Center for Gender Research and Early Detection, Basel, Switzerland.

\* Corresponding author.

Unequal development of both early detection (ED) and early intervention (EI) programs/services for psychotic disorders and of related academic activities has been shown across Europe.

The present ongoing research aims to further fill in the knowledge gap regarding the ED/EI implementation in Central and Eastern European countries. The 17-item questionnaire addressing information about ED/EI in the relevant national educational resources, local policy towards the implementation of ED/EI in the national mental health system, diagnostic and therapeutic methods implemented by local ED/EI and obstacles in its implementation, was disseminated to the colleagues from 23 countries (The Eastern European, Central, Baltic and the Southeast European countries) who had been found through the PUBMED search including the terms: name of the country/region, “mental health”, “psychosis”, “early intervention”, “early detection”. For countries with no ED/EI programs, we asked about the most important factors limiting their implementation.

We hypothesized that the status of the specific education, the guidelines and specific instruments implementation, the service distribution and organization will range from availability in most of the EU member countries, to potential to scale up and even absence in several other countries. Lack of adequate education/information of the professionals has been hypothesized as one of the most prominent reasons for non-implementation.

The obtained results could be used as starting point to plan how to improve utility of the ED/EI services in this region, to accelerate its implementation and to facilitate timely detection and intervention of psychosis across Europe.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0029

### **Implementation of early detection services in France: Current status and further perspectives**

M.O. Krebs

*Centre Hospitalier Sainte-Anne – Univ Paris Descartes – Inserm, Service Hospitalo Universitaire, Paris, France*

*Objective.*– Schizophrenia and chronic psychosis is one of the most disabling disorders striking adolescent or young adults. Early intervention, by improving the general outcome, has already demonstrated its cost effectiveness. However, while early intervention services are now spread all over the world, until now France has not implemented nation-wide programs and the reasons of this delay need to be addressed.

*Methods.*– We have collected all available information regarding early detection – early intervention in France: publications or reports, participations to specialized education or training, organization of meeting, workshop or conferences on the topic. In addition, we also have conducted a survey in 300 general practitioners and a comparative survey in 300 youth (15–25 y.o.), 300 parents and 130 teachers.

*Results.*– Less than 10 centers have started to organize EI services attempting to follow the international recommendations, and even less ED, but none fully achieves a complete EI/ED service. Only 7 groups have published on the topic. There is however an emerging willingness of French practitioners: approximately 40 teams are actually interested and actively seeking training or education. Discussions with these teams raised several issues and underline the needs for French-adapted models and recommendations. Propositions have been made to resolve these issues. From the surveys, it is clear that young people are aware by mental health and if concerned they would seek help to their parents, friends, or GP but not

their teachers. GP are interested in improving early detection, but are poorly trained or educated in this field.

*Conclusion.*– France is now ready for a National plan for ED/EI and will benefit from international organizations. However, widespread dissemination in first-line services will not happen if French-speaking tool-kits are not accessible. A careful adaptation to the specificities of French organization of mental health services is also needed. The ‘Transition Network’ is currently launching a French taskforce to organize these tool-kits and propose some adaptations of ED/EI to our national MH organization, within the frame of the French-speaking branch of IEPA.

*Disclosure of interest.*– MOK received honoraria from and participated in advisory boards or did educational conference for F. Hoffmann-La Roche, Janssen Cilag and Otsuka Lundbeck.

W0030

### **Implementation of early detection services: Economic perspectives**

D. McDaid

*United Kingdom*

*Introduction.*– There is growing evidence on both the effectiveness and cost effectiveness of early intervention and detection services, yet services in Europe remain limited. A narrow focus on effectiveness ignores broader issues concerned with implementation that are vital to making services more widely available.

*Objectives.*– This presentation looks at the role of economic evidence and why it has only had a limited impact. It emphasises the importance of moving beyond narrow cost effectiveness measures.

*Methods.*– Narrative review of literature and illustrative use of return on investment decision modelling tool.

*Results.*– Economic approaches that can help facilitate implementation include identifying the return on investment from early intervention and detection services to different stakeholders, including impacts beyond the health system, conducting budgetary impact analyses and looking at the economic benefits and costs of achieving better levels of fidelity in implementation. There is a now an increased focus on considering local context, system organisational, financing and other factors that either act as barriers or facilitators to implementation.

*Conclusions.*– Powerful arguments can be made for investment in early intervention and detection services, but there is a need to move beyond narrow use of economic information. Impacts across and beyond all of the health system (and not just the mental health system) are relevant to implementation strategies. More emphasis also needs to be placed on better communication of the economic case in an appropriate way for different policy makers, practitioners and wider society.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Declaration of Geneva: Medical oath as an ethical guideline**

R.J. van der Gaag

*Radboud University Medical Centre, Nijmegen, The Netherlands, Department of Psychiatry, Arnhem, Netherlands Antilles*

Ever since the days of Hippocrates at graduation medical doctors pleaded an oath, promising solemnly to meet the (high) ethical standards of their “guild”. The medical oath has always been aimed at providing excellent care according to the professional standards, along with respect for life, the patient and his privacy. Some elements though are time bound: for example in old days young

medical doctors did not only express their respect to their mentors, but also did they promise to take care of them until the end of their days. A kind of pension provision for medical doctors. Such cultural aspects were not taken on board when the medical oath was formulated back in 1948 when the World Medical Association was founded in Geneva. In October 2017 after several years of discussions a revised “Declaration of Geneva” was adopted with the important subtitle “the physicians pledge” at the WMA general assembly in Chicago. It was published straight away in JAMA and will be read at the opening of all the future meetings of the WMA. In this presentation the different elements of the pledge will be presented with emphasis on what has been newly formulated: in particular the respect for the patient’s opinion, importance of well informing the patient and the willingness to aim at shared decision making. The other new element is that every medical doctor promises to take care of his/her own health for better care and as an example. All psychiatrists are medical doctors. . . but many seem sometimes to have forgotten.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Ethical challenges assessed in the clinical ethic committee of psychiatry in the region of Southern Denmark in the period 2010–2015: A qualitative content analysis**

H. Bruun

*University of Southern Denmark, Department of Regional Health Research – Psychiatry, Aabenraa, Denmark*

Ethical considerations are an important part of the daily decision-making process in mental health care. A Clinical Ethics Committee (CEC) of Psychiatry in the Region of Southern has since 2010 been offering a structured ethical analysis of ethical challenges experienced by health care professionals in mental health. When analyzed the CEC makes a written case-report of 5–8 pages. On the basis of a qualitative content analysis of 55 written case-reports from the CEC an overview of the ethical challenges described is given. Although complexity is a recurring theme, the ethical challenges can be grouped into three overarching themes: (1) Healthcare professionals and mental healthcare in a wider social context. (2) Healthcare professionals and institutional aspects of mental healthcare. (3) Healthcare professionals and their relation to patients and relatives. In respect of the complexity, illustrative case-reports of each overarching theme are presented. The findings indicate that difficult ethical challenges are an inherent part of mental healthcare that requires time, space and competence to be dealt with adequately.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0033

### **Apathy in pre dementia: Prevalence, neurobiology and treatment**

K. Lanctot

*Sunnybrook Research Institute, Hurvitz Brain Sciences Program, Toronto, Canada*

*Background.*– Apathy, characterized by diminished motivation, is found in cognitively normal elderly, as well as throughout the spectrum of prodromal dementia states including in those with mild behavioural impairment (MBI) and mild cognitive impairment (MCI). Importantly, the presence of apathy predicts increased risk

of conversion to dementia. This talk will review recent research on the prevalence and neurobiology of apathy and discuss possible treatments.

*Findings.*– The prevalence of apathy in MCI has ranged from 3% to 55% depending on the population and detection methods. Neuroimaging studies assessing structure, functional connectivity, blood flow and metabolism as well as amyloid burden and regional tau depositions reveal consistent differences in those with and without apathy. Findings implicate regions commonly associated with apathy (e.g., frontal involvement), as well as regions typically affected in early AD (e.g., parietal and inferior temporal involvement). Interventions being evaluated include neurostimulation and appear to target a variety of mechanisms. Improved understanding of the underlying neurobiology may have treatment implications.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0034

### **How audio, video and actigraphic sensors can be used for the apathy assessment**

A. König

*Institut Claude Pompidou, Centre de Mémoire de Ressources et de Recherche – Centre Hospitalier Universitaire – Cobtek Cognition – Behavior – Technology Research Lab – University Côte d’azur, Nice, France*

Automatic speech analysis for the assessment of apathy.

*Introduction.*– Apathy is one of the most frequent neuropsychiatric symptoms found in dementia. It has an important impact on quality of life of both patients and their caregivers and represents a strong predictor of progression of the illness. Current clinical assessment methods risk bias resulting from the assessor’s subjectivity, pointing to a need for additional objective and systematic assessment tools. Therefore, the use of information and communication technologies (ICT) such as automatic speech analysis could be of interest in addition to current assessment methods.

*Objectives.*– To investigate whether automatic analysis of linguistic and paralinguistic features extracted from audio recordings of patients’ answers to an open questions about personal interests could be useful for the assessment of apathy in elderly people.

*Methods.*– 150 older persons at different apathy severity stages were recorded while answering the question ‘What interests and motivates you?’. Every participant received the Apathy Diagnostic criteria and Apathy Inventory (AI). Speech signal processing techniques were applied to extract features which were compared to the baseline apathy assessment scores.

*Results.*– Preliminary results show that the feature ‘speech rate’ correlates significantly with the AI. More detailed results will be presented at the workshop.

*Conclusions.*– Our results demonstrate the additional value of vocal analytics for the assessment and monitoring of apathy in elderly people. This time saving automated tool can provide clinicians immediately with reliable data based on non-invasive, simple and low-cost methods.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0035

### How information and communication technologies can be used as therapeutic options for patients with apathy

V. Manera

*CoBTeK Laboratory, Medicine, Nice, France*

New Information and Communication Technologies (ICTs) are more and more employed in the domain of neurodegenerative disorders for patients' treatment and stimulation. In particular, Serious Games (SG, i.e., video-games designed to train specific cognitive and/or physical functions) and Virtual Reality (VR) are now considered as promising solutions to build motivating cognitive and physical trainings, as they embed playful and entertaining aspects. In the present talk we will briefly review the literature concerning the use of VR and SG in people with neurodegenerative disorders, and we will then present some studies conducted by the CoBTeK team employing VR and SG in older adults (apathetic vs. non-apathetic) with mild to moderate cognitive impairment due to neurodegenerative disorders. The results of these studies converge in demonstrating that VR and SG can be successfully employed to create motivating trainings, and that these solutions seem mostly adapted to apathetic patients.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0036

### Relationships between apathy and motor activity in actigraphic studies

R. David

*Institut Claude Pompidou, Nice University Hospital Memory Clinic, Nice, France*

Apathy is a multi-dimensional syndrome (lack of interest, lack of initiative, emotional blunting) that has been described as a decrease in goal-oriented behaviours. It has therefore been hypothesized that apathy could be associated with a decrease in levels of daily locomotor activity associated to goal-oriented behaviours.

The use of actimetry, a wearable device comprising an accelerometer that records variations in individual's movements, has been proposed as an indirect but objective method to assess apathy in daily routine. In Alzheimer's disease, individuals with apathy had reduced actimetric levels of motor activity compared to non apathetic individuals, in different conditions: over a short 1-hour period during a medical consultation, over seven consecutive 24-hour period in ecological conditions with community-dwelling individuals. Additionally, the daytime patterns of motor activity differed between non apathetic individuals, individuals diagnosed with depression and individuals with apathy.

Levels of motor activity were also found to be reduced among individuals with Mild Cognitive Impairment.

The use of actimetry has to be considered as an objective method in addition to the clinical judgement for the diagnosis of apathy, but also to monitor the evolution of apathy and the response the treatments.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0037

### Diagnostic criteria for apathy revisited

P. Robert

*CoBTeK lab, University Cote d'Azur, Nice, France*

Apathy is an important and distressing behavioral syndrome in various neuropsychiatric disorders including Alzheimer's disease and related disorders. Apathy is defined as a persistent deficit of motivation reported by the subject himself or by his entourage, affecting behavioral (decreased goal-directed behavior), cognitive and emotional dimensions. During the 2008 EPA meeting a task force developed Diagnostic criteria for apathy, which are now used in various disease conditions and in clinical practice. Concerning the quantitative assessment until today, apathy is scored with the help of clinical rating scales such as the NPI (Neuropsychiatric Inventory), the AES (Apathy Evaluation scale), the LARS (Lille apathy rating scale) or the AI (Apathy Inventory). However, these tools allow only a punctual and not continuous assessment and risk biases resulting from the assessor's subjectivity, pointing to a need for additional systematic assessment tools. The aim of this presentation is to present an update of the diagnostic criteria for apathy and results of the validation study of an application using serious game designed to assess quantitatively apathy in an implicit, more objective and dynamic way

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0038

### Diagnosing autism in adults

B. Perera

*Barnet-Enfield and Haringey Mental Health Trust, Haringey LD Partnership, London, United Kingdom*

Autism is a neurodevelopmental disorder which is manifested as persistent deficits in social communication and social interactions and restricted, repetitive patterns of behaviour, interests, or activities (DSMV). Prevalence rate is reported to be around 1.1%.

Early diagnosis of autism is important to understand and provide necessary support to individuals and family. However it is often delayed due to multiple reasons. A delay in diagnosis is considered as a missed opportunity to provide necessary support during the critical developmental period. Mean age of diagnosis of Autism has decreased over time. Diagnosis of autism includes a detailed neurodevelopmental history with focus on core symptoms of autism. Availability of diagnostic services varies significantly from one area to another. Post diagnostic support is often important for families to understand and support the individual with autism, however parents often report that post-diagnostic support is unsatisfactory. Comorbid mental disorders and other neurodevelopmental disorders (NDD) such as ADHD and Intellectual disability are often seen in among people with autism. Therefore identification of autism along with other NDD and comorbid mental disorders is important to provide the right support and interventions to improve quality of life of individuals with Autism.

*Disclosure of interest.*– I have received speakers fees from Janssen-Cilag and Flynn pharma.

### Co-morbid mental disorders in autism

H. Ramsay

*St Michael's House & Royal College of Surgeons in Ireland, Psychiatry, Dublin, Ireland*

*Introduction.*– Adults with autism are a heterogeneous group in terms of their level of intellectual ability and their mental health

needs. Reported prevalence of mental disorders in autism varies by study methodology but is likely to be higher than for the general population. Adults with autism have particularly increased rates of specific disorders.

**Objectives.**– This workshop considers evidence on prevalence of co-morbid mental disorders in adults with autism, with a particular focus on co-morbid mental disorders in adults with intellectual disabilities (ID) and autism, using the diagnostic classification system for learning disabilities (DC-LD).

**Methods.**– The literature on co-morbid mental disorders in autism was reviewed. Following this, using a representative sample of adults with ID, the association between autism and DC-LD diagnoses, medication treatments and other clinical features were measured using univariate (Chi-squared test) and multivariate (logistic regression) methods as appropriate.

**Results.**– There are significant differences in the rates of specific mental disorders across DC-LD axes between adults with ID and autism vs. those with ID without autism but attending a psychiatrist. For example, in the sample with ID, there were significant differences in the rates of problem behaviours ( $P < 0.001$ ). There were also differences in treatments used, with notably higher rates of atypical antipsychotic use in those with autism ( $P = 0.001$ ).

**Conclusions.**– There important similarities and differences in terms of both diagnostic co-morbidity and treatment for those with autism and ID attending a psychiatrist vs. those with ID without autism attending a psychiatrist.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0040

### **Behavioural problems in people with intellectual disability and autism**

S. Elstner

*Pfeiffersche Stiftungen, MZEB, Magdeburg, Germany*

People with intellectual disability often present with challenging behaviour. Prevalence rate for challenging behaviour varies from 6 to 40% depending on different settings where research was carried out. Challenging behaviour involves aggression towards others, harm to themselves and destruction of property. Causes of challenging behaviour are complex and multifactorial. Complexity of challenging behaviour causes assessment and management difficulties to health care professionals leading to long stay hospital admissions and unlicensed use of pharmacological treatments. Presence of autism further makes the assessment and management more difficult.

This workshop discusses how the presence of autism increased challenging behaviour and suggest various pathways to assess and manage people with ID, challenging behaviour and autism. It will also address various factors that need to be considered when assessing and managing people with ID, autism and challenging behaviour.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0041

### **Autism in adulthood**

K. Krysta

*Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland*

Autism Spectrum Disorders (ASD) are neurodevelopmental disorders biologically conditioned, and they are usually diagnosed in pre-school or early childhood. Untreated autism in adults often

makes it difficult or even impossible for the patients to live independently. Autistic people cannot express emotions adequately, cannot think abstractly, have high levels of tension and low level of interpersonal skills. They can react with panic and aggression. Unawareness of the disease makes adults with autism have many problems in social, family and professional life. They are discriminated, excluded, unclassified, regarded as arrogant, bizarre. To ensure a minimum of safety they avoid social contacts, prefer loneliness, run away. Other psychological problems may develop in the context of autism, such as depression, mood disorders, oversensitivity. The rehabilitation forms, which may improve their functioning, should reduce anxiety, improve physical and mental health, increase concentration, and engage them in social life, which may lead to, e.g., finding a job, starting to live in protected housing or group homes where patients can count on permanent caregivers.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0042

### **Sensory sensitivities in people with autism**

K. Courtenay

*UCL, Division of Psychiatry, London, United Kingdom*

Sensory difficulties have been understood by people with autism and their carers as important aspects of disorders. They are now recognized in classification systems as features of autism. Diagnosis of autism requires attention to the impact of sensory difficulties on the person.

In general, people with autism can perceive sensory stimuli that differ from people with such sensory deficits as deafness or blindness. The difficulty is in the processing of sensory information manifesting as Sensory Processing Disorder. The modulation of sensation in Autism is abnormal and described in three domains as registration, defensiveness, and gravitational insecurity. Examples include avoiding bright lights or loud sounds (defensiveness). Hypersensitivities are evident too for example, clothing pulled across the skin.

For people with autism, sensitivity in all sense modalities can cause great discomfort that can go unrecognized especially where the person has difficulty in communicating their distress. Excessive stimulation in one sense can lead to behavioural reactions that can be misinterpreted as anxiety or other mental diagnosis. Recognition of sensory sensitivity by a person with Autism can help them alleviate stress.

In the presentation, sensory sensitivities in Autism are described, with an explanation of their aetiology, and an exploration of measures to effectively manage their impact on people's lives.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0043

### **Autism and intellectual disabilities**

M. Rossi\*, M.O. Bertelli

*Fondazione San Sebastiano, Misericordia di Firenze, Firenze, Italy*

\* Corresponding author.

**Aims.**– Some studies report that up to 70% of persons with Intellectual Disability (ID) may present also pervasive autistic traits, as well as up to 70% of those with Autism Spectrum Disorder (ASD) show early cognitive impairment that falls into the area of ID or borderline intellectual functioning. Further complexities arise in the context of co-occurrence Schizophrenia Spectrum Disorders (SSD).

The purpose of this part of the workshop is to systematically define the boundaries and overlapping clinical characteristics of IDD, ASD and SSD; to highlight the most relevant differences in clinical presentation of ASD and SSD in persons with ID; and to improve sensitivity and validity in diagnosing ASD in ID.

*Methods.*– Authors imprint and bring forward an immediate functioning dimension to the participant's eye and hands by implementing and practicing the concepts and techniques identified through a systematic mapping of the last 15 years international literature and results of an original clinical study.

*Results and conclusions.*– The combination of IDD and ASD presents many challenges and deficits across a range of behaviours and skills that are not seen in IDD or ASD alone. Severe IQ has been found related to higher severity of ASD and higher rates of challenging behaviours. Higher rates of stereotypes tend to be related to severity of autism but not to severity of IDD. For the distinction between ASD and SSD, age of onset, interest towards others, hallucinations, flattened mood (and behavioural equivalents), irritability, neuroanatomical anomalies, scores at block design, digit span, and digit symbol were found to be the most useful dimensions.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Person-centered dialectical models of mental disorders: The case of schizophrenia**

G. Stanghellini

*University "G. d'Annunzio" – Chieti Italy and University "D. Portales" – Santiago Chile, Department of Psychological – Humanistic and Territorial Sciences, Chieti, Italy*

This paper builds on the self-disorder hypothesis of schizophrenia and further develops it by integrating the notion of 'selfhood' with that of 'personhood'. An important advance in the recent history of schizophrenia research has been the re-conceptualization of this illness as associated with disorders affecting the structure and the functioning of the minimal self. The self-disorder hypothesis conceives schizophrenia as a basic disturbance of the sense of self. The notion 'selfhood' serves to investigate the prereflective structures and dynamics of experience.

What may remain out of focus is the person's attitude towards these anomalous experiences. The notion 'personhood' serves to investigate the reflective, self-interpreting, stance to experience. The patient's attitude to his or her illness plays a significant role in mental illness. This approach is conducive to the development of a person-centred dialectical (PCD) model of schizophrenia that is concerned not only with the phenomenological description of troubled selfhood but also with how persons with schizophrenia interact and cope with their abnormal experiences. The principal clinical implication is the development of a two-tier descriptive system including phenomenal assessment of disordered selfhood and appraisal of personal background. The recognition of the patient's resources is necessary for effective treatment, as recovery requires not only the reduction of full-blown symptoms but also a change in the patient's attitude with respect to her basic abnormal phenomena. The latter involves the person's own effort to make sense of and cope with her vulnerability [1,2].

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **What is like to be in an at risk mental state for psychosis**

A. Raballo

*Norwegian University of Science and Technology, Department of Psychology, Trondheim, Norway*

At risk mental states designate a variable set of clinical presentations carrying a heightened risk for developing more severe psychopathology, particularly within the psychotic spectrum. Such states, formerly considered as prodromes, are currently conceptualised as prospective and probabilistic signatures of imminent risk of psychosis. They are typically accompanied by profound and characteristic modifications of subjective experience which are essential for the understanding the emergence of psychosis.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0046

### **Activities and initiatives of EPA**

L. Küey

*Istanbul Bilgi University, Department of Psychology, ISTANBUL, Turkey*

Mental health problems that forcibly displaced people (refugees and asylum seekers) experience due to wars, armed conflicts, persecution and human rights violations, and related poverty and trauma currently constitute a serious public mental health problem in Europe. There is increasing evidence that a large proportion of refugees and asylum seekers residing in Europe suffer from the consequences of traumatic events and exhibit psychological problems and mental disorders including, but not limited to, Post-Traumatic Stress Disorder.

The European Psychiatric Association (EPA) considers as one of its major tasks to raise awareness on this important problem and outline strategies for how its member societies and the psychiatric profession at large may contribute to managing these challenges. In line with its policy, EPA has set a special task force, namely "EPA Task Force on Needs of Refugee and Asylum Seeker Patients in Europe" to focus more closely on the mental health consequences of forced displacement. This presentation will give a brief summary of its already fulfilled activities and planned actions aiming to increase professional cooperation and international collaboration regarding the issue of mental health of forcibly displaced people on a European level.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0047

### **Activities and initiatives of WPA**

H. Herrman

*Orygen – The National Centre of Excellence in Youth Mental Health, Centre for Youth Mental Health, Parkville, Australia*

In responding to the needs of people living under extreme stress including forced displacement the WPA's Action Plan 2017–2020 calls attention to the needs and strengths of children and young people. It includes attention to mental health promotion as well as prevention and treatment of mental illness. Three types of actions are anticipated. The first is support for sharing of best practice. The second is building capacity for the profession to work effectively in specific settings of disadvantage. The third is encouraging psychiatrists and other health professionals to use their expertise in facilitating the mental health work of non-specialists across a range of community settings.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0048

### **Evidence on mental health care for forcibly displaced migrants: A review in collaboration with WHO Europe**

D. Giacco

*Queen Mary University of London, Unit for Social and Community Psychiatry, London, United Kingdom*

*Introduction.*– The number of refugees migrating to Europe because of violation to their human rights, persecution and war is increasing. There is a need to identify mental health needs of these groups and models to provide effective care to them.

*Objectives.*– Summarising evidence on prevalence rates of mental disorders in refugees and good practice models for their care.

*Methods.*– A synthesis of the available evidence in scholarly and grey literature on mental disorders and interventions for refugee groups in European countries.

*Results.*– The prevalence rates of mental disorders amongst refugees are variable across studies, due to the characteristics of the studied groups, the context in the host country and methodological inconsistencies.

In general, the rates of psychotic, mood and substance use disorders in these groups appear similar to those found in host countries, whilst post-traumatic stress disorder is clearly more prevalent in refugees than in host populations.

Good practices include: (a) social integration through education, housing and employment; (b) outreach services to facilitate access to care; (c) appropriate coordination of physical health, mental health and social services; (d) provision of information on care entitlements and services; (e) the training of professionals in cultural competence and working with interpreters.

*Conclusions.*– Implementing good practice for mental health care of refugees may require: (a) resources for outreach services, the provision of information to patients, the training of professionals, interpreting programmes and social integration initiatives; (b) coordination and organisational flexibility to integrate health and social services, and to facilitate appropriate referrals and care pathways.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Women’s mental health in the UK: Yesterday, today and tomorrow**

J. Burns

*Canterbury Christ Church University, School of Psychology – Politics and Sociology, Canterbury, United Kingdom*

This paper will plot the progress of women’s mental health in the UK over three generations; looking back one generation, reviewing our current generation and finally considering the next generation of young women. The position of women and the impact on their mental health status will be considered against the backdrops of their changing economic, political and professional standing. I will be presenting the case that ‘time and place’ cannot be ignored when defining women’s mental health issues and hence, must be considered for both treatment and prevention. In conclusion, I shall be considering what may be the challenges ahead in the UK which must be overcome for young women to thrive.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Women’s mental health: Insights from WMH section of the Russian Society of Psychiatrists**

N. Semenova<sup>1,\*</sup>, N. Neznanov<sup>2</sup>, E. Makushkin<sup>3</sup>, B. Kazakovtsev<sup>4</sup>, A. Vasileva<sup>5</sup>

<sup>1</sup>*Moscow Research Institute of Psychiatry MoH RF, Outpatient Psychiatry, Moscow, Russia;* <sup>2</sup>*St.Petersburg V.M. Bekhterev Psychoneurological Research Institute, Administration, St.Petersburg, Russia;* <sup>3</sup>*The Serbsky Federal Research Center for Psychiatry and Narcology, Administration, Moscow, Russia;* <sup>4</sup>*The Serbsky Federal Research Center for Psychiatry and Narcology, Epidemiology, Moscow, Russia;* <sup>5</sup>*St.Petersburg V.M. Bekhterev Psychoneurological Research Institute, International Division, St.Petersburg, Russia.*

\* Corresponding author.

*Purpose.*– To highlight a range of topics – which provide a coherent integrated coverage of the activity of new-born Women’s Mental Health (WMH) Section of Russian Society of Psychiatrists. Key topics include: “Science,” “Clinical activity,” “Education,” and “Social and educational public activities”.

*Results.*– A section on WMH was created in 2015. The section objectives are outlined. Activities in this area started from creation of multidisciplinary national contact network for specialists. The data collection on Russian-held studies started. The respective symposia were arranged in the national and international conferences. The issues of women’s mental health are actively elaborated by Russian specialists in topics overlapping with those stressed by EPA and WPA: women’s mental health and medical issues, women’s mental health and psychiatric treatments in pregnancy, gender and psychosis, post-traumatic stress disorders in women, violence against women, women’s mental health in conflict zones, women’s leadership, etc. The prominent role of female scientists in foundation and development of Russian psychiatry and clinical psychology are emphasized.

*Conclusions.*– The Section seeks to promote and increase knowledge of women’s perspectives in mental health, as well as fosters communication and interaction among the scientific disciplines that comprise its membership. We are all aware that some of the topics to be presented are not new but the data certainly are, and different professionals have different perspective. Much can be expected from the field of awareness of gender consideration in women’s health in Russia, and an example of such an approach is provided. We are very lucky to have great experts interested in participating and we hope this will make our Section more visible and heard.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Women’s mental health in Turkey: Challenges and insights from the WMH section of Psychiatric Association of Turkey**

E. Sönmez

*Caycuma State Hospital, Psychiatry, Zonguldak, Turkey*

Ranked 131st out of 142 countries listed in World Economic Forum’s 2017 Report, Turkey is one of the countries with largest global gender gap and has experienced worsening of gender parity especially in political empowerment and health and survival aspects [1]. Inequalities in various aspects of life, including education and employment, high rates of intimate partner violence, women murder cases, forced early marriages, and more recently the impact of war, forced displacement and informality in the region have all been interrelated causes of mental health prob-

lems for women. The transformation into a more conservative society and predominant conceptualization of women as a dependent member of family by the community evokes feelings of guilt, incompetence and poor self-efficacy. The outcome of these in daily practice is higher numbers of cases of depression, anxiety, trauma-related disorders and suicide.

Gender imbalance also exists among psychiatry professionals. Based on a retrospective analysis of publications from Turkey in international psychiatric scientific journals, the rate of female first and last authors is less than 40% [2]. Only one third of psychiatrists in university hospitals and less than half of those in state hospitals are women.

On the other hand, women are more aware of their psychiatric symptoms and applications to psychiatric care are increasing, together with greater availability of services and efforts for establishing a framework under mental health law in the last few years. Also, formation of multidisciplinary task forces on violence against women and promising work of psychiatrists under Women's Mental Health Working Group of Psychiatric Association of Turkey serve as a base for progressive educational activities and research in the field.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Cognitive, neuroimaging and pharmacological studies of schizotypy: An overview and introduction**

U. Ettinger

*University of Bonn, Department of Psychology, Bonn, Germany*

*Background.*– The phenomenology of schizotypy suggests that this constellation of traits represents a subclinical expression of schizophrenia. Experimental neuropsychological and brain imaging studies are crucial to further bolster this claim. In this talk, I will present new results on cognitive, neuroimaging and pharmacological studies of schizotypy that aim to identify both similarities and dissimilarities between schizotypy and schizophrenia. Genetic risk populations are additionally considered to further demarcate the boundaries between these different schizophrenia spectrum populations.

*Method.*– Higher-level as well as basic cognitive and motor functions are studied in the laboratory in relation to schizotypy, using both extreme groups and continuous sampling methods in healthy volunteers. Schizophrenia patients and clinically unaffected first-degree relatives of patients are studied for comparison.

*Results.*– A replicable impairment in response inhibition is observed in high schizotypy. This impairment and its neural correlates overlaps in part with the deficits seen in schizophrenia. The profile of impairment diverges, however, from that seen in relatives, who are mostly characterised by difficulties in complex sensorimotor transformations on oculomotor tasks. Evidence from pharmacological challenge studies points to selective tolerance of antipsychotic compounds in high, but not low, schizotypal individuals.

*Conclusions.*– The results from these recent studies support the conclusion that schizotypal traits in the general population represent a phenotype that bears resemblance with schizophrenia not only at the level of phenomenology, but also at the levels of brain func-

tion, cognition and neurotransmitter system function. On the basis of this evidence, however, schizotypy can be differentiated from genetic risk status.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0053

### **Psychosocial risk factors, gene–environment interactions, and the role of schizotypy in the psychosis spectrum**

N. Barrantes-Vidal<sup>1,\*</sup>, T.R. Kwapiil<sup>2</sup>

<sup>1</sup>*Universitat Autònoma de Barcelona, Departament de Psicologia Clínica i de la Salut, Barcelona, Spain;* <sup>2</sup>*University of Illinois at Urbana-Champaign, Department of Psychology, Champaign – Illinois, USA.*

\* Corresponding author.

The construct of schizotypy was developed both within the personality and medical traditions. The former proposes schizotypy as part of normal personality, being a source of both healthy variation and predisposition to psychosis, whereas the latter conceptualizes it as the inherited vulnerability to schizophrenia spectrum disorders. Current research seems to be progressively integrating both traditions, as schizotypy is progressively being understood and employed as an index of individual differences both within health and clinical high-risk status as well as a risk marker for psychopathology. The interaction of this vulnerability substrate with other genetic and environmental factors shapes the risk of presenting spectrum disorders and yields a wide range of phenotypic variance. Assessment of schizotypy provides an entry point for identifying individuals possessing liability to psychosis prior to the appearance of clinical manifestations. This should facilitate the study of developmental pathways to psychosis and the identification of protective factors in individuals not presenting with typical confounding factors associated with schizophrenia spectrum disorders. Novel research will be presented that confirms the usefulness of this trait for studying the role of psychosocial risk factors and gene-environment interactions across the broad spectrum of individual differences to subclinical and clinical psychosis manifestations.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

W0054

### **Emotional processing and schizotypy: Multimodal findings in support of the neurobiological continuum hypothesis**

G. Modinos

*Institute of Psychiatry – Psychology & Neuroscience – King's College London, Departments of Psychosis Studies and Neuroimaging, London, United Kingdom.*

*Background.*– The continuum hypothesis proposes a dimensional continuity in the underlying neurobiology of subclinical psychotic-like experiences in healthy individuals (or *schizotypy*) and psychotic symptoms in patients with psychosis. Preclinical models posit that excitation-inhibition imbalances within a cortico-limbic-striatal circuit may give rise to schizophrenia-like physiological and behavioral aberrations, such as hyperemotionality, limbic-striatal overdrive, and decreased gray matter volume. Based on preclinical as well as on imaging research in patient groups, this workshop will summarize our recent studies investigating whether brain gluta-

mate levels in healthy individuals with high positive schizotypy are related to changes in (1) cortico-limbic-striatal response to emotion and (2) gray matter volume (GMV).

**Methods.**– Forty-eight healthy participants were recruited based on their score on the O-LIFE questionnaire and divided into two groups: high schizotypy and low schizotypy, matched by age, gender and IQ. A structural MRI scan, glutamate proton magnetic resonance spectroscopy in the anterior cingulate cortex (ACC), and functional magnetic resonance imaging (fMRI) during emotional processing were acquired at 3 T in a single session. Standalone imaging results as well as fMRI/sMRI × glutamate interactions in corticolimbic regions of interest were analysed with SPM12 and considered significant after voxel-wise  $P < 0.05$  family-wise error correction.

**Results.**– We found that participants with HS showed greater activation than LS subjects in the striatum and marginally in the ACC, hippocampus, medial prefrontal cortex (MPFC) and putamen. Moreover, subjects with HS showed GMV increases in the precuneus and ACC. Although no between-group differences were observed in glutamate concentrations, within the HS group ACC glutamate was inversely correlated with activation in the striatum and marginally in MPFC and amygdala. Moreover, in HS subjects ACC glutamate levels were negatively correlated with local GMV. Such correlations were absent in LS.

**Discussion.**– These findings are in line with a dimensional view of psychosis by suggesting that interactions between corticolimbic circuit structure, neurochemistry, and emotional response are involved in the expression of psychotic-like experiences at non-clinical and clinical levels. These findings may also serve as evidence of potentially protective mechanisms as they are based on high-functioning individuals with high schizotypy.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0055

### How can we improve adherence to treatment in psychotic disorders?

I. Bitter

Semmelweis University, Psychiatry and Psychotherapy, Budapest, Hungary

Data strongly support the beneficial effects of continuous antipsychotic treatment as part of a complex treatment program already after the first episode/hospitalization for schizophrenia (e.g. [1]). There are discussions about the benefits of such treatment, especially about how to interpret psychotic symptoms during treatment discontinuation, however the severe consequences of no antipsychotic treatment in schizophrenia and the benefits of treatment with adequately selected low-medium doses of antipsychotics have been well documented (e.g. [2–4]). The rate of adherence to antipsychotic medication reported during the course of “treatment as usual” is ca. 50%. The call of Andressen is based on evidence based data, that it is important to do as much as possible to ensure treatment adherence as a way of preventing relapse since the time of illness onset [5].

A complex treatment program with well-planned and integrated acute treatment, relapse prevention, and rehabilitation is needed for the improvement of treatment efficacy and adherence to treatment. The program should include psychoeducation.

The Section of Psychopharmacology of the European Psychiatric Association highlighted the need for improvement in teaching psychiatric pharmacotherapy to students, residents, psychiatrists and other professionals [6] and its work on some teaching materials is in progress.

Available data show, that the adherence of health care workers to various guidelines is generally low. Psychiatric and psychopharmacology associations should help (e.g. through their journals, congresses, courses) to improve the knowledge of those, who provide treatment for patients with schizophrenia and other psychotic disorders.

**Disclosure of interest.**– Grants and personal fees from Eli Lilly, and personal fees from EGIS, Janssen/Janssen-Cilag, Lundbeck, Medavante, Gedeon Richter, Pierre Fabré and Servier, outside of this work.

### How can we improve adherence to treatment in bipolar disorders?

A. Erfurth

Otto-Wagner-Spital, 6th Psychiatric Department, Vienna, Austria

Adherence to treatment in bipolar patients is linked to the general dimensions of adherence identified by the WHO:

1. Condition related
2. Therapy related
3. Related to social and economic factors
4. Patient related
5. Related to health system

ad 1. Disorders of the bipolar spectrum are frequent, diagnostic conversion from depression to bipolar disorder is high. Diagnosis of bipolar disorder (as compared to unipolar depression) is particularly difficult. Comorbidities with other psychiatric and medical conditions are frequent. Creating adherence is difficult when the diagnostic process is so particularly complex.

ad 2. Polypharmacy is a common phenomenon in psychiatric treatment, most bipolar patients have complex medication regimens when released from hospital. Polypharmacy undoubtedly reduces adherence rates.

ad 3. Decrease of quality of life, as well as social and economic deprivation obviously affect adherence. In a vicious circle, lack of adherence by itself worsens the brain morphological and functional changes associated with bipolar disorder.

ad 4. Particular lack of adherence has been demonstrated in adolescents, in late-life bipolar disorder, in patients with depressive residual symptoms and in bipolar patients with cyclothymic temperament. Bipolar patients exhibit characteristic cognitive deficits that distinctly influence their capacity to adherence.

ad 5. While psychoeducation can improve medication adherence, the availability of such interventions is still limited.

In summary, a holistic approach to adherence in bipolar disorder should be implemented. Local consensus initiatives to increase adherence are as necessary as global projects.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

W0057

### How can we improve adherence to treatment in anxiety disorders?

S. Pallanti\*, L. Salerno

*Istituto di Neuroscienze, Firenze 50121, Italy*

\* Corresponding author.

Treatment adherence represents a challenge not only for patients but also for the health profession for many decades.

Adherence as defined by WHO [1] is considered as “The extent to which a person’s behavior—taking medication, following a diet, and/or executing lifestyle changes—corresponds with agreed recommendations from a health care provider”.

WHO classifies these factors into 5 categories:

- socioeconomic factors,
- factors associated with the health care team and system in place,
- disease-related factors,
- therapy-related factors,
- patient-related factors.

Anxiety costs correlated has been estimated in European Union [2] and, excluding PTSD and other Stress related Disorders in 2010 the amount were of 1076 euros per subject in the EU, and in Italy about 1013 euros, for a total of 65,995 millions of euros as total costs (in Italy 8244 millions of euros). Of these more than 60% are direct healthcare costs while large amount is due to other costs.

The last 5 years has witnessed significant attention toward adherence to treatment and to medical guidance with cognitive behavioural therapy (CBT) including homework for anxiety and adherence assessment methods have diversified. Other form of Adherence improvement programme involve use of teleducation, educative fictions specifically appointed, anti-fake news educational mass systematic program. While a large component of the adherence process is not assessed in CBT, with patient effort, engagement, and the known role for treatment appraisals and beliefs necessitating the pursuit of improved adherence assessment methods.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### How can we improve adherence to treatment in depression?

M. Tournier

*Université de Bordeaux, Inserm U1219Team of pharmacoepidemiology, BORDEAUX, France*

While antidepressants play an important role in depression treatment, non-adherence to antidepressant is estimated around 40–60% of patients. Treatment adherence presumes patient’s agreement with the recommendations of the therapist and should be defined as a dynamic process, leading to a collaborative relationship.

It is a multifactorial phenomenon, related to type of drugs and dose, relationships with provider, patient and his/her disorders, health system. Some of the most established factors are the attitudes and beliefs of patients and their family about health, depression and antidepressant. In the acute phases, changes in beliefs about antidepressants occur: perceptions become more pro-adherence with treatment experience. In the maintenance phase, the different degrees of adherence are explained by the balance between the perceptions of need and of potential harm.

All these factors are modifiable. Some interventions were implemented in order to improve adherence to antidepressant: shared decision making, educational interventions, behavioural interventions, cognitive and behavioural therapy. The most effective were multifaceted interventions that used all these strategies and increased the intensity and the frequency of visits.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

26th European Congress of Psychiatry

EFPT/ECPC-EPA Symposium

### EFPT/ECPC-EPA Symposium: European Psychiatric Trainees' Research Projects: Key Findings

EFPT0001

#### How is EFPT bridging the gap between clinical practice and research among psychiatry trainees

I. Frankova

Bogomolets National Medical University, Psychosomatic medicine and psychotherapy, Kyiv, Ukraine

With a low proportion of medical graduates choosing psychiatry as a specialty and ongoing stigmatization from within the medical profession, recruitment into psychiatric training remains an issue in many European countries. This is partially caused by a great subjective and economic burden caused by mental disorders and the low public interest in their implications.

European Federation of Psychiatric Trainees (EFPT) is an umbrella organization which is represented by a national trainee association in each European country and aims to develop collaboration between psychiatric trainees. EFPT promotes high quality psychiatric training. Since actual training conditions in different European countries vary widely, the quality of training in some cases is limited due to scarce and inequitably distributed resources.

Research is a fundamental part of every medical discipline, and psychiatry is no exception. But in reality, it is quite hard to get funding for research to a young psychiatrist or psychiatry trainee. An exception is the EFPT Porto Research Award. It is a 10-year annual prize distinguishing each year one European psychiatric trainee that conducted a research project of a high standard. One of the main goals of the EFPT Porto Research Award is to encourage individuals in the early stages of their careers to perform research activities.

This presentation will describe how EFPT is bridging the gap between clinical practice and research among psychiatry trainees on the example of the first edition of EFPT Porto Research Award project: SSRI's vs BNZ in "Golden hours".

#### E-psychiatry in France

A. Fontaine<sup>1,\*</sup>, B. Barbotin<sup>2</sup>, R. Mircea<sup>3</sup>, R. Sayous<sup>4</sup>, G. Radu<sup>5</sup>  
<sup>1</sup> Univ Lille – CHU Lille, Department of Psychiatry, Lille, France; <sup>2</sup> Assistance Publique des Hôpitaux de Paris, psychiatry, Paris, France; <sup>3</sup> Grenoble University Hospital, Psychiatry, Grenoble, France; <sup>4</sup> Lyon University Hospital, Psychiatry, Lyon, France; <sup>5</sup> Memorial University of Newfoundland, Department of Psychiatry/Saint-Clare's Mercy Hospital, St John's, Canada

\* Corresponding author.

*Introduction.*— The last century has witnessed numerous dramatic changes in mental health care. Diverse significant technology breakthroughs have created new possibilities of information access, human interactions, and provision of care. By the virtue of their youth, residents are often said to be more adaptive to new technologies. However, in such a permanently remodelling system, the French psychiatry residents association (AFFEP) wanted to evaluate the position of French residents regarding e-psychiatry.

*Method.*— We conducted an online survey, sent via email to every member of AFFEP. A total of 646 responses were collected from June to November 2015, which represents a response rate of 50.4%.

*Results.*— Residents are well connected on the personal side, but not that much on the professional side: 20% do not have access to an electronic tool on their workplace.

Regarding training, residents rely on technology (57%) and books (33%). Yet, most of them had never heard of MOOC before the study. It is also interesting to note that the residents who benefit from videoconferences do not want it as a way of training.

As for clinical practice, residents are very much in favour of the use of e-health technologies but the majority have never used them (91%) so far.

Finally, data security and burnout have been raised through this study, with 65% of residents accessing data at home outside of working hours.

*Conclusion.*— E-psychiatry is bringing fabulous changes to our daily practice. However, we need to train future psychiatrists to lead this society's profound changes.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

26th European Congress of Psychiatry

## Joint symposium

### Joint symposium with hosting NPA: Social exclusion is harmful for mental health

JS0001

#### Perception and reactions to social cues

J. Grèzes

Lab of Cognitive Neurosciences, Inserm U960, DEC, École Normale Supérieure, Paris, France

Evolutionary theoretical accounts suggest that emotional displays serve a communicative function, implying (1) that emotional signals have co-evolved with recipient's decoding skills and behavioral responses, (2) that the recipient's behavioral response should reflect the social function of the perceived expression, and (3) the perceived possibilities for action offered by emotional displays are contingent on recipient's states and capabilities. We experimentally address these assumptions and reveal (1) that the neural sensitivity to threat-signaling emotions is enhanced in both ventral face-selective cortices and in action preparation motor cortices 200 ms following face presentation (El Zein et al., 2015); (2) that there is a selective impact of threat-signaling emotions on the recipient's action and attention decisions: anger elicits avoidance behaviors while fear prompts affiliative approach tendencies (Vilarem et al. under review), and finally (3) that the processing of threat-signaling emotions is influenced by recipient's traits (anxiety, behavioral inhibition and activation scales). Altogether, these results indicate that emotional displays promote the elaboration of adapted perceptual and action-related decisions.

*Disclosure of interest.* – The author declares that he has no competing interest.

JS0002

#### Loneliness in young adulthood: Findings from an epidemiological cohort study

T. Matthews<sup>1</sup>, A. Danese<sup>1</sup>, A. Caspi<sup>2</sup>, H.L. Fisher<sup>1</sup>, S. Goldman-Mellor<sup>3</sup>, A. Keba<sup>1</sup>, T.E. Moffitt<sup>2</sup>, C.L. Odgers<sup>4</sup>, L. Arseneault<sup>1</sup>

<sup>1</sup> King's College London, Institute of Psychiatry- Psychology and Neuroscience, London, United Kingdom;

<sup>2</sup> Duke University, Department of Psychology and Neuroscience, Durham- NC, USA;

<sup>3</sup> UC Merced, Department of Public Health- School of Social Sciences- Humanities and Arts, Merced- CA, USA;

<sup>4</sup> UC Irvine, Department of Psychology and Social Behavior, Irvine- CA, USA

*Background.* – Loneliness is an established risk factor for ill health and early mortality. Although extensively studied from a gerontological perspective, loneliness is particularly common among young adults as well as the elderly. The aim of this study was to build a detailed, integrative profile of young adults' experience of loneliness, in terms of their current health and functioning and their childhood experiences and circumstances.

*Sample and method.* – Data were drawn from the Environmental Risk Longitudinal Twin Study, a birth cohort of 2232 individuals born in England and Wales in 1994 and 1995. Loneliness was measured using a short form of the UCLA Loneliness Scale when participants were aged 18. Regression analyses were used to test concurrent associations between loneliness and health and functioning in young adulthood. Longitudinal analyses were conducted to examine childhood factors associated with young adult loneliness.

*Results.* – Loneliness was concurrently associated with poor functioning across multiple domains: lonelier young adults were more likely to experience mental health problems, to engage in physical health risk behaviours, and to use more negative strategies to cope with stress. They were less confident in their employment prospects and were more likely to be out of work. Data provided by informants indicated that individuals' feelings of loneliness are visible to others; however, informants also made more negative ratings of lonely individuals' personality and behaviour. Lonelier young adults were, as children, more likely to have had mental health difficulties, and to have experienced bullying and social

isolation. Loneliness was evenly distributed across genders and socio-economic backgrounds.

**Conclusions.**– Young adults' experience of loneliness co-occurs with a diverse range of health and lifestyle-related impairments, making it a risk marker of high clinical relevance. The findings underscore the importance of early intervention to prevent lonely young adults from being trapped in loneliness as they age, with potential implications for health in later life.

**Disclosure of interest.**– The authors declare that they have no competing interest.

## Joint Symposium with EBC: The value of treatment for brain and mental disorders

---

JS0003

### Optimising transition from child to adult mental health care

U. Schmidt

King's College London, Psychological Medicine, London, United Kingdom

**Introduction.**– The peak age of onset for eating disorders (EDs) is from age 15 to 20. In many countries the transition from child to adult mental health care falls right into the middle of this period, causing multiple problems for patients on either side of this border. It also means that when young people approach the age of transition they may have to travel through a dangerous no-man's land with poorly coordinated care. Moreover, there are important differences in approaches to treatment and care for children and adults with EDs and in regards to parental involvement and confidentiality arrangements.

**Objectives.**– The aim of this talk is to review existing practices in eating disorders transition care and to describe service models with optimal transition arrangements for young people with EDs.

**Method.**– The talk will be based on a narrative review of the available literature. In addition, information on transitions from our own ED service (catchment area of 2 million people) was ascertained.

**Results.**– Only two publications, both from the UK, were found that specifically addressed transition care for EDs. In addition, the National Institute for Health and Care Excellence (NICE) has published generic guidelines for transition from children's to adults' services in 2016. Data from our service will be presented.

**Conclusion.**– Service models that are 'trans-age' and designed for youth from adolescence into young adulthood are most likely to serve the needs of this population best.

**Learning objectives.**– To understand how transitions in care affect young people with EDs.

**Disclosure of interest.**– The author declares that he has no competing interest.

## Joint Symposium with EUFAS: Co-occurring substance use and psychiatric disorders: Pathogenesis and treatment

JS0004

### Exploring novel targets in the transition from reward to misery in comorbid substance use and mood disorders

A. Batalla

Radboud University Medical Centre, Department of Psychiatry – Donders Institute for Brain – Cognition and Behaviour, Nijmegen, The Netherlands

The global burden and socio-economic impact of mental disorders is increasing, and is led by substance use disorders (SUD) and mood disorders (MD). These mental illnesses often co-occur and their comorbidity precipitates symptom severity, relapses, suicide rates and treatment resistance. Neuroimaging studies have provided important advances for understanding illness progression, revealing alterations in several neural mechanisms involving systems (e.g. functional MRI, structural connectivity), circuits (e.g. structural integrity, volume) and molecules (e.g. neurotransmission). The identification of these mechanisms is crucial because it may lead to (1) the development of predictive neuroimaging biomarkers, which may help to identify those who will progress to substance use and mood disorders, and (2) novel targets for treatment intervention in those already affected. The transition from recreational substance use to comorbid substance use and mood disorders may derive from decreased function of the brain reward systems that normally mediate natural rewards (i.e., ventral tegmental area, striatum, prefrontal cortex) and progressive recruitment of brain stress systems that drive aversive states (i.e., habenula). Notably, imbalances in these neural substrates mediate phenotypes common to both SUD and MD (e.g., anhedonia), suggesting common targets for treatment. A better understanding of the altered networks involved in psychiatric conditions is of major importance to identify the correlational and/or potential causal relationships among specific symptoms domains (i.e. anhedonia), categorical disorders (i.e. substance use and mood disorders) and treatment options. Such knowledge will contribute to the development of tailored treatment and prevention strategies for those vulnerable individuals.

**Disclosure of interest.**– The author declares that he has no competing interest.

JS0005

### Addiction treatment – What is needed?

C. Drummond

King's College London, and Royal College of Psychiatrists, UK

Alcohol, drugs and tobacco are leading causes of ill health and premature deaths in Europe and worldwide. Substance use disorders are common in mental health and physical health populations and substance misusers have high levels of mental health and physical comorbidity. Yet in many countries addiction and mental health treatment are delivered in different silos. This is not helped by a high level of stigma attached to addictions which often results in patients with comorbidities being excluded from services. There are now a wide range of cost effective treatments available to treat substance use disorders and many countries have clinical addiction treatment guidelines. And yet only a small proportion of those

people affected access treatment, which works against reducing population level harm. A major rethink of how we address substance misuse and comorbidity is needed. This should start with a recognition of parity of esteem with other mental health and physical conditions. The wider healthcare workforce needs to be better trained and resourced to work with substance misusers wherever they present in the health system. Equally addiction specialists need to be able to work across organisational boundaries and deliver addiction treatment in a wider range of health settings. Health care funders need to prioritise treatment of substance misuse and comorbidity, particularly those people with the most complex needs. This makes both moral and economic sense.

## 26th European Congress of Psychiatry Symposium

### Symposium: Resilience and Recovery in People with Chronic Psychiatric Disorders

S0001

#### Are we neglecting the most needy patients again? An European perspective on care for patients with chronic disorders

S. Priebe

Queen Mary University of London, Unit for Social and Community Psychiatry, London, United Kingdom

*Introduction.*– Throughout the history of psychiatry, there has been a constant focus on people with chronic and severe mental disorders. A major driver for the reforms of mental health care in Europe in the 20th century was the concern for these chronic patients, who lived within the walls of asylum and were seen as neglected by society and medicine.

*Objective.*– This presentation will discuss whether recent societal and professional changes might have caused a shift of mental health care away from the most severe and chronic patients.

*Methods.*– An historical overview of mental health care for people with severe mental disorders will be provided.

*Results.*– Over the last 40 years, more money has been spent on mental health care across Europe, so that more staff treat more patients, with an increasing provision of care for patients with less severe disorders. Increasing social inequality and changes in social welfare systems – partly linked to austerity policies – are likely to have affected patients with severe and chronic mental disorders. The focus and some findings of scientific research seem to put less emphasis on chronic patients. Changes in the widely used terminology in psychiatry (e.g. mental health, well-being, users) may jeopardise the traditional role of psychiatry in caring for the most severe patients.

*Conclusions.*– There are worrying signs that societal changes and recent development in psychiatry might determine a reduced focus on severe and chronic patients. Implications and possible reasons for this will be discussed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0002

#### Chances and challenges of working in partnership with users and family carers

M. Amering

Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

*Introduction.*– The active involvement of service users and their relatives and friends is essential for the development of recovery-oriented and rights-based mental health practice and research.

*Objective.*– Present and discuss the chances and challenges of a participatory approach.

*Methods.*– Non-systematic review of experience and evidence on working in partnership with users and family carers.

*Results.*– The Trialogue experience – an exercise in communication between service users, families and friends and mental health workers on equal footing – is indicative of our capacity for surviving and gaining from serious discussions of adverse issues, such as coercive intervention, as well as the great possibilities of cooperative efforts and coordinated action, such as fighting stigma and discrimination. The first triologic WPA Task Force on Best Practice in Working with Service Users and Carers under the leadership of Helen Herrman published ten recommendations to the international mental health community with an urgent call for a partnership approach on all levels of mental health policy and care. Currently, special attention needs to be given to new roles and responsibilities arising from the historical challenge of the UN-Convention on the Rights of Persons with Disabilities for mental health professionals, users of services as well as relatives and friends.

*Conclusions.*– Actual developments regarding new rights to patient autonomy as well as new entitlements for support for living in the community including the right to family life, reasonable accommodation and supported decision-making warrant a partnership approach in order to have a positive real life impact.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0003

## Providing care for people with severe mental illness: What should the research focus be?

R. Borbé

ZfP Suedwuerttemberg, General Psychiatry, Ravensburg, Germany

*Objective.*– Despite encouraging approaches, strengthening the rights of people with severe mental illness, we face a widening mental health treatment gap. Research in this field is crucial to identify needs, study interventions and renew the care system.

The following topics should be addressed:

- Poverty affects people with severe mental illness. Research should address victimization, violence, homelessness and somatic comorbidities.
- Historical research is needed to understand mental health reform processes. This research can help us in striving for improvements in mental health care.
- Research on the role of peer support in care systems in diverse countries (including low- and middle-income countries) and service settings may help sharpen our understanding of the field.
- The patients' perspective, the key to an individualized treatment plan, is often ignored yet. Planning patient-centred community mental health care is based on valuable data.

*Methods.*– Review of literature, guidelines and mental health politics with respect to research for people with severe mental illness.

*Results/discussion.*– Well-founded research is a prerequisite for improving the provision of care for people with severe mental illness. Society and politics play a crucial role in defining the importance of this research.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0004

## Positive courses of severe chronic psychiatric disorders. First results of a longitudinal mixed-methods matched pairs design

J. Krieger

Klinikum Wahrendorff GmbH, Forschung und Entwicklung, Sehnde/OT Ilten, Germany

*Objective.*– The position that individuals with severe chronic psychiatric disorders can recover and establish a certain degree of mental stability that can enable an independent and fulfilling life is main component of the concept “recovery”. To sustain recovery, different variables and interdependent factors are needed, e.g. psychological resilience and empowerment. Actually, there is a lack of longitudinal studies focusing on the interdependency of recovery and resilience in patients with severe chronic psychiatric disorders, especially with an emphasis on overall psychiatric diagnosis.

The study examines residential patients with severe chronic psychiatric disorders who lived in a long-term care institution for psychiatric rehabilitation (SGB XII) in Lower Saxony and who were able to move out and live by themselves in 2016 and 2017.

*Methods.*– Qualitative preliminary-study with focus groups, containing different perspectives. The main study follows a naturalistic mixed-methods-design and a longitudinal course. There will be five follow-ups within 24 months after first measuring time.

*Results.*– The results of the preliminary study will be presented and discussed. Furthermore, there will be given an overview of the current status of the main study, the next steps and possible consequences. The results of the main study should be used in different subject areas, e.g. identification of factors enabling independent living and creation of effective therapy interventions for patients with

severe chronic psychiatric disorders who have lived in a long-term care institution.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Symposium: The Use and Abuse of Neuroimaging in Forensic Psychiatry: What Can We Learn From Neuroimaging Colleagues?

S0005

### The role of neuroimaging studies in our understanding of suicidal behaviour

G. Serafini

University of Genoa, Neuroscience DINOGMI, Genoa, Italy

Suicidal behavior is a relevant and multifaceted public health issue and is commonly associated with a significant disability and psychosocial impairment. The World Health Organization (WHO) reports that every year, approximately 800,000 people die from suicide, with a global mortality rate of 16 per 100,000. To date, no reliable biomarkers are available to predict exactly which subjects will develop suicide over time, but neuroimaging techniques are now providing novel insights into the complexity of this phenomenon offering promising data for understanding the neurobiology of suicidal behavior. Elucidating brain structural/functional deficits may help to clarify the pathophysiological mechanisms underlying suicidal behavior and assist in identifying high-risk individuals in the clinical practice. Structural brain imaging techniques in patients with psychiatric disorders have been used since the 1970s. According to magnetic resonance imaging (MRI) studies, a higher prevalence of white (e.g. periventricular and deep) matter and grey matter abnormalities in the frontal, temporal and/or parietal lobe as well as reduced volumes in the frontal and temporal lobes have been reported in subjects with a history of suicide attempts. Interestingly, all these brain areas have been shown to play a significant role in several psychopathological domains, such as emotional dysregulation and abnormal self-processing, which are supposed to play a role in the emergence of suicide behavior. Furthermore, studies using task-based BOLD fMRI showed aberrant neural activity patterns in suicide attempters. Task-based fMRI has been used to test the neural substrates of specific cognitive and emotional intermediate phenotype of suicide such as error monitoring and decision-making as well. There are also studies that indirectly investigated suicidal behavior using rsfMRI techniques (e.g. they mainly explored key psychopathological predictors of suicidal behavior such as hopelessness, which may provide useful information about suicidality). However, the possible contribution of neuroimaging techniques in our understanding of the complexity of suicide needs to be examined in the light of some shortcomings. First, it is unclear whether the reported abnormalities represent risk markers for suicide or are directly related to the course of illness as a result of disease processes. Moreover, existing neuroimaging studies usually include relatively small and clinically heterogeneous samples that may have seriously limited their statistical power. The potential effect of psychoactive medications on neuroimaging studies cannot be ruled out as well. Studies may also lack detailed information regarding medication doses or duration of treatment.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0006

## The use of neuroimaging in court: Science, ethics and practice

M. Kyriakopoulos<sup>1,2,3,4</sup>

<sup>1</sup> National & Specialist Acorn Lodge Inpatient Children's Unit, London, UK; <sup>2</sup> South London and Maudsley NHS Foundation Trust, London, UK; <sup>3</sup> Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK; <sup>4</sup> Icahn School of Medicine at Mount Sinai, New York, USA

Although medical imaging is commonly used as evidence in the courtroom, neuroimaging presents with special complexity. Structural and functional neuroimaging has been used not only in the identification of the mechanism of injury but also to make inferences about human behaviour or motivation as a result of brain structure and function. The validity, reliability and translational value of neuroimaging findings, objective limitations of their use including the identification of other explanatory possibilities, expertise in the interpretation and recognition of uncertainty where relevant, and use alongside other clinical evidence in a balanced fashion, are paramount in its effective and prudent use in court. Given that legal arguments have been shown to be more convincing when backed up by brain-based data and especially brain images even in the absence of any scientific rationale, such evidence need to be subjected to a high degree of scrutiny before its use in legal proceedings is considered to be acceptable. Standardised guidelines for expert testimony, taking into account scientific progress and ethical/societal considerations in this evolving field, are needed. Neuroimaging is a promising powerful technology which can increase objectivity and assist in the administration of justice.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Symposium: Recent Developments in Perinatal Mood Disorders

S0007

### New findings in perinatal bipolar disorder

A. Wieck

Greater Manchester Mental Health NHS Foundation Trust, Psychiatry, Manchester, United Kingdom

There are few events that have a greater impact on severe mental illness than childbirth. Studies using population databases from Britain, Denmark and Sweden, have found a large increase in the rate of psychiatric admissions in the postnatal period with a peak in the first postpartum month and an overall incidence in the first three months of 1–2 per thousand deliveries. The majority of presenting conditions are postpartum affective psychoses and have a close relationship with bipolar disorder although atypical features can sometimes obscure the overall diagnosis. A small subgroup of women develop episodes exclusively in the postpartum period and some evidence suggests that this may present a disease entity that is distinct from bipolar disorder.

Clinical samples have demonstrated that the onsets of these severe states cluster in the first week postpartum. The illnesses tend to start abruptly within a few days of childbirth, escalate rapidly, fluctuate markedly, and are amongst the most severe seen in psychiatry. Because of the high risk to the safety of the mother and her infant, a high level of awareness of the condition and assertive management is essential.

Irrespective of treatment, about one in three women with a pre-delivery diagnosis of bipolar disorder suffer a relapse after a subsequent delivery and 1 in 5 women experience a severe episode. Women with schizo-affective bipolar and bipolar 1 disorder are at a higher risk than women with bipolar 2 disorder. Because randomized controlled trials are not possible in this patient population, high quality data of the effect of pharmacological prophylaxis is lacking. Nevertheless, a recent meta-analysis of existing treatment studies suggests that medication prescribed up to delivery and in the early postpartum period reduces the recurrence rate significantly.

Current evidence suggest that pregnancy does not increase the risk of bipolar recurrences and there is conflicting data from population studies and clinical samples whether relapses are in fact less common during this time. However, most pregnant women will require pharmacological prophylaxis or treatment. Recent evidence of the reproductive safety of psychotropic medication in pregnancy will be briefly summarized.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0008

### The impact of postpartum PTSD on child development

M. Eberhard-Gran<sup>1,\*</sup>, S. Garthus-Niegel<sup>2</sup>, S. Ayers<sup>3</sup>, J. Martini<sup>4</sup>, T. von Soest<sup>5</sup>

<sup>1</sup> University of Oslo, Institute of Clinical Medicine, Lorenskog, Norway; <sup>2</sup> University Hospital Carl Gustav Carus, Technical University Dresden, Institute and Outpatient Clinics of Psychotherapy and Psychosomatics, Dresden, Germany; <sup>3</sup> City University London, Centre for maternal and Child Health, School of Health Science, London, United Kingdom; <sup>4</sup> TU Dresden, Faculty of Medicine, Department of Child and Adolescent Psychiatry, Dresden, Germany; <sup>5</sup> University of Oslo, Department of Psychology, Oslo, Norway

\* Corresponding author.

*Background.*– Against the background of very limited evidence, the present study aimed to prospectively examine the impact of maternal postpartum post-traumatic stress disorder (PTSD) symptoms on four important areas of child development, i.e. gross motor, fine motor, communication and social-emotional development.

*Method.*– This study is part of the large, population-based Akerhus Birth Cohort. Data from the hospital's birth record as well as questionnaire data from 8 weeks and 2 years postpartum were used ( $n=1472$ ). The domains of child development that were significantly correlated with PTSD symptoms were entered into regression analyses. Interaction analyses were run to test whether the influence of postpartum PTSD symptoms on child development was moderated by child sex or infant temperament.

*Results.*– Postpartum PTSD symptoms had a prospective relationship with poor child social-emotional development 2 years later. This relationship remained significant even when adjusting for confounders such as maternal depression and anxiety or infant temperament. Both child sex and infant temperament moderated the association between maternal PTSD symptoms and child social-emotional development, i.e. with increasing maternal PTSD symptom load, boys and children with a difficult temperament were shown to have comparatively higher levels of social-emotional problems.

*Conclusions.*– Examining four different domains of child development, we found a prospective impact of postpartum PTSD symptoms on children's social-emotional development at 2 years of age. Our findings suggest that both boys and children with an early difficult temperament may be particularly susceptible to the

adverse impact of postpartum PTSD symptoms. Additional studies are needed to further investigate the mechanisms at work.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0009

### **Preconception consultation – Challenges of translating evidence into clinical practice**

E. McDonald

Royal College of Psychiatrists, Perinatal Faculty, London, United Kingdom

Pre-conception counselling needs to be offered to all women of childbearing potential who:

- Have a severe mental illness.
- Have had a previous post-natal psychiatric illness.
- Present with mental disorders with additional complexities such as co-morbidities, social disadvantage, etc.
- Are taking psychotropic medication.

Women with mental health problems should be offered support and advice about their physical and sexual health (including contraception) from the time of diagnosis. Enabling women to plan for pregnancy and parenthood needs to be part of good psychiatric care.

A risk-benefit analysis that focuses on the individual women using a biopsychosocial model is key to ensuring that up-to-date data is incorporated into discussions with women who wish to conceive.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0010

### **The neural correlates of perinatal anxiety and depression**

J.L. Pawluski

Irsat-Inserm U1085, Universit  de Rennes 1, Rennes, France

*Objective.*– At least 1 in 7 women during the perinatal period will have perinatal depression or an anxiety disorder. These maternal mental illnesses can have significant effects on neural, physiological and behavioral plasticity in the mother. Yet our understanding of the neurobiological mechanisms mediating maternal mental illnesses is limited. In fact, much more research has focused on how maternal stress, maternal depression, and perinatal antidepressant medication use affects the developing child than the mother.

*Methods.*– To investigate effects of maternal anxiety and depression on neural circuitry in the maternal brain and understand how selective serotonin reuptake inhibitor (SSRI) medications, commonly used to treat maternal mental illness, may alter brain plasticity a translational approach will be discussed with studies carried out in humans and rodent models.

*Results.*– Main findings show that perinatal depression and anxiety alter plasticity in the maternal brain and maternal care-giving network. These effects are altered with SSRI medications in a brain region specific manner. For example, in rodent models, maternal stress, as a model of aspects of depression and anxiety, can increase synaptic plasticity in the prefrontal cortex, while SSRI treatment can normalize this stress effects. The same effects were not evident in the hippocampus.

*Conclusions.*– This work adds to a much needed area of research aimed at understanding neurobiological changes associated with perinatal anxiety and depression and the role of SSRI treatment in altering these changes in the maternal brain.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Symposium: Childhood Trauma and Eating Disorders: Neurobiological and Clinical Aspects**

S0011

### **Childhood trauma and hypothalamus-pituitary-adrenal axis**

V. Mondelli

Institute of Psychiatry, Psychology and Neuroscience, King's College London, Psychological Medicine, London, United Kingdom

*Background.*– Childhood trauma has been consistently reported as risk factor for development of major psychiatric disorders including psychosis and depression. The biological mechanisms through which childhood trauma contribute to development of psychotic and depressive symptoms remain still unclear. The hypothalamic-pituitary-adrenal (HPA) axis is the main biological system involved in the stress response and abnormalities in the HPA axis activity have been suggested to contribute to onset of psychiatric disorders. In this presentation, I am going to show findings from two main studies which investigated the effects of childhood trauma on HPA axis activity in patients with first episode psychosis (GAP study) and in patients with major depression (BIODEP study).

*Methods.*– We assessed HPA axis by measuring salivary cortisol at awakening (0, 15, 30 and 60 min after awakening) and at noon and 8 PM in a sample of  $n=82$  patients with first episode psychosis and  $n=53$  healthy controls as part of the GAP study. Similar measurements were collected in a sample of  $n=163$  patients with major depression and  $n=55$  healthy controls as part of the BIODEP study. Information on childhood trauma was collected using the Childhood Experience of Care and Abuse questionnaire in the GAP study and using the Childhood Trauma Questionnaire in the BIODEP study. In the GAP study, for further assessment of possible factors modulating the relationship between childhood trauma and HPA axis, DNA was extracted from blood or saliva samples and evaluated for a functional polymorphism at the rs1360780 locus in FKBP5. In the BIODEP study, for further assessment of possible factors modulating the relationship between childhood trauma and HPA axis, we investigated inflammatory markers and possible presence of glucocorticoid resistance.

*Results.*– We did not find a significant association between childhood trauma and cortisol levels during the day or cortisol awakening response (CAR) in patients with psychosis. However, we found a significant interaction between history of childhood abuse and FKBP5 genotype on the CAR in first episode psychosis ( $F=1.132, p=0.01$ ) but not in controls ( $p=0.3$ ). Similarly in depression we did not find a significant association between childhood trauma and cortisol levels during the day or cortisol awakening response (CAR) in the whole sample of patients with depression. However, we found that severity of childhood trauma was positively associated with cortisol levels during the day in subjects who presented glucocorticoid resistance (Spearman's  $r=0.398, p=0.03$ ) but not in those without glucocorticoid resistance ( $p=0.2$ ).

*Conclusions.*– Our findings suggest that only a specific subset of patients (either with a genetic vulnerability or presenting increased inflammation) may be more vulnerable to develop HPA axis abnormalities following experience of childhood trauma.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0012

### Neurobiological effect of childhood trauma exposure in adults with eating disorders

A.M. Monteleone<sup>1,\*</sup>, F. Esposito<sup>2</sup>, A. Prinster<sup>3</sup>, V. Ruzzi<sup>4</sup>, A. Canina<sup>2</sup>, F. Di Salle<sup>2</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> Second University, Department of Psychiatry, Naples, Italy;

<sup>2</sup> University of Salerno, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Neuroscience, Salerno, Italy; <sup>3</sup> National Research Council, Biostructure and Bioimaging Institute, Naples, Italy; <sup>4</sup> University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy

\* Corresponding author.

**Introduction.**— Although childhood maltreatment has been associated to brain alterations in several clinical populations, no study assessed so far its impact on brain structure of eating disorder (ED) patients. Therefore, we specifically assessed whether childhood trauma is associated to brain alterations in patients with Anorexia Nervosa (AN) or Bulimia Nervosa (BN).

**Methods.**— Thirty-six outpatients (20 with AN and 16 with BN) and 16 healthy controls were recruited. ED patients were classified as maltreated (Mal) or non-maltreated (NoMal) according to their childhood exposure to one or more traumatic events assessed by the Childhood Trauma Questionnaire. They underwent a MRI scanning including the acquisition of a diffusion tensor imaging (DTI) sequence and a high resolution T1-weighted scan.

**Results.**— Significantly reduced grey matter volume was detected in the right paracentral lobule and in the left inferior temporal gyrus of Mal patients. DTI analyses revealed reduced white matter integrity in corpus callosum, internal capsule, posterior thalamic radiation, longitudinal fasciculus and corona radiata of Mal patients. Negative correlations emerged between white/gray matter changes and CTQ scores assessing neglect.

**Conclusions.**— Our findings show, for the first time, that childhood trauma affect the integrity of brain structures implicated in the modulation of brain processes, such as reward, taste and body image perception, that play a fundamental role in the psychopathology of EDs.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

S0013

### Childhood traumatic experiences and clinical characteristics of patients with eating disorders

S. Guillaume

CHRU Montpellier, Psychiatric Emergency and Acute Care, Montpellier, France

Patients with eating disorders (EDs) frequently report a history of childhood trauma (CT). CT appears to be frequent in patients with binge episodes or impulsive characteristics. The findings on the association between childhood abuse and symptoms closely related to body concern, such as body dissatisfaction or drive for thinness, have been more discrepant. We investigated whether certain subtypes of CT are associated with more severe features of EDs, independently of psychiatric comorbidity, and whether they act additively. One hundred and ninety-two patients with DSM-V-defined EDs were consecutively recruited. Five clinical characteristics were assessed: restraint, eating, shape and weight concerns on the EDE-Q, and daily functioning. CT was assessed by the childhood traumatism questionnaire. The clinical features were associated with at least one CT subtype (emotional, sexual or physical abuse, emotional neglect). Multivariate analyses

adjusted for lifetime comorbid psychiatric disorders revealed that emotional abuse independently predicted higher eating, shape and weight concerns and lower daily functioning, whereas sexual and physical abuse independently predicted higher eating concern. A dose-effect relationship characterised the number of CT subtypes and the severity of the clinical features, suggesting a consistent and partly independent association between CT and more severe clinical and functional characteristics in EDs. Emotional abuse seems to have the most specific impact on ED symptoms. Last, not all CT subtypes have the same impact but they do act additively.

### Symposium: Circadian Rhythms, Sleep and Activity in the Course, Early Detection and Treatment of Mood Disorders

S0014

#### Impact of circadian phenotypes and genes on the clinical expression of bipolar disorders

B. Etain

University Paris Diderot, Psychiatry and Addictology, Paris, France

Bipolar disorders (BD) are accompanied by circadian deregulations and sleep disruptions, both during acute mood episodes and euthymic periods. It is hypothesized a pathway from circadian genes variants, through chronotypes and sleep disturbances, to various clinical outcomes in BD such as mood relapses, emotional regulation, metabolic disturbances or response to mood stabilizers. We will present several studies supporting the relevance of this pathway and that used samples of remitted patients with BD to assess actigraphic and circadian parameters (phase preference, amplitude and stability of rhythms). We demonstrated associations between several circadian genes (*TIMELESS*, *RORA*, *ASMT*) and the susceptibility to BD. Using actigraphy, we demonstrated that patients with BD had longer sleep duration and latency but also higher variability in fragmentation index. We confirmed these results in a meta-analysis of nine published studies using actigraphy in patients in remission. Using questionnaires, we also demonstrated that patients with BD were more evening type, languid and less flexible in their rhythms. Interestingly, associated genes drove the circadian and sleep outputs in our sample, as shown by association between *ASMT* and sleep disruptions and associations between circadian genes and chronotypes. Finally, we will present new data that established links between sleep, emotional reactivity, metabolic syndrome parameters and risk of recurrences in BD. This presentation will highlight recent research on sleep and circadian rhythms in bipolar disorders and help in the comprehension of complex pathways going from circadian genetic susceptibility to clinical outcomes.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

S0015

#### When variability counts: Modeling the actigraphy signal for more comprehension of various mood states

K. Krane-Gartiser

Norwegian University of Science and Technology, Department of Mental Health, Trondheim, Norway

**Introduction.**– Actigraphy is a validated tool for recording motor activity, but analytic approaches have mainly focused on mean activity levels or sleep–wake cycle measures. Linear and non-linear mathematics applied to motor activity patterns recorded on a minute level may reveal objective differences between mood states, and thereby lead to improved diagnosis and monitoring of symptom changes.

**Objectives.**– To give an overview of studies that compare activity patterns in inpatients with bipolar disorder (BD), unipolar depression and psychotic disorders, as well as within individuals during separate admissions for an acute BD episode.

**Methods.**– Several actigraphy studies undertaken at a psychiatric emergency department in Trondheim, Norway, with inpatients who wore an actigraph for 24 h shortly after admission. Different variability and irregularity measures were applied to group comparisons, a case series of within-individual recordings and a classification analysis.

**Results.**– Unipolar depression with and without clinically assessed motor retardation was objectively separated. In mania, mixed states and schizophrenia, the complexity of time series was increased compared to depression categories. Unipolar depression was distinguished from bipolar depression in within-group analyses during the course of day. Similarly, mania cases demonstrated stable patterns during 24 h compared to depression and schizophrenia cases who showed intra-daily fluctuations. Individuals with separate admissions displayed different patterns according to phase of BD and higher irregularity with increasing psychotic symptoms.

**Conclusions.**– Mathematical modeling of activity patterns identifies similarities and differences between acute states of mood disorders. More complex patterns, and not increased activity, seems characteristic of mania, agitated depression and psychosis.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

S0016

### **Sleep disturbances as predictors of transition to mood disorders and as a target for early interventions in at-risk subject**

J. Scott

*Neuroscience, Academic Psychiatry, Newcastle upon Tyne, United Kingdom*

There has been a significant increase in the understanding of the relationship between circadian sleep dysrhythmias, sleep–wake abnormalities and mood disorders, especially bipolar disorders (BD). It has been shown that sleep disturbances and circadian misalignment are core symptoms of both manic and depressive episodes and that they represent common symptoms of episode prodromes. This presentation now examines whether sleep patterns are associated with risk of developing BD or can distinguish recent onset BD from unipolar disorders of other mental health problems (ADHD, BLPD) in youth.

A systematic review of individuals with emerging BD was undertaken to examine rates and presentations of disruptions in sleep wake cycle, process S, process C and circadian sleep rhythms. In total, 32 studies were identified. Sample sizes ranged from <10 to >1000. Study quality was variable, with some using single questions and/or only interviewing parents, whilst others used objective measures such as PSG and actigraphy, with or without measures of melatonin; about 50% included a comparator group or prospective cohort design.

The heterogeneous nature of the studies means that it is currently unclear if a specific sleep profile represents a clinical marker of

long-term risk for transition to BD. However, dimensions of the sleep–wake cycle may constitute a constellation of symptoms that can predict onset of mood episodes (e.g. prolonged sleep, delayed sleep phase, day-time activity disruptions) and some components differentiate BD from other disorders in youth.

The implications of the findings for research and for clinical interventions will be discussed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## **Symposium: E-mental Health: New Opportunities to Innovate in Affective Disorders**

S0017

### **Self-management in affective disorders: How to use both patient generated data and Internet and CBT-based programmes in routine care**

U. Hegerl

*Universitätsklinikum Leipzig, Department of Psychiatry and Psychotherapy, Leipzig, Germany*

Via smartphones and wearables patients with affective disorders increasingly become producers and owners of a huge amount of data from (1) biosensors assessing, e.g. sleep, movement, voice, heart rate, or skin conductance, (2) geolocation and environmental data, (3) the pattern of smartphone use and (4) selfratings. Using time series analyses data patterns could be identified for an individual patients which are related to or predict mood changes and might be of value for selfmanagement as well as treatment. Results of a systematic review [1] of this dynamic field of research will be presented. Concerning another area of e-mental-health, the CBT-based online-programmes, the evidence for efficiency has become quite robust in the last years. In meta-analyses the efficacy was comparable to that of face-to face psychotherapy. The iFightDepression tool (iFightDepression.com) will be presented. It has been developed based on a European consensus process, is available in 10 different languages, and is offered for free by the European Alliance Against Depression ([www.EAAD.net](http://www.EAAD.net)). A professional guidance is obligatory because this is crucial for efficacy and necessary considering the severity and life threatening aspects of affective disorders. The implementation of such e-mental-health tools in routine care is a complex process which is taking up speed in some countries.

**Disclosure of interest.**– Within the last three years, Prof. Hegerl was an advisory board member for Lundbeck, Janssen and Servier a consultant for Bayer Pharma and a speaker for Roche Pharma.

**Reference**

S0018

### **The effect of smartphone-based treatment interventions in bipolar disorder**

M. Faurholt-Jepsen

*Rigshospitalet – Copenhagen University Hospital, Psychiatric Center Copenhagen, Copenhagen, Denmark*

Unipolar and bipolar disorder combined account for nearly half of all morbidity and mortality due to mental and substance use

disorders, and burden society with the highest health care costs of all psychiatric and neurological disorders. Among these, costs due to psychiatric hospitalization are a major burden. Smartphones comprise an innovative and unique platform for the monitoring and treatment of depression and mania.

The RADMIS trials is a randomized controlled, single-blind, parallel-group design aiming to investigate whether using a smartphone-based monitoring and treatment system, including an integrated clinical feedback loop, reduces the rate and duration of re-admissions more than standard treatment in unipolar disorder and bipolar disorder.

The design and rationale of the RADMIS trial will be presented and discussed at the congress.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

S0019

### **Developing a mHealth framework to improve bipolar disorder self-management: Lithium home monitoring**

N. Cardoner

*Institut de Recerca Parc Taulí, I3PT, Mental Health-OSAMCAT, Sabadell, Spain*

Lithium is a first-line therapy for the acute and long-term treatment of patients suffering from bipolar disorder, due to its well-documented antimanic, antisuicidal and prophylactic properties. In addition, lithium is used as a effective augmentation strategy for drug resistant major depression. Despite the large number of evidence supporting the crucial and indispensable role of lithium as a gold standard treatment in mood disorders, prescription patterns from several countries demonstrate a progressive decreasing of the use of this drug. This phenomenon could be the result of different factors that would act as modulators of behavior of both the physician and patient, leading to a reduction of clinical prescription of lithium but also of patient's adherence. Among these factors, the side effects and the potential toxicity risk, together with the need for regular control via venipuncture may play a significant role. In this scenario, new management and monitoring approaches are needed. We present an innovative medical solution for remote (home) patient monitoring, based on a new device equipped with a unique technology that allow an easy measure of lithium in capillary blood. This technology enables a straightforward and fast control of lithium plasmatic levels, which can lead to overcome the reluctance of clinicians on its use. Moreover, this innovative approach can increase therapeutic adherence by promoting the empowerment of patients in their self-monitoring and, in addition, improving health outcomes by providing direct and rapid information to the healthcare team, using mHealth, useful for the optimization of the clinical control and patient's management.

### **Symposium: Is It Still Time to Challenge Stigma Attached to Mental Disorders?**

S0020

### **Proud to be psychiatrists: Making the most of our specialty**

J. Beezhold

*Norfolk and Suffolk NHS Foundation Trust/UEA, Liaison Psychiatry: Norfolk and Norwich University Hospital, Norwich, United Kingdom*

There is much agreement and effort that has been invested into improving how psychiatry as a medical specialty is perceived. This is driven by our awareness of the almost universal bias in attitudes against those affected by mental disorders. This takes many forms, for example public perceptions, media portrayals, clinical and research funding allocation, choice of specialty and our self-perception.

Expectation and confirmation bias play an immensely important role in maintaining this situation. Put simply, the use of words such as stigma itself creates and reinforces stigma. How this happens will be explored using practical examples. However, expectation and confirmation bias also have a key role to play in changing the image of psychiatry for the better.

This presentation seeks to highlight the importance of expectation and confirmation bias in shaping attitudes using both research evidence and topical examples such as Brexit and Trump.

The presentation then analyses how we have too often fallen into the trap of inadvertently reinforcing unhelpful stereotypes regarding our specialty of psychiatry due to a failure to fully appreciate the power of expectation and confirmation bias.

Suggestions for a way forward are then presented, including examples of practical initiatives and approaches that we can all use to strengthen the image of psychiatry as a medical specialty of excellence.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

S0021

### **The role of mass media and social media for challenging stigma**

G. Sampogna<sup>1,\*</sup>, M. Luciano<sup>2</sup>, V. Del Vecchio<sup>2</sup>, A. Fiorillo<sup>2</sup>

<sup>1</sup> *University of Naples SUN, Department of Psychiatry, Naples, Italy;* <sup>2</sup> *University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy*

\* Corresponding author.

Mass media and social media are communication channels which constitute an immensely powerful source of social influence, having the possibility to reach large numbers of people.

In the field of mental health, mass media and social media can be used to positively influence the opinions toward people with mental disorders, promoting positive stories related to mental health problems and to promote anti-stigma interventions targeted to the general population.

In England, during 2009–2014 the "Time to Change" (TTC) anti-stigma programme has included a social marketing campaign (SMC) using mass media channels, social media and social contact events but the efficacy of such approach has not been evaluated yet.

The strategy to use the new social media has shown to be effective and further population-based campaigns using these new communications channels with longer follow-up period are needed in order to evaluate the long-term effects of those interventions.

The target population included people aged between mid-20s/mid-40s, from middle-income groups. Participants were recruited through an online market research panel, before and after each burst of the campaign. Participants completed an online questionnaire evaluating knowledge [Mental Health Knowledge Schedule (MAKS)]; attitudes [Community Attitudes toward Mental Illness (CAMI)]; and behaviours [Reported and Intended Behaviour Scale (RIBS)].

A total of 10,526 people were interviewed. An increasing usage of the SMC-media channels as well as of the level of awareness of SMC was found.

The increasing use of the social media channels of the TTC has been associated with an improvement in positive attitudes and behaviours in the UK general population towards people with mental disorders.

The social marketing campaign of the TTC represents an important way to effectively reduce stigma. Taking into account these positive findings, further population-based campaigns using social media may represent an effective strategy to challenge stigma.

## Symposium: Resource Oriented Approaches in the Treatment of Refugees

S0022

### Cultural adaptation of minimally guided interventions for refugees: Chances and challenges

E. Heim<sup>1,\*</sup>, M. Harper-Shehadeh<sup>2</sup>, J. Abi Ramia<sup>3</sup>, K. Carswell<sup>2</sup>, E. Van't Hof<sup>2</sup>

<sup>1</sup> University of Zurich, Department of Psychology, Zurich, Switzerland; <sup>2</sup> WHO, Mental Health and Substance Abuse, Geneva, Switzerland; <sup>3</sup> Ministry of Health, The National Mental Health Programme, Beirut, Lebanon

\* Corresponding author.

Evidence shows that cultural adaptation of face-to-face interventions increases their effectiveness and acceptance. One meta-analysis found that the cultural adaptation of the illness explanatory model was particularly relevant in face-to-face interventions. However, evidence on cultural adaptation of self-help and minimally guided interventions is scarce. A recent meta-analysis including eight studies indicated that the more an intervention was culturally adapted, the greater its effectiveness. WHO has recently developed a series of scalable interventions for culturally diverse populations. These interventions are either minimally guided or self-help based. Moreover, these interventions were developed in a 'generic' manner, which means that they use as little culturally-specific information as possible. A careful procedure of cultural adaptation was implemented, using cognitive interviewing with culturally diverse groups. Results show that these interventions are generally acceptable and require only minimal cultural adaptation. Challenges emerge with regard to the framing of the intervention, i.e. the explanatory model provided at the beginning.

### Implementing scalable interventions for common mental disorders in response to the Syrian refugee crisis: First results regarding Problem Management Plus (PM+) programs

M. Sijbrandij

VU University Amsterdam, Clinical, Neuro, and Developmental Psychology, Amsterdam, The Netherlands

The crisis in Syria has resulted in an unprecedented increase in the number of refugees seeking asylum in Syria's neighboring countries

as well as in Europe. Syrian refugees may have been exposed to multiple war stressors such including sexual violence and destruction of their homes and livelihoods, and they have often undertaken a risky and stressful flight leaving their homes for an unknown future. Studies show that refugees are at considerable risk to develop common mental disorders, including depression, anxiety, posttraumatic stress disorder (PTSD) and related somatic health symptoms. The World Health Organization has developed a range of scalable psychological interventions aimed at reducing psychological distress and improving functioning in people living in communities affected by adversity. These interventions, including Problem Management Plus (PM+) and its variants, are intended to be delivered by lay, non-professional people who have not received specialized mental health training.

Previous randomized clinical trial results in a conflict-affected area in Pakistan showed beneficial effects in terms of reductions in anxiety, depression, functional disability, and posttraumatic stress than those who received an enhanced treatment as usual. With these positive findings as a starting point, the recently EU-funded STRENGTHS project will implement, scale-up and evaluate this new generation of low-intensity interventions in the context of the Syrian refugee crisis. The PM+ programmes will be implemented by peer-refugees and evaluated across refugee settings in Europe (Netherlands, Turkey, Switzerland, Germany and Sweden) and the Middle East (Jordan, Lebanon, and Egypt). In this presentation, the evidence base for STRENGTHS project will be outlined. In addition, and preliminary results concerning identification of expected barriers and facilitators implementation of the PM+ programmes will be presented.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Peer support: The potential of ethnically diverse peer navigators to address ethnic health disparities in refugees

I. Missmahl

Germany

Based on the 13 years' experience in Afghanistan and in other countries Ipso has started to train refugees with an academic background in March 2016 to be trained in a one year training as psychosocial counselors. Over 90 refugees from 17 countries have been trained in a one year training and are now delivering monthly more than 1000 counseling sessions in person and online for their countrymen.

The methodology, results and experiences with Ipso's value based counseling approach within the refugee context will be presented and discussed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0025

### Resilience oriented treatment and strategies (ROTS) in refugees and asylum seekers in psychiatric settings

K. Laban

GGZDrenthe, De Evenaar, North Netherlands Centre for Transcultural Psychiatry, Ruinen, The Netherlands

*Background.*– The psychological reaction of people experiencing the same kind of adverse life events differs per person. In recent years the concept of "resilience" is getting more attention, both in finding

an explanation of this phenomenon and a search to find new and more successful treatment strategies.

**Methods.**– The concept of resilience is explained with references to the literature and a resilience-oriented working model is introduced. The model is based on four, interacting, elements: stress, vulnerability, strength and social support. It recognizes the multifactorial etiology of psychopathology and puts emphasis on the importance of personal strength and potentials of recovery. This model has been used in diagnostic and treatment procedures in De Evenaar over 10 years and it has proven its value in a multicultural treatment setting. A short overview of the biological, psychological, social, cultural and religious resources of resilience will be presented. Several resources will be discussed in more detail, illustrated by findings from recent psychological and neurobiological studies. Moreover the basic principles from the Narrative Exposure Therapy (NET) will be presented. The NET is a newly developed trauma therapy which fit very well in a resilience oriented approach.

**Results.**– It will be clear that a resilience-oriented approach is aiming at enhancing powers of natural recovery. The patient is taken serious in his/her 'whole being'. In exploring the resources of resilience also cultural and existential (e.g. religious) aspects can be included as a matter of course. Several resources are studied and found to be very effective in enhancing resilience and for mental health workers as well as patients, the presented model is a useful leading frame of thought and practice.

**Conclusion.**– An approach based on resilience offers a practical framework to help reduce and address the often serious psychological complaints suffered by traumatised asylum seekers and refugees. This approach does not accentuate victimhood but instead explicitly considers all aspects, including healthy aspects, of the person being treated. This of itself has a therapeutic working. Above all though the approach helps patients to mobilize their own strengths and in so doing puts them in command of their own recovery [1–4].

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Symposium: Treating Beyond Symptoms to Improve Outcome: Cognitive Remediation in Psychiatry

S0026

### Using metacognition in cognitive remediation: Implications for therapy delivery and functional outcome

M. Cella\*, C. Redeer, T. Wykes

*Institute of Psychiatry, Psychology & Neuroscience King's College London, Psychology, London, United Kingdom*

\* Corresponding author.

The cognitive problems experienced by people with schizophrenia are a strong predictor of functioning problems and a barrier to recovery. Cognitive Remediation (CR) interventions aim to reduce people's cognitive difficulties, their impact on functioning with the ultimate aim to improve recovery opportunities. Despite being successful in reducing cognitive difficulties CR interventions still have a variable degree of success in transferring improved cognitive skills to people's everyday life. We argue that CR programs with a focus on metacognition can maximise transfer by improving people's awareness of cognitive difficulties and regulation of cognitive processes. In this talk we will present data in support of the usefulness of metacognitive skills in CR. We will discuss evidence from controlled studies exploring the impact of a metacognitive based CR intervention and its impact on functional outcomes. We will present results on how specific metacognitive components (e.g. strategy use) may lead to functional outcomes change. We will also present results showing how metacognitive skills change people's approach to tasks, improving accuracy and proficiency. With our preliminary results supporting the usefulness of metacognitive components this talk will discuss briefly possible ways to include these techniques in CR programs and ways to maximise CR benefit transfer to improve people's lives.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Cognitive remediation in subjects with schizophrenia: Effectiveness and impact on use of psychiatric services

A. Vita

*University of Brescia, Clinical and Experimental Sciences, Brescia, Italy*

Cognitive remediation has been demonstrated to be effective in improving cognitive performance, psychosocial functioning and symptoms in patients with schizophrenia. However, the impact on the use of psychiatric services and the issue of cost-effectiveness of such treatments are still debated. Aim of this study was to investigate the impact of Cognitive Remediation on the use of psychiatric services and costs of treatments in patients with schizophrenia followed in a rehabilitation context, representative of the Italian psychiatric services.

Cognitive remediation in subjects with schizophrenia: effectiveness and impact on use of psychiatric services.

Eighty-four patients with schizophrenia (58 males, mean age  $39 \pm 9.9$ ) received, during a period of 6 months, either a cognitive remediation intervention (Integrated Psychological Therapy or Computer Assisted Cognitive Remediation) or a usual (non-structured, non-cognitively oriented) rehabilitation intervention, in addition to standard care. Data regarding the pattern and costs of service use, (number and days of hospitalizations in acute unit, number and days of stay in rehabilitative facilities, number of total outpatient interventions and number of total rehabilitative interventions), were gathered from an electronic administrative database in the 12 months before and after treatment and compared between Cognitive Remediation and usual rehabilitation groups.

The patients who received Cognitive Remediation showed a reduction of acute unit admissions after treatment. A lower number and duration (and relative cost) of acute unit admissions in the follow-up after treatment emerged in the Cognitive Remediation patients compared with the usual rehabilitation group. Other differences

in the pattern of use of psychiatric services emerged, suggesting a differential use of resources in patients who received Cognitive Remediation, more oriented towards rehabilitation rather than acute phase management.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0028

### Cognitive training in subjects at ultra-high risk for psychosis

M. Nordentoft<sup>1,\*</sup>, L. Glenthøj<sup>2</sup>, T. Kristensen<sup>3</sup>, C. Wenneberg<sup>2</sup>, K. Krakauer<sup>2</sup>

<sup>1</sup> Professor, Mental Health Center Copenhagen, Hellerup, Denmark; <sup>2</sup> Mental Health Services in the Capital Region of Denmark, Mental Health Center Copenhagen, Hellerup, Denmark; <sup>3</sup> Mental Health Services in the Capital Region of Denmark, Mental Health Services in the Capital Region of Denmark, Hellerup, Denmark

\* Corresponding author.

*Background.*– Cognitive deficits are distinct features of the ultra-high risk (UHR) state of psychosis and pose a barrier to functional recovery. Insufficient evidence exists on how to ameliorate these cognitive deficits in patients at UHR of psychosis and hence improve daily living and quality of life.

*Methods.*– The FOCUS trial is a randomized, parallel group, observer-blinded clinical trial enrolling 126 patients meeting the standardised criteria of being at UHR of psychosis. Patients are recruited from psychiatric in- and outpatient facilities in the Copenhagen catchment area. Patients are randomised to one of the two treatment arms: (1) cognitive remediation therapy (CRT) plus standard treatment versus (2) standard treatment. The cognitive remediation (CR) consists of 24 weekly groups-based and manualised sessions targeting neurocognition and social cognition. In addition to the group sessions the patients will be offered 12 individual sessions aiming at maximizing the transfer of the effects of the cognitive training to the everyday lives of the patients. The primary outcome is composite score on The Brief Assessment of Cognition in Schizophrenia (BACS) at cessation of treatment after six months. Secondary outcomes are social and daily functioning, psychosis-like symptoms, negative symptomatology, and depressive symptomatology as measured with the Personal and Social Performance Scale (PSP), Brief Psychiatric Rating Scale Expanded Version (BPRS-E), Scale for the Assessment of Negative Symptoms (SANS), The Schizophrenia Cognition Rating Scale (SCoRS) and The Montgomery-Åsberg Depression Rating Scale (MADRS) respectively.

*Discussion.*– This is the first trial to evaluate the effects of neurocognitive and social cognitive remediation in UHR patients. Our trial results will provide evidence on the effect of targeted and comprehensive cognitive rehabilitation on cognition, daily living and symptomatology as well as a long-term outcome in preventing transition to psychosis in UHR patients.

Trial registration: ClinicalTrials.gov NCT02098408.

S0029

### Cognitive dysfunction and remediation in affective disorders

G. Sachs<sup>1,\*</sup>, E. Maihofer<sup>2</sup>, H. Swoboda<sup>2</sup>, A. Berg<sup>1</sup>, I. Lasser<sup>1</sup>, G. Lenz<sup>1</sup>, A. Erfurth<sup>2</sup>

<sup>1</sup> Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria; <sup>2</sup> Otto-Wagner-Spital, 6th Psychiatric Department, Vienna, Austria

\* Corresponding author.

*Background.*– Cognitive deficits are a core feature in psychiatric disorders. Two studies were performed to further analyse cognitive dysfunction and its remediation in affective disorders.

*Methods.*– Study I – 43 remitted bipolar patients and 40 healthy controls were assessed with a neurocognitive test battery. In a randomised controlled trial, patients were assigned to add-on cognitive psychoeducational group therapy (CPEGT) over 14 weeks or to treatment-as-usual. A 12-month follow-up was performed.

Study II – 90 probands each with major depressive disorder (MDD), schizophrenia and healthy controls were included. A German version of the SCIP (Purdon, 2005) was first validated and then used. 50 patients each with MDD and schizophrenia were tested before and after a combination therapy with drugs and cognitive remediation. *Results.*– Study I – Compared to healthy controls, bipolar patients showed lower performance in executive function and sustained attention. CPEGT and attention predicted occupational functioning. Verbal memory recall was found to be a predictor for symptom severity.

Study II – Schizophrenic patients showed significant cognitive impairment compared to healthy probands. Patients with MDD showed an intermediate degree of impairment. In addition, the SCIP was able to detect an improvement in cognitive function in both MDD and schizophrenia patients after cognitive remediation.

*Conclusions.*– Bipolar patients benefit from CPEGT in the domain of occupational life. Deficits in sustained attention have an impact on occupational impairment. The SCIP in its German version is able to detect cognitive dysfunction and effects of cognitive remediation in MDD patients.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Symposium: Chronic Pain and Risk of Addiction

S0030

### Another important piece in a complex puzzle? Exploring significance of pain in alcohol dependence

A. Jakubczyk\*, M. Koperka, M. Wojnar

Medical University of Warsaw, Psychiatry, Warsaw, Poland

\* Corresponding author.

The use of alcohol is commonly considered a useful pain self-management strategy, with more than 25% of individuals with various pain symptoms reporting the use of ethanol for the purposes of analgesia. In this presentation associations between physical pain and well-recognized risk factors of alcohol dependence: sleep problems, depression, emotion dysregulation and impulsivity will be discussed. Moreover, results of recent research study investigating tolerance of pain as well as pain sensitivity in the group of Polish alcohol-dependent individuals will be revealed. This study showed that in comparison to controls alcohol-dependent individuals were significantly more likely to use ethanol for analgesic purposes ( $p = 0.00014$ ). Moreover, AD patients were characterized by significantly lower pain tolerance ( $p < 0.001$ ) and higher pain sensitivity, i.e. lower pain threshold ( $p < 0.001$ ). Moreover, analysis of the data suggests a significant discrepancy between results of behavioral and questionnaire measures of physical pain in alcohol dependent patients.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Assessing the risk of addiction in chronic pain management

G. Dom

Antwerp University UA-Belgium, Collaborative Antwerp Psychiatric Research Institute CAPRI, Boechout, Belgium

Chronic pain is increasingly prevalent within our Western Societies. Clinical decision making in when and how to start and manage pharmacological treatment of chronic pain is complicated by the risk on addiction to these substances. Indeed, many of these pharmacological compounds preclude addictive properties. The presentation will focus on clinically relevant issues in the treatment of chronic pain, including assessing the risk of initiating or precipitating addictive processes. An overview will be provided on how to assess pain patients on risk of abusing painkillers and how to mitigate the risk of developing subsequent addictive disorders.

*Disclosure of interest.*– Prof. Geert Dom was a member of the Scientific Advisory board Lundbeck for Nalmefene in Belgium.

### Symposium: Exercise Interventions as a Tool for Promoting Recovery in Schizophrenia

S0032

#### Impaired cardiac response to incremental exercise in patients with schizophrenia

K.J. Bar<sup>1,\*</sup>, M. Herbsleb<sup>2</sup>, H. Gabriel<sup>2</sup>, S. Andy<sup>1</sup>

<sup>1</sup> University Hospital Jena, Department of Psychiatry, Jena, Germany;

<sup>2</sup> University Jena, Department of Sports Medicine, Jena, Germany

\* Corresponding author.

The elevated cardiovascular risk of patients with schizophrenia contributes to a reduced life expectancy of 15–20 years. This study investigated whether cardiac autonomic dysfunction (CADF) in schizophrenia is related to chronotropic incompetence, an established cardiovascular risk marker.

We investigated thirty-two patients suffering from paranoid schizophrenia and 32 control subjects matched for age, sex, body mass index and fat free mass. A cardiopulmonary exercise test (CPET) was performed to study heart rate responses to exercise as well as submaximal (ventilatory threshold 1,  $VT_1$ ) and maximal endurance capacities (peak oxygen consumption,  $VO_{2peak}$ ; peak power output,  $P_{peak}$ ). In addition, epinephrine and norepinephrine levels were assessed in a subset of patients. Fitness parameters were significantly reduced in all patients. Most investigated physiological parameters were different at rest as well as during peak exercise being in line with previously described CADF in schizophrenia. In particular, 14 out of 32 patients were classified as chronotropically incompetent whereas no control subject was below the cut-off value. In addition, a positive correlation of a slope reflecting chronotropic incompetence with peak oxygen uptake ( $p < 0.001$ ) was observed in patients only indicating a close correlation to the lack of physical fitness. The catecholamine increase was reduced in patients after exercise.

This study identified a novel cardiac risk factor in patients with schizophrenia. Moreover, it seems to be associated with reduced physical fitness and indicates targets for exercise intervention studies.

#### Suicide prevention in an adolescent population in Kazakhstan

M. Sarchiapone<sup>1,\*</sup>, M. Iosue<sup>2</sup>

<sup>1</sup> University of Molise, Psychiatry, Campobasso, Italy; <sup>2</sup> University of Molise, Department of Medicine and Health Sciences, Campobasso, Italy

\* Corresponding author.

*Background.*– Suicide represents a serious social and public health problem in Kazakhstan, especially among adolescents. For this reason, UNICEF, in close collaboration with the National Centre for Mental Health of the Ministry of Health and local government of Kyzylorda Oblast, provided financial and logistical support for the development, implementation and assessment of the outcomes of a comprehensive school-based mental health promotion and suicide prevention project.

*Methods.*– The project was implemented in all the educational facilities of the Kyzylorda Oblast, involving more than 50,000 adolescents in school grades 8–10 and 1st course of colleges. It included the following components:

- Identification of adolescents at risk for suicide and mental health problems with referral to health and mental health workers.
- Gatekeeper training for school staff.
- Awareness raising intervention for adolescents.
- Building capacity of health and mental health services for management of adolescents at risk for suicide and mental health problems.

In order to assess the outcomes of the intervention, 54 schools were randomly selected leading to a sample of 4839 adolescents (mean age =  $14.14 \pm 1.16$ ; 47.6% male). 3748 adolescents (mean age =  $15.9 \pm 1.23$ ; 44.7% male) also completed the 12-month follow-up assessment, yielding to a good retention rate of 77.45%. The original plan also included a control sample recruited in the Aktobe region, nevertheless due to significant differences in terms of socio-demographic variables and prevalence of psychopathological symptoms it was not possible to compare the two samples.

*Results.*– The comparisons between baseline and follow-up data showed a significant positive effect of the intervention. Anxiety and stress symptoms, as well as suicidal ideation significantly decreased. A significant reduction of emotional symptoms, conduct problems, hyperactivity and peer problems was also observed. These positive results seem somehow enhanced in the subgroup of 180 adolescents identified as at risk during baseline. Indeed, in this subgroup the mean scores of almost all the pathological scales were halved, including the depressive symptoms, while the well-being index significantly increased. The intervention was also effective in somehow reducing perceived barriers to help-seeking, especially among at risk adolescents.

*Conclusions.*– The current mental health promotion and suicide prevention project showed promising positive effects on the overall Kyzylorda adolescents' sample and especially on the subgroup of at risk adolescents.

#### SUPREMOCOL: Suicide prevention by monitoring and collaborative care. A

## regional systems approach in Noord Brabant, the Netherlands

C. Van der Feltz Cornelis<sup>1\*</sup>, C. Van Nieuwenhuizen<sup>1</sup>, J. De Jong<sup>1</sup>, I. Elfeddali<sup>1</sup>, M. Bakker<sup>2</sup>, E. Hofstra<sup>1</sup>

<sup>1</sup> Tilburg University, Tranzo, Tilburg, The Netherlands; <sup>2</sup> Tilburg University, Methods and Techniques, Tilburg, The Netherlands

\* Corresponding author.

Suicide rates are a major public health concern and suicide rates are rising. In the Netherlands, suicide rates used to be amongst the lowest in Europe, but since the economic recession started in 2007, suicide rates have risen with approx. 38% to 1871 suicides in 2015. As most suicides occur in the context of mental disorder, the general idea used to be that treatment of the mental disorder would suffice to address suicidal behavior. Community suicide prevention programs can identify people at risk to commit suicide. However, a challenge remains, which is the finding that people at risk for suicide often do not enter treatment. Hence, system interventions and health services interventions are needed that address swift entrance to care of persons at risk to commit suicide. In the Netherlands, in 2014 and 2015 the province Noord-Brabant ranked 2nd nationally in terms of annual suicide numbers, although it contains 5 specialty mental health institutions and ten general hospital emergency rooms for a catchment area of 2.5 million people. Hence, with a research grant of the Netherlands Organisation for Health Research and Development, the research project SUPRE-MOCOL started in 2016 with the aim to reduce the number of suicides by 20% with the implementation of a suicide prevention system intervention in the province Noord Brabant. This combines identification of people at risk by gatekeepers with the aid of a web-based decision aid, swift entrance to crisis suicide prevention care in the specialty mental health setting, monitoring and casemanagement in a collaborative care model of psychiatric nurse, general practitioner and psychiatrist, and follow up for a year. The results are analysed by a Stepped Wedge Trial Design and Poisson regression analysis. After one year, the suicide rate in Noord Brabant had dropped in terms of absolute and relative numbers, and the national suicide incidence ranking of Noord Brabant had dropped from 2nd to 4th place. The SUPRE-MOCOL system intervention and first phase results will be discussed with the audience.

## From recontact strategies around the world to the French Vigilans Program

G. Vaiva<sup>1\*</sup>, D. Christophe<sup>2</sup>, J. Vincent<sup>3</sup>, D. Stéphane<sup>4</sup>, G. Pierre<sup>3</sup>

<sup>1</sup> CHRU de Lille, Service de psychiatrie adulte 59G08, Lille, France; <sup>2</sup> CHRU de Lille, Service de Psychiatrie Adulte – Dispositif Vigilans, Lille, France; <sup>3</sup> CHRU de Lille, Service de Psychiatrie Adulte, Lille, France; <sup>4</sup> CHRU de Lille, Centre d'Investigation Clinique, Lille, France

\* Corresponding author.

Up-to-date evidence suggests that conventional healthcare provision might not be sufficient to prevent reattempt and suicide completion. *Post-crisis prevention programs* developed a new sub-field of suicidology, and one of them must be distinguished: Brief Contact Interventions (BCI).

BCI serve two key objectives: Help patients in anticipating and coping by providing reliable and efficient tools; Pro-actively ensure preservation of a benevolent, non-intrusive link. Maintaining contact was found specially efficient if set on a regular, personalized, and long-term basis.

The BCIs may take different forms: *Telephone calls* to the suicide attempters; *“Shortletters” mailing*, consists in sending short letters

to the patients; *Postcards mailing*. Instead of letters, personalized postcards are sent; *Texting*. The effectiveness of text messages campaigns is currently tested in a French study.

Two meta-analyses suggested that patients benefitted from the recontact procedures, with significantly less relapse and suicide rates when compared to treated-as-usual controls. BCIs were shown to be differentially effective in subpopulations depending on patients' age, gender and self-harm history. . .

In 2011, ALGOS study tested an algorithm that articulated different types of BCIs during 6 months after a suicide attempt. Results suggested that ALGOS allowed for preservation or restoration of a feeling of belongingness in patients with a 5.6% reduction of reattempt rates in comparison to the treatment-as-usual group ( $p=0.024$ ).

Those results provided solid arguments to release and generalize ALGOS as an open healthcare offer: Vigilans, system developed in a 4.3 million inhabitants territory in the North of France.

### Overcoming the implementation gap in psychotherapy research by means of virtual-reality therapy

L. Valmaggia<sup>1,2</sup>

<sup>1</sup> King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom; <sup>2</sup> South London and Maudsley NHS Trust, London, United Kingdom

The use of Virtual Reality in mental health: Virtual Reality (VR) enables researchers and clinicians to bring social situations into the consultation room. The same virtual social environment can be presented to different participants to assess, in real-time, their neuro-cognitive functioning, appraisal, emotions, body response and behaviour. VR environments can also form the ideal platform for behavioural experiments and for gradual exposure as VR allows the manipulation of the environment, for example one can manipulate the background noise level or the appearance and behaviour of virtual characters. In my talk, I will give an overview of the use of VR in mental health and I will focus on the use of VR in therapy. *Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Enhancing resilience in teenagers by an online-prevention program

S.J. Schmidt

University Hospital of Child and Adolescent Psychiatry and Psychotherapy Bern, University of Bern, Bern, Switzerland

Mental disorders often begin in adolescence and are associated with huge psychosocial and financial burden. However, no satisfying improvements in the efficacy of interventions to treat manifest disorders have been achieved so far. Therefore, the development of prevention approaches for teenagers has attracted increasing interest with the aim to reduce the probability for the onset of a mental disorder or at least to positively influence its course and to minimize costs. Current prevention approaches mainly focus on

specific mental disorders or risk factors and were developed for adults. However, previous results emphasized the lack of specificity of early detection criteria in children and adolescents. Thus, the transdiagnostic promotion of resilience may be more promising in this age-group. Therefore, this talk will exemplify and discuss how resilience in teenagers can be enhanced by psychological interventions. Special emphasis will be put on online-interventions because they offer low-threshold access and may overcome fears and stigmatization as they can be delivered with a high level of confidentiality.

## **Symposium: Recovery-Oriented Approach to Severe Mental Disorders: Focusing on Key Variables to Improve Outcome**

S0038

### **Developing a focus on recovery in mental health systems**

M. Amering

Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

*Introduction.*– Recovery-orientation is widely endorsed as a guiding principle of mental health policy.

*Objective.*– Developing a focus on recovery in mental health systems warrants an understanding of the resulting new scientific and clinical responsibilities.

*Methods.*– Overview of published international guidelines, training modules and system transformation initiatives.

*Results.*– Recovery is more than a bottom-up movement turned into top-down mental health policy in English-speaking countries. It brings together major stakeholders in mental health, who share the responsibility for overcoming conceptual reductionism and unjustified prognostic negativism and move towards a rational and optimistic view of the possibilities of recovery. Recovery brings new rules for services, e.g. user involvement and person-centred care, as well as new tools for clinical collaborations, e.g. shared decision making and psychiatric advance directives. Alternatives to conventional services, pertaining to, e.g. acute crisis interventions and vocational rehabilitation need to be implemented in the context of emerging empirical evidence as well as legal developments with regard to self-determination and social inclusion. These developments are complemented by new anti-discrimination legislation and a call for the inclusion of the lived experience in service planning, quality assurance, research, and delivery. Data show peer support is feasible and effective in different forms.

*Conclusions.*– A proud exploitation and expansion of the possibilities of partnerships that support the promotion of recovery and the resilience and resources of persons with mental health problems and their families and friends has the potential to advance the mental health field combining good results with a good reputation and reduced stigma.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

The implementation of recovery-oriented plans requires an in depth understanding of key factors influencing real-life functioning of people with schizophrenia living in the community. The identification of key factors is challenging, requires sophisticated analyses, often involving several a priori assumptions.

In the present study, we applied a data-driven approach, the neural network analysis, to data collected on psychopathology, cognitive dysfunctions, functional capacity, personal resources and real-life functioning in a sample of 740 community-dwelling individuals with schizophrenia.

The resulting network showed that neurocognition, social cognition, resilience and indices of real-life functioning formed spatially contiguous patterns, with densely interconnected nodes. Psychopathology, instead, split in two subdomains, with positive symptoms being one of the most peripheral nodes. Functional capacity (FC) and everyday life skills (ELS) showed the highest centrality, interconnected with most network nodes. FC bridged everyday functioning and cognition measures and ELS bridged positive and disorganization symptoms, cognition, functional capacity and service engagement with real-word functioning. Interpersonal relationships and work skills showed a lower centrality in the network and a different pattern of connections: in fact, they connected with avolition, but not with FC.

The present findings have substantial treatment implications: positive symptoms do not play a key role in the chain of factors leading to real-life functioning, thus highlighting the need for treatment beyond antipsychotics. In line with the recovery-oriented approaches to schizophrenia, our findings indicate that everyday life skills should be the target of rehabilitation programs. The pattern of connections among the network nodes suggests that no program can fit all and, depending on the patient's characteristics, different rehabilitation programs should be implemented.

### **Treatment effectiveness in the real-world: Addressing adherence, burden and subjective well-being**

P. Gorwood

Hospital Sainte-Anne, CMME, Paris, France

Poor adherence is a major issue in schizophrenia, with frequencies ranging from 20% to 89% and important impact. Indeed, poor adherence is associated with worsening of symptoms, higher rates of relapse, reduced quality of life, unemployment, violence, victimization, suicide attempts, incarceration, and even death (Mallet et al., 2017).

Social functioning is also severely damaged by schizophrenia, which is detrimental for both patients and their families. Improving social functioning is recognized as an important treatment goal, beyond the alleviation of psychotic symptoms and also ranked as important by patients and their families.

Part of the consequences of poor adherence is explained by the limited feedback of antipsychotic treatment benefits and a low to moderate impact of individual, group, family or community-based psychosocial interventions, although many studies demonstrated utility in addressing social functioning impairments such as cognitive remediation therapy and social skills training.

During this presentation, we will review core features associated with, or sometimes explaining, poor adherence and low quality of life in schizophrenia, with a special focus on how to assess functionality levels. Indeed, the FROGS scale which is assessing the functionality of patients with schizophrenia was recently shortened to four items, to facilitate its use by clinicians, as these items cover all aspects of the longer version, and still has the psychometric qualities of the initial scale. Furthermore, we will share the results of a new study showing that a threshold for functional remission can be proposed for the miniFROGS with good consistency and reliability. This means that a quick and simple instrument can be used to assess functionality in patients with schizophrenia at all stages of the disorder, with an easy way to demonstrate to patients the benefit of constant care. Assessment is definitely not a treatment strategy, but not assessing the aim expected by patients (functional recovery) would constitute an important limit, reducing the chances for clinicians to “talk the same language” as patients.

*Disclosure of interest.*– Philip Gorwood received during the last 5 years, research grants from Eli Lilly, Ethypharm and Servier, and fees for presentations at congresses or participation in scientific boards from Alcediag-Alcen, AstraZeneca, Biocodex, Bristol-Myers-Squibb, Ethypharm, Janssen, Lilly, Lundbeck, Naurex, Otsuka, Roche, Sanofi Pasteur MSD, Servier.

S0041

### **Relationships between personal and clinical recovery: Implications for individualization and integration of treatment programs**

A. Rossi

*Department of Biotechnological and Applied Clinical Sciences, DISCAB, L'AQUILA, Italy*

Self-reported ‘personal recovery’ (SRPR) and clinical recovery in schizophrenia reflect different perspectives not necessarily concordant with each other, usually representing the consumer’s or the therapist’s point of views.

By means of a cluster analysis on SRPR-related variables, we identified three clusters: the first and third cluster included subjects with the best and the poorest clinical outcome respectively. The second one was characterized by better insight, higher levels of depression and stigma, lowest self-esteem and personal strength, and highest emotional coping. The first cluster showed positive features of recovery, while the third cluster negative features. The second cluster, with the most positive insight, showed a more complex pattern, a somewhat ‘paradoxical’ mixture of positive and negative personal and clinical features of recovery.

These results suggest the need for a characterization of persons with schizophrenia along SRPR and clinical recovery dimensions to design individualized and integrated treatment programs aimed to improve insight and coping strategies, reduce stigma, and shape recovery styles.

## **Symposium: Progress and Challenges in the Antipsychotic Treatment of Schizophrenia**

S0042

### **Have been too high doses of antipsychotics used in schizophrenia?**

I. Bitter

*Semmelweis University, Psychiatry and Psychotherapy, Budapest, Hungary*

From the 1970s the daily doses of antipsychotics used in the treatment of schizophrenia have increased to extreme doses in spite of the warnings from an increasing number of authors about the disadvantages and dangers of high dose “neuroleptic treatment” [1].

Mackay cited the British National Formulary, which was based on the product licenses. The “advisory maximum daily oral doses” were: for haloperidol “100 (occasionally 200)” mg/day. High doses were published and advertised as useful extension of therapeutic options.

The usefulness of high dose antipsychotic treatment as compared to medium and low doses has been challenged by many clinicians however high level evidence from randomized controlled studies was published only in the 1990s (e.g. [2]). However low doses were proven to effective already from the 1950s and this finding was supported by PET scan studies. The concept of neuroleptic threshold (dosing antipsychotics without having course extrapyramidal symptoms) promoted the use of low doses [3].

Current discussions about the disadvantages of long term use of antipsychotics have not fully addressed the potentially unnecessary use of high doses of antipsychotics. The advantages:disadvantages ratio maybe/is different for 2–5 mg/day haloperidol as compared to doses between 30 and 100+ mg/day.

Recent guidelines already advice the use of low/er doses of antipsychotics.

*Disclosure of interest.*– Research grant from Eli Lilly, personal fees from Eli Lilly, EGIS, Janssen/Janssen-Cilag, Lundbeck, Medavante, Pierre-Fabré, Gedeon Richter, and Servier, outside the submitted work.

In this original work, we have investigated the interest given by the main American social communication media to psychiatric information and to the most relevant mental health conditions. We

have also investigated the interest generated by this information on Twitter users. For that purpose, we have measured the tweets generated about mental health conditions by 15 main United States of America (USA) general communication media from January 2007 to December 2016. We have also analyzed the number of retweets generated by their Twitter followers.

In the decade analyzed, our results show that a total of 13,119 tweets have been sent by the American social communication media about mental health disorders with a heterogeneous distribution with preferential accumulation in a reduced number of disorders. The number of tweets sent regarding each different psychiatric disease analyzed was significantly correlated with the number of retweets generated by followers, that was a total of 1,030,974. However, the probability of a tweet being retweeted was statistically different between the diseases analyzed. For a control, we used tweets generated about the main causes of death in the USA, the main chronic neurological degenerative diseases and infection by the human immunodeficiency virus. In contrary to what we expected, the retweeted/tweet ratio was significantly higher in psychiatric diseases than in the control organic diseases. According to our results, the selected American social communication media and the general public demonstrate a preferential interest for psychiatric diseases.

### **Aggressions to psychiatric trainees by patients in Europe: Assessing the prevalence and policy**

A. Gürçan

Hacettepe University Faculty of Medicine, Department of Psychiatry, Ankara, Turkey

Psychiatric trainees can face the risk of suffering violence during their clinical practice. They might also be exposed to other incidents that affect their safety and the quality of their assistance to patients. This might lead to a loss of natural empathy and in serious cases to burn out. Trainees are particularly vulnerable, due to their daily closeness to patients and their families/care givers. They are also exposed due to their hours on duty and lack of experience towards these problems.

It is essential that the psychiatric trainees get knowledge on how to prevent and manage violence against them and about the legal framework in these cases. They should also be strongly supported by their senior colleagues and their institutions and count on legal advice if necessary. Hospitals and health authorities should establish protocols to be applied in cases of aggression to trainees. EFPT (European Federation of Psychiatric Trainees) aims to investigate the extent and depth of these problems in Europe, in order to raise awareness and affect the policymaking in this field.

In 2017, 25th EFPT Forum, psychiatric trainees from Europe concerned this issue, took this idea as a statement of EFPT and decided to design a study (Violence Against Psychiatric Trainees Project) to determine the current situation among European psychiatric trainees. In this session, preliminary findings and possible future directions of the project will be presented.

### **Supported and valued? A trainee-led review into morale and training within psychiatry**

A. Till

Royal College of Psychiatrists, Psychiatric Trainees' Committee, Liverpool, United Kingdom

Initiated in response to the junior doctor contract dispute in England, *Supported and Valued*, is a trainee-led review into morale and training within psychiatry. Conducted by the Royal College of Psychiatrists Psychiatric Trainees' Committee, 28 focus groups were held within every division and across all four nations of the UK. Each focus group followed a standardised format and concentrated on key lines of enquiry to explore what trainees thought was currently working well and what steps could be taken to improve their training and working lives in the future. Whilst many positives were identified, more must be done to achieve equitable training opportunities throughout the United Kingdom and it is the collective responsibility of all psychiatrists to be ambassadors for the profession and promote recruitment and retention in psychiatry.

## **Symposium: RTMS for Depression in Europe – It's Time for Approval from Health Authorities**

S0046

### **From multicentric studies to clinical guidelines – Two solutions between low and high frequency in the treatment of depression**

E. Poulet<sup>1,2,3,4</sup>

<sup>1</sup> INSERM U1028, CNRS UMR5292, PSYR2 Team, Lyon Neuroscience Research Center, Lyon-1 University, Lyon, France; <sup>2</sup> STEP Group Transcranial Stimulation in Psychiatry – AFPBN, Lyon, France; <sup>3</sup> Department of Emergency Psychiatry, Edouard Herriot Hospital, Hospices Civils de Lyon, Lyon, France; <sup>4</sup> Psychiatrie des Urgences des Hopitaux de Lyon, Lyon, France

To date, rTMS is a non-disputable solution for treating patients suffering from Major depressive episode, scientifically validated in the treatment algorithms for this pathology. Nevertheless, optimal parameters to use remain subject of debate. High frequency rTMS applied to the left dorsolateral prefrontal cortex (DLPFC) benefit of the higher level of proof with high power double blind parallel studies. However, to be efficient, it needs a long course of stimulation with about 40 min per session and 10 to 30 sessions. Shorter sessions would be very interesting at tolerability and medico economical levels. Growing evidences support the interest of applying safer low frequency stimulation to the right DLPFC and to associate this technique with antidepressant treatment as we recently published in a French multicentric study. Other approaches would be to diminish the duration of treatment using new parameters like theta burst stimuli. We propose in this talk to analyze recent publications in the treatment of depression through those different aspects. A synthesis of last recommendations could permit to better positioned rTMS in depression treatment and to argue for our health authorities for the recognition and the reimbursement of the methods in this indication [1,2].

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

Repetitive transcranial magnetic stimulation (rTMS) is an effective and well-tolerated treatment in resistant depression with mild to moderate intensity. The cost and medico-economic value of rTMS in psychiatry remains poorly known by clinicians, whereas they should be aware of economic aspects of such innovative care. We present how we assess rTMS cost production analysis as an in-hospital treatment for depression. The methodology, derived from analytical accounts, was validated by a multidisciplinary task force (clinicians, public health doctors, pharmacists, administrative officials and health economist). It was pragmatic, based on official and institutional documentary sources and from field practice. It included equipment, staff, and structure costs, to get an estimate as close to reality as possible. First, we estimated the production cost of rTMS session, based on our annual activity. We then estimated the cost of a cure, which includes 15 sessions. A sensitivity analysis was also performed. The hospital production cost of a cure for treating depression was estimated at €1932.94 (€503.55 for equipment, €1082.75 for the staff, and €346.65 for structural expenses). This cost-estimate has resulted from an innovative, pragmatic, and cooperative approach. It is slightly higher but more comprehensive than the costs estimated by the few international studies. However, it is limited due to structure-specific problems and activity. This work could be repeated in other circumstances in order to obtain a more general estimate, potentially helpful for determining an official price for the French health care system. Moreover, budgetary constraints and public health choices should be taken into consideration. ### Symposium: Women in Psychiatry – Differences in Career Paths Across Europe

S0048

#### Women in psychiatry – How to break through the glass ceiling

A. Szulc

Medical University of Warsaw, Department of Psychiatry, Pruszkow, Poland

In the last decades, the increase in the number of women entering medicine or psychiatry has not led to an increase in women in leadership positions. Women in academic medicine have continued to experience difficulties in their professional career.

Women in teaching roles in psychiatry can do a great deal to break down these gender barriers. Especially faculty women can be role models and provide mentoring to their colleagues. The insights into women psychiatrists career paths may be helpful to create the strategies for breaking the „glass ceiling” for younger colleagues.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0049

#### Mentoring for women in psychiatry

A. Riecher-Rössler

University of Basel Psychiatric Clinics, Center for Gender Research and Early Detection, Basel, Switzerland

*Introduction.*– More and more young psychiatrists are female. However, women are still underrepresented in leadership positions, be it in research or in the clinic.

Mentoring has been shown to be efficient in many disciplines to advance the career of young female professionals.

*Objectives.*– With this talk, mentoring for young female psychiatrists shall be stimulated.

*Methods.*– Models of mentoring will be presented as well as different studies on mentoring in academic medicine and its success.

*Results.*– The professional career of women in psychiatry is still impeded, not only by institutional but also by psychological barriers such as gender role behavior and gender role stereotypes. Mentoring can help young women to overcome these barriers. Ideally, mentoring programs should start very early, already during the university studies, because important decisions about future career steps are often already made then. Mentoring should not only address young women but also young men, especially regarding their gender role behavior and stereotypes. Mentoring should continue during the further career steps of women, since for them there is not only a “glass ceiling” that excludes them from achieving leading positions, they also have to face specific problems if they have finally achieved such positions.

*Conclusions.*– Mentoring programs considering gender-specific needs should be implemented in the regular teaching during medical studies and in psychiatric Training.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Women in academic psychiatry

M. Amering<sup>1,\*</sup>, A. Gmeiner<sup>2</sup>, B. Schrank<sup>3</sup>, S. Süßenbacher<sup>2</sup>  
<sup>1</sup> Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria; <sup>2</sup> Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria; <sup>3</sup> Karl Landsteiner University of Health Sciences, Department of Adult Psychiatry, Tulln, Austria

\* Corresponding author.

*Introduction.*– Women play a growing and important role in academic psychiatry.

*Objectives.*– Present and discuss recent developments and current challenges for gender parity in academic psychiatry.

*Methods.*– Data on women's progress in high-impact publication activities over the last decades as well as evidence and experience of barriers with regard to the goal of gender parity in academic psychiatry will be presented and discussed.

*Results.*– A retrospective bibliometric review in three high-ranking general psychiatry journals showed an overall increase of the percentage of female authors from 1994 to 2014. Though increases in female authorship were statistically significant for both decades, there was less difference between 2004 and 2014, indicating a possible ceiling effect. Rates of female first authors showed a similar picture and numbers of female corresponding authors plateaued between 2004 and 2014. Within Europe, Scandinavia displayed the most balanced gender-wise first author ratios. The progress towards gender-parity has been slower and less pronounced than could have been expected from women's increasing influx into academic psychiatry suggesting that interventions beyond the mere recruitment of female scientists will be necessary to achieve gender parity and overcome more or less subtle gender biases in academic medicine. Specific interventions on different levels seem effective and warrant further implementation and evaluation.

*Conclusion.*– Despite gains in some areas, considerable deficits with regard to gender parity exist in the current academic psychiatric landscape. Ongoing efforts and interventions to enhance the participation of women on institutional, political and editorial levels are necessary.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Symposium: The Importance of Resilience to the Prevention of Mental Disorders

S0051

### Disentangling resilience and wellbeing

F. Schultze-Lutter<sup>1,\*</sup>, S.J. Schmidt<sup>2</sup>  
<sup>1</sup> Heinrich Heine University, Department of Psychiatry and Psychotherapy, Duesseldorf, Germany; <sup>2</sup> University of Bern, University Hospital of Child and Adolescent Psychiatry and Psychotherapy, Bern, Switzerland

\* Corresponding author.

Resilience and well-being have become commonplace and increasingly used terms in a wide range of scientific as well as mental health political contexts. Yet, both terms lack clear definitions, resulting in an often rather diffuse use of terms that is further aggravated by the confusion about the relationship of the two constructs.

While some use well-being as a proxy measure of resilience, others treat one concept as a component of the other or see interchangeably one as the prerequisite of the other. Thus, in order to get a clearer picture of these two concepts and possible ways to better differentiate the two, we studied the current literature for the definition of these two concepts in relation to each other.

We found that both 'resilience' as well as 'well-being', have so far defied universal definition and common understanding of their respective measurement. Part of the confusion around these two concepts is the overlap in their components, in particular with regard to resilience and psychological well-being, and the lack of research on these concepts both by themselves, in relation to each other and in relation to other concepts like mental health, risk or protective (or promotive) factors.

Our critical and comparative inspection of both concepts highlighted the need for more conceptual cross-sectional as well as longitudinal studies (a) to uncover the composition of these constructs and to reach agreement on their definition and measurement, (b) to detect their potential neurobiological underpinnings, (c) to reveal how they relate to each other, and (d) to determine the potential role of developmental and cultural peculiarities. For the time being, however, the use of the terms resilience and well-being should always be accompanied by a brief explanation of their respective meanings and theoretical framework.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0052

### Cultural aspects of resilience and wellbeing

C.A. Essau

University of Roehampton, Psychology, London, United Kingdom

### Transdiagnostic intervention programme for anxiety and depression in young people

*Introduction.*– Anxiety and depression are among the most common psychiatric disorders affecting young people. These disorders also co-occur frequently with other psychiatric disorders. When left untreated, anxiety and depression which begin early in life can become chronic and are often associated with a negative course. Drawing from the above research, a transdiagnostic treatment protocol ("Super Skills for Life"; SSL) was developed for young people with anxiety and depression. SSL is based on the principles of cognitive behavioural therapy, behavioural activation, social skills training, and uses video-feedback and cognitive preparation as part of the treatment.

*Objectives.*– This study evaluated the effectiveness of SSL in reducing children's anxiety and depressive symptoms, and in enhancing social skills, executive functioning, and emotion regulation.

*Methods.*– A total of 63 children with emotional problems, aged between 8 and 10 years participated in this study. They completed a set of questionnaires to measure emotional problems, social skills and emotion regulation at pre- and post-treatment and at follow-up. They also did experimental tasks that were used to measure cognitive bias and executive functioning.

*Results.*– There was a significant reduction on children's emotional problems, as well as an improvement in executive functioning and positive emotional regulation strategies at post-intervention and at follow-up. Video data taken during the 2-minute speech (i.e., gaze, vocal quality, length, discomfort level, conversation flow), supported the self-report data, in showing significant improvement after the intervention.

*Conclusion.*– This study provides empirical support for the effectiveness of SSL in children with anxiety and depression.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0053

### **Enhancing resilience in a stepwise primary preventive approach**

S.J. Schmidt

*University Hospital of Child and Adolescent Psychiatry and Psychotherapy Bern, University of Bern, Bern, Switzerland*

Interventions with the aim to prevent mental disorders and/or to enhance resilience have become increasingly available. However, their effects are often not sustained over the long-term and their implementation in clinical practice is generally associated with a loss of efficacy and often insufficient. This may be due to the fact that patients in service settings tend to have higher rates of comorbidities and more frequently changing therapy needs than those in research settings. Thus, stepwise or modular interventions are promising as they allow the treatment protocol to be adapted to patients' individual needs. This may be especially relevant for individuals with first signs of an emerging mental disorder and/or deficits in protective factors associated with resilience because mental health problems as well as therapy motivation are highly fluctuating in this early stage of the development of mental disorders. Against this background, this talk will discuss primary prevention approaches to enhance resilience using a stepped or modular design.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Symposium: Individualised Treatments for Obsessive-Compulsive Disorders: From Bench to Bedside**

S0054

### **Biological models in obsessive-compulsive disorder**

J. Menchon

*Bellvitge University Hospital-IDIBELL, University of Barcelona, Cibersam, Department of Psychiatry, Barcelona, Spain*

One of the first consistent neurobiological models of obsessive-compulsive disorder (OCD) was the corticostriatal model. This model suggested a dysfunction of the cortico-striato-thalamo-cortical (CSTC) circuit, which is relevant in behavioral control functions. This model was further developed with the proposal of an imbalance between the direct and the indirect pathways within specific CSTC circuits. However, new data coming from the many neuroimage studies carried out in OCD patients have involved other specific and diverse neuroanatomical regions, such as the bed nucleus of the stria terminalis, cingulate cortex, anterior insula or the amygdala, among others. Another level of studies have examined candidate endophenotypes, neuropsychological markers and cognitive domains, such as compulsivity, cognitive and behavioural inhibition (motor inhibition, cognitive inflexibility), reversal learning, habit formation (shift from goal-directed to habitual responding), their dysfunctions in OCD and its relationship with neuroanatomical regions. At a clinical level, the heterogeneity of OCD symptoms suggests that common and different components of dysfunctional neuroanatomical regions and circuits may be involved in the clinical expression and outcome of OCD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0055

### **The International College of Obsessive-Compulsive Spectrum Disorders (ICOCS) snapshot study: Results and clinical correlates**

B. Dell'Osso

*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Dipartimento di Neuroscienze Unità Operativa di Psichiatria, Milano, Italy*

The International College of Obsessive Compulsive Spectrum Disorders (ICOCS, [www.icocs.org](http://www.icocs.org)) gathered a series of experts in the field of obsessive compulsive disorder (OCD) and related conditions, with the common interest to improve diagnosis and encourage better deployment of resources for assessment and treatment in the field. Amongst the various initiatives aimed at advancing, promoting and facilitating research into the causes and consequences of OCD and related conditions, the creation of a shared "snapshot" database, approximately 10 years ago, allowed to create an international large clinical sample of approximately 500 patients attending OCD tertiary Clinics worldwide, affiliated with the ICOCS. To date, the database has been analysed in different directions, allowing to generate new data in relation to the influence of specific variables (i.e. early onset and long duration of illness) over the long term course of OCD, the lifetime prevalence of specific patterns of comorbidity, of cigarette smoking, of childhood, adolescent and adult onset, of suicide attempts and of geriatric OCD within the collected sample. Of note, in some cases, significant differences were observed when the above mentioned variables were compared across the participating centers, indicating the presence of cultural/geographic peculiarities in patients suffering from OCD. In the course of the presentation, an overview of the ICOCS studies and main results will be provided as well as compared with other similar investigation in the field.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0056

### **Duration of untreated illness, dynamic adherence and response to treatment in OCD**

U. Albert\*, F. Barbaro, S. Bramante, G. Maina

*University of Turin, AOU San Luigi Gonzaga, Department of Neuroscience, Psychiatric Section, Orbassano Torino, Italy*

\* Corresponding author.

*Introduction.*– OCD is a severe, heterogeneous disorder that affects nearly 2% of the adult population. Such heterogeneity may impact on the duration of untreated illness (DUI), that is the interval between the onset of the disorder and the first adequate treatment. Previous studies found that a longer DUI (>24 months) is associated with poor response to drug treatment, although the specific effect on the first treatment is not clear.

*Objectives.*– To determine (1) the mean DUI in a sample of OCD patients, (2) the effect of a longer DUI on treatment response, and (3) factors associated with longer DUI.

*Methods.*– We evaluated 251 subjects with a SCID-I (DSM-IV) diagnosis of OCD who received a pharmacological treatment according to International Guidelines. Response was defined as a YBOCS decrease  $\geq 25\%$ .

**Results.**– The mean DUI was 106.19 months (mean age at onset: 22.21 years, mean age at first contact with mental health professionals: 29.03 years, mean age at first adequate treatment: 31.04 years). Using the median value, a categorical cut-off for DUI of 60 months was calculated. Both using the median cutoff and using the cutoff of 24 months, a longer DUI was predictive of non-response. Factors associated with a longer DUI were an earlier age at onset, not being married, contamination obsessions and washing/cleaning compulsions, comorbid major depression, comorbid personality disorder, comorbid substance use disorder, and comorbid medical disorders.

**Conclusions.**– Clinicians should try to shorten as possible the DUI as it is associated with resistance to treatments and greater medical comorbidities.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

S0057

### **New treatment strategies for OCD**

N. Fineberg

*Hertfordshire Partnership University NHS Foundation Trust, Psychiatry, Welwyn Garden City, United Kingdom*

OCD and related disorders are distressing and disabling disorders with high rates of psychiatric comorbidity. They pursue a chronic relapsing course. Of the disorders, OCD is the most researched. Treatment with CBT or SSRI is effective in about 50% of cases. For treatment-responders, continuation of SSRI is known to provide some protection, but relapse is nonetheless common. For SSRI-resistant OCD, a number of potentially efficacious augmentation strategies have been studied, of which adjunctive low dose antipsychotic is supported by the most robust data, but again the effect is highly variable.

In this lecture, we will present new data from a randomised controlled feasibility trial suggesting that combining SSRI with CBT may be more clinically effective than either monotherapy in the short term and that SSRI monotherapy may be the most clinically effective and cost effective treatment in the longer term. However, the study draws attention to the considerable variability in response that occurs within each treatment arm. There is thus considerable scope for research to identify treatments that produce better overall clinical outcomes, and for clinical or somatic markers to guide treatment selection at the level of the patient, to achieve better individualised outcomes.

To this end, novel pharmacological compounds are under investigation, including drugs acting to modulate glutamate neurotransmission. Highly Specialized Services are helpful for the most severe and enduring cases. For these individuals, experimental somatic treatments involving neuro-modulation or ablative neurosurgery may also be considered. Treatments and services will be discussed.

**Disclosure of interest.**– In the past several years, Dr. Fineberg has received research support from Lundbeck, Glaxo-SmithKline, European College of Neuropsychopharmacology (ECNP), Servier, Cephalon, Astra Zeneca, Medical Research Council (UK), National Institute for Health Research, Wellcome Foundation, University of Hertfordshire, EU (FP7), and Shire. Dr. Fineberg has received honoraria for lectures at scientific meetings from Abbott, Otsuka, Lundbeck, Servier, Astra Zeneca, Jazz pharmaceuticals, Bristol Myers Squibb, UK College of Mental Health Pharmacists, and British Association for Psychopharmacology (BAP). Dr. Fineberg has received financial support to attend scientific meetings from RANZCP, Shire, Janssen, Lundbeck, Servier, Novartis, Bristol Myers Squibb, Cephalon, International College of Obsessive–Compulsive Spectrum Disorders, International Society

for the study of Behavioral Addiction, CINP, IFMAD, ECNP, BAP, World Health Organization, and Royal College of Psychiatrists. Dr Fineberg has received financial royalties for publications from Oxford University Press and payment for editorial duties from Taylor and Francis.

**Acknowledgement.**– This abstract presents independent research funded by the National Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB) Programme (Grant Reference Number PB-PG-0712-28044). The views expressed are those of the author(s) and not necessarily those of the NHS, the NIHR or the Department of Health.

## **Symposium: Women Migrants and Refugees: A Case for Special Mental Health Needs?**

S0058

### **Problems faced by women refugees: An overview**

M. Carisius Kastrop

*Dr, Own Firm, Copenhagen, Denmark*

Women and men have different life conditions, they are exposed to different traumata and experiences of trust. Trust depends upon refugee women's sense of security publicly and at home and data demonstrates that public interest in sexual harassment and abuse is associated to women's general level of anxiety and sense of victimhood.

There is increasing attention paid to providing comprehensive care to refugee women recognising that many are subjected to other severe forms of abuse frequently of a sexual nature. Further, they frequently come from societies where women's role is primarily centred round the home. Such women may need particular attention when having to cope with the refugee situation in order to avoid that their particular needs are neglected in the host country when it comes to integration initiatives. Many migrant women may feel dis-empowered when coming to a new environment, and therapeutic interventions should have empowerment as a goal helping such women to develop skills to gain control over their life without infringing on others rights.

To achieve this we have to listen and support the proposals to solutions these women bring forward even if they do not coincide with our own ideas, discuss their solutions and try to understand their cognitive and emotional world view by building a bridge over cultural incongruence. But also to support any initiative that may diminish women's confidence in being protected against violence and abuse at home. This is a major public health issue presently and a challenge to psychiatry.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **How to address the perinatal needs of women refugees: An example from France**

A.L. Sutter-Dallay\*, E. Glatigny-Dallay

*Perinatal Psychiatry Network, University Department of Adult Psychiatry, Bordeaux cedex, France*

\* Corresponding author.

The reception of migrants has become a major concern of European governments, but also of health professionals, because of the overall precariousness of these populations. The separation

of families during their migration is unfortunately frequent, and many women are alone with their children upon arrival. When a pregnancy is in progress the vulnerability, especially psychological, of these women is extreme, since the perinatal period is in itself and for all women a period of transition and stress. In this paper, we will present, based on a clinical case, the system of prevention and care that was developed by a perinatal psychiatry network, to best support these populations of migrant women and infants as early as possible. This organization is based on the elaboration of coordinated and graduated pathway to care, both for their somatic and psychosocial healths, according to the different vulnerabilities of each family and associating all the actors of the perinatal health. The obstetrical and paediatric teams as well as social services are associated to the work of perinatal psychiatry services (from joint admissions to home visits), with a particular attention to the notion of “joint care”, for the mother and the child, but also the rest of the family.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0060

### Trauma and migration

M. Schouler-Ocak

*Psychiatric University Clinic of Charité at St. Hedwig Hospital, Psychiatry and Psychotherapy, Berlin, Germany*

Forcible displaced people constitute one of the highest risk groups in terms of developing mental disorders and are one of the most vulnerable groups in society. Although the worldwide numbers of refugees and asylum seekers show an upward trend. The proportion of traumatised people with a serious mental disorder is very high, the available healthcare systems are not prepared for this specialised group of traumatised migrants. The precarious situation which many of the afflicted find themselves in means that it is even more important to bring refugees and asylum seekers under the spotlight of diagnostic and therapeutic attention.

Many studies reported on the multiple and highly complex stressors with which refugees are often faced, and which are at risk of having a lasting impact on their mental health. These might be experiences of traumatisation before, during and after the actual journey of migration. If they succeed in leaving the crisis area, this journey is often a long and tortuous one on which they may be exposed to other traumatic events. When they finally arrive in the host country that they may have long been yearning for, they usually have to deal with sharing cramped accommodation, often with very poor sanitary facilities, next door to strangers from other cultures and unable to make themselves understand. A lack of future perspectives exacerbates the situation.

In this talk current data from a representative study on the mental health situation of female refugees and asylum seekers will be presented and discussed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0061

### Risk factors for depression and PTSD amongst homeless refugees

M. Melchior

*Pierre Louis Institute of Epidemiology and Public Health, Social Epidemiology, Paris, France*

Migrants tend to have higher levels of mental health difficulties than the native population, especially if the reasons for which they migrated include violent causes. Additionally, migrants tend to experience high levels of socioeconomic difficulties, which could

further compound their mental health difficulties. We aimed to describe the level of mental health difficulties among migrant women who are homeless, a particularly vulnerable population. Using data from the ENFAMS survey conducted in the Paris region, we find that migrant women who do not have permanent housing have approximately threefold levels of depression and post-traumatic stress disorder compared to the general population. This excess risk is related to exposure to traumatic events and family disruptions prior to, during and after migration. Nevertheless, the level of access to mental health care is negligible. Overall, our findings point to the high vulnerability of migrant women who experience socioeconomic disadvantage, and the need for the health care system to design appropriate interventions to address their mental health needs.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Symposium: Promoting Mental Health Following Terrorist Attacks

S0062

#### Violence: Could psychiatry have a role in understanding and eliminating it?

L. Küey

*Istanbul Bilgi University, Department of Psychology, Istanbul, Turkey*

Scientific models constructed to understand the human violence and aggression refer to the interaction of biological, psychosocial, cultural and economic-political factors. The links between violence, aggression and mental health are well documented. Violence and related consequences should be treated as a major public mental health issue.

The forms and degree of violence are highly determined by the psychosocial milieu. Furthermore, people with high levels of exposure to violence, report more psychological maladjustment and interpersonal problems. The cycle from exposure to later perpetration of aggression triggers the vicious circle of violence.

Mass violence, terrorist attacks and human rights violations, challenge five core adaptive systems subserving the functions of “safety,” “attachment,” “justice,” “identity-role,” and “existential-meaning.” Race, ethnicity, gender, and religion based prejudice and discrimination have caused vast human suffering in almost all societies across the world. Many mass violence acts and terrorist attacks have been executed in the name of such group differences. Violence while creating unstable and risky victories on one side, also creates loss of lives and disability on the other. Neither the “winners” nor the “losers” can live in a trust worthy human environment. Violence begets violence. The mounting of aggression and violence in the social environment diminishes the ability of self-control; this loss of self-control causes feelings of shame and guilt and more hate; and the double helix of violence brings both groups to a common end; even having different reference systems, the outcome is the same: violence towards the other.

Increasing evidence shows that violence we suffer is neither fated nor inevitable; and cooperation and solidarity are also self-reinforcing human behaviors.

Psychiatrists and mental health professionals have a long history of aiming and practicing more inclusive ways of solving conflicts of interests between in-groups and out-groups. This presentation aims to discuss the role that psychiatry and mental health field could play in understanding and preventing the development of violent behavior.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0063

### Utoya, Nice, Munich: Is there a psychopathological link in recent terroristic attacks?

A. Raballo

Norwegian University of Science and Technology, Department of Psychology, Trondheim, Norway

Self-declared anti-multiculturalist, anti-Marxist, anti-Islamist, as well as “the greatest defender of conservative culture in Europe since 1950”, Anders Behring Breivik killed 77 people on July 22, 2011. On July 14th 2016, Mohamed Lahouaiej-Bouhlel, drove a refrigerator truck on the crowd celebrating Bastille Day on the Promenade des Anglais in Nice. A few days later, on the fifth anniversary of Utøya, Ali David Somboly, caused 9 dead and 35 wounded before committing suicide in the Olympia shopping center in Munich. Despite contingent contextual differences, the recognizable psychopathological trajectories of all the three, reveal important commonalities that might be worth analysing.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0064

### The role of scientific societies in promoting positive mental health

A. Fiorillo\*, M. Luciano

University of Campania “Luigi Vanvitelli”, Department of Psychiatry, Naples, Italy

\* Corresponding author.

Terroristic attacks and disasters represent a growing concern in modern society, nurturing the perception of global insecurity in the general population. The impact of terroristic attacks on mental health is not limited to inhabitants of the country under attack; it also extends to people far away and without immediate relation to it. Many international professional bodies are trying to counteract the detrimental effects of terroristic attacks on mental health and wellbeing. In particular, understanding the complex biological, psychological and social roots of violence and terroristic attacks can lead to the formulation of specific interventions that can prevent or alleviate consequences. Moreover, clarifying that terrorism is not a mental disorder but a phenomenon often associated with oppression and absence of opportunities for free expression can reduce stigma attached to mental disorders.

Tasks for psychiatrists will include to: (a) provide a psychopathological analysis of the process of radicalization; (b) clarify the relationship between terrorism and mental health; (c) develop strategies for managing mental health in victims of terroristic attacks; (d) develop guidelines for de-radicalization of terrorists; (e) promote the communication with media professionals.

In conclusion, in an era of uncertainty and terrorism, scientific associations may play a crucial role in the promotion of positive mental health and wellbeing in the general population from an educational, research and clinical practice viewpoint.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Symposium: New Challenges in the Treatment of Negative Symptoms in Schizophrenia

S0065

### Pathophysiology of negative symptoms – Current developments and their implications for treatment

S. Kaiser

Geneva University Hospitals, Adult Psychiatry Division, Geneva, Switzerland

Negative symptoms include two main domains – diminished expression and diminished motivation (or apathy). Diminished expression consists of the individual symptoms alogia and affective flattening, while diminished motivation includes avolition, asociality and anhedonia. Here we provide an overview on recent research differentiating the pathophysiology of apathy and diminished expression.

Research on apathy and diminished motivation has concerned the processes underlying goal-directed behavior, in particular those related to reward processing. The main constructs of interest concern a reduced anticipation of pleasure and reward, a dysfunctional computation of efforts and costs related to an action and finally impaired learning from rewarding outcomes. In addition, apathy has also been linked to cognitive function, in particular an impairment in the processes relevant for planning and executing goal-direct actions.

The domain diminished expression has thus far received less attention. An effect of limited cognitive resources on expressivity has been proposed, while recent research has more directly addressed the processes related to emotional responsivity. Overall, a comprehensive model of diminished expression is still lacking.

The development of treatment approaches is only beginning to take the heterogeneity of negative symptoms into account. Nevertheless there is initial evidence that different psychotherapeutic approaches might specifically improve one negative symptom domain, while there are very few psychopharmacologic studies addressing this issue.

*Disclosure of interest.*– SK receives royalties for cognitive test and training software from Schuhfried (Austria).

S0066

### What are the best assessments to target negative symptoms in clinical and research practices?

S. Dollfus<sup>1,\*</sup>, C. Delouche<sup>2</sup>, R. Morello<sup>3</sup>

<sup>1</sup> University of Caen Normandie, Department of Psychiatry, Caen, France; <sup>2</sup> CHU Caen, Department of Psychiatry, Caen, France; <sup>3</sup> CHU Caen, Department of Biostatistics, Caen, France

\* Corresponding author.

Severe negative symptoms are found in many patients with schizophrenia. The assessment of negative symptoms is challenging due to the low inter-rater reliability and the interrelations with other dimensions, such as depression, extrapyramidal symptoms, social withdrawal secondary to positive symptoms, and institutionalization. Moreover, these symptoms are responsible for impaired social functioning and have a deleterious impact on the quality of life. In this context, the use of standardized assessment tools may be pertinent to improve the identification of negative symptoms and their treatment. A recent review of the literature included nearly 20 tools used to assess the negative dimension of schizophrenia. Recently, new scales have appeared, the most well-known being

the Brief Negative Symptoms Scale (BNSS) and the Clinical Assessment Interview for Negative Symptoms (CAINS), which meet the criteria presented at a consensus conference on the agreement of negative symptoms.

An analysis of the tools highlighted the predominance of assessments based on observer ratings (hetero-assessments) over self-assessments, as well as the need to evaluate five negative dimensions (asociality, blunted affect, avolition, anhedonia, and alogia). Recently Motivation and Pleasure Scale Self-Report (MAPSR), a version of the CAINS self-report, was developed but it fails to cover the five negative dimensions required.

Self-assessment is pertinent as it allows the patients to evaluate their overall functioning and requires their participation and analysis of their own symptoms. Moreover, self-assessment is a time-efficient method for the initial identification of negative symptoms and could be useful for detecting negative symptoms in the early stages of schizophrenic disease. In addition to hetero-evaluation, self-evaluation also provides clinical information not necessarily detected by caregivers or medical staff in a standard interview and can provide some information on the symptoms recognized by the patients themselves.

This presentation aimed to present a novel tool, the Self-evaluation of Negative Symptoms (SNS), and demonstrate its validity, its specificity and sensitivity in patients with schizophrenia compared to healthy subjects and patients with depression.

*Disclosure of interest.*– Expert: Fabre, Janssen, Lundbeck, Gedeon. Conference: Lundbeck/Otsuka, Janssen.

### Pharmacological treatment of negative symptoms in schizophrenia

I. Bitter

*Semmelweis University, Psychiatry and Psychotherapy, Budapest, Hungary*

Negative symptoms represent a core domain of psychopathology in schizophrenia and are associated with poor functioning and structural brain changes. Primary (predominant and persistent) negative symptoms respond poorly to antipsychotic treatment. Clinical studies testing a number of drugs with various mechanism of action could not show clinically meaningful efficacy in the treatment of primary negative symptoms.

Recent development of partial agonist drugs antipsychotic drugs preferentially binding to D3 receptors as compared to D2 receptors, such as cariprazine and F 17464 [1] may offer new options for the treatment of predominant and persistent negative symptoms while having the “traditional” antipsychotic efficacy in the acute phase against positive symptoms and being efficacious in the relapse prevention. Preclinical research about D3 receptors provided a good basis for the clinical development of drugs affecting these receptors [2]. Cariprazine has been found significantly superior in a head to head comparison to risperidone in the treatment predominant and persistent negative symptoms as measured by the Marder factor of the PANSS scale, and this improvement was associated with significant improvement in the functioning of the patients [3].

Non-dopaminergic drugs are also in the phase of clinical development for the treatment of negative symptoms, such as pimavanserin (which is a drug registered by the FDA for the treatment of psychosis in Parkinson’s disease, see Pimavanserin in the references below [4]) and MIN-101 [5].

Drug treatment has to be delivered as part of a comprehensive treatment program [6].

### Cognitive behavioral therapy of negative symptoms in schizophrenia

L. Lecardeur

*Centre Hospitalier Universitaire de Caen, Equipe Mobile de Soins Intensifs – Centre Esquirol, Caen, France*

Current models of negative symptoms include blunted affect, anhedonia, alogia, asociality and avolition. These symptoms can be seen as primary, i.e. intrinsic to the pathophysiology of psychotic disorders and/or as secondary, i.e. induced by other factors such as positive symptoms, comorbid social anxiety or side effects of medication. Negative symptoms are mostly enduring or persistent, they strongly decrease patients’ functioning and do not respond to available antipsychotic medication. The goals of Cognitive behavioral therapy (CBT) are diverse, ranging from specific symptom reduction, increased insight and understanding of illness, distress reduction, and the development of adaptive coping skills. CBT is currently the only psychotherapeutic treatment that has proven evidence of efficacy to alleviate some of negative symptoms (i.e. apathy, avolition, poverty of content and thought, flat affect). The group studies available also report beneficial effects from this type of CBT on negative symptomatology. The aim of the conference is to describe latest results of CBT in the treatment of negative symptoms in patients with schizophrenia.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Symposium: Molecular and Brain Imaging Biomarkers of Response to Lithium Treatment

#### Transcriptomics and miRNomics combining analyses in lymphoblastoid cell lines of bipolar patients identified networks associated with treatment response

A. Cattaneo

*IRCCS Fatebenefratelli Brescia, Biological Psychiatry Unit, Brescia, Italy*

Bipolar disorder is a highly prevalent disorder, and it is considered among the most burdensome condition worldwide, with a high rate of suicide attempts. This is also in part associated with the high heterogeneity of the disorder, that in turn can influence the correct diagnosis and thus the future disease course and outcome. Lithium is the most frequently recommended first-line treatment in clinical practice guidelines, however, around the 30–55% of individuals

do not benefit of the treatment with consequences for the severity of illness. Up to know, there are no biological biomarkers that can identify the patients that will not benefit of lithium treatment and thus that should be treated with different options from the beginning.

Here in this talk, I will show a novel approach to identify possible blood biomarkers associated with treatment response by using lymphoblastoid cell lines obtained from patients with bipolar disorder and characterized for lithium response by using the Alda questionnaire that includes 6 categories of prophylactic response from no response for at least two years of treatment to no relapse for three years.

In particular, first I will show transcriptomic and miRNome signatures specifically associated, in these cells, with patients that do not successfully respond to lithium. Moreover, I will show a combining approach, where genes differentially expressed in responder patients versus non-responders will be integrated with miRNAs, that, similarly, will result as differentially expressed in responders versus non-responders. This will allow the identification of a gene expression signature more specifically associated with treatment response, and of another one associated with non-response to lithium.

The identification of these biomarkers could open a novel scenery not only in the early identification of patients where lithium will fail, but also, in the identification of novel pathways and network to be used for the development of novel pharmacological or non pharmacological interventions.

### DNA methylation signatures of lithium response

C. Marie-Claire<sup>1,\*</sup>, F. Bellivier<sup>2</sup>, B. Etain<sup>2</sup>

<sup>1</sup> INSERM UMR-S 1144, Variability of Response to psychotropic drugs, Paris, France; <sup>2</sup> AP-HP, GH Saint-Louis – Lariboisière – F. Widal, Psychiatrie et Médecine Addictologique, Paris, France

\* Corresponding author.

Lithium (Li) is used as a first line prophylactic agent in bipolar disorder (BD). It has proven its efficacy for acute manic episodes treatment, mood relapses prevention and suicidal behaviors reduction. However, only one third of the patients fully respond to this treatment. In the absence of robust clinical predictors a lengthy treatment trial is needed to characterize responders. Identification of biological biomarkers that are associated with response to Li is a first step toward predictive and personalized BD patients care. Epigenetic modifications such as DNA methylation have been proposed to be associated with response to treatment in several pathologies. In order to identify a profile of differentially methylated regions (DMR) we performed a genome-wide methylation study of total blood DNA from BD patients excellent responders (ER) and non-responders (NR) to Li. We identified 323 DMR in ER as compared to NR (FRD < 0.05). Li response was associated with specific methylation changes in genes involved in neuronal compartments and inflammation. In addition, after correction for co-medications we identified a signature of 3 DMR significantly associated with lithium response in patients. The identification of a signature able to discriminate between ER and NR within a small number of patients is very encouraging and should be tested in prospective studies.

## Symposium: From New Psychotropic Drugs to Psychedelic Medicine: Risks and Challenges of Research Chemicals in Psychiatry

S0071

### Renaissance of serotonergic hallucinogens in psychiatry

B. Quednow

Psychiatrische Universitätsklinik Zürich, Experimentelle und Klinische Pharmakopsychologie, Zürich, Switzerland

After the discovery of the psychedelic effects of LSD in 1943 by Albert Hoffmann, the therapeutic potential of the compound was rapidly and intensively investigated across the 1950s. In the course of the 1960s psycholytic psychotherapy was propagated, whose advocates hoped to initiate salutary psychoanalytical processes in their patients by psychedelic experiences. In the frame of the counter culture of the 1960s and 1970s, self-experiments with serotonergic hallucinogens, such as LSD, mescaline, and psilocybin, got popular resulting in the criminalization of these substances at the beginning of the 1970s. Subsequently, recreational use of serotonergic hallucinogens decreased, while in parallel also human research with these drugs but also psycholytic therapy approaches faded out more and more. Since the end of the 1990s serotonergic hallucinogens now experience a revival in science and youth cultures. With the rise of electronic music styles, the consumption of serotonergic hallucinogens increased again and beyond the classical compounds also “novel psychoactive substances” drugs came to the drug market such as the 2C drugs, NBOMe derivatives, benzodifurans, and novel tryptamines and ergolines. In psychiatry, serotonergic psychedelics, like psilocybin, DMT/Ayahuasca, and LSD, are in the research focus once more and have been recently proposed for the treatment of affective disorders and addiction. Correspondingly, psycholytic therapy approaches are currently controversially discussed again. Surprisingly, even after decades of research the potential neuropsychiatric long-term consequences of repeated administrations of serotonergic hallucinogens are still unclear.

### Gamma-hydroxybutyric acid (GHB): Between euphoria and dependence

H. Beurmanjer

Radboud University, NISPA, Nijmegen, The Netherlands

Gamma-hydroxybutyric acid (GHB); between euphoria and dependence

The drug GHB (Gamma hydroxybutyrate) has long been known as a “relaxant energizer with erotic qualities”. However, recent years have demonstrated addiction as a more dark side of recurrent GHB use. When used in small amounts, GHB provides a peaceful feeling and a sexually stimulating effect, higher doses lead to coma and hypo ventilation. When used regularly, tolerance develops rapidly within a couple of weeks. As a result many of the regular users may develop GHB dependence and finally addiction. In recent years there has been a steady rise in GHB-dependent patients, as indicated by among others a rapid increase in the number of admitted GHB-dependent patients at addiction care centers all over the Netherlands. Relapse and care consumption are among the highest of all substance dependent patients. This group is characterized by high levels of anxiety, poor quality of life and a wide range of other problems.

On the other hand, GHB is used in several countries to treat alcohol dependence, and in The Netherlands detoxification of GHB dependent patients is often assisted by gradual tapering of pharmaceutical GHB. In this talk pros and cons of GHB use and its potential in the treatment of addictive behaviors will be discussed.

### **MDMA as a treatment targeting addictive processes**

B. Sessa

*Imperial College London, Medicine, London, United Kingdom*

As a child psychiatrist I take a developmental perspective to adult mental disorder and addictions. High rates of treatment resistance for PTSD and the challenge of tackling unremitting addictions with high rates of relapse leaves me feeling clinically impotent as a doctor. My work with abused children, seeing them grow into damaged and addicted adults, has brought me to the door of MDMA Therapy as psychiatry's best opportunity for a therapeutic breakthrough. I will describe the on-going MDMA study that I am leading in the UK, based in Bristol, an open-label feasibility study using a course of MDMA-assisted psychotherapy to treat alcohol use disorder.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Symposium: Section Symposium: Using Technology to Respond to the Mental Health Needs For the Mentally Ill Worldwide: Mobile Devices, Telemedicine, Outcomes Management and Virtual Reality**

S0074

### **Advances in mobile mental health: Opportunities and implications for the spectrum of e-behavioral health services**

D. Hilty

*Keck School of Medicine at USC and LAC+USC Medical Center, Los Angeles, USA*

*Objectives.*– (1) Define mobile health (mH), elucidate its roots in medicine, describe its philosophical approach, and link its components with service delivery and outcomes particularly related to mobile mental health (mMH). (2) Compare and contrast mMH to a range of e-MH services including telepsychiatry, and describe how one employs it within a service delivery system – and how health-care may be built around it. (3) Provide an approach to clinical care, education/training, administration and evaluation so that quality care is provided and participants adapt well to incorporation of new technologies.

*Abstract.*– Mobile health, telemedicine and other technology-based services facilitate mental health service delivery and may be considered part of an e-mental health spectrum of care. Web- and Internet-based resources provide a great opportunity for the public, patients, healthcare providers and others to improve wellness, practice prevention and reduce suffering from illnesses. Mobile apps offer portability for access anytime/anywhere, are inexpensive versus traditional desktop computers, and have additional features (e.g. context-aware interventions and sensors with real-time feedback). This paper discusses mobile behavioral health

options, as part of a broader framework of e-behavioral health options. The evidence-based literature shows that many people have an openness to technology as a way to help themselves, change behaviors and engage additional clinical services. Clinicians need an evidenced-based app and to use it in an evidenced-based approach to care. It may be better to be selective with an app or two and track it rather than using too many apps. Mobile health outcomes have been rarely, directly compared to in-person and other e-mental health care options. Nor are they evaluated nor linked with specific goals and desired clinical outcomes. Skills and competencies for clinicians are needed for mobile health, social media and other new technologies in the e-behavioral health spectrum, in addition to research by randomized trials and study of health service delivery models with an emphasis on effectiveness.

S0075

### **The use of a telemedicine model and its logistics to reach as many European refugees as possible**

D. Mucic

*Little Prince Treatment Centre, E-Mental Health, Copenhagen, Denmark*

There is a number of research describing difficulties in dealing with cross-cultural patients. Access to relevant care as well as its availability are often limited due to: (a) lack of respective qualified resources, (b) linguistically, cultural and even racial barriers in addressing of mental health care needs of cross-cultural patient population. By use of various e-Mental health applications, primarily videoconference, we may improve assessment and/or treatment of refugees and asylum seekers on distance, e.g. Arabic speaking psychiatrist located in Sweden would be able to assess and/or treat refugees from Syria located in Germany). Specialized centres for treatment of refugees would also be able to get second-opinion service from remote experts and use it in order to confirm or reconsider diagnosis as well as the treatment options.

*Methods.*– Specialized centres for treatment of refugees might be connected via videoconference in order to exchange expertise and get second-opinion. Various e-mental health apps might be used in order to increase access to care.

*Expected results.*– Establishment of international network of cross-cultural experts enables to:

1. Improve the mental health care across national boundaries by providing psychiatric consultations to other countries within EU.
2. Conduct International Treatment Team with Select Skills (e.g. Sign Language and Many Foreign Languages Staff).
3. Provide Distance Supervision and Staff Consultation.
4. Provide Psycho Education of caregivers.
5. Improve Distance Learning via Case Conferencing and Best Practice Demonstration Across the National Boundaries.
6. Create Data Base over cross cultural and other select skills professionals within EU.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0076

### **Virtual reality in the treatment of fear of heights and other anxiety disorders – Polish experience**

K. Krysta

*Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland*

In the last two decades a new promising method used in mental disorders, especially anxiety disorders has become virtual reality (VR). Virtual reality exposure therapy (VRET) is a more and more popular treatment method for anxiety and specific phobias. It can be an alternative to other, more traditional exposure-based therapies, like cognitive-behavioral treatments and in vivo exposure therapy, and it is based on immersion in virtual environment generated by a computer, which decreases the phenomenon of avoidance and creates good possibilities to work with emotional problems. Patients are exposed to virtual environments that resemble feared real-life situations. The spectrum of anxiety disorders, which can be treated with VRET is very wide and includes: phobias, panic disorder, posttraumatic stress disorder, as well as acrophobia, or fear of heights, which is a widespread and debilitating disorder affecting about 1 in 20 adults and agoraphobia. Here were present results of a Polish study, in which we recruited a group of patients invited to take part in a project of the behavioral therapy of acrophobia or psychogenic vertigo with the use of MOTEK CAREN (Computer Assisted Rehabilitation Environment) system, which is a versatile, multi-sensory virtual reality system used for treatment and rehabilitation of human locomotion. The patients underwent a series of trainings, the preliminary results of which results show a reduction of the STAI scores and salivary cortisol levels. These early observations predict the possibility that this method may become an effective way of behavioral treatment of anxiety disorders.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Symposium: Emerging Disorders or Their Risk Factors: What Should Be the Target of Prevention?**

S0077

### **Indicated prevention in psychosis: Developmental aspects**

F. Schultze-Lutter

*Heinrich Heine University, Department of Psychiatry and Psychotherapy, Duesseldorf, Germany*

Psychotic disorders are a leading cause of disability-adjusted life years (DALYs); and although schizophrenia occurs infrequently in childhood and early adolescence, it is the ninth main cause of DALYs in boys between the ages of 10 and 14 years, and second main cause of DALYs in both genders between the ages of 15 and 19 years. A prodromal phase, which can last several years on average, precedes a majority of first-episode psychoses; it frequently leads to some decline in psychosocial functioning already but also offers an opportunity for an early detection of psychosis, and thus, for its indicated prevention. To this, two clinical high risk approaches, which had been developed in adult samples, are currently mainly followed, the ultra-high risk (UHR) criteria and basic symptom criteria. The UHR criteria were explicitly developed to predict a first-episode psychosis within 12 months, and indeed, the majority of conversions in clinical UHR cohorts do seem to occur within the first 12 months past initial assessment. The main UHR criterion, i.e. the attenuated psychotic symptoms (APS), includes symptoms that resemble positive symptoms of psychosis like delusions, hallucinations, and formal thought disorders with the exception that some insight into the abnormal nature of these experiences is still maintained. In contrast, the basic symptom criteria aim to detect the increased risk of psychoses at the earliest possible time using first subtle disturbances in information processing, which are experienced with full insight. Ideally, these changes should be detected when the person's coping abilities have not yet been compromised

and when the initial symptoms of an emerging disorder have not yet resulted in any functional decline. First results of prospective and community studies indicate that a combination of both approaches might be most favorable to increase sensitivity and a timely risk detection, in addition to establishing a change-sensitive risk stratification approach. However, as earlier indicated by reports of increased rates of hallucinatory experiences in children of the community, developmental aspects might play an important role, recent studies suggest both UHR and basic symptom criteria might be less predictive of psychosis and less clinically relevant in children and adolescents. Thus, an early detection of psychosis in children and adolescent seems to require special efforts.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0078

### **Strategies to identify individuals at high risk of developing first episode mania**

J. Scott

*Neuroscience, Academic Psychiatry, Newcastle upon Tyne, United Kingdom*

*Background.*– A clinical and research challenge is to identify which depressed youth are at risk of “early transition to bipolar disorders (ET-BD).” This paper described a 2-part study that (1) examines the clinical utility of previously reported BD at-risk (BAR) criteria in differentiating ET-BD cases from unipolar depression (UP) controls; and (2) estimates the Number Needed to Screen (NNS) for research and general psychiatry settings.

*Methods.*– Fifty cases with reliably ascertained, ET-BD I and II cases were matched for gender and birth year with 50 UP who did not develop BD during 2 years of prospective follow-up. We estimated the clinical utility for finding true cases and screening out non-cases for selected risk factors and their NNS. Using a convenience sample ( $N=80$ ), we estimated the NNS when adjustments were made to account for data missing from clinical case notes.

*Results.*– Sub-threshold mania, cyclothymia, family history of BD, atypical depression symptoms and probable antidepressant-emergent elation, occurred significantly more frequently in ET-BD youth. Each of these “BAR-Depression” criteria demonstrated clinical utility for screening out non-cases. Only cyclothymia demonstrated good utility for case finding in research settings; sub-threshold mania showed moderate utility. In the convenience sample, the NNS for each criterion ranged from ~4 to 7.

*Conclusions.*– Cyclothymia showed the optimum profile for case finding, screening and NNS in research settings. However, its presence or absence was only reported in 50% of case notes. Future studies of ET-BD instruments should distinguish which criteria have clinical utility for case finding vs screening.

S0079

### **Need for a transdiagnostic approach for prevention of emerging mental disorders**

S.J. Schmidt

*University Hospital of Child and Adolescent Psychiatry and Psychotherapy Bern, University of Bern, Bern, Switzerland*

Mental disorders are a major cause for disability-adjusted life-years in adolescence as well as adulthood. This has led to an increased interest in indicated prevention approaches to reduce the risk for

the development of a mental disorder and thereby the enormous burden and costs associated with it. Such approaches have been evaluated for several mental disorders including psychoses, affective and anxiety disorders. However, due to the limited specificity of early detection criteria, in particular for adolescents, the transdiagnostic promotion of resilience seems to be more promising than focusing on specific mental disorders and/or risk factors. Against this background, this talk will present evidence-based interventions to enhance resilience that target factors commonly related to all mental disorders, such as coping, self-efficacy and social cognition/competences.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Symposium: Current Perspectives on Behavioural Addictions

S0080

### Fascination, immersion and addiction: Why we can't look away about the phenomenology of 'excessive' use

R. Graham

London Digital Mental Well-being Service, Clinical Lead, London, United Kingdom

He stands like a statue,

Becomes part of the machine

Feeling all the bumpers

Always playing clean

He plays by intuition,

The digit counters fall... Pin ball Wizard, (The Who, 1969)

Clinical work with gamers and those that use mobile devices excessively over the last decade reveals many different states of mind and levels of engagement with the technology and the content. The aim of this presentation is to explore our increasingly complex engagement with technology and how a deeper understanding can help individuals regain control, over their use. There will be a particular emphasis on immersive engagement, and how simple models of abstinence or a 'digital detox' may cause distress that reinforces use. In addition, fascination with content that is distressing or punishing is explored as state that increases the risk of mental health problems and excessive use.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Social cognitions and craving reactions in Internet-communication disorder

E. Wegmann<sup>1,\*</sup>, M. Brand<sup>1,2</sup>

<sup>1</sup> General Psychology: Cognition and Center for Behavioral Addiction Research CeBAR, University of Duisburg-Essen, Duisburg, Germany; <sup>2</sup> Erwin L. Hahn Institute for Magnetic Resonance Imaging-Essen, Essen, Germany

\* Corresponding author.

*Introduction.*– Internet-communication disorder (ICD) is considered one type of specific Internet-use disorders and contains the excessive use of online-communication applications.

Cue-reactivity and craving are crucial concepts in both substance-use disorder and behavioral addiction research. Additionally, social cognitions are assumed to be specific predispositions for using online-communication applications.

*Objectives.*– The current study investigates the relevance of cue-reactivity, craving as well as social cognitions, such as social connectivity and fear of missing out, for ICD symptoms.

*Methods.*– These concepts have been recently investigated in subjects with specific Internet-use disorders such as Internet-gaming disorder or Internet-shopping disorder. Studies are summarized, which present the relevance of social connectivity in structural equation models, and which address behavioral correlates of cue-reactivity and craving.

*Results.*– Behavioral data support the theoretical hypothesis that cue-reactivity and craving are mechanisms underlying ICD. Auditory as well as visual cues are associated with the desire to use the smartphone and hence with tendencies of an ICD. It could also be shown that specific social cognitions intervene with cognitive and affective responses to external stimuli.

*Conclusions.*– The findings on cue-reactivity and craving as well as the interaction of social cognitions with further cognitive responses in ICD are consistent with the recently suggested Interaction of Person-Affect-Cognition-Execution (I-PACE) model of specific Internet-use disorders. It suggests that gratification and reinforcement contribute to the development of cue-reactivity and craving. However, social cognitions and the interaction with affective and cognitive components describe main mechanisms of an ICD. Specifications of the I-PACE model for ICD are discussed.

### Treatment of Internet gaming disorder

D. Kuss

Nottingham Trent University, Psychology, Nottingham, United Kingdom

A number of therapeutic approaches for *Internet Gaming Disorder* are available from a global perspective, especially in South East Asian countries. In 2013, Internet Gaming Disorder has been included in the appendix of the DSM-5, signifying a disorder that requires additional research to be included in the main manual. In 2017, the WHO's beta draft for the ICD-11 included the diagnosis of *Gaming Disorder*, which is likely to be included in the upcoming diagnostic manual, suggesting the problem is being taken seriously by clinicians and the research community. In this talk, the results of an analysis of the evidence base for Internet Gaming Disorder treatment will be outlined based on using the Consolidating Standards of Reporting Trials (CONSORT) statement. The findings show that there appear a number of problems of the assessed studies, including how Internet Gaming Disorder was defined and classified; randomisation and researcher blinding have not been applied in many studies; and limited information has been provided regarding participants and effect sizes. In addition to this, it has been reported that cognitive behavioural therapy appears to have the most empirical support; however, the limited quality of the included studies limits possible assessments. Overall, there appears an increased requirement of better research, including more consistent measurements and reports of treatment effects. The international research and treatment community is encouraged to work collaboratively to share knowledge and insight into the effectiveness of different treatment approaches for Internet Gaming Disorder, and to report these accurately based on the collectively agreed standards.

This talk is based on King, D.L., Delfabbro, P.H., Wu, A.M.S., Doh, Y.Y., Kuss, D.J., Mentzoni, R., Pallesen, S., Carragher, N., & Sakuma, H. (2017). Treatment of Internet gaming disorder: An international systematic review and CONSORT evaluation. *Clinical Psychology Review*, 54, 123–33.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0083

### **Comorbidities and psychological correlates of Internet addiction with and without communication features**

T. Lemenager<sup>1,\*</sup>, S. Hoffmann<sup>1</sup>, I. Reinhard<sup>2</sup>, K. Mann<sup>1</sup>, F. Kiefer<sup>1</sup>

<sup>1</sup> Central Institute of Mental Health, Medical Faculty Mannheim/Heidelberg University-Germany, Department of Addictive Behaviour and Addiction Medicine, Mannheim, Germany; <sup>2</sup> Central Institute of Mental Health, Medical Faculty Mannheim/Heidelberg University-Germany, Department of Biostatistics, Mannheim, Germany

\* Corresponding author.

Addictive Internet users present an increased rate of comorbidities, e.g. attention deficit hyperactivity disorder (ADHD), depressive and anxiety disorders. Additionally, deficits in self-concept related characteristics were found in addicted Internet gamers and social network users. The aim of our study was to examine the links from healthy to problematic to addicted Internet users in comorbidities and self-concept-related characteristics. Besides, we examined the association between recently developed ADHD-like symptoms without an underlying diagnosis and addictive Internet use. Results will be presented and discussed in the talk.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Symposium: Behavioural Addictions: Motivations and Classification Updates**

S0084

### **Similarities and differences in the motivational background of substance use and behavioral addictions**

Z. Demetrovics<sup>1,\*</sup>, T. Kurimay<sup>2</sup>, O. Király<sup>1</sup>

<sup>1</sup> ELTE Eötvös Loránd University, Institute of Psychology, Budapest, Hungary; <sup>2</sup> Saint John Hospital, Psychiatry, Budapest, Hungary

\* Corresponding author.

The aim of the presentation is to discuss the motivational background of different substance use and other addictive behaviors. Drinking motives were found to be proximate predictors of alcohol consumption and the development of the Drinking Motives Questionnaire (DMQ) opened the door to examine the motivational background of other substance use behaviors as well as behavioural addictions. The paper summarizes results of the past ten years aiming to understand the motivational background of alcohol and cannabis use and presents more recent findings regarding the motives behind gambling and video gaming. Studies revealed that people have similar motives to gamble and to play video games than they have to drink alcohol or to use cannabis, however, relevant differences were also identified. Findings support the assumption that motives play an important role in behavioral addictions as well as in substance-related addictions, and that they play a significant role in mediating psychiatric symptoms and personality characteristics.

The paper was supported by the Hungarian National Research, Development and Innovation Office (Grant Numbers: K111938, KKP126835).

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0085

### **Physical exercise, motivation, exercise addiction**

T. Kurimay<sup>1,\*</sup>, Z. Demetrovics<sup>2</sup>

<sup>1</sup> Saint John Hospital, Psychiatry and Psychiatry Rehabilitation, Budapest, Hungary; <sup>2</sup> ELTE Eötvös Loránd University, Department of Clinical Psychology and Addiction Institute of Psychology, Budapest, Hungary

\* Corresponding author.

A motivational understanding of addiction, including behavioural addictions helps us to puzzle both the reinforcing and conditioned motivational effects of different forms of addictive cycles. An optimal level of regular physical activity is one of the most important factors of the maintenance of physical and mental health. Too much exercise however can sometimes have adverse effects. Similarly to other addictive behaviors, exercise addiction (EA) can also be described by mood modification, salience, tolerance, withdrawal symptoms, personal conflict, and relapse. EA as all addictions, has a negative interference with social life, which is getting more attention both in the scientific and in the public literature. The prevalence of risk for exercise addiction is approximately 3% among the exercising population. Exercise addiction has not yet been classified in any diagnostic systems, however exercise addiction is often categorized as a behavioural addiction. One of the reason would be the classification difficulties of EA, that research examining exercise addiction is primarily based on self-report questionnaire studies and interviews, while clinical studies are rarely available. Understanding the function of motivations in subjective experiences in salience, compulsion, an impaired control of EA potentially can help us revealing the cyclic nature of relapse. The presentation will review the current evidence and dilemmas for the motivational aspects of EA.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0086

### **Challenges in diagnosis and classification of gaming and gambling disorders**

J.B. Saunders

University of Queensland, Centre for Youth Substance Abuse Research, Brisbane, Australia

With developments in the power and coverage of Internet (on-line) technologies, new forms of problematic gaming and gambling have emerged. Most notable of these have been role-playing games, multiplayer on-line games, and on-line betting. Concern has been expressed from members of the community, families, health professionals and those with problematic gaming and gambling themselves from countries around the world. This presentation focuses on the features of gaming and gambling when they become disorders and will review the central characteristics, which have seen them placed in the addictive disorders sections of DSM-5 and ICD-11, the latter being scheduled for publication in 2018. Gaming and gambling disorder share some features with addictive disorders from psychoactive substances. However some features such as “chasing” and immersion are unique, and whether physiological

features of gaming and gambling disorder such as tolerance and withdrawal (as are seen in substance dependence) exist are matters of continuing research. Gaming and gambling disorders in the draft ICD-11 are defined as comprising (i) impaired control over the activity, (ii) increasing priority in life, such as gaming or gambling take precedence over other interests and responsibilities, and (iii) their continuation or escalation despite negative consequences. The diagnosis also requires significant impairment in personal, family, social, educational, occupational or other important areas of functioning. The presentation will review the current evidence for the addictive nature of these two disorders.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

S0087

### **Behavioural addictions, the role of psychiatric comorbidity**

K. Mann\*, M. Fauth-Bühler, T. Leménager, F. Kiefer  
 Central Institute of Mental Health Mannheim-Heidelberg University,  
 Central Institute of Mental Health Mannheim, Mannheim, Germany  
 \* Corresponding author.

*Background.*– ICD-11 will most likely diagnose Gambling Disorders in the chapter on “Substance related Disorders and Disorders due to Addictive Behaviors” (Gambling and Gaming). Considerable rates of psychiatric comorbidities contributed to this decision. The presentation will contrast findings from an own study with literature reports.

*Methods.*– In the “Baden-Württemberg Study of Pathological Gambling” (Mann et al., 2017), we compared 515 male pathological gamblers receiving treatment with 269 matched healthy controls. We studied differences in sociodemographic characteristics, gambling-related variables, psychiatric comorbidity (lifetime) and family history of psychiatric conditions.

*Results.*– Notably, 88% of the gamblers in our sample had a comorbid diagnosis of substance dependence. The highest axis I comorbidity rate was for nicotine dependence (80%), followed by alcohol dependence (28%). 16% of the patient group suffered from depression, 3% from adjustment disorder, 3% from anxiety disorders and 2% from eating disorders. Compared to relatives of control subjects, first-degree relatives of pathological gamblers were more likely to suffer from alcohol dependence (27.0% vs. 7.4%), pathological gambling (8.3% vs. 0.7%) and suicide attempts (2.7% vs. 0.4%).

*Conclusions.*– Due to a selection bias in treatment seeking gamblers, comorbidity rates were lower than seen in population based samples.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Symposium: Suicidal Behavior in the Vulnerable Populations: Focus on Migrants**

S0088

### **Migrant’s suicidal behaviors: A transcultural perspective**

C. Gramaglia  
 A. Avogadro University of Eastern Piedmont, Medicina Traslazionale,  
 Novara, Italy

Immigration and related health policies are a very important issue in Europe. Because of its location, Italy has become a key destination for migrants from North Africa – they sail across the Mediterranean

Sea – as well as people from Eastern Europe. The National Institute of Statistics (ISTAT) reported that between 2008 and 2015 Italy’s migrant population increased by approximately 63%.

The process of migration includes three phases, pre-migration (the decision and preparation to migrate); migration (the actual transfer); post-migration (the process of integration of immigrants in the new social and cultural context of the hosting country). Each of these phases may represent a stressor leading to an increased risk of developing psychiatric symptoms or disorders, including depression, anxiety, post-traumatic stress disorder, addiction to alcohol and drugs, loneliness, hopelessness, and suicidal behaviors. Nonetheless, the current literature reports no generalizable pattern of suicide among immigrants. It has been suggested that immigrants ‘bring along’ their suicide risk, at least for the initial period they spend in the immigration country, likely due to cultural and/or genetic issues. Overall most immigrant groups do not have an increased suicide risk relative to the local-born population; some may even experience substantially lower risks. On the other hand, a relationship has been found between immigrant status and type of care recommended after assessment for a suicide attempt; clear disparities were identified in the care recommendation practices toward immigrants, compared with hosts, over and above differing policies by the European Centres.

The Emergency Department (ED) is the healthcare facility most frequently used by migrants; data will be presented from a study performed by the Psychiatry Institute, Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy, with the aim of assessing the possible differences between migrants and native Italians in the pathways and results of psychiatric consultation (PC) in the emergency department (ED). Briefly, the proportion of EDP related to suicide attempts was higher in migrants than native Italians, which is consistent with earlier studies in the literature reporting that migrants showed more self-aggressive behaviours than non-migrants and that such behaviour was often a reaction to the stresses associated with migration. Nonetheless, there was no evidence that suicide risk was higher in migrants than residents born locally. Cultural differences should be taken into account when considering expressions of distress, and further research into perceptions of distress and stressful life-events, resilience and coping strategies as possible mediators of suicidal behaviours might be worthwhile.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Suicide attempt rates and intervention effects in women of Turkish origin in Berlin**

M. Schouler-Ocak<sup>1,\*</sup>, M.C. Aichberger<sup>2</sup>  
<sup>1</sup> Psychiatric University Clinic of Charité at St. Hedwig Hospital,  
 Psychiatry and Psychotherapy, Berlin, Germany; <sup>2</sup> Charité –  
 Universitätsmedizin Berlin, Psychiatry and Psychotherapy, Berlin,  
 Germany

\* Corresponding author.

Studies demonstrate that suicidality in female immigrants in some European countries is higher. Particularly, similar findings were reported for girls and young women of Turkish origin compared to women of the same age in Germany. Therefore, an intervention study for the target group of young women of Turkish origin was conducted in Berlin. At the beginning of the study predictors of emotional (suicidal) crisis in women of Turkish origin were analyzed in focus groups. The findings of this approach guided the development of the intervention module. The intervention

consisted of a public awareness campaign, telephone hotline in Turkish language for women in emotional crisis, and the training of key persons. The core part of the intervention phase was the telephone hotline. Basic socio-demographic characteristics, suicide method used, psychiatric diagnosis, follow-up treatment and motives were also collected. All parts of the intervention were subsequently evaluated. Our findings show that particularly young second generation women of Turkish origin present at emergency department after suicide attempts. In this talk the main results will be presented and discussed.

### **Social and ethno-cultural aspects of the dynamics of the rate of suicides in the CIS countries (1990–present time)**

B. Polozhy

*V.P. Serbsky National Medical Research Center For Psychiatry and Addiction, Division for Ecological and Social Problems of Mental Health, Moscow, Russia*

*Introduction.*– Analyzed the dynamics of suicides rate in the CIS countries for the period from 1990 to the present time.

*Methods.*– Medical, statistical, culturological.

*Results.*– An analysis has made it possible to single out 2 groups among them. The first one includes Belarus, Kazakhstan, Russia and Ukraine. The population of these countries refers primarily to the Slavic ethnic group with high (or close to high) level of suicide rate. In this group, suicide rates are directly related to the nature of the social situation: rapid and pronounced growth of suicides is observed in conditions of radical socioeconomic reforms and crises against the background of insufficient anti-suicidal factors. Decrease in the rate of suicides occurs slowly enough with the stabilization of the social situation. The second group of countries comprises the Central Asian States (Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan) and countries of the Transcaucasia (Armenia, Azerbaijan). The population of Azerbaijan and the countries of Central Asia differs in orientation to the eastern model of culture, massively professes Islam and experiences its powerful anti-suicide effect. The culture of the Armenian population (Christians) included an unacceptable attitude towards suicide. In general, in this group of countries, the suicide rate practically does not react to changes in the social situation and remains stable at the inherent low level.

*Conclusions.*– Planning suicide prevention programs in the CIS countries should be differentiated and take into account not only their rate of suicide, but also the socio-economic situation and the ethno-cultural characteristics of the population.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Panel: How Can Psychiatry Contribute to the Promotion of Human Rights of People with Mental Health Problems?

P0001

#### How to fight human rights violations, discrimination and stigma attached to mental health conditions?

P. McGovern<sup>1,\*</sup>, M. Funk<sup>2</sup>, N. Drew<sup>2</sup>

<sup>1</sup> World Health Organisation, Consultant for Mental Health Policy & Service Development, Geneva, Switzerland; <sup>2</sup> World Health Organisation, Mental Health Policy & Service Development, Geneva, Switzerland

\* Corresponding author.

A movement to profoundly transform the way mental health care is delivered and to change attitudes to people with psychosocial, intellectual and cognitive disabilities is gaining momentum globally [1]. The Quality Rights (QR) Initiative offers a rights-based and recovery orientated approach to delivering support for people with psychosocial disabilities. At the core of the initiative is; Freedom from coercive interventions, Respect for the right to legal capacity, Promotion of autonomy & choice, Community inclusion and Recovery [2]. The recent landmark report from the UN special rapporteur on the right to health called for the end to the “reductionist biomedical paradigm that has contributed to the exclusion, neglect, coercion and abuse” of people with psychosocial disabilities and was clear in his call for a paradigm shift [3].

The QR Initiative has recently released WHO QualityRights capacity-building and guidance tools to support increased access to quality mental health and related services and promote the rights of people with mental health conditions or psychosocial, cognitive and intellectual disabilities in countries around the world [4]. These tools have been driven by people with lived experience, disabled people’s organisations and experts from around the world in mental health and human rights.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

A. Heinz, L. Daedelow, S. Müller  
Charité-University Medicine Berlin, Department of Psychiatry and Psychotherapy, Berlin, Germany

The United Nation’s Convention for the Rights of Persons with Disabilities promotes inclusion of patients with mental disorders. Key human rights issues concern living in the community and finding or maintaining employment in the regular labor market. Further human rights concern transparent legal procedures with juridical safeguards against inhuman treatment. Conflicting points of view have been articulated with respect to the right of patients with mental disorders for adequate treatment on the one hand and for personal autonomy on the other, particularly in disease-related situations in which a patient’s action endanger the person’s own health or others. Prototypical cases and situations are addressed and discussed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

P0003

#### How can psychiatry contribute to the promotion of human rights of people with mental health problems?

M. Männikkö  
President, EUFAMI, Leuven, Belgium

People with mental ill health form part of a family. In any discourse on human rights of people with mental health problems, we cannot ignore the relatives. Research has shown that 60% of families caring

for a relative with a mental health problem fall ill themselves. So, how can Psychiatry contribute to the promotion of human rights of those who suffer from mental ill health?

Psychiatry has a responsibility to identify deficiencies in legislation, policies and practices and to advocate for change. There are glaring gaps that clamour for action. Service users' charters of rights need to be urgently developed across Europe. The rights, among others to extensive support, of families of people with mental ill health should be integrated in those charters as much as possible. Psychiatry itself needs to be a proactive listener and practitioners should actively contribute to the creation of reflective communities. Without this

listening approach, we all miss signposts that would enable Psychiatry to revolutionise mental health care and community care. Across Europe, mental health care systems need to evolve into triologue systems where practitioners, users and caregiving relatives work in equal partnership. The triologue system needs to link up to NGOs and users' and relatives' groups to maximise well-being outcomes. Practitioners need to do their utmost to create a network of support groups for relatives of people with mental ill health.

## Plenary Lecture

### Plenary Lecture: Schizophrenia is a Myth with a Strong Genetic Component

PL0001

#### Schizophrenia is a myth with a strong genetic component

R. Murray

*Institute of Psychiatry, King's College London, London, United Kingdom*

Traditional psychiatric textbooks describe schizophrenia as a disease of unknown aetiology. However, this is wrong on two counts. First we now realise that schizophrenia itself is not a disease but rather a clinical syndrome, and one with very fuzzy boundaries. It is simply the name that we give to the severe manifestation of psychosis, and we now know there exists a continuum which stretches into other so-called psychotic disorders, and indeed into the general population. Thus, psychosis is distributed though the population like hypertension, and schizophrenia is the equivalent of severe hypertension.

A recent study encompassing 16 sites across 5 European countries shows that the incidence varied widely, with the figures for South London and Amsterdam being more than 5 times higher than in some Southern European sites. Curiously, psychosis is more common in those living in large cities than in rural areas in Northern but not Southern Europe. These differences presumably reflect differences in exposure to risk factors.

We now know a great deal about the risk factors, or contributory causes, of psychosis. These turn out to be largely the same as for severe psychosis, i.e. schizophrenia. These can be roughly divided into two main types; those which result in (a) aberrant neurodevelopment and (b) those which cause dopamine dysregulation; both characteristic abnormalities found in schizophrenia.

Genetic factors are, of course, pre-eminent. In 2014 a landmark GWAS study of 37,000 people with schizophrenia and 113,000 healthy controls identified 108 loci significantly associated with schizophrenia. Each of these polygenes has only a very small effect but cumulatively they account for about 30% of the variance in occurrence of schizophrenia. Some such as neurexin or TCF4 subtly impair neurodevelopment while others such as DRD2 or AKT3 impact on dopamine signalling. A small proportion of schizophrenia (perhaps 3%) results from copy number variants

(CNVs) impacting on neurodevelopmental genes; these CNVs can have a much bigger effect size, increasing risk 3- to 20-fold.

Various environmental factors have been consistently associated with schizophrenia. Some such as adverse obstetric events (e.g. prenatal infection, perinatal hypoxia) impair neurodevelopment. Others such as abuse of drugs such as amphetamines, cocaine and cannabis which increase striatal dopamine, also increase risk. In recent years it has become clear that heavy use of high potency cannabis is responsible for a significant proportion of psychosis (>20% in South London). Synthetic cannabinoids are an increasing cause of acute psychosis sometimes termed "spiceophrenia". A range of social adversities such as child abuse, adverse life events, migration/minority ethnicity appear also to facilitate dopamine dysregulation and consequent psychosis.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

\* Corresponding author.

*Background.* – Severe mental illnesses like schizophrenia and bipolar disorder are known to be diseases that to some extent, but not entirely can be understood genetically. For schizophrenia the dominating hypothesis is that it is a neurodevelopmental disorder, and that genes, environment as well as gene-environment-interactions contribute to the risk of developing the disease. Children born to parents with severe mental illness are at a higher risk of growing up under unstable life conditions and more frequently show early signs of vulnerability for mental illness themselves.

*Aim.*– We aim to analyse the influences of genetic risk and environmental factors in a population of 7-year-old children with either 0, 1 or 2 parents diagnosed with schizophrenia spectrum psychosis or bipolar disorder. Main outcomes are psychopathology, neurocognition and development.

*Methods/design.*– We have established a cohort of 522 7 year old children and their parents for a comprehensive investigation of the children's neurocognitive, social, behavioural and neuromotor function and psychopathology. The test battery included a large neurocognitive battery, home visits evaluating the degree of stimulation and support in the home, information from teachers,

and measures of stress, and attachment. The parents take part in an anamnestic interview about the child. The participants were recruited via Danish registers to ensure representativity. Data from registers concerning social status, birth complications, somatic illnesses and hospitalization are included.

*Results.*– Generally the children with parents with schizophrenia had lower neurocognitive function, more psychiatric symptoms and poorer motor function. Children with parents with bipolar disorder were not different from control children.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

## 26th European Congress of Psychiatry Presidential Symposium

### Presidential Symposium: Vulnerable People in Humanitarian Emergencies

PS0001

#### Empowering women and girls in humanitarian emergencies

M. Amering

Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria

**Introduction.**– The risk to fail women and girls in humanitarian crises is high.

**Objectives.**– Present and discuss the challenges and opportunities of empowering women and girls in humanitarian crises.

**Methods.**– Non-systematic review of experience and evidence on empowering women and girls in humanitarian crises.

**Results.**– Empowerment of women and girls is central for the health for all at any given time. Humanitarian crises pose a special risk for the mental health of all adults and children. Most often, women and girls are already the most marginalized and vulnerable members of their communities, have their resources constrained and suffer differently and often to a significantly greater extent. Gender responsive humanitarian programming plays a significant role for the success of emergency responses. Core examples of tasks warranting gender-specific attention concern access to reproductive health care, protection against gender-based violence and, essentially, consulting women and girls in recognition of their specific capabilities, needs, and human rights. Recent years have brought these issues into focus and strongly impacted guidelines and programming towards focusing on gender-sensitive and equality approaches in order to strengthen crisis response. It is also noteworthy, that humanitarian crises can offer special opportunities for the empowerment of women and girls with lasting positive effects as evidenced by changes in social structures and power dynamics in war and post-war societies.

**Conclusions.**– A focus on empowering women and girls strengthens the effectiveness and improves the long-term impact of interventions in reaction to humanitarian crises and can help promote additional lasting positive effects for communities and societies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PS0002

#### The WPA program for strengthening the contribution and availability of psychiatrists in situations of conflict and emergency

H. Herrman

Orygen – The National Centre of Excellence in Youth Mental Health, Centre for Youth Mental Health, Parkville, Australia

A capacity-building program is now being developed by WPA under its Action Plan 2017–2020 to strengthen the contribution and availability of psychiatrists in national and international responses to conflict and humanitarian emergencies as well as to severe adversities in city slums and other settings. With partners we will train and support psychiatrists to perform their roles in emergency responses with a special focus on human rights, including tackling the burden of stigma. The program will draw on the past experiences of joint WPA–WHO training for disaster response<sup>8</sup> as well as leading international NGOs such as Basic Needs. The program will support psychiatrists: to respond directly to mental health needs of young people in complex emergency situations and settings of adversity in accord with international protocols; train their peers and other clinicians and community-based workers in their own countries and regions; and support the development of new and existing community-based services in innovative and community directed ways. The trained psychiatrists in turn will be supported in their work by access to online resources and opportunities for regular face-to-face interaction with peers and an expert group. We plan for a global initiative with regional hubs. It is being initiated in Latin America with support from the Juan Jose Lopez Ibor Foundation and the development of the Alliance for Mental Health Responses to Emergencies and Conflicts, in collaboration with citiesRISE <<http://www.citiesrise.org/>>.

**Disclosure of interest.**– The authors declare that they have no competing interest.

26th European Congress of Psychiatry

## State of the Art Lecture

### State of the Art Lecture: Advances in (Adolescent) Eating Disorders Treatment

SOA0001

#### Advances in (adolescent) eating disorders treatment

J. Treasure

*Institute of Psychiatry, Eating Disorders, London, United Kingdom*

Over 30 years ago it was found that involving the family reduced relapse following inpatient treatment in adolescents with a short duration of illness (less than 3 years). This has been replicated, and has since been used as a standalone treatment, with various family permutations (separated parent/individual, multifamily therapy). The treatment is cost effective. For example the length of inpatient stay can be reduced if family therapy is added. Furthermore elements of the intervention have been delivered in self-help forms, sharing skills and information for carers. However 20–30% of cases fail to respond. In particular those who have been ill for over 3 years do not benefit. Non responders may be identified early in the course of treatment. Therefore work to develop new interventions to manage this group of patients is in progress.

Both family therapy and guided CBT are of benefit for binge eating disorder and bulimia nervosa but the evidence base is smaller. In this lecture I will review past evidence and consider new approaches.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

SOA0002

#### Planning ahead for acute mental health crises: Methods and outcomes

C. Henderson

*King's College London Institute of Psychiatry – Psychology and Neuroscience, Health Services and Population Research, London, United Kingdom*

The term 'advance statements' covers a range of interventions which vary with respect to their basis in legislation and the manner in which health professionals are involved in their creation. Advance directives lie at one end of this range because their content is determined solely by the patient. They have not been shown to have an effect on rates of involuntary hospitalisation. The most likely reason for this is that they are enacted only when the holder is deemed to have lost capacity to make treatment decisions.

Routine care plans lie at the other, paternalistic, end of the crisis planning spectrum, as they may be produced without any patient/consumer involvement, although by consensus this is not seen as good practice. Joint crisis plans (JCP) lie toward the centre of this spectrum, as an application of shared decision making. To achieve this, JCPs require an external facilitator, namely an independent third party, to complete the crisis plan. The facilitator, a mental health professional independent of the treatment team, aims to engage the service user and treating mental health professionals in writing the JCP.

The results of a randomized controlled trial of JCPs for people with psychotic or bipolar illness showed reduced use of involuntary hospitalization associated with their use and reported positive views of the plans by service users and mental health professionals, when compared with routine care plans. The larger CRIMSON multi-site trial found a positive effect on service user-rated therapeutic relationships, but no reduction in compulsory admission rate. There was clear evidence that the JCP process had not been fully implemented by many members of staff, because of attitudinal barriers to sharing clinical decision making powers with patients. Increasingly such implementation barriers are being recognised as critical brake on healthcare improvement. Implementation science may therefore be of use for translating the findings of the first trial into routine patient benefit.

*Disclosure of interest.*– I was the principal investigator for the first trial of joint crisis plans and a coapplicant on the CRIMSON trial.

## Oral communications

### Oral communications 01: Anxiety disorders and somatoform disorders part I

OR0001

#### Is there a vicious circle during smoking cessation process: Do anxiety and depression decrease abstinence rates and, in reverse, low abstinence increase anxiety and depression?

P. Masedo<sup>1</sup>, J. Sanz Fernandez<sup>1</sup>, M.D.L.P. García Vera<sup>1</sup>, J. Fernández de Bobadilla<sup>2\*</sup><sup>1</sup> Universidad Complutense de Madrid, Facultad de Psicología, Madrid, Spain;<sup>2</sup> Hospital Univesrsitario La Paz, Cardiología, Madrid, Spain

\* Corresponding author

**Introduction and objectives.**– Some publications demonstrate that low baseline scores on scales of anxiety or depression before smoking cessation, predict abstinence rates. Conversely, other studies suggest that abstinence does not increase anxiety and/or depression, though this remains controversial. There are no publications investigating the presence of a vicious circle between low abstinence rates and anxiety and depression. Our objective is to determine the existence of this virtuous circle during the entire smoking cessation process.

**Methods.**– An analysis of a prospective longitudinal study including 291 smokers was performed. Variables: gender, age, continuous abstinence, scores of the Beck Anxiety Inventory (BAI), the short Beck Depression Inventory (BDI-II) and the Anxiety Subscale of the Hospital Anxiety and Depression scale (HAD-A) and other variables designed to assess BAI, BDI-II and HDA-A changes. A binary logistic regression statistical analysis was performed to determine whether anxiety and/or depression predict abstinence. An ANOVA–one factor analysis was performed to assess whether abstinence predicts a decline in anxiety and/or depression levels.

**Results.**– Low anxiety or depression levels as per BAI, BDI-II-Short y HAD-A scales, significantly predict abstinence. On the contrary, abstinence does not predict anxiety nor depression levels during the smoking cessation process.

**Conclusions.**– Low levels of anxiety and/or depression predict abstinence; but abstinence predicts neither a decline nor an increase in anxiety and/or depression during smoking cessation. Our findings are not consistent with a vicious circle. These conclusions

are clinically relevant and underline the importance of optimizing treatments to control anxiety and depression during the quitting process.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0002

#### Functioning and quality of life in bipolar disorder: How are they correlated? An observational study

C. Girod\*, E. Olié, P. Courtet

CHU de Montpellier, urgences et post urgences psychiatriques, Montpellier, France

\* Corresponding author

**Introduction.**– Studies show that patients with bipolar disorder (BD) have poorer quality of life (QOL) and worst functioning, but only few of them focus on the link between these two variables, and on factors influencing them. Functioning seems to be more “objective”, as it is evaluated by physicians, than QOL, which is more difficult to assess.

**Objectives.**– The aim of this observational study was to search for correlations between QOL and functioning scales.

**Methods.**– A total of 134 patients from the Montpellier FondaMental Advanced Center of Expertise for Bipolar Disorder with BD were included in the study. QOL was measured using the self-report World Health Organization Quality of Life (WHOQOL) scale, and functioning by the physician, using the Functioning Assessment Short Test (FAST) scale. Others parameters were collected like age, adherence (using Medication Adherence Rating scale – MARS), and scores on depression and mania scales. Then correlation analysis was conducted between these parameters.

**Results.**– We found a strong negative correlation between WHOQOL and FAST scales, particularly on the autonomy, professional and cognitive FAST’s sub-scales. However no correlation was detected with adherence, age, or education level. Interestingly, no correlation was found between WHOQOL or FAST and mania scales, whereas a strong one existed between depression scales and WHOQOL and FAST.

**Conclusions.**– We showed that the physician’s evaluation of functioning reflect the QOL estimated by the patient himself. Therefore asking questions about functioning could help physicians to better evaluate QOL.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

OR0003

### **The effects of cilostazol on the monoamine transporter, which is known as cellular target of antidepressants**

H. Itoh<sup>1\*</sup>, Y. Toyohira<sup>2</sup>, N. Yanagihara<sup>2</sup>, S. Saeki<sup>1</sup>

<sup>1</sup> University of Occupational and Environmental Health, Department of Rehabilitation Medicine, School of Medicine, Kitakyushu, Japan;

<sup>2</sup> University of Occupational and Environmental Health, Department of Pharmacology, School of Medicine, Kitakyushu, Japan

\* Corresponding author

*Introduction.*– Depressive disorder is considered to be a common and important neuropsychiatric post-stroke complication. Most inhibitors of the monoamine transporters, especially of the norepinephrine transporter (NET) and serotonin transporter (SERT), are clinically important antidepressants. Those antidepressants increase extracellular monoamine concentration by inhibiting the neuronal re-uptake of monoamines through the monoamine transporters. Most antidepressants act through inhibition of either the NET or the SERT or both transporters. Cilostazol is a selective phosphodiesterase III inhibitor that was originally prescribed as an anti-platelet agent, and increases cerebral blood flows in the cerebral infarction. Additionally, it acted as a neuroprotective agent by increasing cyclic adenosine monophosphate levels. The antidepressive effects of cilostazol on post-stroke depression have been reported, but the exact mechanism of this action is unknown.

*Aims.*– In this study, we examined the effects of cilostazol on NET and SERT function.

*Methods.*– SK-N-SH and SERT-transfected COS-7 cells were incubated with [<sup>3</sup>H]norepinephrine (NE) or [<sup>3</sup>H]serotonin (5-HT) in the presence or absence of cilostazol to assess the monoamine uptake.

*Results.*– Cilostazol decreased the [<sup>3</sup>H]NE uptake by SK-N-SH cells and the [<sup>3</sup>H]5-HT uptake by SERT-transfected COS-7 cells in a concentration-dependent manner.

*Conclusions.*– The blood concentration of cilostazol in treating patients with cerebrovascular disease has been reported to be 13.8 mM after a single oral dose of 100 mg. These results indicate that cilostazol inhibit NET and SERT function at clinically relevant concentration, which is likely to show the antidepressant effect on post-stroke depression.

*Source of findings.*– This study is supported by JSPS KAKENHI Grant Number 16K16456.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

OR0004

### **Anxiety disorders and differentiation of self**

J. Lampis<sup>1\*</sup>, S. Cataudella<sup>1</sup>, A. Busonera<sup>2</sup>, R. Guyonne<sup>2</sup>

<sup>1</sup> University of Cagliari, Faculty of Humanistic Studies, Department of Pedagogy, Psychology, Philosophy, Cagliari, Italy;

<sup>2</sup> University of Rome Sapienza, Department of Dynamic and Clinical Psychology, Rome, Italy

\* Corresponding author

*Introduction.*– Kerr and Bowen (1988) argued that individuals with a less differentiated self were more likely to experience anxiety, function less effectively in stressful situations, and suffer from physiological and relational psychological symptoms in social situations. In the recent years, these suggestions have been the focus of a great empirical research. These studies revealed that well differentiated individuals enjoy good physical and psychological health

(e.g. Skowron, Stanley & Shapiro, 2009; Lampis, Cataudella, Busonera & Skowron, 2017) and are less anxious (e.g. Skowron & Dendy, 2004; Peleg & Yitzhak, 2011).

*Objectives.*– Starting from these premises, the main objective of our investigation was to compare a normative sample ( $n=69$ , control group) and two samples of adults seeking therapeutic services for couple relationship problems ( $n=41$ ) and for anxiety and panic ( $n=47$ ), to analyze differences on the levels of differentiation of self.

*Method.*– The various components of differentiation of self (emotional reactivity, emotional cut-off, emotional fusion and I-position) and the levels of anxiety were investigated using the Differentiation of Self Inventory Revised (DSI-R) and the Symptom Check List Revised (SCL-90-R).

*Results.*– We found that participants of the clinical sample of adults seeking therapeutic services for anxiety and panic had significantly higher scores in the Emotional cut-off scale and significantly lower scores in the I-position scale.

*Conclusion.*– The research revealed the importance of differentiation of self-processes to achieving an understanding of anxiety and panic disorders in research and clinical practice.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Duloxetine augmentation in resistant obsessive compulsive disorder: A double blind controlled clinical trial**

A. Mowla

Shiraz University of Medical Sciences, Psychiatry, Shiraz, Iran

*Introduction.*– The aim of this study is to evaluate the efficacy of duloxetine augmentation in treatment of resistant Obsessive Compulsive Disorder (OCD).

*Methods.*– This augmentation trial was designed as an 8-week randomized controlled, double blind study. Forty-six patients suffering from OCD who had failed to respond to at least 12 weeks of treatment with a selective serotonin reuptake inhibitor (fluoxetine, citalopram or fluvoxamine) were randomly allocated to receive duloxetine or sertraline plus their current anti OCD treatment. Yale-Brown Obsessive Compulsive Scale (Y-BOCS) was the primary outcome measure. Treatment response was defined as 25% or more decrease in scores of Y-BOCS. The mean dosage of duloxetine was 44.4 mg/day (range: 20–60 mg/day) and the mean dosage of sertraline was 123.8 mg/day (range: 50–200 mg/day).

*Results.*– Forty six patients (24 of 30 in duloxetine group and 22 of 27 in sertraline group) completed the trial. Both groups showed improvement over the 8-week study period (mean Y-BOCS total score at week 8 as compared with baseline:  $P < .001$  &  $P < .001$ ) without significant difference ( $P = .861$ ). Those receiving duloxetine plus their initial medications experienced a mean decrease of 33.0% in Y-BOCS score and the patients with sertraline added to their initial medication experienced a mean decrease of 34.5% in Y-BOCS.

*Discussion.*– Our double blind controlled clinical trial showed duloxetine to be as effective as sertraline in reducing obsessive and compulsive symptoms in resistant OCD patients. However, our study is preliminary and larger double blind placebo controlled studies are necessary to confirm the results.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

OR0006

**Increased methylation at SLC6A4 gene is associated with somatization symptoms in women but not in men: A sex-specific effect identified in a non-clinical sample**

H. Palma-Gudiel<sup>1,2</sup>, A. Córdova-Palomera<sup>1,2</sup>, L. Marquès-Feixa<sup>1,2</sup>, J. Moya-Higuera<sup>2,3</sup>, L. Fañanás<sup>1,2</sup>

<sup>1</sup> University of Barcelona, Departament de Biologia Evolutiva, Ecologia i Ciències Ambientals, Barcelona, Spain;

<sup>2</sup> CIBERSAM, Instituto de Salud Carlos III, Madrid, Spain; <sup>3</sup> University of Lleida, Department of Psychology, Lleida, Spain

\* Corresponding author

**Introduction.**– Depression is a leading cause of disability worldwide with a striking difference in its prevalence according by sex; women being twice as vulnerable as men. The SLC6A4 gene encodes the serotonin transporter, which reuptakes serotonin from the synaptic cleft. This transporter is one of the main pharmacological targets of currently available antidepressants. Thus, both genetic and epigenetic variability at this gene have been researched in association with depression and associated phenotypes.

**Objectives.**– To assess methylation variability at the SLC6A4 gene in association with anxious-depressive disorders and subclinical psychological symptoms.

**Methods.**– Overall, 148 twin subjects (UB twin register) from the general population were assessed for lifetime history of psychiatric disorders (DSM-IV criteria, SCID) and psychological symptoms as experienced in the last 30 days (Brief Symptom Inventory, BSI). Peripheral blood-derived genomic DNA methylation at SLC6A4 promoter region was assessed by means of pyrosequencing technology (5 CpG sites analyzed).

**Results.**– SLC6A4 methylation was significantly associated with gender of the participants ( $P < 0.001$ ); women being more methylated than men in all 5 CpG sites analyzed. SLC6A4 methylation was significantly associated with the somatization subscale score of the BSI ( $P < 0.02$  in all 5 CpG sites analyzed) in a female-specific fashion. SLC6A4 methylation was not associated with categorical diagnosis.

**Conclusions.**– SLC6A4 methylation correlated to the somatization dimension of the BSI scale in women. Sex-specific methylation of this region points to its relevance in mediating known sex differences with regard to psychopathology.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0007

**Acute cardiovascular risk in general population with anxiety in Russia/Siberia: Gender features. WHO program Monica-psychosocial study**

V. Gafarov, E. Gromova, D. Panov\*, I. Gagulin, A. Gafarova  
FSBI Institute of Internal Medicine SB RAMS, Collaborative Laboratory of Cardiovascular Diseases Epidemiology, Novosibirsk, Russia

\* Corresponding author

**Purpose.**– To evaluate the influence of personal anxiety on risk of myocardial infarction (MI) and stroke in general population of Russia/Siberia.

**Methods.**– In frame of the third screening WHO program “MONICA-psychosocial” a random representative sample of the population aged 25–64 in Novosibirsk in 1994 (men:  $n = 657$ , women:  $n = 870$ ) was surveyed. The program included: registration of socio-demographic data; personal anxiety was studied with Spielberger test. Over 16-year period cases of MI and stroke incidence in women (15 and 35) and men (30 and 22) were identified, respectively. Cox regression model was used for relative risk assessment (HR)

**Results.**– Over 16 years, the risk of myocardial infarction and stroke in women with high anxiety level (HLA) was 4.19-fold and 3.5-fold higher, respectively. HR was 3.7 and 4.43 in men, respectively. After adjustment for age and social parameters, HR risk of MI and stroke was 5.16 and 3.5, respectively for women;  $HR = 1.79$  and  $HR = 3.2$  for men with HLA, respectively. The risk of MI was higher in women aged 55–64y with HLA ( $HR = 5.95$ ), than men ( $HR = 3.56$ ). The greatest risk of stroke in presence of high anxiety was in divorced ( $HR = 5.017$ ) and widowed men ( $HR = 3.848$ ), aged 55–64 years ( $HR = 5.8$ ).

**Conclusion.**– Anxiety is the most potent psychosocial risk factors for myocardial infarction and stroke in general population. The risk of MI was higher in women but stroke in men over 16-years period.

**Prenatal hypercortisolemia alters the course of neuronal maturation of hippocampal neurons and anxiety-like behavior in the rat**

J.R. Pascual\*, I. Cuevas, M. Valencia  
Pontificia Universidad Católica de Valparaíso, School of Kinesiology, Faculty of Sciences Laboratory of Developmental Neurobiology, Valparaíso, Chile

\* Corresponding author

**Introduction.**– It has been reported that adult individuals exposed to severe early stressful experiences exhibit posttraumatic stress disorder (PTSD) and hippocampal volume reduction. Since the stressful environmental conditions generate elevated levels of circulating glucocorticoids (GCs), it is likely that GCs could modify the time course of hippocampal development, predisposing individuals to exhibit long-term PTSD. Thus, the objectives of the current study were to analyze whether prenatal administration of synthetic GCs alters the hippocampal neuronal morphology, brain derived neurotrophic factor (BDNF) expression and anxiety-like behaviors at three postnatal ages: infancy (postnatal day 22, P22), adolescence (P52) and young adulthood (P82).

**Methods.**– Pregnant animals were randomly classified in two groups: control-saline (CON,  $n = 6$ ) and betamethasone-treated (BET,  $n = 5$ ). Mothers of BET-P22, P52 and P82 groups received two courses of betamethasone subcutaneously ( $170 \mu\text{g kg}^{-1}$ ) on gestational day 20 (G20), separated by an 8-hour interval. CON mothers received equal volume (1 mL) of saline. Anxiety-like behavior and neuronal changes were performed at P22, 52 and 82. The dose used here is equivalent to that used in cases of preterm delivery.

**Results.**– Prenatal BET administration is related with (i) a significant anxiety-like behavior, (ii) hippocampal neuronal atrophy, and (iii) diminished BDNF expression. These neurobehavioral changes were significant in late (P52 and P82) but not early (P22) postnatal ages.

**Conclusions.**– Prenatal administration of synthetic GCs (BET) during the last trimester of gestation in a rat's animal model is associated with protracted changes in hippocampal neuronal morphology, BDNF expression and anxiety-like behavior in the offspring.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparative and additive benefits of cognitive restructuring versus exposure-only treatment in anxiety: A longitudinal multilevel meta-analysis on symptom relapse

I. Podina<sup>1</sup>, V. Andreea<sup>2</sup>, F. Liviu<sup>3</sup>, F. Christoph<sup>2</sup><sup>1</sup> University of Bucharest, Psychology, Bucharest, Romania;<sup>2</sup> University of Zurich, Psychological Institute General intervention psychology and psychotherapy, Zurich, Switzerland;<sup>3</sup> Babes Bolyai University, Evidence-Based Psychological Assessment and Interventions Doctoral School, Cluj-Napoca, Romania

\* Corresponding author

**Introduction.**– Although exposure-based treatments seem to be a success story for anxiety disorders, relapse is not uncommon. There is a continued controversy over whether exposure (EXP) should be complemented or replaced by cognitive techniques, such as cognitive restructuring (CR), in order to reduce or prevent relapse rates in anxiety. This is an important theoretical and clinical debate. Objective: Therefore, the aim of the meta-analysis was (a) to compare EXP to CR with respect to symptom relapse in anxiety disorders and (b) to contrast EXP vs. EXP + CR for potential additive advantages.

**Methods.**– Traditional and longitudinal multilevel meta-analyses were conducted in order to examine the magnitude of the difference between EXP vs. CR and EXP vs. EXP + CR. Symptom specific outcomes were examined.

**Results.**– Overall, 21 randomized controlled trials examining EXP vs. CR and 20 randomized controlled studies examining EXP vs. EXP + CR were included in the current meta-analysis. None of the longitudinal analyses of growth from termination to follow-up produced statistically significant effects (EXP vs. CR:  $B_0$  coeff. = 0.05,  $P = 0.50$ ,  $B_1$  coeff. =  $-0.02$ ,  $P = 0.75$ ; EXP vs. EXP + CR:  $B_0$  coeff. = 0.14,  $P = 0.09$ ,  $B_1$  coeff. =  $-0.01$ ,  $P = 0.93$ ). Potential moderator variables were examined.

**Conclusions.**– Theoretical and clinical implications will be discussed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Unraveling the neural circuit mechanism for treatment of fear disorders via alternating bilateral sensory stimulation in mice

H.S. Shin<sup>1</sup>, J. Baek, S. Lee

Institute for Basic Science, Center for Cognition and Sociality, Daejeon, Republic of Korea

\* Corresponding author

**Introduction.**– Patients with post-traumatic stress disorders (PTSD) suffer from fear memories which persist even after the actual fear-inducing aversive situation is gone. The Eye Movement Desensitization and Resetting, a psychotherapy regiment utilizing alternating bilateral sensory stimulation (ABS), is being used for treating PTSD patients. However, innate brain mechanisms underlying those treatment effects have not been defined.

**Objective.**– To study the neural mechanism for fear memory erasure. **Methods.**– We successfully established long-lasting fear reduction in mice by pairing non-invasive visual stimulation with the conditioned stimulus during fear extinction. Using optogenetic tools and electrophysiology, we have tried to define the circuit mechanism underlying the ABS-mediated fear memory erasure.

**Results.**– Among the several patterns of visual stimuli tested, alternating bilateral stimulations (ABS) was the most effective in the enhancement of fear extinction with consequential erasure. Optogenetic manipulation revealed that the superior colliculus-mediadorsal thalamus circuit is involved, with necessity and sufficiency, in preventing the return of fear. The ABS-pairing drove mediadorsal thalamic activities throughout the extinction session, and induced a sustained enhancement of inhibitory neurotransmission in the amygdala.

**Conclusions.**– These results demonstrate that simultaneous and persistent engagement of the colliculo-thalamic pathway during fear extinction induces plasticity changes in the amygdala, leading to sustained attenuation of traumatic memories resulting in their erasure.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Adjunctive risperidone for post-traumatic stress disorder: A systematic review and meta-analysis

S. Suttajit<sup>1\*</sup>, S. Suttajit<sup>2</sup>, M. Srisurapanont<sup>1</sup>, N. Maneeton<sup>1</sup>, B. Maneeton<sup>1</sup><sup>1</sup> Faculty of Medicine, Chiang Mai University, Department of Psychiatry, Chiang Mai, Thailand;<sup>2</sup> Chiang Mai University, Faculty of Pharmacy, Chiang Mai, Thailand

\* Corresponding author

**Introduction.**– Failure to respond to treatment occurs in 40–47% of patients with Post-traumatic stress disorder (PTSD). Early studies suggested that adjunctive risperidone with antidepressants may have benefit in patients with PTSD.

**Objectives.**– To systematically review the efficacy and the tolerability of risperidone, as an adjunctive treatment, for PTSD.

**Methods.**– We considered all relevant randomized, controlled trials (RCTs) of risperidone, as adjunctive therapy, was investigated in comparison with placebo or other treatments in patients with PTSD. The primary outcome was the change in scores of PTSD rating scales. Secondary outcomes measures were leaving the studies early, Clinical Global Impressions-Severity (CGI-S), Clinical Global Impression-Improvement (CGI-I) scale, Hamilton Anxiety Rating Scale (HAM-A) score, and adverse events.

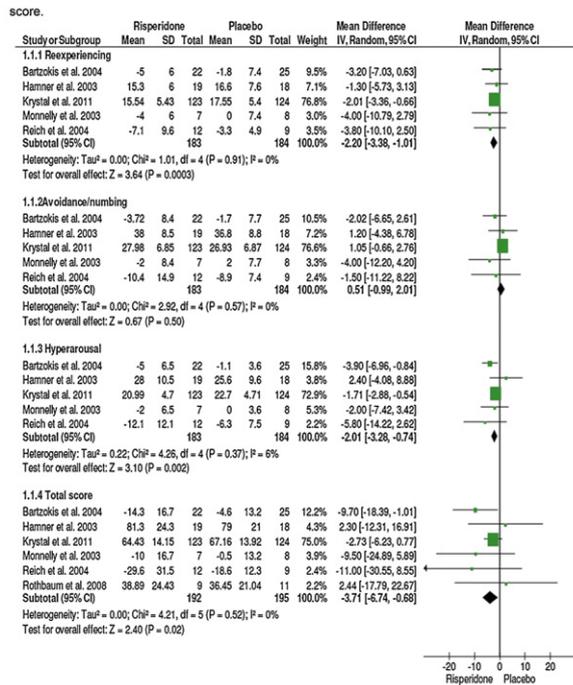

The Cochrane Central Register of Controlled Trials, PubMed, PsycINFO®, the EU Clinical Trials Register database, and Clinical Trials.gov were searched (June 2013). Data was entered into the Review Manager (RevMan) software (Version 5.3).

**Results.**– Six RCTs ( $n = 387$ ) were included. The PTSD total score was significantly lower in the risperidone group compared with the placebo group (mean difference  $-3.71$ , 95% confidence interval  $-6.74$  to  $-0.68$ ). Significantly greater improvements in re-experiencing and hyperarousal subscales were found in the risperidone group.

There were significant differences, favouring the risperidone group, on the CGI-S and the HAM-A score. The average dosage of risperidone was 2.05–2.5 mg/day.

Figure 1 Risperidone versus placebo: average change or endpoint in PTSD subscores and total score.

**Conclusions.**– Our results suggest that low dosages of risperidone might be effective in the adjunctive treatment of PTSD, particularly in the areas of re-experiencing and hyperarousal.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– Generalized anxiety disorder (GAD) is a chronic psychiatric condition characterized by excessive anxiety and worry. Limited published research has quantified the GAD prevalence and its burden in China.

**Objectives.**– This cross-sectional study examined the prevalence and burden of GAD among adults in urban China.

**Methods.**– This study utilized existing data ( $n = 36,520$ ) from the National Health and Wellness Survey (NHWS), a cross-sectional and self-administered online questionnaire of a representative sample of urban adult population in China. Prevalence of self-reported diagnosed GAD and undiagnosed [positively screened (Generalized Anxiety Disorder (GAD-7) score  $\geq 10$ ) without a reported GAD experience] were estimated. GAD patients were compared with non-anxious respondents (negatively screened without a history of GAD experience/diagnosis) in terms of quality of life (QoL), resource utilization, and work productivity and activity impairment using multivariate generalized linear models, controlling for demographics and clinical characteristics.

**Results.**– The prevalence of undiagnosed/diagnosed GAD was 4.6% in China with only 0.5% of GAD patients reporting a diagnosis. Compared with non-anxious respondents, GAD patients had significantly lower mental component summary scores (34.3 vs. 35.0), physical component summary scores (47.8 vs. 51.2), and health state scores (0.59 vs. 0.69) using the SF-36v2, more work productivity (52.2% vs. 29.5%) and activity impairment (47.2% vs. 26.4%),

and greater number of healthcare provider visits (2.4 vs. 1.4), emergency room visits (0.7 vs. 0.4) and hospitalizations (0.5 vs. 0.2) in the past six months.

**Conclusions.**– GAD may be substantially under-diagnosed in urban China. More healthcare resources should be invested to alleviate the burden of GAD.

**Disclosure of interest.**– This study was funded by Pfizer Investment Co., Ltd. The analysis was provided by Kantar Health LLC who received funding from Pfizer Investment Co., Ltd.

### Ventral striatal activity during win anticipation: A comparison between euthymic bipolar type II and unipolar patients

E. Allauze<sup>1\*</sup>, L. Samalin<sup>1</sup>, P.M. Llorca<sup>1</sup>, X. Caseras<sup>2</sup>

<sup>1</sup> Universite Auvergne, NPsy-sydo Ea 7280 Uda, Clermont-Ferrand, France;

<sup>2</sup> Cardiff University, Mrc Centre For Neuropsychiatric Genetics And Genomics, Cardiff, United Kingdom

\* Corresponding author

**Introduction.**– Early differentiation between bipolar and unipolar depressed patients is crucial for a correct treatment plan and patients' prognosis. This differentiation is particularly challenging in bipolar type II disorder, where the identification of potential biomarkers for the disorder has become a research priority.

**Objectives.**– The aim of the study was to investigate the activity in the ventral striatum during the anticipation of potential win (reward) in euthymic bipolar type II and unipolar patients.

**Methods.**– This cross-sectional study compared the BOLD responses in the ventral striatum between a group of healthy controls ( $n = 14$ ) and euthymic bipolar type II ( $n = 18$ ) and unipolar ( $n = 18$ ) patients, during a widely used fMRI paradigm including periods of win anticipation and win outcome.

**Results.**– During win anticipation, both bipolar II and unipolar patients showed increase bilateral BOLD activity compared to healthy controls. However, only bipolar II participant showed increased BOLD activity during win anticipation compared to loss anticipation. Less compelling results were obtained during win output, where unipolar depressed showed increased BOLD for the contrast win output > loss output only compared to healthy controls.

**Conclusions.**– Activity in the ventral striatum—a key node of the reward brain network—associated with the anticipation of potential win appears increased in euthymic bipolar patients compared with unipolar and control participants. This difference, though, seem to only be observed when accounting for activity associated with anticipation of potential loss, likely associated with an overall increased arousal. Abnormally elevated ventral striatum activity during reward anticipation may be biomarker of Bipolar II.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>1</sup> Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico University of Milan, Department of Psychiatry, Milan, Italy;

<sup>2</sup> Stanford University School of Medicine, Department of Psychiatry and Behavioral Sciences, Stanford, CA, USA

\* Corresponding author

**Introduction.**– Limited evidence is available about differential pharmacological management of Bipolar Disorder (BD) I vs II. Indeed, pharmacological treatment choices have been usually based on specific clinical dimensions rather than diagnostic subtypes.

**Objectives.**– The present study was aimed to assess different patterns of psychotropic prescription in European and American bipolar patients, not in a syndromal episode, referred to Milan and Stanford University BD Clinics, respectively, and stratified by bipolar subtype.

**Methods.**– Prevalence and clinical correlates of antidepressant (AD), antipsychotic (AP), and mood stabilizer (MS) use, in aggregate and individually, were compared in BDI versus BDII patients, either in Milan and Stanford pooled sample and in Milan vs Stanford samples.

**Results.**– BDI ( $n=424$ ) vs BDII ( $n=239$ ) patients (Milan and Stanford pooled) significantly more often took APs (69.8% vs 44.8%), MSs (68.6% vs 57.7%), and valproate (40.1% vs 17.5%), but significantly less often ADs (23.1% vs 55.6%) and lamotrigine (9.9% vs 25.2%). Milan ( $n=380$ ) compared with Stanford sample ( $n=283$ ) significantly more often took APs (BDI and BDII), ADs (BDII), and valproate (BDII), but significantly less frequently MSs (BDI) and lamotrigine (BDI).

**Conclusions.**– The present study highlights specific differences in BD psychotropic prescription patterns, either considering the geographic areas of recruitment and the diagnostic subgroups. Investigation on pharmacotherapy in relation to bipolar subtype and treatment location is warranted in order to enhance clinical management of patients suffering from different bipolar disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>1</sup> National Institute of Mental Health, Applied Brain ElectroPhysiology, Klecany, Czech Republic;

<sup>2</sup> Third Faculty of Medicine, Charles University, Department of Psychiatry, Prague, Czech Republic;

<sup>3</sup> National Institute of Mental Health, Inpatient Ward 2: Mood Disorders, Klecany, Czech Republic;

<sup>4</sup> Second Faculty of Medicine, Motol University Hospital, Charles University, Department of Paediatric Psychiatry, Prague, Czech Republic

\* Corresponding author

**Introduction.**– Studies in adults show that approximately 30–60% of individuals diagnosed with bipolar disorder (BD) retrospectively report the onset of their illness in childhood.

**Objectives.**– To determine psychopathology, cognitive functions and identify early markers in EEG cortical sources, cortical connectivity and event-related potentials (ERPs) in a sample of offspring of parents with BD (BDO) compared to healthy controls (HC).

**Methods.**– Lifetime and current presence of DSM-5 diagnoses were assessed in 43 BDO (mean age:  $12.5 \pm 3.1$  years) and 43 HC matched for sex, age and IQ. ERP (P300, N2/P3) and EEG were available for 34 subjects in both subgroups. The comparison of the distribution of current densities and functional connectivity was done by independent *t*-tests of log-transformed s/eLORETA values.

**Results.**– Thirty-seven BDO (86%) and 18 controls (42%) met criteria for at least one lifetime psychiatric diagnosis (adjusted  $OR=7.2$ ). While the groups did not differ in ERP and extended neuropsychological testing, significant differences were observed in alpha-1, beta-3 and gamma sources in resting EEG: BDO showed decreased alpha-1, beta-3 and gamma sources in temporal gyri and cingulate as well as decreased connectivity in alpha-1 between bilateral temporal areas and an increase within the right fronto-temporal areas in gamma band.

**Conclusions.**– We found a higher rate of lifetime anxiety and mood disorders in children at confirmed familial risk for BD. The differences in activity during resting EEG could represent trait vulnerability marker for later onset of BD and suggest an altered functioning of cortical networks in high-risk population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Relationship between childhood adversity and impulsivity in major depression and bipolar types I and II

A. Do, T. Cassis\*, M. Saint Laurent, P. Cervantes, N. Low  
Institute of research, McGill University Health Center, Psychiatry, Montreal, Canada

\* Corresponding author

**Background.**– Impulsivity in mood disorders has been associated with increased risk for substance misuse and suicide. Childhood adversity is also common risk factor for impulsivity in mood disorders. To date, there is data lacking related to the specific differences and predictors (including childhood adversity) of impulsivity among the mood disorder types.

**Aims.**– To examine the prevalence of impulsivity in patients with major depression (MDD), bipolar type I (BPI) or bipolar type II (BPII). To examine childhood adversity as a modifier of the association between impulsivity and mood disorder type.

**Methods.**– Participants were recruited from the McGill University Health Center in Montreal, Quebec. Mood diagnoses were determined using the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID). Barrett's Impulsivity Scale (BIS) was impulsivity in the attentional, motor and non-planning domains. Childhood adversity was assessed using the Childhood Experiences of Care and Abuse Questionnaire (CECA-Q). ANOVA and kruskal-wallis tests and linear regression models were conducted.

**Results.**– Impulsivity in the attentional and non-planning domains was greater in BPII than MDD and BPI. However, when childhood adversity is examined, the association between mood disorder type was explained by maternal psychological abuse which is associated with greater impulsivity in the attentional domain. Similarly, for impulsivity in the non-planning domain, the association between

mood disorder type was accounted for by (1) maternal psychological abuse and (2) maternal physical abuse. Psychological abuse by mother is associated with greater impulsivity in the motor domain.

**Conclusions.**– Childhood adversity accounts for the differences in mood disorders types and impulsivity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Evaluation of a cognitive remediation program, specific of working memory, in bipolar patients with memory complains**

F. Coppola

CHU, Psychiatrie, CHU La Colombière, service la traversière, Montpellier, France

Bipolar disorder is part of the most expensive and invalidating diseases in the world.

The psychosocial repercussions are important and can be invalidating.

Therefore, a functional handicap is so found during the phases of decompensation, but also in intercritical periods when various factors can be involved, particularly cognitive deficits or cognitive complaints.

A deficit in working memory is reported by several studies and seems to play an important role in the functioning of the patients. Cognitive remediation is a treatment in development in bipolar disorder, but few programs are available.

COGMED is a cognitive remediation program, specific of working memory, having demonstrated its efficiency in patients with traumatic brain injury or attention deficit/hyperactivity disorder.

Its duration is of 5 weeks and is made at home on the Internet. We led a prospective study in order to evaluate the efficiency of this program in the functional improvement, for euthymic bipolar patients with memory complains. Forty patients were included.

A clinical and neuropsychological evaluation was made before and later Cogmed program. The primary endpoint was patients functioning assessed by the FAST Scale.

There was a significant improvement in global functioning, and particularly in these following functional domains: autonomy, cognitive and occupational.

Number of manic episodes was negatively correlated with the Functional improvement.

We also found a significant decrease of memory and attentional complains, assessed by Mac-Nair scale, which is a self-report questionnaire.

COGMED is an effective program to decrease the functional handicap and cognitive complains in euthymic bipolar patients.

\* Corresponding author

**Introduction.**– Lithium is the most recommended treatment for the prophylaxis of Bipolar Disorder (BD). Tremor is common adverse effects of lithium. This side effect is a frequent complaint of lithium-treated patient and has an important impact on the patient's quality of life. It is associated with poor adherence and treatment discontinuation.

**Objectives.**– The objective is to investigate the prevalence of lithium-associated tremor, its associated factors and its consequences.

**Methods.**– We conducted a literature review and descriptive analysis of the FACE-BD database (including  $n = 2415$  patients with BD) to analyze the prevalence of lithium-associated tremor. The influence of clinical conditions such as age, sex, type of bipolar disorder, duration of illness, duration of lithium treatment, associated treatments, comorbidities and biological data were also analyzed. The impact of this tremor will also be studied on the compliance and social functioning.

**Results.**– First results show a prevalence of 45.6% ( $n = 257$ ) lithium-associated tremor in lithium-treated patient in FACE-BD database, in agreement with the other studies. Factors associated with tremor and consequence (residual symptoms, functioning) will be described.

**Conclusions.**– This exploration will refine knowledge of lithium-associated tremor. We will also discuss the management of this side effect with drug strategies next to our results.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction.**– Treatment of bipolar disorder in developing world rural areas is complicated by difficulties to ensure safe monitoring of medication, and patients therefore seldom get access to best practice treatment.

**Objective.**–Development of a user-friendly device and a system making it possible to measure and monitor medication levels.

**Methods.**– To ensure safe mood stabilizing treatment in rural areas a micro sensor system is being developed by collaborators in a European consortium

**Results.**– An integrated approach for compiling and analyzing high-quality lithium treatment response data will be presented. By means of micro-sensor devices patients in rural areas are able to self-measure and subsequently send Lithium level results via smartphone to their psychiatrists.

**Conclusions.**– This project represents a concerted effort and a potential solution solving the problem of delivering efficacious and safe'state of the art' medical treatment for Bipolar disorder in places where Health care resources are particularly sparse.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0020

### Facial emotion recognition in bipolar disorder

U. Espinos

Asociacion Bipolar de Madrid, Psychology, Alcobendas, Spain

**Background.**– This study aims to research the recognition of facial emotions in a clinical sample of people with bipolar disorder as results found in the investigation to determine if the bipolar subjects are competent for the recognition of emotions are contradictory.

**Methods.**– Participants were 21 persons with bipolar disorder in euthymic phase and 21 control subjects. Both groups passed tests of an e-prime program having as a purpose the recognition of emotions with positive and negative valence and intensity of each emotion perceived. The emotions presented belonged to the category of joy, anger, sadness, fear or neutral.

**Results.**– The results showed no significant differences in the recognition of facial expressions in persons with bipolar disorder and control subjects. Differences were found in the reaction time: people with bipolar disorder were slower to recognize emotions, especially those of low intensity. There are significant differences between the control group and the bipolar disorder group, the latter having a longer reaction time in all emotional patterns, except in anger. People with bipolar disorder have greater variability than the control group in all emotions, except in anger.

**Conclusions.**– Clearly different patterns are obtained among subjects with bipolar disorder compared to controls in the sense that they present a greater selective difficulty for negative emotional expressions (except in the case of anger) and for neutral ones.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Effect of lurasidone on cognition in children and adolescents with bipolar depression: A 6-month interim analysis of a 2-year open-label extension study

K.E. Burdick<sup>1</sup>, R. Goldman<sup>2\*</sup>, M. Tocco<sup>2</sup>, L. Deng<sup>3</sup>, J. Cucchiaro<sup>4</sup>, A. Loebel<sup>4</sup><sup>1</sup> Icahn School of Medicine at Mount Sinai, Psychiatry, New York, USA;<sup>2</sup> Sunovion Pharmaceuticals Inc., Medical Affairs, Marlborough, USA;<sup>3</sup> Sunovion Pharmaceuticals Inc., Statistics, Marlborough, USA;<sup>4</sup> Sunovion Pharmaceuticals Inc., Medical Affairs, Fort Lee, USA

\* Corresponding author

**Introduction.**– Limited data are available on cognitive function in pediatric patients with bipolar disorder.

**Objective.**– To evaluate the effects of lurasidone on cognition in children and adolescents with bipolar depression.

**Methods.**– Patients aged 10–17 years with bipolar I depression who completed 6 weeks of double-blind (DB), placebo-controlled treatment with flexibly dosed lurasidone (18.5–74 mg/d) were enrolled in a 2-year, open-label study in which patients were continued on lurasidone, or switched from placebo to lurasidone. Cognitive function was assessed with the Brief CogState battery, which evaluates four cognitive domains: processing speed (detection task), attention/vigilance (identification task), visual learning (one card learning task), working memory (one back task, speed & accuracy). Based on normative data, an overall cognitive composite Z-score was calculated as the average of the standardized Z-scores for each of the four cognitive domains. We present here the results of a 28-week interim analysis.

**Results.**– Two hundred and twenty-three patients completed the DB study and entered the open-label extension study; 69.5% completed

28 weeks of treatment (mean daily dose, 52.6 mg). The cognitive composite Z-score showed impairment at DB baseline (–0.94). At week 28, overall improvement was observed in the cognitive composite Z-score (mean change, +0.19). For CogState domains, mean change at week 28 in Z-scores was observed for processing speed (+0.13), attention/vigilance (+0.18), visual learning (+0.18), working memory accuracy (+0.07), and working memory speed (+0.29).

**Conclusions.**– In this study of pediatric bipolar depression, 28 weeks of lurasidone treatment was not associated with cognitive impairment as measured by the Brief CogState battery.

### Symptom improvement associated with lurasidone treatment of children and adolescents with bipolar I depression: Results of a short-term placebo-controlled trial

M. Singh<sup>1</sup>, R. Goldman<sup>2\*</sup>, M. Tocco<sup>2</sup>, A. Pikalov<sup>2</sup>, L. Deng<sup>3</sup>, J. Cucchiaro<sup>4</sup>, A. Loebel<sup>4</sup><sup>1</sup> Stanford Child Health Research Institute of Stanford University, Psychiatry and Behavioral Sciences, Stanford, USA;<sup>2</sup> Sunovion Pharmaceuticals Inc., Medical Affairs, Marlborough, USA;<sup>3</sup> Sunovion Pharmaceuticals Inc., Statistics, Marlborough, USA;<sup>4</sup> Sunovion Pharmaceuticals Inc., Medical Affairs, Fort Lee, USA

\* Corresponding author

**Objective.**– To evaluate change in specific depressive symptoms in children and adolescents presenting with bipolar depression who received short-term treatment with lurasidone.

**Method.**– Data in this secondary analysis were derived from a study of patients 10–17 years ( $n=343$ ) with bipolar I depression who were randomized to 6 weeks of double-blind treatment with lurasidone 20–80 mg/d or placebo. The primary endpoint was change from Baseline to Week 6 on the Children's Depression Rating Scale, Revised (CDRS-R) total score. Change from Baseline to Week 6 for each individual CDRS-R item was assessed with an ANCOVA using an LOCF approach. Cohen's  $d$  effect sizes were also calculated at Week 6.

**Result.**– At week 6 endpoint, treatment with lurasidone was associated with significant improvement vs. placebo in the CDRS-R total score (–21.0 vs. –15.3;  $P<0.0001$ ;  $d=0.45$ ). A total of 13 CDRS-R items (76%) were significantly improved on lurasidone: impaired school work ( $P=0.023$ ;  $d=0.25$ ), difficulty having fun ( $P=0.004$ ;  $d=0.31$ ), social withdrawal ( $P<0.0001$ ;  $d=0.43$ ), sleep disturbance ( $P=0.0001$ ;  $d=0.43$ ), appetite disturbance ( $P<0.05$ ;  $d=0.22$ ), irritability ( $P=0.026$ ;  $d=0.24$ ), excessive guilt ( $P=0.0032$ ;  $d=0.32$ ), low self-esteem ( $P=0.012$ ;  $d=0.27$ ), depressed feelings ( $P=0.0068$ ;  $d=0.29$ ), excessive weeping ( $P=0.014$ ;  $d=0.27$ ), depressed facial affect ( $P=0.0009$ ;  $d=0.36$ ), listless speech ( $P<0.0001$ ;  $d=0.43$ ), and hypoactivity ( $P=0.012$ ;  $d=0.27$ ). Improvement in 4 items was not significant: excessive fatigue, physical complaints, morbid ideation, and suicidal ideation.

**Conclusions.**– In this placebo-controlled study of children and adolescents with bipolar depression, 6 weeks of treatment with lurasidone was effective in treating a wide range of depressive symptoms assessed by the CDRS-R.

<sup>4</sup> McGill University, Department of Psychiatry, Montreal, Canada;

<sup>5</sup> Helsinki University Central Hospital, Psychiatry, Helsinki, Finland;

<sup>6</sup> University of Helsinki, Department of Psychiatry, Helsinki, Finland

\* Corresponding author

**Introduction.**– Predominant polarity is a relatively new concept, involving categorizing patients with bipolar disorder (BD) based on polarity of their preceding illness course, using cut-off of two thirds of episodes.

**Objectives.**– Few prospective studies have investigated its predictive validity, or associated clinical features. We examined them within a long-term cohort study of bipolar I (BD-I) and bipolar II (BD-II) patients.

**Methods.**– In the Jorvi Bipolar Study (JoBS), 191 BD-I and BD-II psychiatric in- and outpatients were carefully diagnosed at baseline using SCID-I/P-interviews, and followed using life-chart methodology up to five years. Predominant polarity could be defined for 188 (98.4% of all) patients, based on their preceding illness course. Information on their prospective illness phases was available for 175 (93.0%) of these patients.

**Results.**– Predominant polarity was defined as manic in 30 (16%), intermediate in 90 (48%) and depressive in 68 (36%). The three groups differed in terms of their psychiatric comorbidity, with those with manic polarity having less anxiety, but more psychotic symptoms lifetime. Patients with manic polarity also spent significantly more time euthymic during follow-up. Analyses are ongoing, and the final results will be presented in the meeting.

**Conclusions.**– Psychiatric in- and outpatients with BD I or II can be classified according to their predominant polarity, and this classification has at least some predictive validity in long term. Those with predominantly manic polarity may be the most distinct of the three groups. Patients in different polarity groups differ also in their other clinically relevant characteristics, such as psychiatric comorbidity.

\* Corresponding author

**Introduction.**– Bipolar disorder and major depressive disorder are among the most frequent and the most severe mood disorders. Due to their shared symptomatology, and often unreported and delayed onset of manic or hypomanic episodes in bipolar disorder, patients with bipolar disorder are often mistakenly diagnosed with unipolar major depression.

**Objectives.**– The aim of the study was to explore the differences in the alterations of the investigated soluble adhesion molecules (sVCAM-1 and sICAM-1) with regard to unipolar (UD) and bipolar depression (BD) types, compared with healthy control group.

**Methods.**– The study has explored serum levels of sVCAM-1 and sICAM-1 in patients with bipolar ( $n=43$ ) or unipolar depression ( $n=93$ ) and compared them to healthy controls ( $n=73$ ). The adhesion molecules' levels of patient group have been analyzed in acute and remission phases.

**Results.**– Both patients in acute episode of unipolar and bipolar depression showed altered levels of adhesion molecules when compared to healthy control group. The results additionally show down regulation of sVCAM-1 and up regulation of sICAM-1 levels in both patient groups.

**Conclusions.**– Our results suggest that adhesion molecules, particularly sVCAM-1, could be relevant markers to distinct between patients with BD and UD as well as a component of complex inflammatory network associated with their partly common etiopathogenic base.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>5</sup> Sapienza University of Rome, Psychiatry Residency Training Program, Faculty of Medicine and Psychology, Sapienza University of Rome, Italy., Rome, Italy

\* Corresponding author

**Introduction.**– Volumetric hippocampal alterations have been reported in patients bipolar disorder (BP) and history of suicidal thoughts and behavior, but the effect of suicidality on the hippocampal subfields is still unknown in this population.

**Objectives.**– To investigate the relationship between history of suicide ideation/attempts and hippocampal subfield volumes in subjects with BP.

**Methods.**– We measured hippocampal subfields in 15 patients with BP and a lifetime history of suicide attempts (BP-SUI), 20 patients with BP without such history but with history of suicide ideation (BP-IDSUI), 20 patients without history of suicide attempt or ideation (BP-NSUI) and 30 healthy controls (HC). Hippocampal subfield volumes were obtained with 3T scans using FreeSurfer. Differences among groups were investigated using ANOVAs followed by post-hoc Scheffè test.

**Results.**– NSUI demonstrated greater volumes than SUI in the right CA1, CA2/3, CA4/DG, and subiculum. In the same subregions, HC showed greater volumes than SUI and IDSUI. Moreover, HC also showed greater left fimbria volumes than SUI, NSUI, IDSUI and greater right presubiculum volumes than SUI. NSUI showed greater right CA1 than IDSUI.

**Conclusions.**– Smaller volumes in the right CA2/3-DG and CA1-subicular complexes could represent the indirect evidence of the failure of emotional and stress regulation mechanisms in patients with suicidal thoughts and behavior. The greater damage in those regions in patients who attempted suicide could explain the higher reactivity to emotional stressful stimuli in this sub-population that could lead to suicide.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>5</sup> “Sapienza” University of Rome, *Psychiatry Residency Training Program, Faculty of Medicine and Psychology, Roma, Italy*

\* Corresponding author

**Background.**– Lithium treatment has been associated with different effects on limbic and subcortical gray matter structure volumes. Discrepancy could be explained by the time-dependent effect of lithium.

**Objectives.**– We investigated the effects of long- and short-term lithium treatment on limbic and subcortical gray matter structure volumes in patients with bipolar disorder (BP)

**Methods.**– Volumes of deep gray matter structures were measured using FreeSurfer in 40 subjects: 10 patients with BPI who were never exposed to lithium [no-exposure group (NE)], 10 patients with BP exposed to lithium for < 24 months [short-exposure group (SE)], 10 patients with BP exposed to lithium for > 24 months [long-exposure group (LE)] and 10 healthy controls (HC).

**Results.**– No differences between LE and HC were found. LE and HC have greater bilateral hippocampal and amygdalar volumes than NE. SE showed greater bilateral amygdalar volumes than NE and no differences as compared with LE. SE showed smaller bilateral hippocampal volumes than LE and HC, while no differences were found as compared with NE. Among the four groups, Among the four groups, no differences were found in the caudate, putamen, pallidum, thalamus and nucleus accumbens.

**Conclusions.**– Lithium treatment demonstrates a time-dependent selective effect on the hippocampus and the amygdala. Its action seems to differ between those two structures, with a short-term effect on the hippocampus and a long-term effect on both structures.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Treatment compliance in patients with bipolar I disorder during remission**

N.B. Tepe-Bal<sup>1\*</sup>, U. Altunoz<sup>2</sup>, H.H. Ozsan<sup>3</sup>

<sup>1</sup> *Ankara Dr. Abdurrahman Yurtaslan Oncology Research & Training Hospital, Psychiatry, Ankara, Turkey;*

<sup>2</sup> *Klinikum Wahrendorff, Transcultural Psychiatry & Psychotherapy, Hannover, Germany;*

<sup>3</sup> *Ankara University School of Medicine, Psychiatry, Ankara, Turkey*

\* Corresponding author

**Introduction.**– Treatment compliance in patients with bipolar disorder is a complex issue which is determined by a wide array of factors.

**Objectives.**– Here, we aimed to explore the factors affecting the treatment compliance in patients with bipolar I disorder (BD-I) during remission.

**Method.**– The study sample consisted of 50 patients (M/F = 18/32, age = 40.6 ± 11.7) with BD-I according to DSM-IV-TR during remission (The Hamilton-Depression-Scale Scores < 7, The Young-Mania-Rating-Scale Scores < 7) who applied to an outpatient-psychiatric clinic of a university hospital between October 2014–July 2015. Sociodemographic data form, the Mini International Neuropsychiatric Interview, the Functioning Assessment Short Test (FAST), the Schedule for Assessment of Insight (SAI), the UKU Side Effect Rating Scale (UKU), the Multidimensional Scale of Perceived Social Support (MSPSS), the Medication Adherence Rating Scale (MARS) were applied to the participants. Higher scores on MARS suggest better compliance to treatment.

**Results.**– Total scores on MARS differed significantly depending on gender (M/F = 7.9 ± 1.8/6.5 ± 2.3), employment (employed/unemployed = 7.7 ± 1.9/6.1 ± 2.3), marital status (married/not-married = 7.7 ± 2.0/6.2 ± 2.3) and comorbid generalized anxiety disorder (GAD) (not-present/present = 7.9 ± 1.6/4.6 ± 1.7) ( $P < 0.05$ ,  $P < 0.02$  and  $P < 0.001$ , respectively). The MARS Scores were significantly negatively correlated with total UKU scores ( $r = -0.374$ ,  $P = 0.007$ ) and positively correlated with SAI scores ( $r = -0.422$ ,  $P = 0.002$ ). Linear regression analysis yielded that comorbid GAD and employment status were the only significant variables affecting MARS scores ( $P < 0.05$  for both).

**Conclusions.**– Co-morbid GAD and unemployment are related negatively with treatment compliance in patients with BD-I during remission. Treatment of the co-morbid GAD, especially with cognitive-behavioral therapeutic approaches and supporting occupational activities can positively affect treatment compliance, which should be revealed in further studies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>4</sup> *Sunovion Pharmaceuticals Inc., Medical Affairs, Fort Lee, USA*

\* Corresponding author

**Introduction.**– Lurasidone has demonstrated efficacy and safety in the short-term treatment of bipolar depression in children and adolescents.

**Objective.**– To evaluate the long-term safety and effectiveness of lurasidone in children and adolescents with bipolar depression.

**Methods.**– Patients aged 10–17 years with bipolar I depression who completed 6 weeks of double-blind (DB), placebo (Pbo)-controlled treatment with flexibly-dosed lurasidone (Lur) (18.5–74 mg/d) were enrolled in a 2-year, open-label (OL) study in which patients continued on (or switched to) lurasidone. We present results of

an interim analysis at Week 28. Efficacy was assessed using the Children's Depression Rating Scale, Revised (CDRS-R).

**Result.**– Overall, 347 patients were randomized to lurasidone or placebo. At Week 6, significant improvement was observed for lurasidone vs. placebo in CDRS-R total score (–21.0 vs. –15.3;  $P < 0.0001$ ). 223 patients entered the open-label (OL) study, and 155 (69.5%) completed 28 weeks of treatment; 0.9% discontinued prior to Week 28 due to lack of efficacy; 8.1% discontinued due to an adverse event. For the combined lurasidone group ( $n = 223$ ), mean change in CDRS-R total score, from OL baseline was –10.0 at Week 52 (observed case analysis), and –7.7 (LOCF-endpoint). During OL treatment, the 3 most common adverse events in the combined lurasidone group were headache (19.7%), nausea (14.3%), and anxiety (9.9%). Minimal effects were observed on weight, metabolic parameters, and prolactin levels.

**Conclusion.**– In children and adolescents with bipolar depression, long-term treatment with lurasidone was safe and generally well-tolerated, and was associated with continued improvement in depressive symptoms.

### **Influence of family group psycho-education on relapse rate and duration of hospitalization in patients with bipolar disorder type I**

S.M. Zamir<sup>\*</sup>, M. Javani Jooni, S.A. Haji Seyedjavadi  
Qazvin university of medical sciences, PsychiatryPsychiatry, Qazvin, Iran

\* Corresponding author

**Keywords:** Bipolar disorder, Family group psycho-education

**Introduction.**– Bipolar disorder is disabling because of frequent recurrences. Besides pharmacotherapy, psycho-education can be helpful in reducing patients' symptoms and recurrences of disorder, leading to improvement of their quality of life.

**Objectives.**– In this study we considered the influence of family group psycho-education on relapse rate, duration of hospitalization and quality of life in patients with bipolar disorder.

**Method.**– This randomized controlled clinical trial has been done on 64 patients with bipolar disorder hospitalized in psychiatry ward who were allocated into 2 groups. Patients in the control group received the usual treatment. Family of the patients in intervention group were received 4 sessions of group psycho-education. The patients were evaluated with Hamilton Depression Rating Scale, Young Mania Rating Scale and Quality of life Mc Master questionnaire. Patients were reexamined after 9 months follow up for recurrence and hospitalization rate.

**Results.**– Data analysis showed a significant reduction in the number of hospitalization days in the group was received family psycho-education, in patients with mixed and mania period, but not in recurrence rates. The effect of training on the number of hospitalization days dependent on the level of education of the recipient's, patient's location, duration of illness and number of hospitalizations before starting research. All quality of life subscales were influenced.

**Conclusion.**– Family group psycho-education for patients with Bipolar disorder can improve their quality of life and diminished the risk of disorder recurrence.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

#### **Serum levels of IGF-I in delirious and non-delirious acutely ill older medical inpatients**

D. Adamis<sup>1\*</sup>, C.S. Chu<sup>2</sup>, K. Finn<sup>3</sup>, V. Melvin<sup>1</sup>, J. Williams<sup>4</sup>, G. McCarthy<sup>1</sup>, D. Meagher<sup>5</sup>

<sup>1</sup> Sligo Mental Health Services, Psychiatry, Sligo, Ireland;

<sup>2</sup> Kaohsiung Veterans General Hospital, Department of Psychiatry, Kaohsiung, Taiwan R.O.C.;

<sup>3</sup> Cork institute of Technology, School of Biological Science, Cork, Ireland;

<sup>4</sup> Sligo University Hospital, Pathology Department, Sligo, Ireland;

<sup>5</sup> University of Limerick, Psychiatry, Limerick, Ireland

\* Corresponding author

**Introduction.**– Delirium is a common disorder in elderly medical inpatients with serious adverse outcomes. The issue of the association of low levels of Insulin like Growth Factor I (IGF-I) and delirium still remains controversial.

**Objectives.**– To investigate the relation of serum levels of (IGF-I) and the occurrence of delirium.

**Methods.**– Prospective, longitudinal, observational study. Consecutive elderly inpatients (aged 70+), were assessed twice weekly with Montreal Cognitive Assessment (MoCA), Confusion Assessment method (CAM), Acute Physiology and Chronic Health Evaluation II (APACHE-II). Delirium has been define with CAM. Previous history of dementia was evaluated with the Informant Questionnaire on Cognitive Decline in the Elderly (IQCODE). IGF-I levels were estimated with ELISA method.

**Results.**– The sample consisted of 198 participants (mean age 80.63; SD: 6.81; range: 70–97). Of these 92 (46.5%) were females. Eighty-six (43.4%) were identified with a history of dementia. Incident or prevalence delirium has been identified with CAM in 40 participants (20.2%). Using Generalized Linear Model for the analysis of the longitudinal data it was found that low MoCA scores and low levels of IGF-I were significant associated with any delirium during hospitalisation (Wald  $\chi^2 = 29.62$ ; df:1,  $P < 0.001$  and Wald  $\chi^2 = 7.235$ , df:1,  $P = 0.007$  respectively).

**Conclusions.**– The results shows that low levels of IGF-I are independently associated with the occurrence of any delirium (incident or prevalent) during the hospitalisation of medically ill older people.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

#### **Prevalence of depressive symptoms among victims of sexual abuse: Cross sectional study from Oman**

M. Al Shekaili<sup>\*</sup>, Y. Al Kalbani

Almasarra hospital, child and adolescent psychiatry, Muscat, Oman

\* Corresponding author

**Background.**– Child sexual abuse is a form of child abuse in which an adult or older adolescent uses a child for sexual stimulation. There is a dearth of such studies in Oman and Arab world.

**Objectives.**– The current study aimed to measure the prevalence of depressive symptoms among sexually abused children attending tertiary care child and adolescent mental health department in Muscat.

**Methods.**– A cross-sectional analytical study was conducted among all sexually reported cases attending tertiary care child and adolescent mental health department in Muscat.

This data was collected by reviewing the medical records and interviewing the patients as semi structural interview for DSM5 EPA 2013. The Depression Scale for Children was utilized to assess depressive symptomatology. A binary logistic regression model was used to decipher the adjusted and unadjusted odds ratios (ORs). **Results.**– Total of 33 cases of child sexual abuse were participated in the study, with response rate of 89%. The prevalence of depression symptoms was 63%. Logistic regression analysis indicated that frequency of the abuse, female gender and frequent and repeated sexual act abuse were significant predictors of depression multivariate analysis ( $OR=5.000$ , 95% confidence interval [CI]: 1.084–23.0613,  $P=0.003$ ;  $OR=8.5000$ , 95% CI: 1.6808–42.985,  $P=0.0097$ ; respectively).

**Conclusion.**– This study showed that depressive symptoms are common among sexually abused children in Oman. Therefore, detecting and promptly treating depression in this vulnerable population is pivotal to optimize their psychological well-being and prognosis of their future life.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Risk and type of new onset seizures in patient with/without dementia**

M. Habeych<sup>1</sup>, T. Falcone<sup>2</sup>

<sup>1</sup> School of Medicine, University of Cincinnati, UC Department of Anesthesia, Cincinnati, USA;

<sup>2</sup> Cleveland Clinic, Epilepsy Center, Cleveland, USA

\* Corresponding author

Risks of new onset seizures (NOS) and types associated to dementia are estimated. A cohort of 2,885,336 patients with/without dementia and 60 years or more from the Optum Insight Clinformatics-data Mart database was followed from 2005 to 2014. Group differences were analyzed using continuity-adjusted chi-square and hazard ratios with 95% confidence intervals (CI) calculated after logistic regression analysis. Two point seventy-six percent of patients ( $n=79,561$ ) had a dementia diagnosis with 56% of them women. Dementia patients have 6.5 times increased risk for undifferentiated seizures (95% CI 4.4–9.5), a 6 fold elevated risk for partial seizures (95% CI 5.5–6.6), 5.2 times higher risk for generalized epilepsy (95% CI 4.9–5.5) and undifferentiated epilepsy (95% CI 4.8–5.2). And, 4.75 increased risk for generalized seizures (95% CI 4.5–5.0) and partial epilepsy (95% CI 4.4–5.1). In conclusion patients of 60 years of age or older have higher risks of NOS associated with a dementia diagnosis.

\* Corresponding author

**Introduction.**– Schizophrenia is associated with high rates of abuse or dependence of nicotine, cannabis, alcohol, or cocaine. Very few studies assessed the frequency of opioid use disorders in subjects with schizophrenia. Moreover, to our knowledge, there is no study investigating the frequency of subjects receiving opioid maintenance therapy among patients receiving antipsychotic medications.

**Objectives.**– To assess the frequency of subjects receiving opioid maintenance therapy in patients receiving antipsychotic medications.

**Methods.**– A data set from National Information System of French healthcare Social Security which covers 97% of the French population was matched with the public and private hospitals inpatients and outpatients diagnosis data system, using the social security number which all French citizen affiliated to the French Health System have. All subjects from Hauts-de-France area, North France, receiving opioid maintenance therapy, i.e. methadone, buprenorphine, or buprenorphine/naloxone, and antipsychotics prescribed by any Medical Doctor (e.g., hospital physicians, general practitioners, psychiatrists...) in patients with ICD-10 diagnoses of schizophrenia, schizotypal disorders, delusional disorders, brief psychotic disorders, substance/medication-induced psychotic disorders, schizoaffective disorders, and other schizophrenia spectrum disorders in 2015, were included in the study.

**Results.**– The analysis of the data sets showed that among the subjects with ICD-10 diagnoses of schizophrenia spectrum included in the study and receiving antipsychotic medications ( $n=20473$ , 0.4% of the general population), 2.6% received methadone or buprenorphine ( $n=532$ ).

**Conclusions.**– The rates of patients with schizophrenia spectrum receiving opioid maintenance therapy was not uncommon, more frequent than the rate of subjects receiving opioid maintenance therapy in the general population (0.70%).

### **Adolescent early birds vs night owls: Chronotype and the psychological health of youth**

G. Gariepy\*, F. Elgar

McGill University, Institute for Health and Social Policy, Montreal, Canada

\* Corresponding author

**Objective.**–Recent evidence suggests that preference in the timing of sleep, or chronotype, relates to adolescent psychological health. The hypothesis is that night owls struggle more than early birds

because they get less sleep, in part due to early school start times. Yet few studies have adjusted for sleep duration and none controlled for school start time. We examined the association between chronotype and indicators of youth psychological health, controlling for sleep duration and school start time.

**Methods.**– Data were collected in the 2014 Canadian Health Behaviour in School-Aged Children survey (29,635 students; ages 10–18). Chronotype was estimated using the mid-cycle sleep time on weekends, corrected for catch-up sleep. We examined scores for emotional problems (range: 0–33), emotional well-being (0–22), behavioral problems (0–28) and prosocial behaviours (0–25). We analyzed data using school random-effects regressions, adjusted for sleep duration, school start time, individual and family characteristics, rurality, season, latitude, and province.

**Results.**– The average mid-sleep time (chronotype) was 4:21 a.m. A later chronotype was associated with worse psychological health scores. Each hour delay in mid-sleep was associated with 0.4 (95% CI 0.3, 0.5) higher point score on emotional problems and 0.2 (95% CI 0.1, 0.3) on behavioral problems and 0.2 (95% CI 0.1, 0.3) lower point score on emotional well-being and 0.3 (95% CI 0.2, 0.4) on prosocial behaviors.

**Conclusion.**– The circadian typology of adolescents relates to indicators of psychological health even after adjusting for sleep duration and school start time. Studies are needed to further clarify the mechanism underlying this association.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0035

### **Changes in hormones, melatonin and cortisol, related to the psychological and sleep states of high school students**

H. Kim<sup>1</sup>\*, Y. Minjoon<sup>2</sup>, K. youngjae<sup>2</sup>, K. Jiyong<sup>2</sup>

<sup>1</sup> Korea International High School KIS, Jeju, not special, Seogwipo-si-Je-ju do, Republic of Korea;

<sup>2</sup> Gwangju Seoseok High school, not special, Gwangju, Seo-gu, Republic of Korea

\* Corresponding author

**Objectives.**– We investigated the actual condition of the depressive mood and sleep disturbances of high school students. In addition, we made a study on the correlation of cortisol and melatonin hormone concentration to their depression and sleep disturbances.

**Methods.**– We used a questionnaire with Zung depression scale and Pittsburgh sleep index score. Melatonin and cortisol concentration in saliva sampled at 7 am and 11 pm were measured by ELISA and statistical analysis was performed with SPSS 21.

**Results.**– According to the survey of 39 first-year and second-year high school students, there were 38.5% of the students with a depressive mood and 69.2% of students with sleep disturbance. Sleep-disturbances students suffered from depressive moods more than normal-sleep student and depressive-mood students showed a significant increase in cortisol at 7 am. In addition, students with depressive moods and students with sleep disturbances have showed a significant increase in melatonin at 11 pm. There was no grade-specific difference.

**Conclusion.**– In conclusion, Korean high school students frequently suffer from depressive moods and sleep disturbances, and these students also showed changes in the concentration of related hormones, cortisol and melatonin. In particular, students with depressive moods experience a “phase delayed” phenomenon in which their normal circadian rhythms are delayed. This suggests that high school students’ psychological and sleep disturbances

may also affect hormones in their bodies. Therefore, it is necessary to take measures to reduce psychological and sleep disturbances.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cognitive function and home-environmental outcomes in perinatally acquired HIV-positive pre-and-school age children on cART in South Africa**

A. Lentoor

Medunsa, School of Medicine, Clinical Psychology Department, Pretoria, South Africa

**Introductions.**– Studies from developed countries have been able to demonstrate that neurocognitive impairments among HIV+ children is common and can occur as early as infancy.

**Objectives.**– For this very reason, neurocognitive outcome among HIV+ children from developing countries should be considered as an essential aspect of paediatric HIV management.

**Methods.**– The Wechsler Preschool and Primary Scale of Intelligence-III was administered to assess the neurocognitive functioning of 152 perinatally HIV-infected children on cART, aged 3 years to 7 years 6 months (mean age: 63.13 months). The primary caregivers (n = 152) completed the Home Screening Questionnaire to assess the quality of home- environment of the children.

**Results.**– The results provide evidence that the quality of the home-environment differentially impacts neurocognitive development of children despite being on cART. A large percentage of (>70%) of the children presented with subnormal global neurocognitive functioning (FSIQ) (M=81.47, SD=12.81). Older HIV+ boys and girls who lived in a suboptimal and poor quality home-environment were worse off neurocognitively when compared to younger boys and girls, F (2,149)= 14.42, P<0.001. Verbal neurocognitive development had a negative association (r=−0.18, P<0.05) with poor quality home-environment.

**Conclusions.**– The results highlights that it is not enough to focus attention on the medical management of paediatric HIV patients. HIV+ children are vulnerable to developing neurocognitive deficits that can impact negatively on their ability to thrive academically and adhere to their treatment. The need for a psychosocial intervention to improve overall health and future quality of life of this population is recommended.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Suicide attempts in bipolar disorder: Risk factors in a cohort of 220 patients**

H. Maatallah<sup>\*</sup>, D. Rahma, B. Imen, A. Faten, C. Wissal, C. Majda Razi Hospital, Psychiatry E, Tunis, Tunisia

\* Corresponding author

**Introduction.**– In bipolar disorder (BD), a significant proportion of elevated mortality is attributable to suicide. Indeed, in BD, lifetime suicide attempts (SA) are estimated to range, from 25% to 50%. Suicidal behaviour is a complex phenotype now recognized by DSM-5 as an independent crosscutting clinical entity.

**Objectives.**– We wanted to investigate risk factors for attempted suicide in bipolar patients.

**Method.**– We undertook a retrospective study including a sample of BD type I out-patients. The inclusion criteria were: patients hospitalized between January 1 2000 and December 31 2015 and at least two years’ follow.

This study examined factors putatively associated with SA in BD. Factors were subcategorized into: sociodemographics, clinical characteristics of bipolar disorder and comorbidities,

*Results.*– A total of 220 adult bipolar out-patients were recruited and 48% of them had a personal history of SA. The proportion of attempted suicide was higher in women than in men (60%).

This sample of suicid attempters was characterized by low socio economic status, family conflicts and poor social integration.

Early onset of bipolar disorder, traumatic life events notably childhood trauma ( $P < 0.002$ ), family history of affective disorder ( $P < 0.004$ ) and family history of SA ( $P < 0.0018$ ) were significantly associated to SA in the two genders.

Comorbid substance use disorder was a predictor of SA in men ( $P < 0.002$ ), while comorbid personality disorder predicted SA in women ( $P < 0.004$ ).

In both genders anxiety disorder, eating disorder, somatic disorder did not predict SA.

*Conclusion.*– These risk factors may be signs of a clinical subgroup at risk of suicidal behaviour, and seem to be important for suicide risk assessment in acutely admitted BD patients.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Guanfacine for autism spectrum disorder: Use in an outpatient unit**

V. Muñoz Martínez\*, G. Jimenez Londoño

Ciudad Real University Hospital, Psychiatry, Ciudad Real, Spain

\* Corresponding author

*Introduction.*– Autism spectrum disorders (ASD) are frequently marked by symptoms consistent with attention-deficit/hyperactivity disorder (ADHD), namely inattention, hyperactivity and impulsivity. Individuals with co-occurring ASD and ADHD symptoms are more severely impaired, with significant deficits seen in social processing, adaptive functioning, and executive control.

*Aim of the study.*– Sometimes, hyperactivity, impulsiveness, and distractibility are common problems in children with ASD. Guanfacine is approved for children with attention-deficit/hyperactivity disorder but not well studied in ASD.

*Method.*– The study subjects were recruited from an outpatient programme that treats children with Developmental Disorders. Subjects scored 15 points or higher on the Conners Index. Twenty children were studied in order to diagnose ASD, and if it was necessary due to lack of response to specific hyperactivity symptoms and/or adverse side effects, their medication was changed.

*Results.*– Twenty subjects (boys:  $n = 18$ , girls:  $n = 2$ ; age range = 7.8 years), their medication was changed to Guanfacine and the patients were re-evaluated a month after. It was observed that the patients showed improvement in the hyperactivity symptoms compared to when they were medicated with psychostimulants. The modal dose of guanfacine at week 4 was 3 mg/day (range: 1–4 mg/day).

*Conclusions.*– There is good evidence suggesting that as many as 50% of children with ASD exhibit significant co-occurring ADHD symptoms. Careful evaluation for the potential presence of ADHD symptoms is warranted for all individuals with ASD. Extended-release Guanfacine appears to be safe and effective in reducing hyperactivity, impulsiveness, and distractibility in children with ASD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Life trajectories of adverse experience: Tracing the paths to suicide**

C.E. Notredame<sup>1,2\*</sup>, G. Beauchamp<sup>3</sup>, M. Séguin<sup>3,4</sup>

<sup>1</sup> CHU de Lille, Child and Adolescent Psychiatry, Lille, France;

<sup>2</sup> Quebec Network on Suicide, Mood Disorders and Related Disorders RQSHA, Psychosocial, Ethical and Aboriginal Health Research, Montréal, Canada;

<sup>3</sup> Quebec Network on Suicide, Mood Disorders and Related Disorders, Psychosocial, Ethical and Aboriginal Health Research, Montréal, Canada;

<sup>4</sup> Université du Québec en Outaouais, Psychology, Gatineau, Canada

\* Corresponding author

*Introduction.*– According to the most recent causal models of suicide, distal (early) adverse life events influence the probability of engaging in suicidal behaviors by altering vulnerability to stressors, while proximal (late) adversity is seen as a cumulative trigger for the suicide. However, real-life developmental sequences are not that clear-cut, and empirical evidence is still lacking about how adverse experiences dynamically affect suicidal trajectories over time.

*Objectives.*– Identify and describe the types of life trajectories of individuals who died by suicide based on the burden of adversity they experienced.

*Methods.*– Psychological autopsies and life trajectory interviews were used to collect extensive adverse events calendars for 393 individuals who died from suicide. Data were analyzed by a panel of experts with a clinical narrative approach to derive an overall burden of adversity rating for every 5-year interval. Growth mixture models (GMM) allowed for identifying typical patterns of burden trajectories. Fittings were compared to determine the number and shape of trajectory patterns that best explained the data.

*Results.*– The most accurate GMM derived 4 trajectory patterns from the individual evolutions of burden throughout life, but also from the ages of death. In the two first trajectories, individuals died earlier. Either starting from low or intermediate burden, they both grew to high scores at the age of death. The 2 “late-death” curves slowly increased or decreased to finally converge to a low level of burden.

*Conclusions.*– Profiling the types of adverse trajectories to suicide could guide more targeted prevention strategies.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **A prospective longitudinal investigation of the (dis)continuity of mental health difficulties between mid- to late- childhood and the predictive role of familial factors**

C. O'Connor<sup>1\*</sup>, U. Reulbach<sup>2</sup>, B. Gavin<sup>3</sup>, F. McNicholas<sup>4</sup>

<sup>1</sup> University College Dublin, School of Psychology, Dublin, Ireland;

<sup>2</sup> Child and Family Centre Drogheda, University College Dublin, Trinity College Dublin, School of Medicine, Dublin, Ireland;

<sup>3</sup> University College Dublin, Children's Mental Health Clinic, School of Medicine, Dublin, Ireland;

<sup>4</sup> University College Dublin, Our Lady's Children's Hospital Crumlin, Lucena Clinic, Dublin, School of Medicine, Dublin, Ireland

\* Corresponding author

*Objective.*– Understanding individual variation in the continuity of youth mental health difficulties is critical for identifying the factors that promote recovery or chronicity. This study establishes the proportion of children showing psychopathology at 9 years, whose pathology had either remitted or persisted at 13. It describes the sociodemographic and clinical profiles of these groups, and investi-

gates the factors in 9-year-olds' familial environments that predict psychopathological remission vs. persistence.

**Method.**– The study utilised data from a prospective longitudinal study of 8568 Irish children. Child psychopathology was assessed using the Strengths and Difficulties Questionnaire (SDQ). Analysis established the rates of continuity of SDQ classifications between 9–13 years. Analysis also investigated the familial factors that predicted the remission vs. persistence of psychopathological symptoms, controlling for socio-demographic and child factors.

**Results.**– Average SDQ scores improved between the ages of 9 and 13,  $F(1.7292)=276.524$ ,  $P=.037$ . Of children classified abnormal aged 9, 41.1% remained so classified at 13, 21.4% were reclassified borderline, and 37.6% normal. Demographic and child risk factors for persistence of pathology were maleness ( $b=-1.00$ ,  $P=.001$ ,  $CI=.20-.67$ ), one-carer households ( $b=-.71$ ,  $P=.041$ ,  $CI=.25-.97$ ), poor physical health ( $b=-.64$ ,  $P=.025$ ,  $CI=.30-.92$ ), and low cognitive ability ( $b=.61$ ,  $P=.002$ ,  $CI=1.26-2.70$ ). Controlling for these factors, the only familial variable at 9 years that predicted subsequent pathological persistence was caregiver depression ( $b=-.07$ ,  $P=.027$ ,  $CI=.87-.99$ ).

**Conclusion.**– The analysis highlights substantial rates of psychopathological discontinuity in a community sample and identifies the children most at risk of chronic mental health problems. These results will inform the targeting of early interventions and distribution of clinical resources.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>2</sup> I.M. Sechenov First Moscow State Medical University, Department of Neurology, Moscow, Russia;

<sup>3</sup> A.I. Yevdokimov Moscow State University of Medicine and Dentistry, Department of Faculty Therapy and Professional Diseases, Moscow, Russia

\* Corresponding author

**Introduction.**– The diagnostic of contribution of emotional factors in cognitive impairment in patients with essential hypertension (EH) is often necessary for choosing the treatment strategy.

**Objectives.**– To assess cognitive functions in patients with EAH and evaluate the connection of the revealed cognitive disorders with the presence of anxiety and depression.

**Methods.**– The study has involved 39 naive middle-age patients with uncomplicated EAH, stage 1–2, average age is  $51.9 \pm 6.5$  and 49 normotensive persons, average age is  $47.9 \pm 6.2$ . The following methods were used: Trail Making test, MoCA test, Verbal fluency test, Stroop test, CERAD 10-word list, Pictogram test, Hamilton Depression Rating Scale and Hamilton Anxiety Rating Scale.

**Results.**– EH patients significantly differ from healthy persons by the following parameters: MoCA ( $28.17 \pm 1.7$  vs  $29.06 \pm 1.1$ ;  $P=0.029$ ); letter fluency ( $10.56 \pm 3.5$  vs  $13.53 \pm 3.3$ ;  $P=0.003$ );

Stroop 2 ( $69.3 \pm 9.0$  vs  $62.4 \pm 13.6$ ;  $P=0.016$ ); Stroop 3 ( $128.2 \pm 45.6$  vs  $114.4 \pm 30.6$ ;  $P=0.043$ ); anxiety level ( $3.22 \pm 4.1$  vs  $0.59 \pm 1.3$ ;  $P=0.01$ ) and depression level ( $1.94 \pm 3.7$  vs  $0.22 \pm 0.8$ ;  $P=0.009$ ).

Pictogram test has revealed the predominance of concrete images over symbolically generalized for EH patients ( $1.9 \pm 1.4$  vs  $0.9 \pm 0.9$ ;  $P=0.04$ ); decreasing quantity of the accurately recalled words ( $7.7 \pm 2.1$  vs  $9.7 \pm 2.4$ ;  $P=0.006$ ), and essential quantity of not recalled words ( $5.4 \pm 2.3$  vs  $2.9 \pm 1.7$ ;  $P=0.001$ ).

Correlation analysis has revealed the presence of negative correlations between depression level and such parameters of cognitive functioning as MoCA score ( $-0.61$ ;  $P \leq 0.05$ ); letter fluency ( $-0.53$ ;  $P \leq 0.05$ ); immediate recall in CERAD 10-word list ( $-0.5$ ;  $P \leq 0.05$ ).

**Conclusion.**– The obtained results prove the connection of the cognitive impairments revealed for AH patients with marked anxiety and depression.

The research was supported by RFBR; project No. 17-06-00954.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Outcome measures for autism spectrum disorders: A systematic review

U. Provenzani\*, L. Fusar Poli, N. Brondino, S. Damiani, M. Rocchetti, M. Vercesi, P. Politi

University of Pavia, Department of Psychiatry and Behavioral Sciences, Pavia, Italy

\* Corresponding author

**Introduction.**– Clinical trials for autism spectrum disorders (ASD) are constantly increasing. However, no consensus has been reached about which outcome measures should be preferred, especially when assessing core symptoms.

**Objectives.**– First, we systematically reviewed published trials for ASD, analyzing their outcome measures. Second, we examined the relationship between outcome measures, type of intervention, study design, and characteristics of samples (age and IQ).

**Methods.**– We conducted a systematic search to identify any published controlled trial investigating the efficacy of interventions in patients with ASD. The Web of Knowledge<sup>SM</sup> database was searched between 1980 and 2016, including abstracts in English only. Reference lists of relevant reviews on the topic were hand-searched for inclusiveness.

**Results.**– A total of 406 trials were included in the final database (354 RCTs and 52 non-randomized trials), with approximately 17240 participants involved. A total of 327 outcome measures were identified; only 8 of them were used in more than 10% of the studies. Of note, 31% of the studies used at least one ad-hoc measure, and 9% studies used ad-hoc scales only. Figure 1 illustrates the relationship between the most commonly used scales and studies characteristics.

**Conclusions.**– Evaluation of outcomes in trials for ASD is heterogeneous, often relying on non-specific tools for this condition. More consensus should be reached on the choice of these measures, especially when core symptoms are assessed.

### Psychiatric comorbidity and medication usage in adult autism spectrum disorder (ASD): Results from the Ncmh adult Asd cohort

J. Underwood<sup>1\*</sup>, K. Kendall<sup>1</sup>, J. Thomas<sup>1</sup>, J. Hall<sup>2</sup>

<sup>1</sup> MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University School of Medicine, Cardiff, United Kingdom;

<sup>2</sup> Neuroscience and Mental Health Research Institute, Cardiff University College of Biomedical and Life Sciences, Cardiff, United Kingdom

\* Corresponding author

*Background.*– Autism spectrum disorders (ASD) are lifelong neurodevelopmental conditions, with increasing rates of adult diagnosis. This study investigates the prevalence of comorbid mental health disorders and psychotropic medication usage in a clinically ascertained cohort of individuals diagnosed with ASD as adults.

*Methods.*– Clinical psychiatric data for individuals with ASD was accessed from the National Centre for Mental Health (NCMH) case database. Inclusion criteria were diagnosis of ASD at age ≥ 18 consistent with ICD10 Diagnostic Criteria made by a trained secondary health care professional.

*Results.*– A total of 105 individuals with ASD diagnosed as adults were age and sex matched with a cohort of 76 control individuals. 80 individuals (76%) with adult diagnosed ASD were men, matched to 55 (72.4%) of the controls. The average age of those with ASD was 37.81 years, 40.70 years for the controls.

Ninety-four (89.5%) of the ASD cohort self-reported a comorbid psychiatric diagnosis, with Depression (62.9%) and Anxiety (55.2%) the most common. Dyslexia (21.9%), Dyspraxia (18.1%) and ADHD (19.0%) were also prevalent. The percentage of individual who reported OCD was 17.1 and 11.4% previous psychosis. The most significant lifetime psychotropic usage was of antidepressants, reported by 78.7% of those who responded, with short-term anxiolytic (31.2%) and hypnotic (19.1%) usage also over-represented.

*Discussion.*– Individuals diagnosed with ASD as adults have a high prevalence of comorbid anxiety and depression, alongside anticipated ADHD, dyslexia and dyspraxia. Lifetime antidepressant prescription was correspondingly high, with commensurate usage

of short-term anxiolytics and hypnotics. These findings demonstrate the importance of screening for depression and anxiety in adults with ASD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The effects of adverse childhood experience and social support on self-injury behaviours in adolescents: Is there any gender difference?

Y. Wan<sup>1\*</sup>, M. Shuangshuang<sup>2</sup>, S. Ying<sup>2</sup>, M. Danielle<sup>1</sup>, C. Ruoling<sup>1</sup>, T. Fangbiao<sup>2</sup>

<sup>1</sup> University of Wolverhampton, Education- Health and Wellbeing, Wolverhampton, United Kingdom;

<sup>2</sup> Anhui medical university, School of Public health, Hefei, China

\* Corresponding author

*Background.*– There are less investigation on the effects of adverse childhood experience (ACEs) and social support (SS) on self-injury behaviours in adolescents, and gender differences in the effects.

*Objects.*– To examine the associations of ACEs and SS with self-injury behaviours in schoolgirls and boys in China, and gender differences in the associations.

*Method.*– We conducted a school-based health survey in 3 provinces in China in 2013–2014. Overall, 14,820 students aged 11–19 years completed standard questionnaires, to record the details of ACEs and SS, and over one year's non-suicidal self-injury behaviour (NSSI), suicide ideation (SI) and suicide attempt (SA).

*Results.*– The percentage of participants who had ≥ 1 ACEs was 89.4. The prevalence of NSSI, SI and SA was 26.1%, 17.5% and 4.4% respectively. They were significantly associated with increased ACEs and reduced social support. In adolescents with low SS, girls had a higher risk of NSSI than boys (adjusted OR 1.35,  $P=0.007$ ). In adolescents with high ACEs score (5–6) and moderate or low SS, girls versus boys had around two times higher to have SA (corresponding ORs were 2.11, 1.86 and 1.99, respectively;  $P<0.05$ ). No gender differences were found within other groups in the associations of NSSI, SI and SA with ACEs and SS.

*Conclusions.*– ACEs and less SS increased the risk of self-injury behaviours in adolescents. While both girls and boys had similar effects from ACEs and SS, we should target high-risk groups of NSSI, SI and SA for gender differences accordingly.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Importance of an early EMDR intervention in emergency room to prevent post-traumatic stress disorder and concussion-like persistent symptoms: A pilot randomized controlled study

S. Al Joboory<sup>1\*</sup>, T.S.J. Juliane<sup>1</sup>, G.J. Cedric<sup>2</sup>, E. Lagarde<sup>3</sup>, A. Regis<sup>1</sup><sup>1</sup> Hôpital Cadillac, CASPERTT, Lormont, France;<sup>2</sup> Hôpital Pellegrin, Urgences, Bordeaux, France;<sup>3</sup> Inserm U1219, Bordeaux Population Health Center, Bordeaux, France

\* Corresponding author

**Background.**– Up to 20% of patients presenting at an Emergency Room (ER) after a stressful event will suffer durably of various very diverse long-lasting symptoms (headaches, memory problems, personality changes etc., with a potentially significant decline in quality of life. These symptoms can be grouped under the term Post-Concussion-Like Symptoms (PCLS). This procession of symptoms, initially described in traumatized brain, is also found in patients with all types of trauma.

The results of a recent study of injured patients suggest that there is a strong correlation between symptoms of PCLS and symptoms of post-traumatic stress disorder (PTSD), and that stress plays a major role.

**Objectives.**– Assess the feasibility of EMDR in ER and compare the effectiveness of an early single EMDR intervention after stressful event, to reassurance or usual care.

**Method.**– This monocentric randomized, controlled open-label study was conducted in the ER of Bordeaux University Hospital. It included patients with a high risk for PCLS or PTSD randomized in three groups: a reassurance session, a session of EMDR, and usual care.

**Results.**– At 3-month recall, the rate of patients with PTSD was 3% in the EMDR group versus 16% and 19% in the reassurance and control groups. The PCLS rate was 15% in the EMDR group versus 47% and 65% in the reassurance and control groups.

**Conclusion.**– This is the first randomized, controlled trial that shows that a single EMDR intervention is both feasible and effective to prevent PTSD and PCLS

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Effects of bilateral alternated stimulation on memory of emotional and neutral content

S. Baier<sup>1\*</sup>, P. Mouglin<sup>1</sup>, A. Quaderi<sup>1</sup>, F. Guillaume<sup>2</sup><sup>1</sup> Université Nice–Sophia Antipolis, psychology, Nice, France;<sup>2</sup> Aix-Marseille université, psychology, Marseille, France

\* Corresponding author

Making repetitive saccadic eye movements has been found to increase subsequent episodic memory retrieval and also to increase subsequent top-down attentional control. We tested this idea by examining the effect of saccade execution on retrieval conditions that differed in emotional content. In this study, we assessed the

effects of Bilateral Alternating Stimulation (BAS) typically used in EMDR (Eye Movement desensitization and reprocessing) therapy and emotional priming on face recognition. Twenty-five adults performed two similar face-recognition tasks. During study phase, participants either saw happy faces primed with neutral scenes or happy faces primed with traumatic scenes (IAPS database) that they later had to remember. Immediately after study and before recognition, participants carried out the same three short series of saccade execution or a fixation task: visual BAS (horizontal saccadic bilateral alternating eye movements) during one session and a visual fixation control task during the other one. Our results confirm that engaging in BAS enhances recognition. To date, this is the first research studying the effect of BAS on recognition processes. Moreover, it is the first to use an Old/New recognition paradigm and an estimation of response certainty of participants but also to study, at an electrophysiological level, the effect of BAS on evoked potentials associated with recognition. Our results confirm the beneficial effect of BAS on recognition performance and may have important implication on understanding the mechanisms at stake in EMDR treatment with PTSD patients.

### Empathy in Bosnian war veterans with and without posttraumatic stress disorder

E. Becirovic<sup>1\*</sup>, E. Avdibegovic<sup>1</sup>, R. Softic<sup>2</sup>, M. Mirkovic Hajdukovic<sup>1</sup>, A. Becirovic<sup>3</sup><sup>1</sup> UKC Tuzla, Klinika za psihijatriju, Tuzla, Bosnia, Hercegovina;<sup>2</sup> UKC Sarajevo, Klinika za psihijatriju, Sarajevo, Bosnia, Hercegovina;<sup>3</sup> UKC Tuzla, Poliklinika za laboratorijsku dijagnostiku, Tuzla, Bosnia, Hercegovina

\* Corresponding author

**Introduction.**– It is little known how critical life events, such as traumatic experiences, affect empathy. There is a belief that victims of extreme violence should be more vulnerable to the suffering of others. Psychosocial literature claim opposite. Being a victim of collective violence often inhibits empathy towards others. Studies on relationship of empathy and posttraumatic stress disorder (PTSD) are rare. Their findings are still pretty inconclusive.

**Objectives.**– To evaluate empathy in war veterans with and without symptoms of post-traumatic stress disorder.

**Methods.**– The research is a cross-sectional study conducted between March and July 2015 in a group of 205 war veterans, of whom 104 war veterans were with symptoms of post-traumatic stress disorder and 101 without PTSD symptoms. The study used the Harvard Trauma Questionnaire (HTQ), the Toronto Empathy Questionnaire (TEQ) and the questionnaire on sociobiographical data.

**Results.**– The average score on the Toronto empathy questionnaire for the overall sample of respondents was  $33.39 \pm 7.68$ , which indicates a moderate level of empathy in relation to the total score of the score (0–64). The difference  $[F(1, 205) = 11.799, P = 0.001]$  was significant in the mean values of the total empathy score between war veterans with ( $35.18 \pm 7.15$ ) and without PTSD symptoms ( $31.53 \pm 7.81$ ).

**Conclusion.**– Bosnian war veterans with symptoms of PTSD have higher total score of empathic response.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Suicidality factors in alcoholics among indigenous population of Far North

N. Bokhan<sup>1</sup>, A. Mandel<sup>2</sup>, V. Kuznetsov<sup>3</sup>, I. Mandel<sup>4</sup><sup>1</sup> Mental Health Research Institute, Administration, Tomsk, Russia;<sup>2</sup> Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Science, Addictive States Department, Tomsk, Russia;<sup>3</sup> Kargasok Central Territorial Hospital, psychiatrist, Kargasok, Tomsk Region, Russia;<sup>4</sup> Sechenov First Moscow State Medical University, Department of Critical Care Medicine, Moscow, Russia

\* Corresponding author

**Keywords:** Factors of suicidal behavior, Index of suicidality, Mental and substance use disorders, Ethnicity, The Narym Selkups

**Introduction.**– Suicidal death rate among drug addicts is 7–15% and in alcoholics is similar to the patients with depression (11–15%).

**Objectives.**– To identify cause-effect interrelationships between suicidal behaviour, sociodemographic and psychological factors among Far North Siberian population.

**Methods.**– We registered all cases of death: medical death certificates for 5-year period 2008–2013 ( $n=1501$ ), materials of exemption to institute criminal proceedings in connection with ascertainment of fact of suicide ( $n=117$ ), acts of postmortem forensic medical examination ( $n=104$ ). As analytical tool indexes of suicidality were used.

**Results.**– The suicidality index was 94.4 points. Number of completed suicides exceeded number of attempted suicides. Fatal suicides were characterised by self-evocation, for non-fatal suicides – self-cuts, to the same extent for men and women; poisoning by chemicals was more attractive among women (28.9% of cases) and less typical for men (6.3% of cases). With fatal suicides, the share of gunshot wounds was high. In 52.1% suicide was committed in alcohol abuse. A “double” psychiatric diagnosis was found in 10.9% of cases in male suicides (4.0% – a combination of alcoholism with personality disorder, in 6.9% – mental retardation with alcoholism). Among suiciders there was a high specific weight of the Selkups – persons of the indigenous ethnicity (10.3%).

**Conclusion.**– Suicidality index among Far North Siberian population exceeded 90 points. The most significant predictors of suicidal behaviour were mental and substance use disorders, ethnicity, family history, loneliness.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Genetic epidemiology of chronic psychiatric disorder in Caribbean Island: A pilot study

S. Florence<sup>1\*</sup>, N. Nathou<sup>2</sup>, M.O. Krebs<sup>3</sup><sup>1</sup> University of Saint-Étienne, médecine, Saint-Étienne cedex 2, France;<sup>2</sup> CHU de Point-à-Pitre, psychiatry, Pointe-à-Pitre, Guadeloupe;<sup>3</sup> Centre hospitalier Sainte-Anne, psychiatry, Paris, France

\* Corresponding author

**Introduction.**– Schizophrenia spectrum (SSD), bipolar (BD) and Pervasive developmental disorders (PDD) are chronic psychiatric conditions with high heritability (>70%). A current challenge is to identify rare genetic variants at risk for these disorders in non-European populations. Our study aimed to estimate the interest and feasibility of a genetic study in an insular Caribbean population.

**Methods.**– We assessed first and second degree familial history of psychiatric disorder of 2889 patients aged over 16 living in North islands of Guadeloupe. Diagnosis of patients and relatives were surveyed upon healthcare professionals and medical records.

**Results.**– A total of 172 multiplex families were identified in these islands. Twenty percent, 10% and 11% of respectively PDD, SSD and BD's patients had first or second degree familial history of psychiatric disorders. SSD, but also BD and PDD patients' relatives suffered mainly from SSD (65%, 67% and 72% respectively).

**Discussion.**– In the literature, 20% to 30% of patients suffering from SSD had familial history of psychiatric disorder. Though our small percentage of 10% may be due to methodological bias, we interrogated the importance of environmental factors. Besides, the high rate of SSD in our cohort raised the possibility of a diagnostic bias from BD to SSD. Such a bias was already described in Afro-American and Caribbean populations, raising the hypothesis of a particular expression of SSD-BD continuum in non European populations.

**Conclusion.**– This study provides key elements towards the interest and feasibility of a genetic study of chronic severe psychiatric conditions in the West Indies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Burnout in medical students before residency: Systematic review and meta-analysis

A. Frajerman<sup>1\*</sup>, Y. Morvan<sup>2,3</sup>, P. Gorwood<sup>2</sup>, B. Chaumette<sup>4</sup><sup>1</sup> Service Hospitalo Universitaire SHU, centre hospitalier Sainte-Anne, Paris, France;<sup>2</sup> Inserm U894, Centre of Psychiatry and Neurosciences, Paris, France;<sup>3</sup> UFR SPSE, laboratoire CLIPSYD, université Paris-Nanterre, Nanterre, France;<sup>4</sup> Department of Neurology and Neuorsurgery, McGill University, Montreal, Canada

\* Corresponding author

**Introduction.**– Applying concept of burnout to medical students before residency is relatively recent and the estimated prevalence varies significantly between studies.

**Objectives.**– The objective of this study was to estimate the prevalence of burnout in medical students worldwide.

**Methods.**– We did a systematic research on Medline, restricted to English language. All original studies on prevalence of burnout in medical students before residency published between 1st January 2010 and 30th September 2017 were selected. Information on studies characteristics were extracted independently by two investigators. Prevalence of burnout was extracted if it was assessed by validated questionnaires. Statistical analyses were made using the OpenMetaAnalyst software.

**Results.**– Prevalence of burnout was extracted from 23 studies including 16,769 medical students. Among them, 8011 were suffering from burnout and we estimated the prevalence to be 45.8% [35.8%; 55.8%]. The information about the prevalence of each subset of symptoms was given in eight studies including 6926 students. The prevalence of emotional exhaustion subset was estimated to be 42.2% [33.6–50.9%], the prevalence of depersonalization to be 25.8% [15.2–36.3%] and the prevalence of personal accomplishment to be 21.2% [10.2–32.1%].

**Conclusions.**– The results of this meta-analysis are alarming with one student in two suffering from burnout, even before the residency. However, if data on prevalence needs to be cautiously discussed, nonetheless it should encourage the development of preventive strategies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Adults with intellectual disabilities in China: Co-morbid psychiatric disorder and its association with health service utilization

P. He<sup>1</sup>, X. Zheng

Peking University, Institute of Population Research, Beijing, China

\* Corresponding author

**Introduction.**— Adults with intellectual disabilities often have multiple co-morbid disorders. Psychiatric disorders in this population have been poorly studied in developing countries.

**Objectives.**— We aimed to investigate the prevalence of psychiatric disorders in adults with intellectual disabilities (ID) and whether co-morbid psychiatric disorders were associated with health service utilization.

**Methods.**— We obtained data from the Second National Sample Survey on Disability, conducted in 31 provinces in China, and selected a sub-sample of 13,631 adults aged 18 years and above with intellectual disabilities. ID were defined by intelligence quotient (IQ) score under 70, deficits in two or more in adaptive behaviors, and age of onset under 18. Psychiatric disorders were identified according to the International Statistical Classification of Diseases, Tenth Revision (ICD-10). Logistic regressions were used for data analyses.

**Results.**— The prevalence of psychiatric disorders in adults with ID was 16.7%. The most prevalent type of psychiatric disorder was dementia. Older adults, females, being minorities, urban residents, being literate, low-income groups, and having severe ID, were associated with elevated risk of psychiatric disorder among adults with ID. Compared with individuals without psychiatric disorders, those with co-morbid psychiatric disorders were more likely (OR: 2.14, 95%CI: 1.94, 2.36) to use medical services and less likely (OR: 0.70, 95%CI: 0.59, 0.84) to use rehabilitation services.

**Conclusions.**— This study informs that further longitudinal studies are needed and has implications for the role of social factors in the ecologic studies of psychiatric disorders in population with ID.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

### Improving child and women's mental health among ultra-poor families: Two-year results of a cluster-randomized trial in West Africa

L. Ismayilova<sup>1\*</sup>, A. Tô-Camier<sup>2</sup><sup>1</sup> University of Chicago, School of Social Service Administration, Chicago, USA;<sup>2</sup> Trickle Up, Evaluation Department, Ouagadougou, Burkina Faso

\* Corresponding author

**Objective.**— Behavioral interventions alone may be insufficient for improving mental health in low-income countries. This study tests the effects of economic intervention, alone and in combination with a family-focused component, on the mental health of children and women living in ultra-level poverty.

**Methods.**— Funded by the Network of European Foundations, this three-arm cluster-RCT included 10–15 year-old children and women from 360 ultra-poor households from twelve villages in Burkina Faso. Villages were randomized (4 villages/120 households per arm) to the wait-list arm, the economic intervention (Trickle Up/TU arm), or to the economic strengthening plus family coaching component (TU+ arm). Intervention effects were tested using repeated-measures mixed-effects regressions.

**Results.**— At 12 months, compared to the control arm, mothers from both intervention groups receiving economic intervention

demonstrated a reduction in the PHQ-9 depression score (Cohen's  $d = -0.67$ ,  $P = .001$  and  $d = -0.48$ ,  $P = .005$ ) and the GAD-7 anxiety score ( $d = -0.64$ ,  $P = .001$  and  $d = -0.51$ ,  $P = .002$ ), maintaining effects at 24 months. However, only children from the TU+ showed a reduction in depressive symptoms at 12 months (medium effect size  $d = -0.53$ ,  $P = .003$ ) and 24 months ( $d = -0.50$ ,  $P = .004$ ), compared to the control condition and the economic intervention alone (at 24 months  $d = -0.37$ ,  $P = .041$ ). At 24 months, small effect size improvements in self-esteem were detected in the TU+ group, compared to the control and TU conditions ( $d = 0.30$  and  $d = .27$ , respectively). Trauma symptoms significantly reduced in the TU+ group at 12 months ( $IRR = 0.62$ ,  $P = .042$ ), compared to the control.

**Conclusion.**— Integrating psycho-social intervention involving all family members with economic empowerment strategies may be an innovative approach for improving emotional well-being among ultra-poor families.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

### Glutamate anterior cingulate cortex glutamate activity in autism spectrum disorder with and without emotional dysregulation

G. Joshi<sup>1\*</sup>, A. Gonenc<sup>2</sup>, A. Belser<sup>1</sup>, B. Hoskova<sup>1</sup>, M. De Leon<sup>1</sup>, J. Biederman<sup>1</sup><sup>1</sup> Massachusetts General Hospital, Pediatric Psychopharmacology, Boston, USA;<sup>2</sup> McLean Hospital, McLean Imaging Center, Belmont, USA

\* Corresponding author

**Objectives.**— To use magnetic resonance spectroscopy (MRS) to identify biomarkers for emotional dysregulation (ED) in youth with autism spectrum disorder (ASD) as measured by subscales of the Child Behavior Checklist (CBCL).

**Background.**— Previous research has noted significantly high glutamate (Glu) levels in the anterior cingulate cortex (ACC) of ASD youth (Joshi et al., 2012), as well as correlations between Glu levels in the ACC and CBCL subscale scores in subjects with ED (Wozniak et al., 2012). This study compares Glu levels in the dorsal ACC (dACC) in ASD subjects with and without ED, and healthy controls (HCs).

**Methods.**— We measured Glu concentrations in the dACC of 43 youth (aged: 8–18 years), with and without ASD, using high field (4.0 Tesla) proton MRS. ASD subjects were grouped based on CBCL subscale scores previously associated with deficits in emotional regulation. ASD subjects with ED (>180) were further separated into those with severe emotional dysregulation (SED) (>210) ( $n = 11$ ) and deficient emotional self-regulation (DESR) (<210, >180) ( $n = 18$ ).

**Results.**— ASD + ED subjects had significantly higher Glu levels than subjects with only ASD and HCs ( $P = 0.006$ ). ASD + SED subjects had higher levels of Glu than the other groups ( $P = 0.003$ ). Severity of ASD, as measured by the Social-Responsiveness-Scale (SRS), was positively correlated ( $P = 0.057$ ) with Glu levels in the dACC. Subjects with ASD + SED had the strongest positive correlation ( $P = 0.001$ ) between severity of ED and Glu levels in the dACC.

**Conclusions.**— These results suggest that glutamatergic dysregulation in the dACC could be a useful biomarker of ASD and ED in youth.

**Disclosure of interest.**— Dr. Gagan Joshi is supported by the National Institute of Mental Health (NIMH) of the National Institutes of Health (NIH) under Award Number K23MH100450. He receives research support from Pfizer and the Simons Center for the Social Brain as a principal investigator (PI) for investigator-initiated studies. Additionally, he has received research support from Duke

University and Sunovion Pharmaceuticals as a site PI for multi-site trials. He is a co-investigator for a clinical trial sponsored by the U.S. Department of Defense. He received an honorarium from the Governor's Council for Medical Research and Treatment of Autism in New Jersey for grant review activities and speaker's honorariums from the American Academy of Child and Adolescent Psychiatry, Massachusetts General Hospital Psychiatry Academy, and the Medical Society of Delaware.

<sup>3</sup> Ajou university school of medicine, Department of Humanities and Social Medicine, Suwon, Republic of Korea;  
<sup>4</sup> Ajou university school of medicine, Office of Biostatistics, Suwon, Republic of Korea

\* Corresponding author

**Introduction.**– Firefighters are vulnerable to posttraumatic stress symptoms (PTSS), dissociation and depression. There've been many reports about the relationships between resilience and PTSS/dissociation, but few about depression mediating on them.

**Objectives.**– This study aimed to investigate the relationships between resilience and PTSS/dissociation and whether depression mediates the effects of resilience on PTSS/dissociation.

**Methods.**– A total of 115 firefighters participated in study. Data were collected via the Life Events Checklist (LEC), Impact of Event Scale-Revised (IES-R), Dissociative Experience Scale (DES-K), Beck Depression Inventory (BDI), and Connor-Davidson Resilience Scale (CD-RISC). Structural equation modeling and path analysis were applied to estimate the relationships between resilience, depression, PTSS, and dissociation by AMOS 21.

'Resilience→PTSS/Dissociation' were not significant, but indirect paths 'Resilience→Depression→PTSS/Dissociation' were significant.

**Conclusions.**– The relationships between resilience and PTSS/dissociation were fully mediated by depression, not directly by resilience. Tailored strategies and interventions based on resilience and depression may prevent PTSS/dissociation in firefighters and improve treatments outcomes.

**Diagnostic criteria of post-traumatic stress disorder; gender differences**

E. Lassemo<sup>1</sup>, I. Sandanger<sup>2</sup>

<sup>1</sup> SINTEF, Health, Trondheim, Norway;  
<sup>2</sup> University of Tromsø, Psychiatry, Tromsø, Norway

\* Corresponding author

**Introduction.**– Potentially traumatic events (PTEs) occur frequently in the Norwegian general populations at 466 (women) and 641 (men) per 100,000 person years (PYs). With subsequent incidence of post-traumatic stress disorder (PTSD) at 88 and 31 per 100,000 PYs. The ability to cope with trauma, determine if PTSD develops. From the literature, we know that men and women are exposed to different trauma, and that women and men react differently to trauma.

**Objectives.**– The aim of the present study was; to, stratified by gender, examine which ICD-10 diagnostic criteria (B-D) were present in trauma victims who developed subsequent PTSD.

**Methods.**– Data were from 1634 men and women, aged 18 and above, participating in the Oslof (Oslo and Lofoten) study. To obtain an accurate diagnosis based on ICD-10 criteria an updated electronic version-CIDI-M 1.1, of the Composite International Diagnostic Interview (CIDI) was used. We included reaction to severe stress, and adjustment disorders (ICD-10 code F43.1).

**Results.**– Among trauma victims, all diagnostic criteria were significantly more frequent among women than men. Among those fulfilling PTSD diagnostic criteria, most gender difference disappeared. While remembering the trauma was more frequent among women, loss of interest was more frequent among men. While consulting a physician was significantly more common among women trauma victims, the gender difference disappeared in PTSD cases.

**Conclusions.**– Women experience more of the diagnostic criteria for PTSD when exposed to trauma. Screening victims of trauma and designing individual crisis intervention therapy will benefit from including the implications of these findings.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>3</sup> Hospital 103, Military Academy of Medicine, Department of Psychiatry and Psychological Medicine, Hanoi, Vietnam

\* Corresponding author

**Introduction.**– Depression and schizophrenia are common and often stigmatized psychiatric disorders worldwide and in Vietnam. Public stigma leads to delayed treatment utilization and worsens treatment outcome.

**Objectives.**– This research aims to understand whether expectations of course of illness and illness attribution have an impact on public stigma.

**Methods.**– In 2013 a survey ( $n=910$ ), using unlabelled vignettes depicting a person suffering from schizophrenia or depression was carried out in Hanoi. All respondents were asked whether they believe the person is suffering from a mental illness. As an indicator for stigma desire for social distance was measured. Items asking for the perception of course of illness were clustered by factor analysis. A regression analysis was used to evaluate the impact of these factors on social distance.

**Results.**– Significantly more respondents, 85% compared to 60% thought that the psychotic person is suffering from a mental illness. This attribution of mental illness was correlated with higher levels of social distance only in the schizophrenia vignette. For both diagnosis, the factor analysis revealed three factors:

– loss of social functioning;

– lifelong dependency;

– positive expectations towards treatment outcome.

While for schizophrenia both negative prognostic perceptions were associated with more social distance, for depression only the expectation of lifelong dependency was. Though, only for depression positive expectations towards treatment outcome were correlated with lower levels of social distance.

**Conclusion.**– These results indicate an impact of prognostic expectations on desire for social distance and support strategies that aim at maintaining social integration and strengthening autonomy.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>3</sup> Evangelic Hospital Königin Elisabeth Herzberge, Department of Psychiatry, Psychotherapy and Psychosomatics, Berlin, Germany

\* Corresponding author

**Introduction.**– Migration in mental health care remains a highly important issue. Today, about 176,000 Vietnamese migrants live in Germany, which makes them the largest Southeast Asian migrant population. However mental health care utilization among this population is minimal. Among the factors influencing mental health care utilization, patient's perception of their burdens is crucial. This emic perspective is also shaped by culture. Thus, innovative research designs are needed to broaden the understanding of such culturally shaped factors.

**Objectives.**– This study aims to investigate the emic categories of self-reported burdens of Vietnamese and German psychiatric outpatients. Moreover, interviews with Vietnamese patients will be conducted to explore whether additional emic categories will emerge.

**Methods.**– Vietnamese patients ( $n=117$ ) and German patients ( $n=117$ ) filled out the Patient Health Questionnaire (PHQ, 2000). Patients' statements about their self-reported burdens were coded by the psychiatrists, the psychologist and the anthropologists.  $\chi^2$ -tests were conducted to explore differences in frequency of reported burdens between Vietnamese and German patients.

**Results.**– The results revealed significant differences between Vietnamese and German patients. Subsequently, a semi-structured interview was developed and  $n=10$  Vietnamese patients were interviewed. The interviews delivered contextualized information on the found categories and revealed additional emic categories of burdens.

**Conclusion.**– This study illustrates how an interdisciplinary mixed-method approach allows for an in-depth understanding of culturally shaped perceptions of patient's burdens. Clinicians should consider these emic categories and integrate them in their clinical interviews and apply questionnaires, which are co-structured using ethnographic data.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Audit on the management of depression and anxiety in oncology patients undergoing breast surgery and their relative**

E. Saliba

Mater Dei Hospital, Malta, Psychiatry, Birkirkara, Malta

**Introduction.**– This is an audit regarding mental illness in oncology patients. The aim was to identify patients and relatives who suffered from depression and anxiety post breast disease diagnosis. Moreover, the management of mental illness (whether psychiatric or psychological) was assessed.

**Objectives.**– To identify the pick up rate of depressed and anxious patients undergoing breast surgery including surgery for benign breast disease. To study management of depression and anxiety.

**Method.**– This audit was carried out over an 8 week period, during which time a total of approximately 50 patients and their relatives were included. The cohort of patients was limited to those admitted under surgical care and reviewed at the pre-operative assessment clinic (POAC). The Hospital Anxiety and Depression Scale (HADS) was used to pick up cases of depression and anxiety.

**Results.**– Total number of cases of depression (both patients & relatives): 13/91 (14%). Total number of cases of anxiety (both patients & relatives): 13/91 (14%).

**Conclusion.**– Depression was diagnosed in patients with malignancy but not those suffering from benign breast disease. Relatives of patients suffering from malignancy were more likely to suffer from anxiety than the patients themselves. There is no correlation between mental illness (both depression and anxiety) and

stage of tumour, grade and lymph node involvement. Most of the patients and relatives taking psychiatric drugs had them prescribed according to NICE guidelines. Counselling was not a popular form of psychological therapy for patients and relatives who suffered from depression or anxiety.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Cholinesterase inhibitors and survival in Alzheimer's disease in Down syndrome**

A. Strydom

*Institute of Psychiatry, Psychology and Neuroscience, King's College London, Forensic and Neurodevelopmental Sciences, London, United Kingdom*

*Introduction.*– Individuals with Down syndrome (DS) have a genetic predisposition to Alzheimer's disease (AD), but there is considerable variation in the clinical course, which is not well understood. Furthermore, there is little evidence to guide pharmacological treatment.

*Objectives.*– We used data from a large number of individuals with DS diagnosed with dementia in clinical services in England to explore factors associated with age of onset and predictors of survival. In addition, we investigated the effect of cholinesterase inhibitors or memantine on survival and function.

*Methods.*– Retrospective clinical cohort study design using clinical data (demographics, age at diagnosis, age at death, health comorbidities including depression, thyroid disorder and epilepsy) from specialist intellectual disability services in England, UK ( $n = 310$ ). Predictors of age at diagnosis were identified using inferential statistics and confounders adjusted for using multivariate regression. Survival rates were estimated using Kaplan–Meier estimates, and hazard ratios using multivariate Cox regression.

*Results.*– We describe the typical age at diagnosis and survival of individuals with DS diagnosed with dementia. Median survival time (5.59 years; 95% confidence interval 4.67, 6.67) for those on medication ( $n = 145$ , mainly cholinesterase inhibitors) was significantly greater than for those untreated ( $n = 165$ ) (3.45 years, 95% confidence interval 2.91, 4.13;  $P < 0.001$ ). Sequential assessments demonstrated an early effect in maintaining cognitive function.

*Conclusions.*– Cholinesterase inhibitors appear to offer some benefit in people with Down syndrome and AD that is comparable to sporadic AD; a trial to test the effect of earlier treatment (prodromal AD) in Down syndrome may be indicated

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

<sup>2</sup> *Alberta Health Services, Department of Public Health, Fort McMurray, Canada;*

<sup>3</sup> *University of Alberta, Department of Family Medicine, Edmonton, Canada;*

<sup>4</sup> *Northern Lights Regional Health Centre, Department of Psychiatry, Fort McMurray, Canada*

\* Corresponding author

*Objectives.*– To assess the prevalence rates for MDD in residents of Fort McMurray six months after the wildfire and to determine the demographic, clinical and other predictors of likely MDD in the respondents.

*Methods.*– Quantitative data was collected in this cross sectional survey through self-administered paper-based questionnaires, with random selection procedures used to choose study participants from a variety of settings in Fort McMurray. The PHQ-9 was used to assess the presence or absence of likely MDD in respondents.

*Results.*– Overall, 486 out of 588 respondents with an age range of 18 to 88 and about a two-thirds being females completed in full all of the key psychometric questionnaires and were included in the analysis. The one month prevalence rate for likely MDD six months after the disaster was 14.8% overall (10.4% for males and 17.1% for females). Three out of 18 variables with meaningful relationship to the likely MDD from the univariate analysis made a significant contribution to the logistic regression model. The corresponding odds ratios included 2.77 (95% CI of 1.03–7.46) and 12.75 (95% CI of 2.22–73.21) for those who received limited or no support respectively from friends or family and 5.31 (95% CI of 1.3–20.1) for those who had history of an anxiety disorder before the wildfire.

*Conclusion.*– Our study has established that whilst a prior diagnosis of an anxiety disorder significantly increased risk for developing MDD following wildfires, high level support from family and friends may be protective against likely MDD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

frontal theta cordance change, absolute and relative prefrontal theta power, theta power in specific electrodes, etc.) in the prediction of response to antidepressants.

**Aims.**– The aim of naturalistic study was to compare the ability of previously identified QEEG parameters in the prediction of response to various antidepressants.

**Methods.**– All patients were treated with antidepressants (SSRI-58, SNRI-46, NDRI-17, others-18) for  $\geq 4$  weeks. EEG was performed at baseline and week 1 (10/20 system International System).

**Results.**– Only change of prefrontal cordance at week 1 (PFCC\_1), prefrontal cordance value (PC\_1) at week 1 and relative theta power at baseline and week 1 (RT\_B, RT\_1) were identified as predictors. ROC analysis revealed significantly better predictive ability of PFCC\_1 in term of AUC value comparing to other identified predictors-see Table 1 for details.

**Conclusion.**– The change of prefrontal theta cordance seems to be more reliable predictor of treatment outcome than other theta QEEG parameters (Table 1).

This study was supported by the grants of MH CR nr.15-29900A, MH CZ - DRO (NIMH-CZ, 00023752) and the project Nr. LO1611 from the MEYS under the NPU I program. No other conflicts of interests. **Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### A meta-analysis of dose escalation of antidepressants in unipolar depression concerning double-blind randomized controlled trials

L. Bartova<sup>1</sup>, M. Dold<sup>1</sup>, R. Rupprecht<sup>2</sup>, S. Kasper<sup>1</sup><sup>1</sup> Medical University of Vienna, Department of Psychiatry and Psychotherapy, Vienna, Austria;<sup>2</sup> Klinik und Poliklinik für Psychiatrie und Psychotherapie der Universität Regensburg, Bezirksklinikum Regensburg, Regensburg, Germany

\* Corresponding author

**Introduction.**– Initial antidepressant monotherapy is often associated with insufficient response in unipolar depression (UD). One of the next therapeutic steps represents increasing the daily dose of the administered antidepressant, which is also called dose escalation.

**Objectives.**– We included all available double-blind randomized controlled trials (RCTs), whereby the antidepressant dose was either increased or maintained in depressed patients with insufficient response to a standard-dose antidepressant treatment, and compared the treatment outcomes.

**Methods.**– The mean change in total scores of the Hamilton Rating Scale for Depression represented the primary outcome. Response rates and discontinuation rates due to -any reason, -inefficacy, and -adverse effects were defined as secondary outcomes. Hedges' g and risk ratios represented effect sizes.

**Results.**– Seven double-blind RCTs with 8 relevant study arms including 1208 patients treated with fluoxetine (N=2, n=448), sertraline (N=2, n=272), paroxetine (N=2, n=146), duloxetine (N=1, n=255), and maprotiline (N=1, n=87) were enrolled. No significant

differences between dose escalation and continuing standard-dose treatment were detected, neither for the overall pooled antidepressant groups (N=7, n=999; Hedges' g = -0.04, 95% CI: -0.20 to 0.12; P=.63), nor for the individual antidepressants. No significant differences were found for response-rates, all-cause discontinuations and dropouts because of inefficacy. However, dose-escalation was associated with significantly more drop-outs due to adverse effects (P=.04). The severity of depressive symptoms at baseline and the different amounts of dose increments showed no significant impact on the effect sizes.

**Conclusions.**– Dose-escalation seems not to be superior to continuing a standard-dose after initial non-response to a standard-dose antidepressant monotherapy in UD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Predictors of poor 6-week outcome in a cohort of major depressive disorder patients treated with antidepressant medication: The role of entrapment

S. Carvalho<sup>\*</sup>, F. Caetano, C. Martins

Hospital Magalhães Lemos, Psychiatry, Porto, Portugal

\* Corresponding author

**Introduction.**– Increasing evidence supports the role of entrapment, and other evolutionary variables, in the genesis of depression. However, only few studies attempted to assess its influence in remission.

**Objectives.**– This study, the first of its kind, intends to evaluate evolutionary strategies, child maltreatment, neglect and life events and difficulties (LEDs) as predictors of remission in depressed patients undergoing pharmacological treatment in a psychiatric outpatient sample.

**Methods.**– A cohort of 139 depressed outpatients undergoing pharmacological treatment was followed prospectively in a naturalistic study during 6 weeks. Two major evaluations were considered: baseline and 6-weeks. Patients were allocated to the Texas Medication Algorithm Project. Variables evaluated at baseline and tested as predictors of remission included: demographic and clinical data, severity of depression, evolutionary variables (entrapment, defeat, social comparison, external shame and submissive behaviour), LEDS and child maltreatment (parental physical and sexual abuse and parental negligence and hostility before seventeen).

**Results.**– Of the 139 patients, 24.5% remitted at week 6. For the logistic regression:

- higher load of life events and difficulties of the entrapment/humiliation dimension (in the year prior to the index episode);
- higher levels of entrapment predict non-remission.

These variables accounted for 28.7% of the variance.

**Conclusions.**– This study supports the importance of entrapment, not only as a contributing factor for depression but also as a predictor of remission in major depressive disorder patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Long-term risk of developing dementia after electroconvulsive therapy for depression

S. Hjerrild<sup>1\*</sup>, P.E. Buchholtz<sup>1</sup>, R. Rosenberg<sup>2</sup>, P. Videbech<sup>3</sup><sup>1</sup> Aarhus University Hospital, Department for Affective Disorders, Risskov, Denmark;<sup>2</sup> Copenhagen University Hospital, Department of Psychiatry, Copenhagen, Denmark;<sup>3</sup> Copenhagen University Hospital, Center for Neuropsychiatric Depression Research, Copenhagen, Denmark

\* Corresponding author

**Introduction.**– Severe depression is associated with an increased risk of developing dementia, but whether electroconvulsive therapy (ECT) modulates this risk remains unknown. Further, concerns have been raised about the long-term cognitive effects of ECT treatment

**Objectives.**– To estimate long-term risk of developing dementia in patients with severe depression treated with ECT.

**Methods.**– Retrospective cohort study of 1626 patients with depression treated with ECT in a period from 1976 to 2000 at Aarhus University Hospital (ECT-group). The control group was 15.226 age, sex and diagnosis matched patients admitted to psychiatric departments in the same periods but without ECT treatment. Prior psychiatric admissions were used as a proxy for disease severity. Dementia diagnoses were retrieved in the national patient health registry. Follow-up was at 5 years, 10 years and full follow-up (from index to death or 31.03.2017).

**Results.**– Adjusted hazard ratios (HR [95% confidence interval]) for receiving a dementia diagnosis in the ECT-group compared to the control group was 0.44 [0.24–0.81] at 5-year follow-up, 0.59 [0.38–0.91] at 10-year follow-up and 0.98 [0.78–1.23] at full follow-up.

**Conclusions.**– The risk of developing dementia was decreased in patients with depression treated with ECT compared to patients not treated with ECT, but at full follow-up no difference was found. In our sample, the treatment of severe depression with ECT was not associated with an increase in the risk of developing dementia and indeed a potential protective effect was indicated.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Depression is associated with increased risk of cardiovascular diseases in primary care population in Latvia

R. Ivanovs<sup>1\*</sup>, A. Kivite<sup>2</sup>, I. Mintale<sup>3</sup>, J. Vrublevska<sup>1</sup>, R. Logins<sup>1</sup>, L. Berze<sup>1</sup>, E. Rancans<sup>1</sup><sup>1</sup> Riga Stradins University, Department of Psychiatry and Narcology, Riga, Latvia;<sup>2</sup> Riga Stradins University, Department of Public Health and Epidemiology, Riga, Latvia;<sup>3</sup> University Clinic of Paul Stradins, Department of Cardiology, Riga, Latvia

\* Corresponding author

**Introduction.**– Cardiovascular diseases (CVD) are the leading cause of morbidity and mortality worldwide. There is extensive evidence that depression contributes not only to the onset but also to the progression and prognosis of CVD. Recent research suggests that depression may have a more important role in the development of CVD in women, but not in men.

**Objectives.**– To examine association of depression and prevalence of CVD in primary care population in Latvia.

**Methods.**– This cross-sectional study was carried out within the framework of the National Research Program BIOMEDICINE at 24 primary care facilities. During one-week period in 2015 all consecutive adult patients attending General practitioner (GP) for medical reasons were invited to complete the Patient Health Questionnaire (PHQ-9) followed by socio-demographic questionnaire and physical measurements. The Mini International Neuropsychiatric Interview (MINI) was conducted over the telephone within 2 weeks after visit to GP. The multivariate model has been developed by using binary logistic regression.

**Results.**– The study population consisted of 1565 subjects, 31.2% men and 68.8% women. According to medical records 17.1% had CVD. The screening test of depression (PHQ-9) was positive for 14.7% of individuals. According to the MINI 10.3% had current and 28.1% had lifetime depression. When analysis was stratified by gender, depressive symptoms (PHQ-9  $\geq$  10) were associated with 2.04 ( $P=0.004$ ) times higher odds of CVD in women, but lifetime depression (MINI) was associated with an odds ratio of 3.29 ( $P=0.03$ ) in men.

**Conclusions.**– Current depressive symptoms in women and lifetime depressive episode in men is associated with higher prevalence of CVD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparison of the effectiveness of allopurinol and placebo in reducing depressive symptoms in patients with major depressive disorder

H. Jamilian<sup>1\*</sup>, B. Sadeghi Sedeh<sup>2</sup>, F. Ranjbaran<sup>1</sup><sup>1</sup> School Of Medicine, Arak University Of Medical Sciences, Psychiatry, Arak, Iran;<sup>2</sup> School Of Medicine, Arak University Of Medical Sciences, Social Medicine, Arak, Iran

\* Corresponding author

**Introduction.**– Depression is one of the most common psychiatric disorders. It causes severe loss of functioning, disability and also the risk of suicide. Xanthine oxidase inhibitor allopurinol may increase the level of tryptophan (serotonin precursor) and hereby improve the symptoms of depression.

**Objectives.**– The aim of this study was to compare the effectiveness of allopurinol and placebo in reducing depressive symptoms of major depressive disorder.

**Methods.**– In this randomized double blind clinical trial 70 patients with major depressive disorder (according to the clinical interview based on DSM-5 criteria) randomly divided into two equal groups. Both groups received citalopram 40 mg per day for 6 weeks. Intervention group received allopurinol 300 mg per day for 6 weeks. Control group received placebo. Hamilton depression scale was done at the beginning of the study, the end of the third week, and the end of the study (sixth week). Liver function tests blood level of uric acid were done at the beginning of the study, and after 2, 4 and 6 weeks.

**Results.**– Intervention group (citalopram plus allopurinol) showed a significantly greater improvement on Hamilton depression scale than the placebo group (citalopram plus placebo) at the end of the third week and the end of the study ( $P<0.001$ ). There was not any significant difference between two groups regarding liver function tests and blood level of uric acid.

**Conclusion.**– Allopurinol as augmentation therapy is more effective than placebo in the treatment of major depressive disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>7</sup> Karachi medical and dental college, Public health, Karachi, Pakistan;

<sup>8</sup> Dow University of Health Sciences, Institute of Nursing, Karachi, Pakistan

\* Corresponding author

**Background.**– In Pakistan rates of depression particularly in women are high, as well as other risks to the growth and development of young children and child mortality. Although many cost-effective interventions have been developed in the West however these hardly available in Pakistan due to the poor health systems and lack of appropriately trained mental health professionals

**Objectives.**– To test the efficacy of Learning through Play Plus (LTP plus Thinking Healthy) program in low resource setting of Pakistan.

**Method.**– Women aged 18–44 years with children aged between 0–30 months, scoring 14 or above on EPDS, meeting inclusion criteria and gave informed consent were included ( $n = 811$ ). Assessment included Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7 (GAD7), WHO quality of Life Scale, Parenting Stress Index, Home Observation for the Measurement of the Environment Inventory and Ages and Stages Questionnaire. Total 10 group sessions of LTP Plus were delivered by Lady Health Workers (LHWs), co-facilitated by a psychologist.

**Results.**– Results indicated that there was a significant mean difference between LTP Plus and routine care group on PHQ-9, GAD-7, WHO QOL, PSI, Home inventory and Ages and Stages Questionnaire ( $P < 0.000$ ).

**Conclusion.**– Results of this LTP Plus study has provided local evidence that the distribution of competencies in mental health across non-specialist health disciplines in primary care can lead to more accessible, efficient and potentially cost-effective health care and can better address the mental health needs of mothers and children in this low resource setting.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Risk factors analysis for late-onset depression and the relationship with cognition based on the default mode sub-network

R. Liu<sup>1</sup>, Y. Yingying<sup>2</sup>, H. Zhenghua<sup>2</sup>, Y. Yonggui<sup>2</sup>, W. Qiao<sup>1</sup>

<sup>1</sup> Southeast University, School of Information Science and Engineering, Nanjing, China;

<sup>2</sup> Southeast University, Department of Psychosomatics and Psychiatry, ZhongDa Hospital, School of Medicine, Nanjing, China

\* Corresponding author

**Introduction.**– Abnormal functional connectivity (FC) in the default mode network (DMN) is an important role in the cognitive impairment in the late-onset depression (LOD) patients. However, little

is known about the FC of DMN sub-networks as the risk factors for the LOD.

**Objectives.**– This study is to explore the risk factors of the LOD based on the DMN sub-networks and further investigate the correlation with the cognition.

**Methods.**– Total 30 LOD patients and 40 health control underwent the resting-state functional magnetic resonance imaging and cognitive assessments. Firstly, FCs within the DMN sub-networks were determined by placing seeds in the ventral medial prefrontal cortex (vmPFC) and posterior cingulate cortex (PCC). Secondly, the multivariable logistic regression was used to identify the risk factors. Finally, the correlation analysis was performed to investigate the relationship between the risk factors and the cognitive value.

**Results.**– The study showed that the FCs between the vmPFC and right middle temporal gyrus (vmPFC-MTG.R), between the vmPFC and left precuneus (vmPFC-PCu.L), between the PCC and PCu.L (PCC-PCu.L) were the risk factors of the LOD. Furthermore, both of the vmPFC-MTG.R and PCC-PCu.L correlated with the processing speed ( $R = 0.35, P = 0.002$ ;  $R = 0.41, P = 0.001$ ). The vmPFC-MTG.R correlated with semantic memory ( $R = 0.31, P = 0.009$ ).

**Conclusions.**– The results further suggest that the FCs within the DMN sub-networks associated with cognitions can be considered as the risk factors, which may be used to predict the appearance of LOD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The link between lipid profile and mood disorders development at elderly patients

S. Opris<sup>1</sup>, R. Draghici, A. Avadanei

National Institute of Gerontology and Geriatrics “Ana Aslan”, Biology of Aging, Bucharest, Romania

\* Corresponding author

It has been established that there is a correlation between serum lipids levels and psychopathological conditions. In this study we included 242 patients: 134 with mood disorders (MD) vs. 108 control group. Atherogenic index (AI) was computed as log (TG/HDL) and HeartScore from a cardiovascular disease risk assessment system. Study data revealed that HDL-cholesterol levels were lower, atherogenic indices higher and HeartScore showed an intermediate risk in MD patients compared with the controls. Patients with MD have significant low HDL-cholesterol ( $53.38 \pm 17.98$  vs.  $58.50 \pm 21.02$ ;  $P < 0.05$ ). AI and HeartScore were significantly increased in MD patients vs. control ( $0.35 \pm 0.31$  vs.  $0.27 \pm 0.31$ ;  $P < 0.01$  respectively  $2.94 \pm 2.37$  vs.  $2.41 \pm 1.9$ ;  $P < 0.05$ ). At MD patients, AI and HeartScore were significant negative correlated with HDL ( $r = -0.83$ ;  $P < 0.00001$  respectively  $r = -0.502$ ;  $P < 0.00001$ ). Also, we found a positive significant correlation between AI and HeartScore at MD patients ( $r = 0.51$ ;  $P < 0.00001$ ). The prevalence of dyslipidemia at MD patients increased from 42.37% in the low risk AI group to 60.68% in the high risk AI group. For HeartScore, the prevalence of dyslipidemia increased too, from 43.20 to 56.66%. Multivariate logistic regression analysis showed that, compared to low risk AI, patients with high AI had 2.00-fold risk for MD [OR 2.00, 95% CI: 1.10–3.63;  $P = 0.022$ ]. Also, patients with high HeartScore were 2.09 (OR 2.09, 95% CI: 1.21–3.58;  $P = 0.006$ ) times likely to have MD. These findings suggest that lipid abnormalities are strongly involved in the pathophysiology of mood disorders. Longitudinal studies are needed to confirm whether these indices maintain their prognostic capacity in long term.

### **Association between cannabis use and prevalence of major depression in a community-based sample from Southern Spain**

A. Porras Segovia<sup>1\*</sup>, P. De Jaime<sup>1</sup>, P. Calvo-Rivera<sup>2</sup>, J. Cervilla<sup>3</sup>  
<sup>1</sup> *University Hospital San Cecilio, Mental Health Services, Granada, Spain;*

<sup>2</sup> *Unidad de Salud Mental Comunitaria, Unidad de Salud Mental Comunitaria, Peñarroya, Córdoba, Spain;*

<sup>3</sup> *University of Granada, Psychiatry department, Granada, Spain*

\* Corresponding author

*Introduction.*– Major depressive disorder (MDD) is one of the world leading causes of disability. Cannabis has been frequently linked to psychosis, but its association with depression is not as well studied. *Objectives.*– The aim of our study is to explore the association between cannabis use and MDD in the province of Granada, Southern Spain.

*Methods.*– This is a cross-sectional study based on a community-dwelling adult population living in the province of Granada, Southern Spain. Adults aged 18–80 years were interviewed using the Mini-International Neuropsychiatric Interview (MINI). A variety of exposure assessments were also undertaken, including self-reported cannabis use.

*Results.*– Our sample is composed of 810 respondents, 48% male and 52% female. Mean age was 47.2 years. Current (2 weeks) prevalence of MDD was 5.2% (95% CI 3.7–6.7). Bivariate analysis showed that cannabis used was associated with an increased risk of MDD, with an OR of 3.2 (95% CI 1.5–6.7). Multivariate factor regression analysis revealed that cannabis use was independently associated with MDD (OR=2.95; 95% CI 1.11–7.81; *standard deviation* = 1.465; *P* value = 0.029)

*Conclusions.*– Our results support the findings of previous studies that described cannabis use as a risk factor for developing depression. Mechanisms by which cannabis could lead to depression include neurochemical alterations of monoamines, impaired cognitive performance and psychosocial failure

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Childhood maltreatment and major depression: Results from the Granad-ep study**

A. Porras Segovia<sup>\*</sup>, P. De Jaime, P. Calvo, J. Cervilla  
*University Hospital San Cecilio, Mental Health Services, Granada, Spain*

\* Corresponding author

*Introduction.*– Major depressive disorder (MDD) is one of the world leading causes of disability. It is assumed that the disorder is the result of a complex interaction between biological and psychosocial factors.

*Objectives.*– The aim of our study is to explore the association between childhood maltreatment and MDD.

*Methods.*– This is a cross-sectional study based on a community-dwelling adult population living in the province of Granada, Southern Spain. The Mini International Neuropsychiatric Interview (MINI) was our main diagnostic tool. Childhood maltreatment was assessed through the abbreviated Childhood Trauma Questionnaire.

*Results.*– Our sample is composed of 810 respondents, 48% male and 52% female. Mean age was 47.2 years. Current (2 weeks) prevalence of MDD was 5.2% (95% CI 3.7–6.7). An increased prevalence of MDD was found among those who had suffered childhood sexual abuse (OR= 19.1\*, 95% CI 2.6–139.3), although no significant association was found for other types of childhood maltreatment.

*Conclusions.*– Sexual childhood abuse was associated with MDD, although this association disappeared when adjusting for number of LTEs, as both variables may be collinear with each other. Furthermore, authors have described a synergistic interaction between childhood abuse and LTE (Power et al., 2012). One of the ways childhood abuse could predispose to MDD is through the theory of learned helplessness, which states that children repeatedly subjected to traumatic experiences, against which they find themselves defenceless, may lose their capacity to cope with hardship in their adulthood.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Factor structure of the EURO-D Depression Scale in people over 50 in Europe with SHARE**

C. Portellano Ortiz<sup>1\*</sup>, J. Garre-Olmo<sup>2</sup>, L. Calvo-Perxas<sup>2</sup>, J.L. Conde-Sala<sup>1</sup>

<sup>1</sup> *University of Barcelona, Cognition, Development and Educational Psychology, Barcelona, Spain;*

<sup>2</sup> *Institut d'Assistència Sanitària, Girona Biomedical Research Institute IDIBGI, Research Unit, Girona, Spain*

\* Corresponding author

*Objectives.*– The aims of this study are: to analyze the factor structure of the EURO-D depression scale; to explore the variables associated with depression and with the EURO-D factors in the SHARE participant countries; and to compare the presence of depression and the factor predominance in the total sample.

*Method.*– A total of 62,182 participants in Wave 5 (2013) of the 15 participant countries of the Survey of Health, Aging and Retirement in Europe (SHARE) were included. Instruments: The SHARE study and the EURO-D scale. Factor, bivariate and multilevel analyses were performed.

*Results.*– A poor self-perception of physical health and economic difficulties were the two variables associated with higher levels of depression, also in both factors. Suffering and Motivation were the two resulting factors identified in the EURO-D factor analysis. In the Suffering factor, female gender and younger age ( $\leq 60$ ) were associated with higher levels of depression, as well as with less activity and exercise, older age ( $\geq 71$ ), widowhood and lower educational level in the Motivation factor

*Conclusions.*– Poorer self-perception of physical health, female gender, economic difficulties, widowhood, lower levels of activity and exercise and lower educational level were associated with higher depressive symptomatology. In the countries of southern Europe, the Motivation factor predominated.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

Peters Veterans' Administration Medical Center and Icahn School of Medicine at Mount Sinai, Psychiatry, New York, NY, USA, USA

\* Corresponding author

**Introduction.**— Sensory processing patterns have been proposed as a stable dimension which may help to better characterize individuals with major affective disorders; however, to what extent specific impairments in sensory processing are involved in the pathophysiology of these disabling conditions is unclear.

**Objectives.**— Our aim was to investigate whether specific sensory profiles may predict the response to psychoactive medications, with particular regard to antidepressants, according to depression, alexithymia, and hopelessness levels.

**Methods.**— We recruited a sample of 402 outpatients who received maintenance treatment and were in stable psychopathological conditions. Subjects completed the Adolescent/Adult Sensory Profile (AASP), Toronto Alexithymia Scale (TAS-20), second version of the Beck Depression Inventory (BDI-II), and Beck Hopelessness Scale (BHS) according to a longitudinal study design including three time points of measurements.

**Results.**— Subjects with lower ability to register, seek for sensory information, and greater sensory sensitivity/avoidance better responded to antidepressant medications according to their reduced depression levels. Similarly, participants with greater sensory sensitivity better responded to antidepressants as reported by lower hopelessness levels. Regression analyses revealed that the use of antidepressants was the first variable able to predict depression, hopelessness, and alexithymia levels at baseline, and after three and six months of treatment, respectively, but the pattern of sensory sensitivity contribute to the prediction of depression and hopelessness. This pattern together with low registration predicted even changes in alexithymia levels.

**Conclusions.**— The careful investigation of sensory processing patterns may provide intriguing insights into specific illness characteristics and treatment response.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

## Severity, course-trajectory and within-person variability of individual symptoms during 9 years in outpatients with major depression

W. van Eeden<sup>1\*</sup>, E. Giltay<sup>1</sup>, A. van Hemert<sup>1</sup>, B. Penninx<sup>2</sup>, C. Ingrid<sup>1</sup>

<sup>1</sup> Leiden University Medical Center, Psychiatry, Leiden, The Netherlands; <sup>2</sup> VU University Medical Centre, Neuroscience Campus, Amsterdam, The Netherlands

\* Corresponding author

Depression shows a large heterogeneity of symptoms between- and within persons over time. However, most outcome research assessed depression as a single underlying latent construct with the sum-score on self-rated scales as an indicator for severity.

Data were derived from the Netherlands Study of Depression and Anxiety (NESDA), a longitudinal cohort study. We included 558 participants with a current MDD at baseline. The Inventory Depressive Symptomatology–Self-Report (IDS-SR) was used to analyze 26 depressive symptoms at up to 6 time points during 9 years of follow-up. Course-trajectories and within-person variability were modelled using 14,508 linear regression models per item and per person.

Patients were on average 42.9 years (*SD* 12.2) with 64.9% women. The highest baseline severity scores were found for the items regarding energy and mood states (Figure 2). Each of the symptoms showed the strongest decline within the first year of follow-up. The core-symptoms depressed mood and anhedonia had the most favorable course, whereas sleeping problems and (psycho-)somatic symptoms were more persistent over the course of 9 years (Figure 3). Within-person variability was highest for mood symptoms and lowest for suicidal ideation (Figure 4).

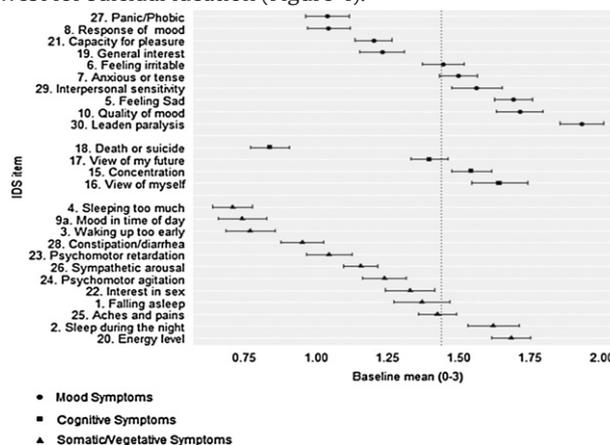

Fig. 2

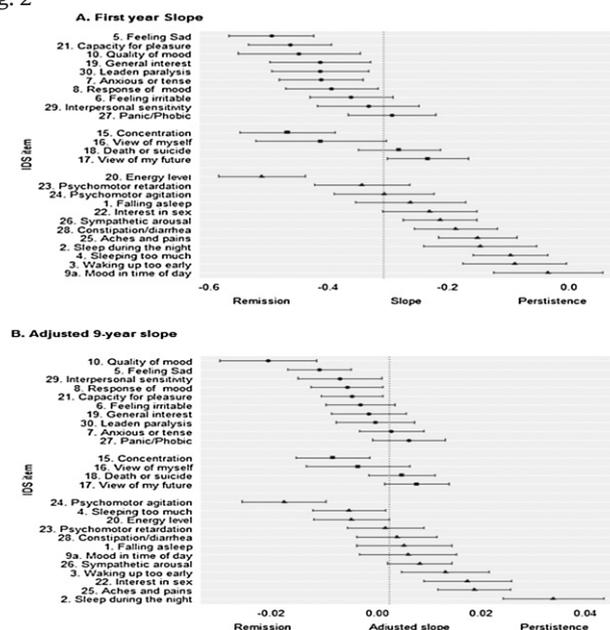

Fig. 3

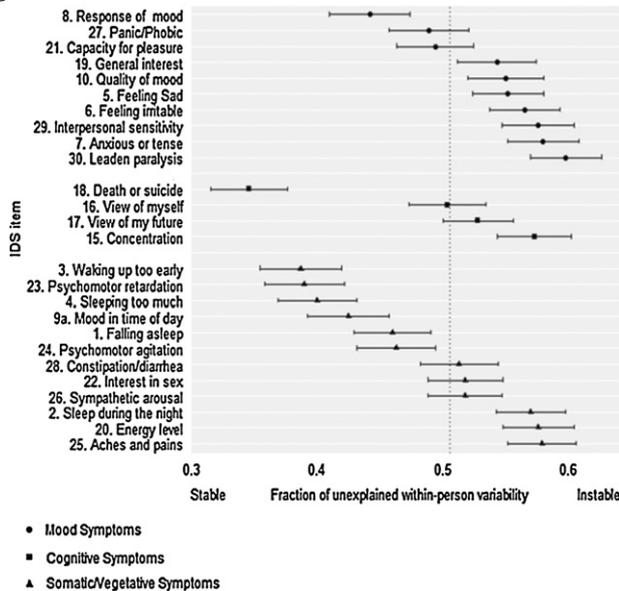

Fig. 4

Symptom trajectories were subject to “regression to the mean” effects. We used only the items from the self-rated IDS-SR as outcome measures.

There was evidence for large heterogeneity both between depressive symptoms and within persons over time, which strengthens the idea that a symptom-focused approach in clinical care and research is of importance over and above merely using sum-scores for depression severity.

### Personality and psychological distress in Portuguese international students: The role of stress and social support

M. Carmo<sup>1</sup>, M.J. Soares<sup>1</sup>, A.P. Amaral<sup>2\*</sup>, M.J. Martins<sup>3</sup>, A.T. Pereira<sup>1</sup>, A. Macedo<sup>1</sup>

<sup>1</sup> University of Coimbra, Department of Psychocological Medicine, Faculty of Medicine, Coimbra, Portugal; <sup>2</sup> Institute Polytechnic of Coimbra and University of Coimbra, Coimbra Health School and Department of Psychological Medicine, Faculty of Medicine, Coimbra, Portugal; <sup>3</sup> University of Coimbra, Department of Psychocological Medicine, Faculty of Medicine, CINEICC, Faculty of Psychology and Educational Sciences, Coimbra, Portugal

\* Corresponding author

*Introduction.*– Personality traits are determinants of stress and psychological distress. International students are more exposed to stress, which contributes to psychological distress and social support is believed to be a protective factor of both of these.

*Objective.*– to study the mediation role of stress in the relationship between big-five personality traits and psychological distress, exploring the impact of social support as a covariate.

*Methods.*– A total of 103 Portuguese international students (aged 23.59 years;  $SD=2.08$ ; 78.6% women) answered PoMS, PSQ and NEO-FFI-20 scales and a question about social support.

*Results.*– High neuroticism ( $r=.623$ ) and stress ( $r=.728$ ); low levels of extroversion ( $r=-.285$ ), conscientiousness ( $r=-.253$ ), agreeableness ( $r=-.229$ ) and social support ( $r=-.329$ ) were correlated with negative affect ( $P<0.01$  for all). Mediation analysis showed a significant total effect of neuroticism in negative affect. Neuroticism directly and indirectly influenced negative affect through its effect on stress increase; social support did not have a significant impact on stress and negative affect. The direct effects of extroversion, conscientiousness and agreeableness on negative affect were not significant. However, they had total and indirect significant effects on affect: they decreased stress, which in turn increased negative affect. Social support had a protective effect that minimized stress.

*Conclusion.*– The diathesis-stress model explains the relation between personality traits, stress and psychological distress. Contrary to neuroticism, extroversion, conscientiousness, agreeableness, and perceived social support are protective factors that can buffer against the effects of stressors. These findings may have practical implications to the support of international students.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The role of perfectionism and paranoia on depression: Preliminary results

A.C. Pires<sup>1</sup>, M.J. Soares<sup>2</sup>, A.T. Pereira<sup>2</sup>, A.I. Araújo<sup>3\*</sup>, M.J. Martins<sup>1</sup>, A. Macedo<sup>2</sup>

<sup>1</sup> Faculty of Medicine, University of Coimbra, Psychological Medicine Department, Coimbra, Portugal; <sup>2</sup> Faculty of Medicine of the University of Coimbra, Psychological Medicine Department, Coimbra, Portugal; <sup>3</sup> Faculty of Medicine, University of Coimbra, Psychological Medicine Department, Macieira de Cambra, Portugal

\* Corresponding author

*Keywords:* Depression; Paranoia; Socially-prescribed perfectionism

*Introduction.*– Socially-Prescribed Perfectionism (SPP) is characterized by a high dependence on others’ approval, which can lead to self-devaluation. Some theories defend that paranoid beliefs are a coping strategy to deal with low self-esteem. The result may be a paradoxical psychological distress.

*Objectives.*– The purpose of this study is to investigate the relationship between SPP and depression and verify if paranoia has a mediating role.

*Methods.*– The non-clinical sample ( $n=90$ ) was mostly composed of female (80%) and single (62.2%) individuals. Mean age was 34 years old ( $SD=12.9$ ). All participants filled in three scales: Multidimensional Perfectionism Scale–short version, Revised General Paranoia Scale and Depression, Anxiety and Stress Scale–short form. Spearman correlations were examined, and mediation models were used with bootstrapping methodology.

*Results.*– Significant positive associations were found between the variables. A simple mediation model was performed with Persecutory Ideas as a mediator of the relationship between SPP and depression, which explained 17% of the variance. Results showed that the total effect, the direct effect of SPP on depression and the indirect effect were significant.

*Conclusions.*– The results contribute to the understanding of the psychological mechanisms involved in depression generated by SPP. Considering that 17% of the variance was explained, other variables may be involved. Further study is needed, and final results of

this project may shed light into this. Findings suggest however the importance of addressing paranoid ideation in future therapeutic and preventive interventions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Personality traits and burnout among trainee-teachers of the regional center for educational and training professions of Casablanca (Morocco)

Z. Elboukhari<sup>1</sup>, F.Z. Azzaoui<sup>1</sup>, A. Ahami<sup>1</sup>, H. Hami<sup>2</sup>, S. Boulbaroud<sup>3</sup>, M. Elhioui<sup>1</sup>

<sup>1</sup> Unit of Cognitive and Behavioral Neuroscience and Applied Nutrition, Faculty of Science, Department of Biology, Kenitra, Morocco; <sup>2</sup> Laboratory of Genetics and Biometry, Faculty of Science, Department of Biology, Kenitra, Morocco; <sup>3</sup> Polydisciplinary Faculty, Sultan My. Sliman University, Beni Mellal, Morocco

\* Corresponding author

*Introduction.*– Personality has been conceptualized from a variety of theoretical perspectives, and at various levels of abstraction or breadth. In personality research, the most common unit of measurement of individual differences remains trait. Today, a consensus seems to emerge as a general taxonomy of personality traits known as the Big Five, an expression introduced by Goldberg.

*Objectives.*– Studying the personality traits and its relation to burnout among trainee-teachers.

*Methods.*– A cross-sectional study carried out among 140 trainee-teachers of the Regional Centre of education and training of Casablanca. The assessment of the personality traits and Burnout was conducted by two scales: The Big five personality test and MBI (Maslach burnout inventory).

*Results.*– The obtained results showed that 70% of trainee-teachers have a low extraversion, 32% have a low awareness, 50.7% of them represent a low professionalism, 89% have a low neuroticism and 17.9% have a low opening experience. Correlational analyzes showed that the personality trait of agreeableness is positively associated with extraversion ( $r=0.31$ ,  $P<0.001$ ). Also, the neuroticism is positively associated with professional conscience ( $r=0.25$ ,  $P<0.01$ ). The only significant correlation between Personality test and burn out is found between neuroticism and emotional exhaustion ( $r=0.22$ ,  $P<0.01$ ).

*Conclusion.*– The five personality traits and burnout experienced by the trainee-teachers may cause among certain of them, exhaustion with a great psychological suffering and result in negative impacts. It is therefore desirable to deepen and diversify research perspectives in the field of prevention.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Borderline personality disorder as a mediator of the relation between self-reported childhood traumatic experiences and psychotic-like experiences among patients with mood disorder

I. Baryshnikov\*, K. Aaltonen, G. Joffe, M. Heikkinen, E. Isometsä  
The University of Helsinki, The Department of Psychiatry, Helsinki, Finland

\* Corresponding author

*Introduction.*– Psychotic-like experiences (PEs) are a common phenomenon among patients with mood disorders. Several state-

and trait-related factors influence reporting of PEs, including mood related cognitive biases, anxiety and features of borderline personality disorder (BPD). A substantial number of studies have suggested that childhood traumatic experiences (CEs) are an important risk factor for both psychotic and mood disorders. Specifically, patients with BPD often report CEs. Thus, we hypothesized that features of BPD may mediate the relationship between self-reported PEs and CEs.

*Objectives.*– To investigate relationships between self-reported CEs, PEs and features of BPD.

*Methods.*– As part of the Helsinki University Psychiatric Consortium study, the McLean Screening Instrument (MSI), the Community Assessment of Psychic Experiences (CAPE-42) and the Trauma and Distress Scale (TADS) were filled in by patients with mood disorders ( $n=252$ ) in psychiatric care. Correlation coefficients between total scores of scales and their dimensions were estimated, multivariate regression and mediation analyses were conducted.

*Results.*– Total scores of MSI correlated strongly with scores of CAPE-42 “frequency of positive symptoms” ( $\rho=0.56$ ;  $P\leq 0.001$ ) and moderately with TADS ( $\rho=0.4$ ;  $P\leq 0.001$ ). Total score of MSI and its dimension “cognitive symptoms” fully mediated relation between TADS and CAPE-42. Items of MSI “dissociative symptoms”, “identity disturbance” and “distrustfulness” shown a partial mediating role (43% (CI = 25–74%); 40% (CI = 30–73%); 18% (CI = 12–50%), respectively).

*Conclusions.*– Self-reported cognitive-perceptual symptoms of BPD may fully mediate the relationships between CEs and PEs, whereas affective, behavioral and interpersonal symptoms only partially. Recognition of BPD symptoms in patients with mood disorders reporting PEs is important.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Perfectionistic self-presentation as a mediator between narcissism and psychological distress: Preliminary results

B. Silva<sup>1</sup>, C. Marques<sup>2</sup>, A.T. Pereira<sup>2</sup>, M.J. Brito<sup>1</sup>, M. Coroa<sup>2,3\*</sup>, A. Macedo<sup>2,3</sup>

<sup>1</sup> University of Coimbra, Faculty of Medicine, Coimbra, Portugal; <sup>2</sup> University of Coimbra, Psychological Medicine, Faculty of Medicine, Coimbra, Portugal; <sup>3</sup> Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

\* Corresponding author

*Introduction.*– Narcissism is a complex personality trait characterized by grandiosity and self-entitlement, which has been associated with perfectionism and distress. Perfectionistic self-presentation is associated with low levels of self-esteem and dysfunctional cognitive and emotional processes. When associated with perceived failure it may lead to psychological distress in the form of symptoms such as depression and anxiety.

*Objectives.*– The present study aims to investigate the mediating role of perfectionistic self-presentation in the relationship between narcissism and psychological distress (depression and anxiety).

*Methods.*– The sample was composed by 215 university students, 72.6% female and 27.4% male, with a mean age of 21.89 years ( $SD=2.12$ ), which completed several instruments including the Portuguese versions of scales that assess narcissism, perfectionistic self-presentation, depression and anxiety.

*Results.*– We found significant and positive correlations between the variables. Simple mediation analyses revealed that perfectionist self-presentation mediates the relationship between narcissism and depression and between narcissism and anxiety.

**Conclusions.**– These findings allowed a greater understanding of the relationship between narcissism, perfectionistic self-presentation and psychological distress. Psychological interventions in narcissistic individuals should target perfectionistic self-presentation to reduce psychological distress.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Episodic memory in autism spectrum disorder: A meta-analysis**

P. Desaunay<sup>1</sup>\*, A. Briant<sup>2</sup>, D.M. Bowler<sup>3</sup>, P. Gérardin<sup>1</sup>, F. Guérolé<sup>4</sup>, F. Eustache<sup>2</sup>, J.J. Parienti<sup>5</sup>, B. Guillery-Girard<sup>2</sup>

<sup>1</sup> Rouen University Hospital, FHUPEA, Rouen, France; <sup>2</sup> Normandie Univ, UNICAEN, PSL Research University, EPHE, Inserm, U1077, Caen Hospital, Research Unit, Caen, France; <sup>3</sup> City University of London, Psychology, London, United Kingdom; <sup>4</sup> Caen University Hospital, U1077, Child Psychiatry, Caen, France; <sup>5</sup> Caen University Hospital, Biostatistics and Clinical Research Unit, Caen, France

\* Corresponding author

**Introduction.**– Episodic memory is a complex memory system implicating some abilities that are affected in autism spectrum disorder (ASD). Studies conducted on this topic report contrasting results. Hence, we conducted a meta-analysis of episodic memory impairments in ASD and evaluated possible moderators of these impairments, such as the type of material (visual vs. verbal), items (semantically related vs. semantically unrelated items), and retrieval task (free recall vs. recognition).

**Methods.**– Twenty-nine case-control studies published from 1997 to February 2017 comparing groups of children, adolescents and adults with ASD to typically developing controls (TD) were included, corresponding to a total of 1057 participants (548 with ASD and 509 TD).

**Results.**– Results showed that ASD participants demonstrated significantly reduced episodic memory (Cohen's  $d = -0.28$  [–0.40; –0.16];  $P < 0.001$ ) particularly in the visual domain ( $d = -0.38$  [–0.66; –0.09];  $P = 0.01$ ), with no difference in memory for verbal material ( $d = -0.12$  [–0.27; 0.03];  $P = 0.11$ ). However, subgroup analysis revealed a verbal free recall difficulty for semantically related items ( $d = -0.51$  [–0.86; –0.17];  $P = 0.004$ ), but not for semantically unrelated items ( $d = 0.21$  [–0.23; 0.65];  $P = 0.36$ ).

**Discussion.**– This meta-analysis confirmed the presence of episodic memory difficulties in ASD for verbal material when ASD people are provided unsupported retrieval tasks after on semantically related items. This profile confirms difficulties in ASD in processing complex information implicating binding with semantic knowledge when no support is provided. Our results extend the scope of this difficulty to non-verbal material as has recently been observed in a meta-analysis of working memory tasks (Wang et al., 2017, *Neuropsychol Rev* 27:46–61).

### **Perceived social support and medication compliance among patients with psychiatric disorders**

S. Harfush

Tanta University, psychiatric and mental health nursing, Tanta, Egypt

**Keywords:** Social support; Medication compliance; Patients with psychiatric disorders

Current studies about increasing compliance to decrease treatment and healthcare costs have gained more significance. Social sup-

port is an important component in the recovery of patients with psychiatric disorders; therefore, it is difficult to ignore its role in improving patient's compliance to treatment.

**Aims.**– This study aimed to assess the levels of perceived social support, medication compliance and their relationship.

**Design.**– The present study follows a cross sectional design.

**Setting.**– The study was conducted at the Psychiatric Inpatient Wards of “Tanta University Hospital” and Psychiatry- Neurology and Neurosurgery Center.

**Subjects.**– The study subjects were 144 psychiatric patients.

**Tools.**– **Tool (1):** Socio-demographic data sheet. **Tool (2):** Multidimensional perceived social support scale (MSPSS). **Tool (3):** Drug attitude inventory (DAI).

**Results.**– Overall, 74.3% of patients had a poor social support and only 21.5% of them had good medication compliance. There was a statistical significant correlation between perceived social support and medication compliance.

**Recommendations.**– Development of social skills training program for patients with psychiatric disorders aimed to teach them how to obtain help and support from family, friends, and significant others. Training psychiatric hospital staff to increase their understanding about the importance of their supportive role to provide appropriate nursing intervention for patients with psychiatric disorders.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Anxiety increases the risk of cardiovascular diseases in men but not women: A cross-sectional study of primary care population in Latvia**

R. Ivanovs<sup>1</sup>\*, A. Kivite<sup>2</sup>, I. Mintale<sup>3</sup>, J. Vrublevska<sup>1</sup>, R. Logins<sup>1</sup>, L. Berze<sup>1</sup>, E. Rancans<sup>1</sup>

<sup>1</sup> Riga Stradins University, Department of Psychiatry and Narcology, Riga, Latvia; <sup>2</sup> Riga Stradins University, Department of Public Health and Epidemiology, Riga, Latvia; <sup>3</sup> University Clinic of Paul Stradins, Department of Cardiology, Riga, Latvia

\* Corresponding author

**Introduction.**– Anxiety has been recognized as independent risk factor for development and prognosis of cardiovascular diseases (CVD). Recent evidence suggests possible gender differences for prognostic influence of anxiety, indicating that general anxiety and tension are more consistent CV risk factors for men than women.

**Objectives.**– To examine the association of anxiety and the prevalence of CVD in primary care population in Latvia.

**Methods.**– This cross-sectional study was carried out within the framework of the National Research Program BIOMEDICINE at 24 primary care facilities. During one-week period in 2015 all consecutive adult patients attending General practitioner (GP) for medical reasons were invited to complete the Generalized Anxiety Disorder questionnaire (GAD-7) followed by socio-demographic questionnaire and physical measurements. The Mini International Neuropsychiatric Interview (MINI) was conducted over the telephone within 2 weeks after the visit to GP. The multivariate model has been developed by using binary logistic regression.

**Results.**– The study population consisted of 1565 subjects, 31.2% men and 68.8% women. According to medical records 17.1% ( $n = 268$ ) had a CVD. The screening test of anxiety (GAD-7) was positive for 10.1% of individuals. According to the MINI any anxiety disorder was detected in 16.1% of patients. Most prevalent anxiety disorders were agoraphobia and generalized anxiety disorder, 8.1% and 6.1% respectively. When regression analysis was stratified by gender, current anxiety disorder (MINI) was associated with higher

odds of CVD in men (odds ratio = 7.16, 95% CI 1.81–28.34), but not women.

**Conclusions.**– Current anxiety disorder is associated with a higher prevalence of CVD in men, but not women.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Coping style among doctors and its correlation with depression and subsequent burnout and perceived stress during the residency training**

P. Pariwatcharakul<sup>1,2\*</sup>, W. Ratta-apha<sup>1,3</sup>, N. Saisavoey<sup>1,2</sup>, T. Sumalrot<sup>1</sup>, J. Wankaew<sup>1,4</sup>, N. Sanguanpanich<sup>5</sup>, P. Ketumarn<sup>2</sup>

<sup>1</sup> Faculty of Medicine Siriraj Hospital, Mahidol University, Department of Psychiatry, Bangkok, Thailand; <sup>2</sup> Faculty of Medicine Siriraj Hospital, Mahidol University, Siriraj Piyamaharajkarun Hospital, Bangkok, Thailand; <sup>3</sup> Faculty of Medicine Siriraj Hospital, Mahidol University, Siriraj Center of Research Excellence Management Unit, Bangkok, Thailand; <sup>4</sup> Faculty of Medicine Siriraj Hospital, Mahidol University, Counseling Clinic for Medical Students and Residents, Bangkok, Thailand; <sup>5</sup> Faculty of Medicine Siriraj Hospital, Mahidol University, Research Division, Bangkok, Thailand

\* Corresponding author

**Introduction.**– Understanding doctors' coping style is important for planning for mental health promotion strategies.

**Objectives.**– To assess coping styles and depression of doctors prior to the beginning of their residency training and to assess the relationship between each coping style and subsequent perceived stress and burnout.

**Methods.**– The Thai versions of Proactive Coping Inventory and Patient Health Questionnaire were emailed to all of the first-year residents at a university hospital in Academic Year 2015 just 1 week before the beginning of their residency training. Sets of follow-up questionnaires including Thai versions of Perceived Stress Scale and Maslach Burnout Inventory (MBI) were sent out at 1, 3 and 6 months later. Statistical analyses were performed using SPSS 18.

**Results.**– Among 277 doctors, 102 (36.8%) responded to the survey. The respondents aged 25–33 years (mean = 26.8, SD = 1.2) and 69.6% were female. Depression was found in 9.8% of the respondents. Each coping style was not correlated with any subsequent overall MBI and Perceived Stress scores. Moreover, reflective coping which were negatively correlated with depersonalization sub-score of MBI at the 3rd month ( $r = -.363$ ,  $P = 0.030$ ), did not sustain its correlation at the 6th month of residency training.

**Conclusions.**– Depression was not uncommon among young doctors even before the beginning of their residency training program. No specific coping style showed protective effect against subsequent perceived stress and burnout during the residency training. The results suggest that intervention or mental health promotion programs for doctor that focus only on coping strategies of doctors are unlikely to be successful.

### **Is the stereotype of the mad psychiatrist a justified prejudice? A comparison of personality traits between psychiatrists and other specialists**

S. Taib<sup>1\*</sup>, C. Arbus<sup>1</sup>, L. Schmitt<sup>1</sup>, A. Pelissolo<sup>2</sup>, A. Yrondi<sup>1</sup>

<sup>1</sup> CHU de Toulouse, Purpan, service de psychiatrie et psychologie médicale, Toulouse, France; <sup>2</sup> Assistance publique–Hôpitaux de Paris, pôle de psychiatrie et d'addictologie, Créteil, France

\* Corresponding author

**Introduction.**– Psychiatrists often suffer a stigmatised image and are considered to be just as sick as their patients. This idea is found in many media. Movies and TV shows categorise psychiatrists in three main clusters (“Dr Dippy”, “Dr Wonderful” and “Dr Evil”). We tried to determine whether this assumption was correct or not.

**Materials and methods.**– We designed a prospective observational study. We distributed locally and nationally a french version of the TCI-226, developed by Cloninger. Data were collected during August 2016.

**Results.**– A total of 224 doctors (54 psychiatrists and 170 other specialists) completed the survey. We did not find any difference between the two populations, based on the personality traits defined in Cloninger's model. When compared to the general population, psychiatrists demonstrated higher scores for Novelty Seeking, Reward Dependence and Cooperativeness, in association with lower Self-Transcendence scores. The other specialists presented the same differences when compared to the general population, in addition to differences among Persistence and Self-Determination scores.

**Discussion.**– Our results do not allow us to conclude to any differences when the personality of psychiatrists is compared to the other specialists' one. Moreover, the connection between personality traits and movies archetypes does not seem to fit perfectly any of the three stereotypes previously described in the literature. The clinical implication of such stereotypes are however paramount, likely helping patients to better accept their disease.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– At a group level, psychotherapies for depression produce equivalent outcomes. However, at an individual level, responses differ for different therapies. Predictors of (differential) outcome have been identified in the context of randomized trials,

but this information has not been used to predict which treatment works best for the depressed individual.

**Objectives.**– In this presentation, we focus on individual predictions of acute and long term depression outcomes in the context of a randomized trial comparing Cognitive Therapy ( $n=76$ ) and Interpersonal Psychotherapy ( $n=75$ ).

**Methods.**– We used the Personalized Advantage Index (PAI), recently developed by DeRubeis and colleagues, to combine predictors into an algorithm that generates actionable treatment recommendations for individual patients.

**Results.**– For a majority of the trial participants, a clinical meaningful advantage was predicted in either CT or IPT, compared to the other treatment. Moreover, those who were randomized to their predicted optimal treatment had far better outcomes than those randomized to their predicted non-optimal treatment.

**Conclusions.**– Although the utility of the PAI approach will need to be evaluated in prospective research, this study promotes the development of a treatment selection approach that can be used in regular mental health care, advancing the goals of personalized medicine.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A systematic review of subjective side effects following ECT treatment**

S. Vann Jones<sup>1\*</sup>, R. McCollum<sup>2</sup>

<sup>1</sup> Cornwall Partnership Foundation Trust, Complex Care & Dementia, Launceston, United Kingdom; <sup>2</sup> Devon Partnership Trust, Franklyn Hospital, Exeter, United Kingdom

\* Corresponding author

**Introduction.**– Electroconvulsive therapy (ECT) is a highly effective treatment for severe depression however there is debate around the specific long term effects of the treatment on subjective memory.

**Objectives.**– This review aimed to summarise all studies that have assessed the post-treatment effects of ECT on meaningful memory loss.

**Methods.**– The systematic review was completed in accordance with PRISMA reporting guidelines. Studies measuring subjective memory at baseline followed by at least one measurement after the completion of treatment using a clearly described method were included. A follow-up period of at least 24 hours after the completion of therapy was required. No limit was placed on the maximum length of follow up. Both prospective and retrospective studies were included

**Results.**– A total of 16 studies were identified for inclusion in the review. There was considerable heterogeneity in memory assessment method, treatment modality used and length of follow up. Those studies that reported outcomes at six months showed relative stability in subjective memory complaints compared to one month with some suggestion that subjective memory complaints resolve post-treatment in those followed up for sufficient time. Four studies (25%) included patients who had received ultra-brief pulse. Two of these compared brief versus ultrabrief and both reported that ultra-brief was associated with fewer cognitive side effects.

**Conclusions.**– The few studies that assessed subjective memory several months beyond the end of ECT suggest that subjective memory scores tend to recover over time with ultrabrief pulse showing fewer side effects than brief-pulse therapy. However, there is considerable heterogeneity both between and within studies limiting meaningful conclusions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0087

### **Early improvement as a resilience signal predicting later remission to antidepressant treatment in patients with major depressive disorder: Systematic review and meta-analysis**

S. Wagner<sup>1\*</sup>, A. Engel<sup>1</sup>, J. Engelmann<sup>1</sup>, D. Herzog<sup>1</sup>, N. Dreimüller<sup>1</sup>, M. Müller<sup>1</sup>, A. Tadic<sup>2</sup>, K. Lieb<sup>1</sup>

<sup>1</sup> University Medical Center, Department of Psychiatry and Psychotherapy, Mainz, Germany; <sup>2</sup> Agaplesion Elisabethenstift, Department of Psychiatry, Psychosomatics and Psychotherapy, Darmstadt, Germany

\* Corresponding author

Early improvement of depressive symptoms during the first two weeks of antidepressant treatment has been discussed to be a resilience signal predicting a later positive treatment outcome in patients with major depressive disorder (MDD). However, the predictive value of early improvement varies between studies, and the use of different antidepressants may explain heterogeneous results. The objective of this review was to assess the predictive value of early improvement on later response and remission and to identify antidepressants with the highest chance of early improvement. We included 17 randomized controlled trials investigating early improvement in 14,779 adult patients with MDD comparing monotherapy with an antidepressant against placebo or another antidepressant drug. 62% (range: 35–85%) of patients treated with an antidepressant and 47% (range: 21–69%) with placebo were early improver, defined as a >20%/25% symptom reduction after two weeks of treatment. Early improvement predicted response and remission after 5 to 12 weeks of treatment with high sensitivity (85%; 95%-CI: 84.3 to 85.7) and low to moderate specificity (54%; 95%-CI: 53.1 to 54.9). Early improver had a 8.37 fold (6.97–10.05) higher likelihood to become responder and a 6.38 fold (5.07–8.02) higher likelihood to be remitter at endpoint than non-improver. The highest early improver rates were achieved in patients treated with mirtazapine or a tricyclic antidepressant. This finding of a high predictive value of early improvement on treatment outcome may be important for treatment decisions in the early course of antidepressant treatment. Further studies should test the efficacy of such early treatment decisions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Depression in lesbian, gay and bisexual French adolescents**

X. Wang<sup>1\*</sup>, M. Cosquer<sup>1</sup>, M. Zhuang<sup>2</sup>, C. Joussemel<sup>1</sup>

<sup>1</sup> Centre hospitalier de psychiatrie de l'enfant et de l'adolescent, pôle universitaire de la Fondation Vallée, Gentilly, France; <sup>2</sup> St. Louis University, School of Education, St. Louis, USA

\* Corresponding author

**Introduction.**– Depression in adolescents is a concern for public authorities, and many studies have indicated that adolescents that identify as lesbian, gay, or bisexual (LGB) have higher levels of depression than their heterosexual peers (HETERO). However, in France, no prior studies have been focused on this subject.

**Objective.**– This study examines the prevalence of depression in French adolescents, taking into account sexual attraction.

**Methods.**– A multicenter cross-sectional school survey “Portrait d'adolescents” was conducted in France in 2013. All adolescents of 13 to 20 years old completed a questionnaire including the Adolescent Depression Rating Scale (ADRS): depressed (score  $\geq 6$ ).

**Results.**– Among 14,265 adolescents analyzed, 4.5% was in the LGB group and 95.5% in HETERO group. LGB adolescents were more

likely to have depression than HETERO peers (26.4% vs. 11.5%). Girls were found to be more depressed than boys in both groups (28.8% vs. 18.2% in LGB group; 16.1% vs. 6.7% in HETERO group) (see Figure 1). Only 24.1% of LGB adolescents and 15.2% HETERO adolescents who had depression had been to see a doctor.

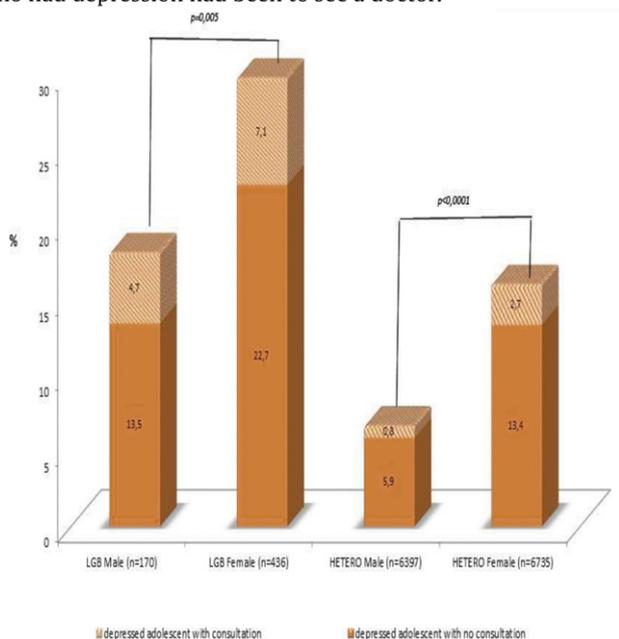

Fig. 1

**Conclusion.**– This study confirms that adolescents who have a homosexual or bisexual attraction have a greater risk of depression than their heterosexual peers, especially in adolescent girls. Progress is needed to orientate the adolescents with depression to consult a professional.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### A combination of polymorphisms in three genes contributes to premorbid personality disorders in male patients with schizophrenia

M. Alfimova<sup>1\*</sup>, V. Golimbet<sup>2</sup>, V. Kaleda<sup>3</sup>, G. Korovaitseva<sup>1</sup>, E. Krikova<sup>1</sup>, D. Tikhonov<sup>3</sup>

<sup>1</sup> Mental Health Research Center, Clinical Genetics, Moscow, Russia; <sup>2</sup> Mental Health Research Center, Clinical Genetics Lab, Moscow, Russia; <sup>3</sup> Mental Health Research Center, Dep endogeneous mental disorders and affective states, Moscow, Russia

\* Corresponding author

Most genetic association studies of schizophrenia focused on a search for association between gene polymorphism and disease or its clinical features. However less attention is paid to a role of genetic variants in premorbid functioning. The aim of the present study was to investigate the relationship between the genes, which were previously reported to be associated with symptoms, course and outcome of schizophrenia, and premorbid personality disorders in patients with schizophrenia. We studied the T102C polymorphism of the serotonin receptor type 2A (5-HTR2A) gene,

the 5-HTTLPR polymorphism of the serotonin transporter gene and the Val66Met polymorphism of the brain-derived neurotrophic factor (BDNF) gene. In the literature, genotypes CC (5-HTR2A), LL (5-HTTLPR) and allele Met (Val66Met BDNF) were associated with worse cognitive functioning and poor outcome in patients with schizophrenia (Golimbet et al., 2002, Notaras et al., 2015, Golimbet et al., 2017). The study included 270 male patients diagnosed with ICD-10 F20 code. Premorbid personality was assessed using clinical interviews, medical records, information from relatives and the Premorbid Adjustment Scale. Patients were stratified into three groups according to the severity of personality pathology:

- slight ( $n = 110$ );
- moderate ( $n = 112$ );
- severe ( $n = 48$ ).

Results showed that the frequency of the combined genotype S allele (5-HTTLPR)\*ValVal (Val66Met)\*TT (5-HTR2A) was significantly higher in the 1st group compared to group 2 ( $P = 0.038$ ) and group 3 ( $P = 0.001$ ). In conclusion, genetic variants examined have a moderating effect on the severity of premorbid personality disorders in patients with schizophrenia. This work was supported by RFBR grant N17–29–02088.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The association between the GWAS risk Allele rs2514218 (C) and schizophrenia is confirmed in the Russian population

M. Alfimova<sup>1\*</sup>, N. Kondratiev<sup>1</sup>, T. Lezheiko<sup>1</sup>, N. Kolesina<sup>1</sup>, V. Kaleda<sup>2</sup>, L. Abramova<sup>3</sup>, V. Golimbet<sup>1</sup>

<sup>1</sup> Mental Health Research Center, Clinical Genetics, Moscow, Russia; <sup>2</sup> Mental Health Research Center, Dep endogeneous mental disorders and affective states, Moscow, Russia; <sup>3</sup> Mental Health Research Center, Dep endogeneous mental disorders and affective states, Moscow, Russia

\* Corresponding author

Recently, a genome-wide association study (GWAS) from the Psychiatric Genomic Consortium reported about the discovery of new 108 loci associated with the risk of schizophrenia. One of the loci is the gene coding for the dopamine D2 receptor, which is regarded as a prominent candidate gene for schizophrenia due to its binding to antipsychotic drugs. The top single nucleotide polymorphism (SNP) reported in this locus is rs2514218, located about 47 kb upstream from DRD2. The C allele is the risk allele. We attempted to replicate this finding in an independent sample selected from the Russian population. We studied in total 1747 patients [962 women, 785 men, aged from 17 to 70 years, mean age 35.6 (13.8) years]. Overall, 1571 patients were diagnosed with paranoid schizophrenia (ICD-10 code F20.0), 82 with schizoaffective disorder (F25), 75 with schizotypal personality disorder (F21), 37 with other forms (codes F20.1, F20.2, F20.6). The control group included 1285 healthy people [645 women, 640 men, aged from 17 to 74, mean age 28.4 (11.7) years] without a family history of psychiatric disorders. Genotyping was performed using high resolution melting (HRM) method. The distribution of genotypes was as follows: TT = 922, TC = 687, CC = 138 in the patient group and TT = 626, TC = 535, CC = 124 in controls. There was a significant between-group difference in genotype frequencies ( $\chi^2 = 6.0$ ;  $df = 2$ ;  $P = 0.04$ ). The frequency of the CC genotype was higher in patients compared to controls ( $\chi^2 = 4.4$ ;  $df = 1$ ;  $P = 0.03$ ). In conclusion, our results confirm the association between the risk allele rs2514218(C) and schizophrenia in the Russian population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– Treatment of predominant negative symptoms (PNS) with available antipsychotics may lead to worsening of the targeted symptoms. As antipsychotics may cause side effects, which mimic negative symptoms, choosing the right agent to treat these symptoms can be difficult.

**Objective.**–The objective of the present poster is to present efficacy data of cariprazine versus different comparators in the treatment of PNS.

**Methods.**– Data of PNS population were analyzed from 3 different clinical studies:

- study-1. A phase-3 randomized, double-blind, risperidone-controlled, parallel-group, 26 weeks study in PNS patients;
- study-2. A randomized, double-blind, 6 weeks, placebo and aripiprazole controlled study in patients with acute schizophrenia;
- study-3. A randomized, double-blind, placebo-controlled, relapse prevention study investigating cariprazine versus placebo.

For the efficacy analyses change from baseline to end of 6 weeks or 6 months period on the PANSS-FSNS was analyzed.

**Results.**– Study-1 ( $n=546$ ). The difference in mean change from baseline in the PANSS-FSNS was statistically significant for cariprazine versus risperidone from week 14 onwards ( $-1.5$ ,  $P=0.002$ ). Study-2 ( $n=112$ ). The PNS sub-population of patients were analyzed. The difference in mean change from baseline in the PANSS-FSNS was statistically significant for cariprazine versus aripiprazole at week 6 ( $-2.0$ ,  $P=0.05$ ). Study-3 ( $n=20$ ). The difference in mean change from baseline in the PANSS-FSNS was statistically significant for cariprazine versus placebo at week 26 ( $-2.25$ ,  $P=0.03$ ).

**Conclusion.**– Cariprazine showed superior efficacy in the treatment of PNS of schizophrenia versus all investigated comparators, namely placebo, risperidone as well as aripiprazole regardless the design and length of the studies.

**Disclosure of interest.**– I am a co-worked of Gedeon Richter Plc.

\* Corresponding author

**Context.**– The progress made in schizophrenia treatments has had a substantial effect on evolution of the disease and expectations of clinicians who now aim to achieve both symptomatic and functional remissions. Symptomatic remission frequently goes with improved functioning, but this relationship isn't systematic. Functional remission is evidenced by ability of patients to adapt to difficulties of societal life and to reintegrate their environment. The Functional Remission Observatory Group in Schizophrenia (FROGS) scale is a specific tool recently developed in French language.

**Objective.**– In a population of schizophrenic patients being treated for an episode of clinical destabilization and followed for a period of twelve months, the main objective is to evaluate the proportion of patients achieving functional remission and its relationship to clinical remission.

**Methodology.**– R092670SCH4033 was a French, multicentric, prospective, national, non-interventional study, follow-up of one year, three evaluations: D0, D180 and D360. Inclusion: schizophrenia patients (DSM IV), age: 18 to 37, time since long acting antipsychotic initiation: <2 months. Evaluation methods: CGI-I, FROGS scale, 8 items PANSS scale, PSP scale, Insight Scale, SWN scale, EuroQol-5D. Judgment criteria: Functional remission defined on the FROGS scale.

**Results & conclusion.**– The study is in finalization, data of the 303 patients who completed the study will be frozen in September, statistical analyses will be performed in October, so final results will be shown on the poster [1–3].

### **Transition to psychosis and its association to EEG resting-state microstates in high-risk individuals**

\* Corresponding author

**Introduction.**– The importance of reliably identifying the risk of psychosis transition in high-risk individuals (at-risk mental state, ARMS) has been increasingly acknowledged in recent years. Biomarkers can be highly valuable in heightening prediction specificity. One promising biomarker in this regard are EEG resting-state microstates; these exhibit specific abnormality patterns in patients with schizophrenia, in particular shortening of one microstate class (labeled D). Microstate abnormalities have been previously reported in ARMS as well; however, it is not known whether these are predictive of a future transition into psychosis.

**Objectives.**– To examine the association of temporal microstate characteristics with transition risk in high-risk individuals.

**Methods.**– We analyzed resting-state EEG data of 25 healthy controls, 58 medication-naïve schizophrenia patients and 57 ARMS of whom 20 later transitioned to psychosis (ARMS-T), recruited via the FePsy (Früherkennung von Psychosen) project. Preprocessed EEG data was spatially clustered into four microstates and labeled according to previously established norms. Mean coverage of total analysis time was computed for each microstate class and included in 4 (group) × 4 (microstate class) ANOVA. Preliminary results are reported.

**Results.**– A significant interaction between group and microstate class was observed. Follow-up analyses indicated that microstate class D coverage was lower in ARMS-T compared to all other groups.

**Conclusion.**– ARMS-T exhibited similar changes in microstate D as those previously reported for patients with schizophrenia. This raises the possibility that microstate D abnormalities might not simply index symptom severity, but also an increased risk of transition to psychosis in vulnerable individuals.

### Measuring effectiveness of long acting antipsychotics: Are we doing it right? The minimum effective dose method

C. Gómez Sánchez-Lafuente<sup>1</sup>, R. Reina Gonzalez<sup>2</sup><sup>1</sup> Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain; <sup>2</sup> Hospital Universitario Virgen de la Victoria, General Medicine, Málaga, Spain

**Introduction.**– Measuring equivalent dose has been a major issue since we started to use antipsychotics. Recently, another method was found to be useful: the minimum effective dose method, that has been used by Rothe et al to measure oral and Long acting injectable antipsychotics.

**Objectives.**– To compare the doses usually used in the clinical practice with the minimum equivalent dose between 4 LAI antipsychotics: olanzapine pamoate, paliperidone palmitate, risperidone Consta, and aripiprazol in the Abilify formulation

**Methods.**– We made a search in the database of the Virgen de la Victoria hospital of Malaga of all the patients less than 35 years diagnosed according to criteria of DSM V of acute psychotic disorder or schizophrenia that were being treated with one LAI in monotherapy and that were clinically stable at the beginning of 2016. We searched among the clinical data about relapses during 2016 of each patient. We compared the dose used in clinical practice with the minimum dose found in the previous studies: 50 mg/4 weeks for paliperidone, 210 mg/2 weeks for olanzapine, 400 mg/4 weeks for aripiprazole and 25 mg/2 weeks for risperidone.

**Results.**– Results are shown in Figures 1 and 2.

Fig. 1 Clinical relapses

Drug	Dosage	N	Mean age	Total relapses
Paliperidone	50 mg/28d	4	30,2	2
	75 mg/28d	18	28,4	10
	100 mg/28d	39	28,7	9
	150 mg/28d	29	28,1	8
Olanzapine	210mg/14d	4	26,6	1
	300mg/14d	8	28,3	2
Aripiprazole	300 mg/28d	7	29,5	2
	400 mg/28d	37	28,8	5
Risperdal	37.5 mg/14d	15	32,1	4
	50 mg/14d	18	30,9	6
<b>Total</b>		<b>179</b>	<b>29,16</b>	<b>49</b>

Fig. 2

**Conclusion.**– In this study, paliperidona has been statistically less effective than other drugs preventing relapse at minimum dose. We need between 2 and 3 times higher dose to be at least as effective

as the other drugs. Aripiprazol 400 mg every 4 weeks has been the most effective antipsychotic preventing relapse, but the difference has not been significant between olanzapine 210 mg/14d and aripiprazol 400 mg/4w.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0095

### Can be IL-2 and IL-1beta specific biomarkers of negative dimension in schizophrenia?

L. Gonzalez-Blanco<sup>1</sup>, P. García-Portilla<sup>2</sup>, L. García-Álvarez<sup>3</sup>, L. de la Fuente-Tomás<sup>3</sup>, C. Iglesias<sup>2</sup>, P. Sáiz<sup>2</sup>, S. González<sup>4</sup>, A. Coto<sup>4</sup>, J. Bobes<sup>2</sup><sup>1</sup> University of Oviedo, Servicio de Salud del Principado de Asturias, Psychiatry, Oviedo, Spain; <sup>2</sup> University of Oviedo, CIBERSAM, Servicio de Salud del Principado de Asturias, Psychiatry, Oviedo, Spain; <sup>3</sup> University of Oviedo, CIBERSAM, Psychiatry, Oviedo, Spain; <sup>4</sup> University of Oviedo, Department of Cellular Morphology and Biology, Oviedo, Spain

\* Corresponding author

**Introduction.**– Cytokine disturbances in schizophrenia (SZ) are widely described. But contradictory data about the relation between cytokines and psychopathology is published [1,2].

**Objectives.**– To analyze the relationship between pro-inflammatory cytokines and clinical dimensions (positive, negative, depressive, cognitive) in SZ.

**Methods.**– Sample: 73 outpatients with SZ, length of illness  $\leq 10$  years, under stable maintenance treatment [mean age ( $31.7 \pm 6.5$ ), males (61.6%)].

**Evaluation.**– PANSS, Clinical Assessment Interview of Negative Symptoms (CAINS) -Motivation & Pleasure (MAP) and Expression domains-, Calgary Depression Scale (CDS), MATRICS Consensus Cognitive Battery (MCCB), Personal and Social Performance (PSP). Biomarkers: TNF- $\alpha$ , interleukin(IL)-6, IL-2, IL-1 $\beta$ , IL-1RA.

**Statistical analyses.**– Bonferroni corrected Pearson correlations and multiple linear regression.

**Results.**– Only IL-2 and IL-1 $\beta$  showed statistically significant correlation:

– IL-2 with PANSS-Total ( $r=0.311$ ,  $P=0.008$ ), PANSS-General ( $r=0.288$ ,  $P=0.015$ ), CAINS-MAP ( $r=0.310$ ,  $P=0.008$ ), PSP ( $r=-0.420$ ,  $P<0.001$ );

– IL-1 $\beta$  with PANSS-Total ( $r=0.362$ ,  $P=0.002$ ), PANSS-Negative ( $r=0.324$ ,  $P=0.006$ ), PANSS-Negative Marder ( $r=0.370$ ,  $P=0.001$ ), PANSS-General ( $r=0.309$ ,  $P=0.009$ ), PSP ( $r=-0.396$ ,  $P=0.001$ );

– multiple linear regression models, adjusting for confounders (age, gender, education, length of illness, smoking, BMI, waist circumference, antipsychotic equivalent doses, treatment with antidepressants, benzodiazepines or stabilizers), identified that PANSS-Total, Negative, Negative Marder and General scores are predicted by IL-1 $\beta$  concentrations, while CAINS-MAP and PSP score is predicted by IL-2 levels;

– cognitive performance, positive and depressive symptoms severity did not correlate with any cytokine.

**Conclusions.**–

– IL-2 specifically mark severity of the MAP domain of negative dimension;

– IL-1 $\beta$  is not specific as it also predicts severity of general and global symptomatology.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Higher baseline C-reactive protein mark poor clinical course in the first ten years of schizophrenia: One-year follow-up study

L. Gonzalez-Blanco<sup>1\*</sup>, P. García-Portilla<sup>2</sup>, L. García-Álvarez<sup>3</sup>, L. de la Fuente-Tomas<sup>3</sup>, C. Iglesias<sup>2</sup>, P. Sáiz<sup>2</sup>, J. Bobes<sup>2</sup>

<sup>1</sup> University of Oviedo, Servicio de Salud del Principado de Asturias, Psychiatry, Oviedo, Spain; <sup>2</sup> University of Oviedo, CIBERSAM, Servicio de Salud del Principado de Asturias, Psychiatry, Oviedo, Spain; <sup>3</sup> University of Oviedo, CIBERSAM, Psychiatry, Oviedo, Spain

\* Corresponding author

**Introduction.**– C-reactive protein(CRP) was associated with more severe psychopathology and worse cognition in schizophrenia [1,2]. However, no data on CRP and longitudinal clinical course exists.

**Objectives.**– To evaluate if increased CRP predict clinical outcomes at 1-year follow-up.

**Methods.**– One-year follow-up study of 50 stable outpatients with schizophrenia (<10 years of illness) (mean age=31.1±6.5; 62% males). Patients were classified in two groups: those with low grade inflammation (LGI; CRP=3–10 mg/L; N=14 [28%]) vs. those with normal level (NL; CRP ≤3 mg/L; N=36[72%]). Acute inflammation (CRP >10 mg/L) was an exclusion criteria. At baseline, these groups differed in duration of illness [6±2.7 vs 3.5±3.4years; t=2.410 (P=0.02)] and BMI [30.3±5.8 vs 26.5±4.2; t=2.517 (P=0.015)] but there were no statistically significant differences in other demographic, clinical and psychometric variables (PANSS, BNSS, CAINS-Motivation/Pleasure & Expression-, Calgary Depression). Clinical course for each psychopathological dimension was determined using the formula: [follow-up -baseline scores]. Positive values were interpreted as worsening, while negative improvement.

**Results.**– At 1-year follow-up, total sample only improved significantly (P<0.05) in PANSS-Total [55.8±16.2 – 59.9±17.3], PANSS-General [26.9±7.9 – 29.7±8.9] and CAINS-Expression [4.9±4.2 – 5.7±4.3]. Patients with LGI showed worsening of scores on PANSS-Positive, Negative, General, and Total scales, compared to patients with NL [0.86±2 vs –1.3±3.4; 0.86±2.7 vs –1.2±3.2; 0.93±5.5 vs –4.2±5.2; 2.6±6.1 vs –6.7±8.4; respectively (all P<0.05)]. Multiple regression analyses including covariates (BMI, waist circumference, smoking, duration of illness, antipsychotic doses), showed that only CRP=3–10 mg/L predict worse clinical course on PANSS-Positive, General and Total.

**Conclusions.**– Higher baseline CRP may be a biomarker of poor clinical course in first ten years of schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Alteration of inflammatory cytokines in different age-at-onset schizophrenia with neurodevelopmental deficits

H.Y. Chen<sup>1\*</sup>, J.Y. Liu<sup>1</sup>, J.J. Lin<sup>2</sup>, M.K. Lu<sup>3</sup>, H.P. Tan<sup>4</sup>, F.L. Jang<sup>2</sup>, S.H. Lin<sup>1</sup>

<sup>1</sup> Clinical Medicine, Medicine, Tainan, Taiwan R.O.C.; <sup>2</sup> Chimei Medical Center, Psychiatry, Tainan, Taiwan R.O.C.; <sup>3</sup> Jianan Mental Hospital, Health, Tainan, Taiwan R.O.C.; <sup>4</sup> Kaohsiung Veterans General Hospital Tainan Branch, Psychiatry, Tainan, Taiwan R.O.C.

\* Corresponding author

**Introduction.**– Studies have suggested a role of inflammation and immunity in the pathogenesis of symptoms in schizophrenia through the immune system and the brain development. Early age of onset is associated with genetic factors and neurodevelopment in schizophrenia.

**Objectives.**– This study aimed to identify immune abnormality associated with neurodevelopmental deficits in early- and adult-onset schizophrenia patients.

**Methods.**– We enrolled early-onset schizophrenia (EOS), adult-onset schizophrenia (AOS), and healthy controls in this study. The serum levels of IL-1β, IL-4, IL-6, IL-10, IL-12 and TNF-α from schizophrenia patients and healthy controls were determined by enzyme-linked immunosorbent assay (ELISA). Measurements also included the Neurological soft signs (NSS), and Minor physical anomalies (MPA) in all participants to separate neurodevelopmental deficits groups.

**Results.**– The study included 84 early-onset schizophrenia (EOS), 126 adult-onset schizophrenia (AOS), and 122 healthy controls. There was a significant difference between EOS and AOS patients in IL-4 level. We found similar results in schizophrenia patients with the neurodevelopmental deficits and non-deficits. The ROC curve analysis showed that the AUC of IL-4, IL-6 and IL-12 was 0.83 and accuracy was 0.78 for EOS patients and healthy controls. Moreover, the discriminant analysis conducted of IL-4, IL-6, IL-12 correctly classified 83% cases into EOS patients and healthy controls, and cross-validation rate was 82%. Results showed that IL-4, IL-6 and IL-12 had a good classification ability.

**Conclusions.**– Cytokine production is altered in EOS and schizophrenia patients with neurodevelopmental deficits. These findings support that cytokines may contribute to the clinical and pathophysiological features of schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Paliperidone palmitate 3-monthly formulation in schizophrenia – baseline interim analysis of a naturalistic, 52-week, prospective study

L. Hargarter<sup>1\*</sup>, P. Bergmans<sup>2</sup>, I. Usankova<sup>3</sup>, P. Cherubin<sup>4</sup>

<sup>1</sup> EMEA Medical Affairs, Janssen-Cilag, Neuss, Germany; <sup>2</sup> Biostatistics & Programming, Janssen Cilag Benelux, Breda, The Netherlands; <sup>3</sup> Global Clinical Operations EMEA MAO, Janssen Cilag, Moscow, Russia; <sup>4</sup> EMEA Medical Affairs, Janssen Cilag, Paris, France

\* Corresponding author

**Objectives.**– To evaluate remission rates, treatment response, tolerability and PP3M patterns of use in schizophrenia patients, transitioned to paliperidone palmitate 3-monthly formulation (PP3M)

**Methods.**– Baseline interim analysis of the first 200 patients enrolled (patient's characteristics, disease severity, remission status, functional status, first dose of PP3M) in a 52-week, prospective, single arm, open-label, international study in patients previously stabilized on PP1M

**Results.**– A total of 200 patients analyzed: 62.5% male, mean age: 36.8 [standard deviation (SD) 8.0] years, body weight 78.3(17.0), BMI 27.2(5.2) kg/m<sup>2</sup>, time from first psychosis to initiation of PP3M 11.9 (7.7) years, number of previous psychiatric hospitalizations 3.2 (2.9), median time on previous PP1M treatment: 394.5 days (range: 85–1876); mean PANSS total score: 51.7 (11.0) with 57.5% (115/200) of patients fulfilling the symptom severity criteria of remission; PSP total score: 65.5 (14.0); WHODAS total score 16.2 (14.1) in patients with remunerated work items (n=78) and 21.6

(14.9) in patients without remunerated work items (N = 115); Goal Attainment Score (GAS): 36.8(4.3) with 63% reporting one, 14% two and 15.5% three goals; in 98.5% of patients dose conversion from PP1 M to PP3 M was according to label; mean dose of first PP3 M application: 358 (115.7) mg eq. with following dose distribution: 175 mg eq.: 11%; 263: 23%, 350: 39%, 525: 27%;

**Conclusions.**– When transitioning from PP1M to PP3M, the majority of patients fulfilled the symptom severity criteria of remission; PP3M dose conversion (from previous PP1M) was according to the label and dose distribution of first PP3M was corresponding to PP1M dosing in naturalistic studies.

### **Increased mortality following myocardial infarction in patients with schizophrenia: A nationwide cohort study**

P. Kugathasan<sup>1\*</sup>, T.M. Laursen<sup>2</sup>, S.E. Jensen<sup>3</sup>, J. Aagaard<sup>1</sup>, R.E. Nielsen<sup>4</sup>

<sup>1</sup> Centre for Psychosis Research, Psychiatry, Aalborg University Hospital, Aalborg, Denmark; <sup>2</sup> National Centre for Register-Based Research, Aarhus University, Aarhus, Denmark; <sup>3</sup> Department of Cardiology, Aalborg University Hospital, Aalborg, Denmark; <sup>4</sup> Unit for Psychiatric Research, Psychiatry, Aalborg University Hospital, Aalborg, Denmark

\* Corresponding author

**Introduction.**– Patients with schizophrenia have an excess mortality, primarily caused by ischemic heart disease. In fact, the relative risk of myocardial infarction (AMI) in patients with schizophrenia is about 2-fold higher than in the general population. While the general population is experiencing improved survival following AMI, it is unknown whether patients with schizophrenia have benefitted similarly from these improvements.

**Objective.**– To investigate rates of mortality following AMI and trends in mortality over time in patients with schizophrenia compared to the rates in the general population.

**Methods.**– The study included all cases of schizophrenia (ICD-8; 295 and ICD-10; F20) in Denmark from 1st January 1980 to 31st December 2015. These were matched 1:5 on year of birth and gender to controls from the general population not diagnosed with a psychiatric disorder. The two cohorts were followed until death, emigration or end of study period. We used first time AMI (ICD-8; 410 and ICD-10; I21) as a time-dependent covariate.

**Results.**– We included 36,962 patients diagnosed with schizophrenia and 184,810 matched controls. We showed that controls with AMI had a hazard rate ratio (HR) of 3.27, schizophrenia controls had a HR of 4.50, and schizophrenia patients experiencing AMI had a HR of 9.94. Patients with schizophrenia showed an increased mortality rate 1-year and 5-years after AMI, with no difference in 30-day mortality between the groups.

**Conclusions.**– Patients with schizophrenia experiencing AMI are not benefitting similarly from the improvements in cardiac procedures and treatments as compared to people in the general population experiencing AMI.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Relationships between dysglycaemia, immune activation and psychotic experiences: Findings from the ALSPAC birth cohort**

B. Perry<sup>1\*</sup>, R. Upthegrove<sup>2</sup>, A. Thompson<sup>1</sup>, S. Marwaha<sup>1</sup>, S. Zammit<sup>3</sup>, G. Khandaker<sup>4</sup>

<sup>1</sup> University of Warwick, Department of Mental Health and Wellbeing, Birmingham, United Kingdom; <sup>2</sup> University of Birmingham, Psychiatry, Birmingham, United Kingdom; <sup>3</sup> Cardiff University, Psychiatry, Cardiff, United Kingdom; <sup>4</sup> University of Cambridge, Psychiatry, Cambridge, United Kingdom

\* Corresponding author

**Background.**– Psychosis is associated with dysglycaemia and inflammation, but longitudinal population-based studies are scarce.

**Aims.**– Using a population birth cohort to investigate:

– the association between dysglycaemia, inflammation and psychotic experiences (PEs);

– whether dysglycaemia moderates or mediates the association between inflammation and psychotic experiences (PEs).

**Method.**– In the Avon Longitudinal Study of Parents And Children (ALSPAC) birth cohort, insulin resistance (IR), interleukin 6 (IL-6) and C-reactive protein (CRP) levels were measured at age 9 and 18 years. PEs were measured at 12 and 18 years. We used logistic regression to examine cross-sectional and longitudinal relationships between IR and PEs. Linearity of association was tested. Correlation between markers of dysglycaemia and inflammation were tested cross-sectionally and longitudinally. We tested interaction between IR and IL-6 with regards to risk of PEs at age 18. We tested whether IR mediated the relationship between IL-6 and PEs.

**Results.**– Based on 2627 participants, IR at age 18 years was associated with PEs; adjusted OR = 2.32 (95% CI, 1.37–3.97). IR correlated with inflammatory markers cross-sectionally and longitudinally. There was a significant interaction between IL-6 (age 9) and IR at (age 18) with regards to risk of PEs (age 18) ( $P = 0.03$ ). There was no evidence that IR mediated the relationship between IL-6 and PEs.

**Implications.**– PEs in early-adulthood are associated with IR, which exaggerates the effect of inflammation on the risk of PEs. There is an interplay between immune and metabolic alterations with regards to risk of psychosis, which may be useful for understanding disease pathogenesis and for clinical practice.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **First criminal behavior among adults with serious mental illness: Further evidence of the role of gender and substance use disorders**

J. Moamai

University of Ottawa at Pierre Janet Hospital, Psychiatry, Gatineau, Canada

**Introduction.**– Substance use disorders (SUD) are well known risk factors for criminal behavior (CB) among patients with serious mental illness. However, the mediating effect of gender on this association has not been specifically explored.

**Objectives.**– To examine the impact of gender on the clinical characteristics of subjects who exhibited first CB and were admitted (1991–2016) to a Quebec psychiatric hospital.

**Methods.**– CB is defined as the hospitalization of an accused under a criminal custody order for any conviction. File information was collected for all adult (18–69 years) admissions during the study period. First, a descriptive analysis of the clinical characteristics of

632 subjects with CB was performed. Then, a cross-sectional study comparing clinical features of 400 first time admitted subjects and 232 multiple admission cases was conducted.

**Results.**– Overall, 10.5% of first time admitted patients had at least one conviction for CB. The CB rates significantly correlated with male gender (84%) and younger age (median: 35 years). Most subjects were admitted only once (64%), with an average of 42 days in the hospital. The CB cases were more likely to be suffering from SUD (10 vs. 5%). No significant correlation with other clinical characteristics such as alcohol misuse, comorbid personality, bipolar or schizophrenic disorders was observed.

**Conclusions.**– Among patients with serious mental illness, first criminal behavior is associated with male gender, younger age and comorbid SUD. Our findings also provide further supportive evidence that drug misuse may have a greater impact than alcohol misuse on the first instance of CB.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Oxidative and nitrosative markers in obsessive-compulsive disorder: A systematic review and meta-analysis**

A. Maia<sup>1</sup>, J. Oliveira<sup>1</sup>, M. Lajnef<sup>2</sup>, H. Lamothe<sup>3</sup>, L. Mallet<sup>3</sup>, R. Tamouza<sup>2</sup>, M. Leboyer<sup>2</sup>, A.J. Oliveira-Maia<sup>1</sup>

<sup>1</sup> Champalimaud Centre for the Unknown, Champalimaud Clinical Centre, Lisbon, Portugal; <sup>2</sup> Institut Mondor de Recherche Biomédicale, Inserm Unit U955, Team 15 “Translational Psychiatry”, Créteil, France; <sup>3</sup> Institut du cerveau et de la moelle épinière, unité mixte de recherche UMR S1127, Centre national de la recherche scientifique CNRS, UMR 7225, Paris, France

\* Corresponding author

**Introduction.**– Obsessive-compulsive disorder (OCD) is a chronic psychiatric illness with a lifetime prevalence of 2.3% in adults, with nearly two-thirds of patients reporting severe role impairment. The exact aetiology and pathophysiology of OCD remain unknown. However, immune dysfunction and unbalanced oxidative status have been reported, evoking a systemic involvement. Moreover, recent research suggests that pathways involved in oxidative and nitrosative stress (O&NS) may constitute novel therapeutic targets.

**Objectives.**– To review published evidence on the association between OCD and altered blood O&NS markers.

**Methods.**– We conducted a systematic review of case-control studies evaluating blood O&NS markers in OCD patients and controls, following the PRISMA statement. Search terms and selection criteria were published a priori. A random effects meta-analysis, using standardized mean differences, was performed for each biomarker when at least two studies were available.

**Results.**– Twelve studies met inclusion criteria, involving a total of 385 patients and 417 controls. Ten blood O&NS markers were eligible for quantitative analysis. We found that 8-hydroxydeoxyguanosine, nitric oxide, malondialdehyde, superoxide dismutase and glutathione peroxidase were significantly increased, and that total antioxidant status was significantly decreased, in OCD patients when compared with controls.

**Conclusions.**– Our results suggest that OCD patients have a systemic oxidative imbalance when compared to controls. Quality of evidence is impaired by the limited number of publications and by the quality of the studies. More robust studies are needed in order to support this association.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction.**– The age at onset is a useful predictor for schizophrenia prognosis. Early onset (EO) schizophrenia predisposes individuals to greater cognitive deficits and more severe symptoms. In this study, we aimed to validate the risk alleles for schizophrenia, analyzing their effect on the age at onset (AAO), age at antipsychotic treatment initiation, and age at first hospitalization.

**Objectives.**– The main objective of this study was to validate the effect of the known schizophrenia risk alleles in determining anticipation in EO schizophrenia.

**Methods.**– We recruited 224 schizophrenia patients in Toronto from the Centre for Addiction and Mental Health (CAMH). All participants were diagnosed using the DSM-IV (SCID-I/P) criteria. Genomic DNA was extracted from white blood cells and genotyped using Illumina 2.5. We performed a secondary analysis focusing on well-known risk alleles ( $n = 106$ ). Information about age at onset, age at first hospitalization and age at antipsychotic treatment initiation was collected through a detailed life-chart administered at the time of the SCID. The data analysis performed using the CAMH Specialized Computing System, a cluster computer available at CAMH.

**Results.**– The SNP rs55661361 was statistically significant and was associated with anticipation in the EO schizophrenia group. The same SNP (rs55661361) produced significant association with the age at antipsychotic treatment initiation. We also found the SNP rs6704641 significantly associated with age at first hospitalization.

**Conclusions.**– This study identified the risk loci that may warrant further research in schizophrenia, paving the way for new target discoveries to produce better pharmacological treatments.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

#### **Refining suicide prevention: Advances in psychotherapeutic tools**

R. Calati<sup>1</sup>, J. Lopez-Castroman<sup>2</sup>, P. Courtet<sup>3</sup>

<sup>1</sup> Inserm U 1061, Neuropsychiatry: Epidemiological and Clinical Research, Montpellier, France; <sup>2</sup> CHRU de Nîmes, Department of Adult Psychiatry, Nîmes, France; <sup>3</sup> Lapeyronie Hospital, CHU de Montpellier, Department of Emergency Psychiatry & Post-Acute Care, Montpellier, France

\* Corresponding author

**Introduction.**– Psychotherapies for suicide prevention are receiving growing consideration.

**Objectives.**– Our aim was to evaluate related literature published over the last 3 years.

**Methods.**– We searched for studies focused on psychotherapies for suicide prevention. Any form of suicidal phenotype [death (SD), attempt (SA), ideation (SI), self-harm (SH), but also non-suicidal

self-injury (NSSI) was considered. Articles [meta-analyses (A), reviews (B), and original studies (C)] published between 2014 and 2017 were included.

**Results.**–

– different psychotherapies seemed to be efficacious in the reduction of both SA and NSSI. After a recent SH episode, Cognitive Behavior Therapy (CBT) and Problem-Solving Therapy (PST) were associated with fewer SH repetition at follow-up and SI improvement. Dialectical Behavior Therapy (DBT) was found to reduce SH frequency. Interventions directly addressing suicidal thoughts and behavior during treatment were effective immediately post-treatment and long term on SD and SA, whereas treatments addressing symptoms indirectly associated with suicide (e.g., hopelessness, depression, anxiety, quality of life) were effective only at long term;

– concerning children and/or young people, effective treatments were: CBT (SH and SI), PST (SI), and interpersonal psychotherapy (IPT) (SI). Similarly, promising interventions for elderly in reducing SI were PST and IPT;

– Abandonment Psychotherapy was superior to treatment as usual in reducing suicidal relapse and SI both if administered by certified psychotherapists and nurses. Moreover, Acceptance and Commitment Therapy was found to reduce SI.

**Conclusions.**– Results indicated an encouraging growth of this research field in the last years and the presence of a number of promising interventions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Altered Th17 pathway in schizophrenia: Evidences from genetic, gene expression and biochemical studies

M. Debnath<sup>1\*</sup>, M. Subbanna<sup>1</sup>, V. Shivakumar<sup>2</sup>, P.M. Talukdar<sup>1</sup>, J.C. Narayanaswamy<sup>2</sup>, S. Varambally<sup>2</sup>, V. Ganesan<sup>2</sup>

<sup>1</sup> National Institute of mental Health and Neuro Sciences, Human Genetics, Bangalore, Karnataka, India; <sup>2</sup> National Institute of mental Health and Neuro Sciences, Psychiatry, Bangalore, Karnataka, India

\* Corresponding author

**Introduction.**– The immuno-inflammatory origin has emerged as a paradigmatic underlying mechanism of schizophrenia in recent times. However, the molecules or cells that confer major effect are yet to be discerned. Th17 cells, a recently identified lineage of T lymphocyte have been demonstrated as a predominant inducer of autoimmunity/inflammation in various pathological conditions. Altered levels of cytokines like IL-17, IL-23, and IL-22 indicate a dys-regulated Th17 pathway in schizophrenia. However, understanding of genetic and transcriptional regulation of this pathway is currently unknown in schizophrenia.

**Objectives.**– To understand the role of Th17 pathway in schizophrenia by examining genetic variation within *IL17* gene, quantifying gene expression of transcription factors like RORC and STAT3 and determining plasma levels of fifteen cytokines belonging to Th17 pathway.

**Methods.**– *IL17* (rs2275913; G197A) genotyping was done in 221 schizophrenia patients and 223 healthy subjects by PCR-RFLP method. Quantification of lymphocyte gene expression of RORC and STAT3 was performed using TaqMan assay. Plasma levels of a panel of fifteen Th17 pathway related cytokines were estimated by Multiplex Suspension Array in Bioplex platform.

**Results.**– RORC gene expression was significantly higher in schizophrenia patients [ $F(1, 103)=5.89$ ;  $P=0.017$ ; partial  $\eta^2=0.054$ ]. Female schizophrenia patients carrying AA geno-

type of *IL17* (G197A polymorphism) exhibited higher score of bizarre behaviour [ $F(2,161)=4.82$ ;  $P=0.009$ ;  $\eta^2=0.057$ ] and apathy [ $F(2,161)=3.69$ ;  $P=0.027$ ;  $\eta^2=0.044$ ]. In addition, significantly elevated levels of IL-6 ( $P=0.012$ ) and IL-22 ( $P<0.01$ ) were observed in schizophrenia patients.

**Conclusions.**– Our findings suggest a possible role Th17 pathway in the pathobiology of schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Alterations in bioelectric activity of the brain and therapeutic effects of neurofeedback in stroke patients with depressive states

A. Trofimova<sup>1</sup>, E. Silina<sup>2</sup>, O. Dobrushina<sup>3\*</sup>, A. Chernorizov<sup>4</sup>, S. Isaychev<sup>4</sup>

<sup>1</sup> International Institute of Psychosomatic Health, Psychology, Moscow, Russia; <sup>2</sup> First Moscow State Medical University, Department of human pathology, Moscow, Russia; <sup>3</sup> International Institute of Psychosomatic Health, Director, Moscow, Russia; <sup>4</sup> M.V. Lomonosov Moscow State University, Psychology, Moscow, Russia

\* Corresponding author

**Introduction.**– Post-stroke depression may be related both to situation and to alterations in brain physiology. Thus, neurophysiological approach may be reasonable.

**Objectives.**– To study the bioelectric activity of the brain and effects of neurofeedback in stroke patients with depressive states.

**Methods.**– The study included 25 stroke patients who underwent 17 sessions of neurofeedback during a 28-days period. Assessment included Beck Depression Inventory, State-Trait Anxiety Inventory, Hospital Anxiety and Depression Scale, quantitative EEG.

**Results.**– Strong correlations ( $r>0.8$ ,  $P<0.01$ ) of depression severity with beta-rhythm were found in left occipital, frontal, central parts. Average correlations ( $r>0.3$ ) of depression severity with alpha rhythm were recorded in the left occipital-temporal area, with theta rhythm in the left occipital region, with beta rhythm over all areas, especially in the left hemisphere. The recall of the stroke psychotrauma was associated with regression of the beta and alpha rhythms and with growth of the theta rhythm. After 15 neurofeedback trainings a tendency towards normalization of brain activity was noticed: a decrease in alpha rhythm in both hemispheres in 1.24–1.95 times, in theta rhythm in 1.11–1.51 times, an increase in beta rhythm in 1.14–1.49 times, which correlated with a decrease in the severity of the depressive state.

**Conclusions.**– Post-stroke depressive states are related to alterations in brain bioelectric activity across a wide range of rhythms and brain areas. Neurofeedback treatment results in concomitant improvements in neurophysiological and emotional states.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The genetics of cognitive functions in major depressive disorder. A review

E.K. Fischer<sup>\*</sup>, A. Drago

Psykiatrisk Forskningsenhed Vest, Forskningsenheden, Herning, Denmark

\* Corresponding author

**Introduction.**– Cognition represents mental processes that interpret the world, organize feelings, communicate, think and remember. Those activities are impacted during major depressive disorders (MDD). Cognition has a genetic base. A better understand-

ing of its biological underpinnings would pave the way to more effective strategies to treat mood disorders.

**Methods.**– Five main systems were reviewed for association between a genetic background and cognition, with a focus on MDD:  
– glutamatergic and GABAergic;  
– serotonergic;  
– dopaminergic;  
– neurotrophic factors;  
– cholinergic.

Research was primarily based on clinical association reports, animal models were also included. Results from the GWAS analyses on cognition were also included. Pubmed served as a research engine. The genes belonging to each system were manually extrapolated from [www.genecards.com](http://www.genecards.com), and organized in molecular pathways.  
**Result.**– The following genes were identified (underlined = human evidence): *GRIA2*, *GRIA3*, *GRIA4*, *GRIK4*, *GRIK3*, *GRIN2B*, *GRIN2A*, *GRIN2C*, *GRIN3A*, *GRIN3B*, *DLG4*, *SHANK*, *GRM1*, *GRM2*, *GRM3*, *GRM4*, *GRM5*, *GRM7*, *SLC1A3*, *SLC1A2*, *GAD1*, *GAD2*, *SLC6A4*, *HTR1A*, *HTR2A*, *HTR3*, *HTR3E*, *HTR3A*, *HTR1B*, *HTR2C*, *DRD2*, *DRD4*, *DRD1*, *COMT*, *MAO-A*, *CHRM1*, *CHRNA7*, *CHRN2*, *BDNF*, *TNF*, *CTNBL1*, *PTPR*, *ATXN2*, *CYP2D6*, *APBA1*, *CADM2*, *HSE1*, *NRXN1* and *HEY1*.

**Discussion.**– Cognition is a multigenetic-driven biologic event. Cognition may be severely impacted during MDD and cognitive resilience or amelioration during treatment are considered positive prognostic factors for a full recovery. Based on previous evidence of genetic influence on animal models and human samples, a set of molecular pathways is created and will be prioritized in GWAS molecular pathway analysis in pharmacogenetic investigations.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### New ways to learn psychopharmacology: Receptor polygomis

C. Gómez Sánchez-Lafuente<sup>1</sup>, R. Reina Gonzalez<sup>2</sup>

<sup>1</sup> Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain; <sup>2</sup> Hospital Universitario Virgen de la Victoria, General Medicine, Málaga, Spain

**Introduction.**– Many books show the receptor profile in a difficult way to learn. This traditional approach has been criticized due to excessive information and passive transfer of expert knowledge  
**Objectives.**– We are currently developing this graphics, formally called “Polygomis” because the polygon shape to help students understand and apply basic science concepts like receptor binding profile.

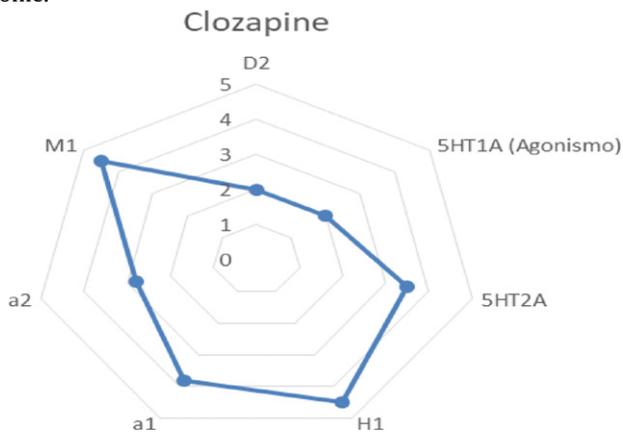

Fig. 1

**Methods.**– We made a systematic computerized literature search of clinical studies using MEDLINE, The Cochrane Library and Trip look-

ing for papers with comparing data about antipsychotics receptor binding affinity

**Results.**– The results are shown in figures. Figure 1 is the clozapine receptor binding profile polygomis and Figure 2 is a comparison between 2 antipsychotics binding profile: risperidone and olanzapine. Each vertex of the heptagon represents one receptor: dopamine D2, muscarinic M1, serotonin 5-HT1A and 5-HT2A, histamine H1, alpha 1 and alpha 2 receptors

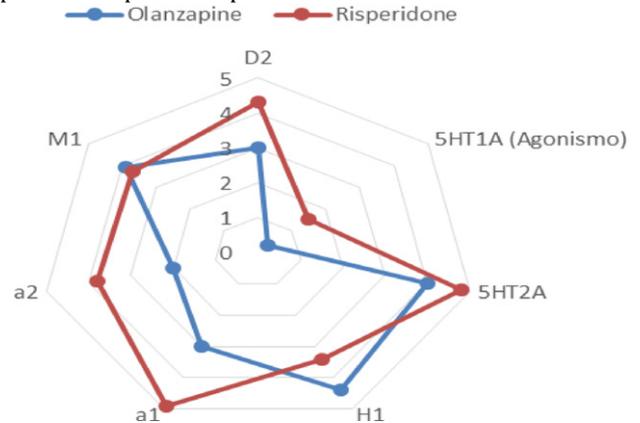

Fig. 2

**Conclusion.**– We consider this way to learn antipsychotics visual and easy to get an idea of the side effects. Polygomis can be shown adding or removing specific receptors. Any graphic could be built, like one with two or more antipsychotics to compare them. Our study has several limitations. This graphics could be expanded to old drugs such as perphenazine and sulpiride but we did not find reliable data for the design. The receptor binding profile in laboratory is a standard one and the clinical effectiveness of the antipsychotic could differ from one patient to each other. Some receptor function is not known. Some antipsychotics, like clozapine, have effects not clearly correlated with the binding profile.

\* Corresponding author

**Introduction.**– Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease affecting multiple organ systems. Psychiatric disorder in SLE is a serious and well-recognized problem that remains a significant source of morbidity.

**Objectives.**– To investigate the frequency and type of psychiatric disease in patients suffering from SLE.

**Methods.**– This is a retrospective and descriptive study conducted in Internal Medicine and Neurology Departments for a period of 14 years.

**Results.**– The study included 185 SLE patients. Fifteen of the 40 patients with neuropsychiatric manifestations had psychiatric disorder. A psychosis occurred in 8 women (4.3%). The diagnosis was concomitant with the diagnosis of lupus disease in 7 cases with a mean age of 32.7 years. Two patients had a favorable evolution after

a prescribed sedative symptomatic treatment for an average duration of one week. A state of acute confusion was noted in 7 women (3.8%). The mean age at the time of this confusion was  $34 \pm 6.5$  years. The evolution was favorable in all cases after an average duration of 40 days.

**Conclusion.**– Psychiatric abnormalities are polymorphic and common accompaniments of SLE. Those disorders are to be anticipated because they can interfere with compliance with the treatment of lupus, but also with the management of lupus.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Stigmatizing attitudes towards mental illness among medical students

B. Atienza-Carbonell<sup>1</sup>, H. Hernández-Èvole<sup>1\*</sup>, V. Balanzà-Martínez<sup>2</sup>

<sup>1</sup> Universitat de València, Medicine Department, Valencia, Spain; <sup>2</sup>

Universitat de València, CIBERSAM, Medicine Department, Valencia, Spain

\* Corresponding author

**Introduction.**– Medical students are at greater risk of depressive symptoms or depression than the general population. A positive attitude towards mental illness is important and desirable in future clinicians as it may impact on the provision of healthcare.

**Methods.**– A cross-sectional, online survey was conducted to evaluate the attitudes and degree of stigma towards mental illness among pre graduate students. All second-year students were invited to complete the CAMI, RIBS and MAKs questionnaires before taking the Psychological Medicine course. Participation was kept voluntary and responses were anonymized.

**Results.**– During the last two semesters, 518 of 602 students (response rate=86,04%) completed the survey. Nearly a quarter (22.5%) of the sample would not be willing to work with someone with a mental health problem. Moreover, 40.6% of the students agreed or strongly agreed that stress is a mental health condition, whereas 97% supported that for schizophrenia. Men showed higher scores ( $P < 0.05$ ) on the “benevolence” CAMI subscale, which corresponds to having more compassion and empathy towards mental health patients than women. Men were also more likely than women to consider grief as a mental disorder ( $P < 0.05$ ). Students currently or ever living with someone with a mental health problem scored higher on the CAMI ( $r = 0.122$ ;  $P < 0.005$ ).

**Conclusions.**– Significant gender differences were found regarding knowledge and empathy and compassion attitudes. Anti-stigma preventive measures should be implemented to educate the next generation of healthcare professionals.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Stress, inflammation and depression: Integrative role of the endocannabinoid pathway

J. Lazary<sup>1\*</sup>, N. Eszlari<sup>2</sup>, G. Juhasz<sup>3</sup>, G. Bagdy<sup>3</sup>

<sup>1</sup> Semmelweis University, Department of Psychiatry and

Psychotherapy, Budapest, Hungary; <sup>2</sup> Semmelweis University,

Department of Pharmacodynamics, Budapest, Hungary; <sup>3</sup>

Semmelweis University, Department of Pharmacodynamics, Budapest, Hungary

\* Corresponding author

**Background.**– The endocannabinoid (eCB) system is implicated in pathomechanism of affective disorders but human genetic studies with interacting stress factors are lacked in this field.

**Methods.**– We recruited 854 volunteers into our study. Phenotype was measured by the Zung Self Rating Depression Scale (ZSDS), Brief Symptom Inventory (BSI), the STAI State-Trait Anxiety Inventory (STAI trait, STAI-T; STAI state, STAI-S) and Childhood Adversity Questionnaire. Four SNPs (rs1049353 rs470736, rs2180619 in CB1 receptor gene; R315Q in CB2 receptor gene and C385A in (fatty acid amide hydrolase, FAAH) were genotyped from DNA of buccal samples.

**Results.**– Single effect of R315Q on ZSDS score was significant ( $P = 0.003$ ). Epistatic effects were detected between C385A and R315Q on ZSDS score ( $P = 0.014$ ), BSI-ANX ( $p_{\text{int}} = 0.018$ ) and STAI-T ( $p_{\text{int}} = 0.003$ ). Further interacting effects of R315Q and CNR1 polymorphisms (rs1049353 and rs470736) were significant on ZSDS score ( $p_{\text{int}} = 0.0003$ ;  $p_{\text{int}} = 0.0002$ , respectively). Epigenetic effect of childhood trauma was pronounced in case of CNR2. Risk allele carriers of R315Q exhibited higher STAI-T and BSI-ANX scores if they were exposed by higher number of childhood trauma ( $p_{\text{int}} = 0.018$ ;  $p_{\text{int}} = 0.002$ , respectively).

**Conclusion.**– Besides the well-known role of eCB in the stress response our data suggest that eCB signalling can be the shared molecular pathway of neuroendocrinological and neuroimmunological component in pathomechanism of affective disorders via genetically determined variants of FAAH, CNR1 and CB2 genes.

### Recovery model implementation in psychiatric in-patient settings: Pilot study

L. Lipskaya-Velikovsky<sup>1\*</sup>, A. Biran<sup>2</sup>, O. Bart<sup>1</sup>

<sup>1</sup> Tel Aviv University, Department of Occupational Therapy, School of

Health Professions, Sackler Faculty of Medicine, Tel-Aviv, Israel; <sup>2</sup> The

Jerusalem Mental Health Center, Occupational Therapy, Jerusalem, Israel

\* Corresponding author

**Introduction.**– Today, the recovery model guides mental health services, including psychiatric hospitals (e.g. NMHDU 2011). However, delivery of recovery oriented services in inpatient settings is still a challenge. A recent qualitative study classified affecting factors into three levels: the environment, the inpatient and the service provider (Chen et al., 2013).

**Objectives.**– To evaluate impact of factors at the environment, the inpatient and the service provider levels on the recovery model implementation in hospitals.

**Methods.**– Forty-five service providers and 42 inpatients from three types of wards (acute locked, acute open and day-hospitalization) of two hospitals participated in this cross-sectional study. Data was collected on the inpatients' cognition, functional capacity and illness severity. Service providers' information included professional status and evaluation of the recovery model knowledge and attitudes. Implementation of the recovery model was measured with the Recovery Self-Assessment, inpatients' and service providers' versions.

**Results.**– Differences were found between the three types of wards in recovery orientation as reported by service providers ( $\chi^2_2 = 15.3$ ,  $P < .001$ ), but not as reported by inpatients ( $\chi^2_2 = 2.34$ ,  $P > .05$ ). Providers' internalized knowledge and attitudes toward recovery (but not formal education in the field), functional capacity of inpatients and age of illness onset were associated with recovery implementation ( $0.31 < r < 0.48$ ,  $P < .05$ ) and explained it ( $F_3 = 8.63$ ,  $P < .01$ , Adj  $R^2 = 0.37$ ).

**Conclusions.**– These findings confirm quantitatively multilevel nature of factors that affect the implementation of recovery model in psychiatric hospital and detect the most relevant ones. The results may assist hospital personnel to promote implementation of the recovery model in psychiatric hospital.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Effects of immunomodulatory drugs on the development of chronic opiate dependence in experimental animals**

E. Markova<sup>1\*</sup>, M. Starostina<sup>2</sup>, N. Beregovoy<sup>2</sup>, R. Agaveliyan<sup>3</sup>

<sup>1</sup> Federal State Budgetary Scientific Institution Research Institute of Fundamenta, Neuroimmunology Laboratory, Novosibirsk, Russia; <sup>2</sup> Federal state budgetary institution “Research institute of molecular biology and biophysics”, Central mechanisms of regulation and management Lab., Novosibirsk Новосибирск, Russia; <sup>3</sup> Novosibirsk State Pedagogical University, Department of Correctional Pedagogy and Psychology, Novosibirsk, Russia

\* Corresponding author

**Background.**– Morphine immunomodulatory activities have been characterized in animal and human studies. Morphine can decrease the effectiveness of several functions of both natural and adaptive immunity, and significantly reduces cellular immunity.

**Objectives.**– We examined effects of two immunomodulatory drugs on the development of morphine dependence, function of brain cells and cellular immune response in animals.

**Methods.**– Wistar and OXYS male rats were used in experiments. Morphine dependence was developed by the method of compulsory drink. Myeloid (100 µg/kg), T-activine (10 µg/kg) were injected intraperitoneally on the 1st and 10th days of soldering. Immunomodulator’s effects on the nervous cells, behavioral and immune parameters in animals were estimated.

**Results.**– OXYS rats were highly sensitive to morphine and showed accelerated development of chronic dependence. T- aktivin or Myeloid administration significantly increased a period of dependence formation from 25 days to 32–35 days in all animals and changed OXYS rat’s behavior in the “open-field” test. It was shown also protective effects of six myelopeptides (which are part of myeloid) in hippocampal slice culture treated with toxic morphine dose, as well as on morphine-induced oxidative stress and apoptosis in neuroblastoma C-1300 cells. The use of both immunomodulators in the development of morphine dependence prevents the suppression of the delayed type hypersensitivity reaction in all animals.

**Conclusion.**– T-activin and myeloid increased the opiate dependence development period reduced the morphine-induced immunosuppression and possess antiapoptotic and antioxidant properties in the toxic effect of morphine on nervous cells. Hence, their use promising both for treatment and for the prevention of opiate addiction.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Innate immunity alterations in schizophrenia: A computational deconvolution study of leukocyte counts**

P. Karpiński<sup>1</sup>, D. Frydecka<sup>2</sup>, J. Samochowiec<sup>3</sup>, M. Sasiadek<sup>4</sup>, B. Misiak<sup>4\*</sup>

<sup>1</sup> Wroclaw Medical University, Department of Genetics, Wroclaw, Poland; <sup>2</sup> Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland; <sup>3</sup> Pomeranian Medical University, Department of Psychiatry, Szczecin, Poland; <sup>4</sup> Wroclaw Medical University, Department of Genetics, Wroclaw, Poland

\* Corresponding author

**Introduction.**– Accumulating evidence indicates various immune system dysregulations in patients with schizophrenia. For instance, several alterations in the levels of distinct leukocytes subpopulations have been reported in this group of patients. However, previous studies investigating leukocyte counts in schizophrenia have provided mixed findings and used various analytical techniques.

**Objective.**– In this study, we aimed to estimate leukocyte counts based on data from peripheral blood DNA expression profiles.

**Methods.**– We translated a computational deconvolution approach to estimate leukocyte counts using publicly available data from studies profiling global DNA expression. Our analysis was performed on two independent datasets, representing a total of 711 schizophrenia patients and 713 healthy controls.

**Results.**– We found significantly lower levels of CD8+ and NK cells as well as significantly higher levels of granulocytes in patients with schizophrenia across both datasets. In addition, there was significantly lower level of CD4+ cells in one dataset. Differences in CD8+ cells were not significant after co-varying for age and sex in one dataset.

**Conclusions.**– Taking into account concordant results in both datasets, our study indicates that patients with schizophrenia present specific alterations of innate immunity, manifesting in decreased levels of NK cells and increased levels of granulocytes. Longitudinal studies are needed to disentangle whether these alterations are specific to any phase of the illness and whether antipsychotic treatment contributes to changes in the levels of NK cells and granulocytes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Histone deacetylase inhibition during CUMS prevents anhedonia in male rat**

A. Nahavandi\*, M. Goudarzi

Iran university of medical sciences, physiology, Tehran, Iran

\* Corresponding author

Pleasure unresponsiveness or anhedonia, is a symptom of neuropsychiatric conditions, but in major depression it is the core one. There is “anhedonic phenotype” in normal population, as well. Stress is risk factor for anhedonia through epigenetic modifications. As phenotype, anhedonia is potent risk factor, for mental disorders. Stress modulate histone deacetylase and mineralocorticoid receptors’ gene expression. here, we studied histone deacetylase inhibitor, “valproic acid”, on stress induced anhedonia control.

**Material and method.**– Male rats, (200–250g) living in standard situation for light, food and water were choosed randomly. Rats divided into two CUMS and non-stressed groups. Both groups divided to VPA treated and saline, sub-groups. Six weeks CUMS, protocol induce anhedonia. Treatment (VPA, 200 mg/kg day or saline) started from second week of CUMS and continued all along it. After

stress SCT and NORT, applied. Fresh and fixed brain samples, for RT-PCR and Nissl staining, prepared.

**Results.**– SCT and NORT were both impaired, in CUMS+saline group compared with non-stressed ( $P<0.001$ ). Comparison of CUMS+VPA with non-stressed subgroups showed no difference in behavioral tests. MC4R and HDAC expression were both increased in CUMS+saline ( $P<0.001$ ). Both genes' expressions were decreased in CUMS+VPA, compared with stress+saline ( $P<0.001$ , MC4R) and ( $P<0.001$ , HDAC). Gene expression in CUMS+VPA and non-stressed, showed no difference. Nissl showed decreased NAC cell count, in CUMS+saline, compared with non-stressed group ( $P<0.001$ ). In CUMS+VPA cell count there was no difference, compared with non-stressed.

**Conclusion.**– In this study, we showed that valproic acid as an HDAC controlled the impact of stress, and prevented it is anhedonic manifestations at least partly by modulation of HDAC and MC4R genes.  
**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A psychophysiological study of cognitive disorders in naive middle-age patients with uncomplicated essential hypertension and white matter lesions**

E. Pervichko<sup>1\*</sup>, T. Ostroumova<sup>2</sup>, M. Darevskaya<sup>1</sup>, E. Perepelova<sup>3</sup>, V. Perepelov<sup>2</sup>, A. Vartanov<sup>1</sup>, S. Kozlovskiy<sup>1</sup>, O. Ostroumova<sup>4</sup>, V. Parfenov<sup>2</sup>, Y. Zinchenko<sup>1</sup>

<sup>1</sup> Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia; <sup>2</sup> I.M. Sechenov First Moscow State Medical University, Department of Neurology, Moscow, Russia; <sup>3</sup> I.M. Sechenov First Moscow State Medical University, Pediatric Clinic, Moscow, Russia; <sup>4</sup> A.I. Yevdokimov Moscow State University of Medicine and Dentistry, Department of Faculty Therapy and Professional Diseases, Moscow, Russia

\* Corresponding author

**Introduction.**– Presence of cognitive disorders (CD) alongside essential hypertension (EH) is most commonly associated with white matter lesions (WMLs).

**Objectives.**– To assess cognitive functions in EH patients and healthy persons and evaluate the connection of the revealed CD with the presence of WMLs.

**Methods.**– The study involved 39 naive middle-age patients with uncomplicated EH, stage 1–2, average age is  $51.9 \pm 6.5$  and 49 normotensive persons, average age is  $47.9 \pm 6.2$ . WMLs have been revealed in 6 persons from the control group and 16 persons from the EH group. Brain MRIs have been obtained using a 3-TMR scanner MAGNETOM Skyra 3T (“Siemens”). The assessment of cognitive functions has been conducted using a Trail Making test, MoCA test, Verbal fluency test, Stroop test, CERAD 10-word list and Pictogram test.

**Results.**– Patients with WMLs differ significantly from persons with normal appearance white matter (NAWM) in the following indicators in Pictogram test: quantity of the concrete images ( $0.7 \pm 0.1$  VS  $2.7 \pm 0.9$ ;  $P=0.009$ ); inertness of mental processes ( $0.80 \pm 0.2$  VS  $0.05 \pm 0.01$ ;  $P=0.009$ ); decreasing accuracy of recalled words ( $3.7 \pm 1.1$  VS  $0.8 \pm 0.9$ ;  $P=0.02$ ); decreased recall of affective words ( $5.71 \pm 2.3$  VS  $3.0 \pm 1.8$ ;  $P=0.02$ ). TMT has revealed the presence of differences between groups in B-scores: ( $81.33 \pm 15.6$  VS  $115.18 \pm 13.7$ ;  $P=0.02$ ).

**Conclusion.**– The results indicate differences in cognitive functioning between NAWM and WMLs in respect not only to patients with EH but for their peers without EH as well. These results necessitate further research aimed at verification of the hypothesis about the connection between CD in EH patients with WMLs.

The research was supported by RFBR; project No. 17-06-00954.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A role of T cell subsets in the immunodysfunction of schizophrenia**

C. Sahbaz<sup>1\*</sup>, N. Zibandeh<sup>2</sup>, A. Kurtulmuş<sup>1</sup>, İ. Kırpınar<sup>1</sup>, F. Şahin<sup>3</sup>, T. Akkoç<sup>2</sup>

<sup>1</sup> Bezmialem Vakıf University, Psychiatry, Istanbul, Turkey; <sup>2</sup> Marmara University, Immunology, Istanbul, Turkey; <sup>3</sup> Yeditepe University, Biomedical Engineering and Genetic, Istanbul, Turkey

\* Corresponding author

**Introduction.**– Schizophrenia has been associated with increased level of peripheral pro-inflammatory markers. These findings have supported to conceptualize schizophrenia as a chronic low-grade inflammatory disorder.

**Objective.**– The underlying mechanisms of this phenomenon may include changes in circulating cells and their activation profiles. An investigation of T cell subsets and their activation profiles might be helpful to understand the underlying mechanism of the immunopathogenesis in schizophrenia.

**Method.**– A total of 40 stable-chronic subjects with schizophrenia (all medicated; 9 of all with treatment resistant schizophrenia) and 40 age-sex-smoking status matched controls were recruited in this study. Peripheral blood mononuclear cells (PBMC) were isolated and phenotyped (CD3+, CD4+, CD8+, CD14+, CD19+, CD20+, CD16+56+, CD25+ and FoxP3+), and after 72 h co-culture with anti-CD3+ measured their Th1/Th2/Th17 cytokines (IL-2, IL-4, IL-6, IL-10, IFN, TNF, IL-17) production and change of CD4+CD25+ and CD4+CD25+FoxP3 cells proliferation. In addition, the cytokines were performed in plasma. In a large panel of immun cell subsets and cytokines were measured by multi-color flow cytometry.

**Results.**– Schizophrenic patients showed lower percentage of CD3+ cells compared to healthy controls; after in vitro stimulation, levels of cytokines IL-6, IFN-g, TNF-a, IL-17 were found significantly higher than controls, CD+4CD+25FoxP3 regulatory cells proliferation was found lower than controls, CD4+CD25+ activated T cells proliferation was found higher than controls. Furthermore, immun cells panel was associated with a strong bias to Th reg rather Th 17(IL-10/IL-17).

**Conclusion.**– Our data suggest that dysfunction of T regulatory cells cause imbalance in T cell mediated autoimmunity in schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– Bipolar disorder (BD) and schizophrenia (SZ) are staging disorders with progressive cognitive/functioning

decline. Among etiopathogenic hypothesis, immuno-inflammatory dysfunction re-emerged recently, setting the innovative field of immunopsychiatry.  $\beta_2$ -microglobulin ( $\beta_2m$ ) is a potential biomarker for cognitive decline:

– part of MHC-I molecules at cell surface, its circulating concentration reflects cellular immunity activation;

– while MHC-I has a pivotal role in neuro-development/plasticity,  $\beta_2m$  is implicated in cognitive ageing processes.

However, its relationship with psychiatric condition remain unclear. We hence hypothesized that serum  $\beta_2m$  level may reflect acute episodes and functioning impairment in BD and SZ.

**Methods.**– We analyzed  $\beta_2m$  levels in a cohort of 128 BD/59 SZ acute episode inpatients assessed twice (admission & discharge), compared with 46 BD/46 SZ stabilized outpatients and 115 healthy controls. Subjects were clinically assessed by standardized interview: MADRS, YMRS, PANSS for symptom dimensions and GAF, CGI, FAST for global functioning. Data analysis compared serum  $\beta_2m$  between groups (ANOVA/group-by-group *t*-test) then admission vs discharge (paired *t*-test). Finally, we explored correlations with clinical scores.

**Results.**– Significant  $\beta_2m$  level differences appeared between groups ( $P < 10^{-4}$ ) but remained stable on discharge vs admission. In BD,  $\beta_2m$  levels were higher on acute episode ( $1.88 \pm 0.53 \mu\text{g/mL}$ ) compared to euthymia ( $1.65 \pm 0.42 \mu\text{g/mL}$ ,  $P < .005$ ) and controls ( $1.58 \pm 0.41 \mu\text{g/mL}$ ,  $P < 10^{-5}$ ). In SZ, patients had higher  $\beta_2m$  levels ( $1.84 \pm 0.54 \mu\text{g/mL}$ ,  $P < .002$ ) compared with controls, correlated with PANSS disorganization sub-score (N7+G11+G10+P2+N5 items,  $P < 10^{-3}$ ).

**Conclusion.**– These preliminary data suggest serum  $\beta_2m$  as a state biomarker of acute phase BD and a disorganization severity biomarker in SZ. Further analysis will investigate it on a staging and functioning perspective.

### Psychological interventions in patients undergoing bariatric surgery – preliminary results of a systematic review

D. Storman<sup>1\*</sup>, M.J. Świerż<sup>1</sup>, M. Storman<sup>2</sup>, K. Jasińska<sup>1</sup>, M.M. Bała<sup>3</sup>  
<sup>1</sup> Jagiellonian University Medical College, Student's Scientific Group of Systematic Reviews, Systematic Reviews Unit, Polish Cochrane Branch, Faculty of Medicine, Kraków, Poland; <sup>2</sup> Medical University of Warsaw, Medical University of Warsaw, Warsaw, Poland; <sup>3</sup> Jagiellonian University Medical College, Department of Hygiene and Dietetics, Kraków, Poland

\* Corresponding author

**Introduction.**– Bariatric surgery (BS) is the most effective treatment for morbid obesity. BS preoperative weight loss (WL) and lifestyle interventions can result in fewer complications and lower chance of weight regain.

**Objectives.**– To assess the effectiveness of perioperative psychological interventions (PI) in morbidly obese patients undergoing BS.

**Methods.**– A protocol is currently awaiting for acceptance in PROSPERO. We comprehensively searched electronic databases for relevant studies. Screening and data extraction were performed by two independent reviewers. Third reviewer resolved conflicts.

**Results.**– Of 10,339 identified papers we included 9 studies (12 papers), recruiting 2417 patients (79% women) in total. Mean age was 44.9 (18 to 68). Mean number of patients was 269 (43–929). Five studies provided PI after BS and 4 both before and after. Four studies gave intervention as group sessions, 3 as individual and 2 as mixed. Mean number of PI sessions was 11 (4 before and

7 after BS). Single session duration ranged from 15 to 180 min. BMI loss was 9.4–16.6 in intervention and 10.7–16.4 kg/m<sup>2</sup> in control group, while WL: 33.7–48.7 kg and 38.1–45.3 kg respectively. Results regarding WL were not consistent between studies. Only 2 studies showed significant difference in WL between the groups (1 in favour of intervention, 1 in favour of control group). Final results will be presented at the conference.

**Conclusions.**– It is unclear whether PI provides additional weight loss as study results are not consistent.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Objectives.**– Emotional job demand is a growing issue in european countries. However, associations between this occupational risk and addictive behaviors are underexplored. Our aim was to examine the associations between stressful exposure to the public in the workplace and alcohol, tobacco and cannabis use.

**Methods.**– From the French population-based Constances cohort, 10,794 men and 14,040 women reported a current job with a daily exposure to the public. Stressful exposure to the public (often versus rarely) was self-reported as well as the following dependent variables: weekly alcohol consumption, frequency of heavy episodic drinking, alcohol use risk categories (mild, dangerous, problematic or dependence) defined with the Alcohol Use Disorders Identification Test, smoking status, daily tobacco consumption and monthly cannabis consumption. Logistic regressions provided odds ratios of substance use, stratifying for gender and adjusting for sociodemographic confounders, depression, effort-reward imbalance and perceived health status.

**Results.**– Among men, stressful exposure to the public was positively associated with frequency of heavy episodic drinking, smoking status and daily tobacco consumption. Among women, positive associations were observed with smoking status, daily tobacco consumption, and monthly cannabis consumption. Regarding alcohol use in women, positive associations were found with daily alcohol consumption and with alcohol use risk categories as follows: OR (95%CI)=1,32 (1,14–1,52) and OR (95%CI)=2,12 (1,44–3,11) for being in the “dangerous” and in the “problematic or dependence” categories compared to the “mild” one, respectively.

**Conclusions.**– Workers exposed to emotional demand should benefit from screening for addictions as well as from interventions aiming at reducing substance use by decreasing work stress.

**Disclosure of interest.**– Guillaume Airagnes has received speaker and consulting fees from Lundbeck. Cédric Lemogne has received speaker and consulting fees from Daiichi-Sankyo, Janssen, Lundbeck, Otsuka Pharmaceuticals and Servier. Frédéric Limosin

has received speaker and consulting fees from Astra Zeneca, Euthérapie-Servier, Janssen, Lundbeck, Otsuka Pharmaceuticals and Roche. Marcel Goldberg and Marie Zins have nothing to declare.

### Thyroid axis functioning in patients with high suicide risk

B. Berentaitė\*, A. Marciulionienė, K. Butkute-Sliuoziene, V. Steibliene, V. Adomaitiene

Lithuanian University of Health Sciences, Psychiatric Clinic, Kaunas, Lithuania

\* Corresponding author

**Introduction.**– Dysfunction of the thyroid gland is frequently associated with affective and psychotic disorders [Bauer 2008; Bunevicius 2016], but the role of thyroid hormones in association with suicidal behavior is not clearly defined. The suicide rate in Lithuania is the highest in Europe [WHO, 2015], therefore the analysis of factors for suicide risk remains an important task.

**Objectives.**– To evaluate thyroid axis functioning in patients with high suicide risk, hospitalized in psychiatric hospital in comparison to healthy donors-controls.

**Methods.**– Adults, non-psychotic patients, without cognitive impairment, hospitalized due to high suicide risk were invited to participate in the study. All 56 patients filled the sociodemographic questionnaire. Blood samples were assessed for Thyroid stimulating hormone (TSH), free thyroxine (FT4) and free triiodothyronine (FT3) concentrations. Blood samples of 120 healthy blood donors were served as control group.

**Results.**– There were no significant mean age differences among patients and controls ( $36.46 \pm 13.13$  years vs.  $34.31 \pm 12.96$  years, respectively;  $P=0.307$ ). Patient group had higher prevalence of women (66.1% vs 42.5%, respectively;  $P=0.003$ ), so all hormone comparisons were controlled for gender. In our study, patients in comparison to controls had lower mean FT3 concentrations ( $4.0 \pm 0.84$  pmol/L vs.  $5.22 \pm 0.86$  pmol/L, respectively;  $P < 0.001$ ) and lower mean FT4 concentrations ( $13.57 \pm 2.62$  pmol/L vs.  $16.79 \pm 2.28$  pmol/L;  $P < 0.001$ ), without significant differences in TSH concentrations ( $1.83 \pm 1.45$  mU/L vs.  $1.63 \pm 1.36$  mU/L,  $P=0.36$ ).

**Conclusions.**– Patients, hospitalized with high suicide risk in comparison to the healthy control group had lower FT3 and lower FT4 concentrations without differences in TSH concentrations. Lower free thyroid hormones concentrations in patients with high suicide risk did not affect thyroid hormone activity in pituitary.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Perceived stigma as a potential moderator of treatment outcome in persons with gender dysphoria: A two-year follow-up study

G. Castellini<sup>1</sup>\*, A.H. Fisher<sup>2</sup>, M. Maggi<sup>2</sup>, V. Ricca<sup>1</sup>

<sup>1</sup> University of Florence, Department of Neuroscience, Psychology, Drug Research and Child Health, Florence, Italy; <sup>2</sup> University of Florence, Department of Experimental, Clinical, and Biomedical Sciences, Florence, Italy

\* Corresponding author

**Introduction.**– Enacted and perceived transphobia is a relevant issue in clinical management of persons with gender dysphoria (GD). The reduction body dissatisfaction is an important target of hormonal treatment.

**Objective.**– To evaluate whether internalized transphobia represented a moderator of the effects of hormonal treatment in GD persons.

**Methods.**– Fifty male-to-female (MtF), 50 female-to-male (FtM) were evaluated by means Main Outcome Measures. Subjects were studied by means of the Structured Clinical Interview, the Symptom Checklist (SCL-90), the Body Uneasiness Test (BUT), the Attitudes Toward Transgendered Individuals Scale (ATTI). The evaluation was repeated 2 years prospectively, after cross-sex hormonal treatment.

**Results.**– Both MtF and FtM groups reported a significant reduction of SCL-90 and BUT scores across time. When stratifying patients on the basis of transphobia scores a significant effects on BUT reduction was observed: the group with low internalized transphobia reported a stable reduction of BUT scores across time, while the group with high internalized transphobia reported a not significant reduction of these psychopathological feature (Figure 1).

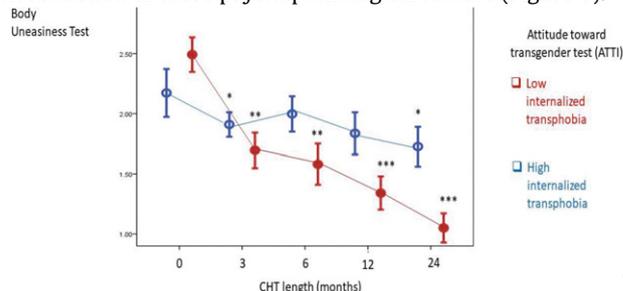

Fig. 1 Internalized transphobia and body uneasiness change after CHT.

**Conclusions.**– Hormonal treatment is effective in reducing psychopathology in persons with GD. Internalized stigma is a relevant matter of concern in GD clinical management, as it might moderate the effects of cross-sex hormonal treatment in terms of psychopathology reduction.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Differential association between cytokines and cerebral activations during experience of social exclusion

I. Conejero<sup>1</sup>, E. Olié<sup>2</sup>, E. Thouvenot<sup>3</sup>, F. Cyprien<sup>4</sup>, T. Mura<sup>5</sup>, N. Menjot De Champfleury<sup>6</sup>, S. Guillaume<sup>2</sup>, S. Finge<sup>7</sup>, P. Courtet<sup>2</sup>

<sup>1</sup> Nîmes University Hospital, Psychiatry, Nîmes, France; <sup>2</sup> Department of Emergency Psychiatry and Post-Acute Care, hôpital Lapeyronie, CHU de Montpellier, Psychiatry, Montpellier, France; <sup>3</sup> Department of neurology, CHU de Nîmes, Neurology, Nîmes, France; <sup>4</sup> Inserm, Unit 1061, Montpellier, France; <sup>5</sup> CHU de Montpellier, CHU de Montpellier, Montpellier, France; <sup>6</sup> CHU de Montpellier, Neuroradiology, Montpellier, France; <sup>7</sup> CHU de Nîmes, Immunology, Nîmes, France

\* Corresponding author

**Objective.**– To measure the association between cerebral activations during experimental social exclusion and levels of inflammatory markers in subjects having a history of major depressive episode with or without suicidal act.

**Methods.**– A total of 116 euthymic females divided into 3 groups: 45 having a history of depression and suicide attempt, 43 having a history of depression without suicide attempt and 28 healthy subjects. During fMRI, they performed cyberball game, a validated social exclusion task. Blood levels of cytokines IL-1B, IL-6, TNF- $\alpha$  and IL-2 were measured prior to fMRI. Analyses were performed in regions of interest: insula, orbitofrontal cortex (OFC) and anterior cingulate cortex (ACC).

**Results.**– Baseline IL-1 Beta was negatively associated with R-OFC ( $P=0.01$ ), whereas baseline IL-2 was positively associated with R-ACC ( $P=0.02$ ); R-insula ( $P=0.002$ ) and R-OFC ( $P=0.004$ ). These associations remained significant after controlling on group, the

type of mood disorder (unipolar or bipolar) and level of social distress.

**Conclusion.**– Baseline IL-1 and IL-2 blood levels show differential association with cerebral activations involved in perception of social exclusion, independently of suicidal behavior or mood disorder history. Our results may help to better understand the role of basal inflammation in social stress and its link with pathophysiology of mood disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Case-control study of suicide in children and young people using linked primary and secondary routinely collected electronic health records**

M. Del Pozo Banos<sup>1\*</sup>, K. Lloyd<sup>1</sup>, M. Dennis<sup>1</sup>, D. Gunnel<sup>2</sup>, J. Scourtfield<sup>3</sup>, A. John<sup>1</sup>

<sup>1</sup> Swansea University, Medical School, Swansea, United Kingdom; <sup>2</sup> Bristol University, Medical School, Bristol, United Kingdom; <sup>3</sup> Cardiff University, School of Social Sciences, Cardiff, United Kingdom

\* Corresponding author

**Introduction.**– Recent studies have focused on health care contacts for all those who complete suicide to highlight opportunities for intervention. In Wales, electronic health records (EHR) are routinely collected, providing an invaluable opportunity for researching suicide risk factors readily available to practitioners.

**Objectives.**– In this study, we linked primary and secondary EHRs in a bid to identify suicide risk factors for those between 10 and 24 years of age.

**Methods.**– We linked seven different datasets: National Statistics Annual District Deaths Extract, Welsh Demographic Service, Welsh Primary Care GP, Patient Episode Database for Wales, Outpatient Dataset, Emergency Department Data Set and National Community Child datasets. After identifying a total of 490 cases, we matched them with 10 controls of same gender and age ( $\pm 1$  year). We identified cases' and controls' mothers and cohabitants. We measured a number of factors from this population, including self-harm, mental health issues and drugs and alcohol misuse, and fed them into a conditional logistic regression model.

**Results.**– Preliminary results suggest that environmental factors extracted from cohabitants have a statistically significant effect even after adjusting for deprivation. In addition, self-harm and mental health events seem to be the strongest factors by far of those considered in the study.

**Conclusions.**– Our preliminary analysis indicate that the use of linked EHR for the study of suicide can yield interesting results. Once completed, we hope this study will help to identify other suicide risk factors readily available for practitioners and can therefore be quickly used to identify opportunities for intervention and improve care.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The influence of mass media on body satisfaction in young females: The role of emotional reappraisal**

S. Martunov<sup>1</sup>, G. Arina<sup>2</sup>, O. Dobrushina<sup>3\*</sup>

<sup>1</sup> International Institute of Psychosomatic Health, Founder, Moscow, Russia; <sup>2</sup> M.V. Lomonosov Moscow State University, Psychology, Moscow, Russia; <sup>3</sup> International Institute of Psychosomatic Health, Director, Moscow, Russia

\* Corresponding author

**Introduction.**– Dismorphophobia and related disorders are a major challenge of contemporary mental healthcare. It is supposed that persistent translation of ideal body image by mass media may interfere with body satisfaction in young females.

**Objectives.**– To study the psychological factors mediating the influence of mass media on body satisfaction in young females.

**Methods.**– A total of 164 females aged 18–30 years underwent a survey regarding frequency and specifics of TV and magazines consumption (hours per week, types of programs and magazines), the needs and desires actualized by mass media, the emotions they feel for the women with ideal body seen on TV and in magazines. Satisfaction with body (form, legs, breast, waist, hips, face, skin, height, total score), health, intelligence, temper, happiness was assessed with visual analogous scales (the difference between the actual and desired), and depression - with Beck's inventory. Multiple regressions were performed for the total body satisfaction score.

**Results.**– After multi-step regression, the following significant variables influencing body satisfaction were identified: body mass index, feelings of guilt and envy for the women with ideal body translated by mass media, the difference between actual and desired happiness or Beck's score ( $R=0.65$ ,  $P<0.0001$ ). Quantity of consumption and types of mass media had no predictive value.

**Conclusions.**– The negative influence of mass media on body satisfaction in young females is governed by the depressive emotional reappraisal of the perceived media products with feelings of guilt and envy for the women with ideal body.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Characteristics of rural suicide in Romania**

M.M. Dumitru

"Saint Nicolae" Hospital, Psychiatry, Roman, Romania

**Introduction.**– Although suicide is a public health problem in Romania, there are no national studies on complete suicide depending on the home environment of the suicide person.

**Objectives.**– The objective of this study was to analyze the cases of completed suicide depending on the home environment of the suicidal person.

**Methods.**– Was used the National Institute of Statistics database on the number of suicides between 2009–2013 and the data was analyzed with the SPSS 14 program.

**Results.**– Over the period 2009–2013 were registered 12,799 cases of complete suicide, males 84.7%, male/female ratio = 5.5. The annual rate of suicide in the rural area was 15.2/100,000, while in urban area was 8.5/100,000.

In the urban environment, the suicidal methods more used were shooting ( $P=0$ ,  $RR=17.8982$ ), narcotics intoxication ( $P=0$ ,  $RR=14.2268$ ), drug intoxication ( $P=0.5012$ ,  $RR=2.2348$ ), fall from height ( $P=0$ ,  $RR=5.2711$ ), throwing in front of a car or road accident ( $P=0$ ,  $RR=2.6339$ ) and use of sharp objects ( $P=0.000433$ ,  $RR=1.6433$ ), while voluntary pesticide intoxication ( $P=0.00904$ ,

RR=0.5099) and hanging ( $P=0$ , RR=0.9356) were more frequently used in rural areas.

Suicidal persons from urban area were more often divorced ( $P=0$ ), while rural suicidal were more often unmarried ( $P=0.041465$ ) or married ( $P=0.025775$ ).

Urban residents chose more often to commit suicide in a health facility ( $P=0$ ) or in another location ( $P=0$ ), while rural residents usually commit suicide in their own home ( $P=0$ ).

**Conclusions.**– There are statistically significant differences between the characteristics of suicide in urban and rural areas. Knowing these differences can help us develop suicide prevention interventions tailored to vulnerable groups.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Role of dopamine transporter ((DAT)) in alcohol dependence – a genetic association and imaging study**

T. Grover<sup>1\*</sup>, R. Gupta<sup>1</sup>, A. Ambekar<sup>2</sup>, C. Bal<sup>3</sup>, G. Arora<sup>3</sup>, R. Singh<sup>1</sup>, M. Vaswani<sup>4</sup>, A. Sharma<sup>1</sup>

<sup>1</sup> All India Institute of Medical Sciences, Anatomy, New Delhi, India; <sup>2</sup>

All India Institute of Medical Sciences, Psychiatry, New Delhi, India; <sup>3</sup>

All India Institute of Medical Sciences, Nuclear Medicine, New Delhi, India; <sup>4</sup> University of Minnesota, Psychiatry, Minneapolis, USA

\* Corresponding author

**Introduction.**– Alcohol manifests its effect mainly through activation of dopamine or the reward pathway. Dopamine transporter (DAT) is a critical regulator, responsible for the re-uptake of dopamine from the synaptic cleft into the presynaptic neurons. Thus, DAT levels and genetic factors affecting them maybe useful markers in conditions like alcohol dependence (AD).

**Objectives.**– Genotyping the DAT1 40bp VNTR and DAT imaging using SPECT-CT in AD subjects.

**Methods.**– The study group comprised 100 each of male AD patients (DSM IV criteria), recruited from the National Drug Dependence Treatment Centre, AIIMS and controls from the general population. Subjects interviewed using a pre-designed questionnaire and WHO ASSIST tool and 5 mL peripheral blood drawn after informed consent. Genomic DNA isolated was screened for DAT1 40bp VNTR. SPECT-CT imaging using 99mTc-TRODAT-1 performed to measure striatal DAT levels in 20 AD patients and 20 controls.

**Results.**– DAT1 genotype frequencies revealed 10 repeat allele (10r) to be the most frequent in our subjects (87.8% controls; 78.2% cases). The 9 repeat (9r) allele was more pronounced in cases (22%) compared to controls (12%) ( $P=0.09$ ). Correlation of SPECT results and DAT1 genotypes of the 20 AD subjects and controls revealed the patients to have a higher 9r frequency (17.5% cases; 13.2% controls) and significantly reduced DAT availability in the left striatum ( $0.89 \pm 0.41$  cases;  $1.21 \pm 0.34$  controls) ( $P=0.02$ ) and putamen ( $1.02 \pm 0.47$  cases;  $1.38 \pm 0.37$  controls) ( $P=0.02$ ).

**Conclusion.**– A comparatively higher 9r allele frequency and significantly reduced DAT availability are indicative of diminished dopaminergic functioning in AD patients, suggesting it to be genetically regulated.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Live stream suicide**

M. Guimarães<sup>1</sup>, J.R. Gomes, O. Güete-Tur, M.D.C. Cruz  
Centro Hospitalar do Algarve, Serviço de Psiquiatria do Hospital de Portimão, Portimão, Portugal

\* Corresponding author

**Introduction.**– On June 2016, according to internetworldstats, 50.1% of the world have access to the Internet. The webcam gained popularity with the video streaming over the Internet with the telecommunications application software (MSN or Skype). The live streaming (transmission or reception of video or audio thought the Internet) has been recently incorporated in websites such as Facebook or Youtube.

**Aims.**– Carry out an internet search for news about consummate suicides and suicide attempts in live streaming and make characterisation of this population and discuss some strategies to the prevention of this events.

**Methods.**– A survey of institutional or personal sites was conducted using the Google search site, with the descriptors such as “live”, “stream”, “webcam”, “suicide”, “self-injury” and “self-harm”. Results restricted between January 2000 and March 2017.

**Results.**– The survey, conducted between January 1 and March 1, 2017, resulted in a total of 30 cases. Of these, 10 occurred between 2016 and 2017, using the Facebook and Youtube. 21 resulted in consummate suicide and 9 suicide attempts. Sex distribution is 11 women for 19 men, the average age 24 years. The most frequent method was hanging. The United States of America is the country where most news comes out; there are also cases from different countries over the world.

**Discussion/conclusions.**– We reflect on the impact on this method used to expose suicidal behaviours, the perspective of the transmitter and the viewer. We conclude that a greater focus is needed in this emerging practice in order to develop strategies to the prevention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Personality traits and genetics as risk factors for suicidality in depressed patients**

M. Hambrich<sup>1\*</sup>, R. Vulturar<sup>2</sup>, A. Chis<sup>2</sup>, D. Cozman<sup>1</sup>

<sup>1</sup> “Iuliu Hatieganu” University of Medicine and Pharmacology,

Medical Psychology Department, Cluj-Napoca, Romania; <sup>2</sup> “Iuliu Hatieganu” University of Medicine and Pharmacology, Department of Molecular Sciences, Cluj-Napoca, Romania

\* Corresponding author

**Introduction.**– The presence of personality traits that mediate the suicide risk is a recurrent theme among the studies that research suicide behaviour (SB). SB is mediated by hereditary dimensions, like personality traits, impulsivity, aggression, independently from the coexisting psychiatric disorder. Our hypothesis is that these personality traits might be an intermediary phenotype between genetics, stress factors and SB.

**Objectives.**– The current study aims to elaborate a model in order to quantify the suicide risk, based on personality traits, neurobiological and clinical markers.

**Methods.**– A total of 164 participants (122 diagnosed with a depressive episode and 42 healthy subjects) were included through convenient sampling procedure from the patient population of the IIIrd Psychiatry Clinic of the Cluj County Emergency Hospital. Among the diagnosed subjects, a subgroup of 27 had a history of at least one suicide attempt. Personality traits were assessed by Barratt Impulsiveness Scales-11 (BIS) and Temperament and Character Inventory (TCI-R) and SB through Paykel Suicide Scale (PSS). Also,

these patients were genetically tested for several polymorphisms that influence impulsivity traits, such as 5-HTTLPR (a polymorphism in the serotonin transporter gene), the Val158Met polymorphism in COMT (Catechol-O-methyltransferase) and Val66Met in Brain-derived neurotrophic factor (BDNF) genes.

**Results.**– There were significant differences between the personality traits, and genetic makeup of the subgroups diagnosed with depressive disorder, with and without documented suicide behaviour.

**Conclusions.**– Several personality traits, influenced by genetics, might be discriminating elements between patients that eventually commit a suicide attempt and those that do not.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Psychopathological characteristics and adverse childhood events are differentially associated with suicidal ideation and suicidal acts in mood disorders**

D. Janiri\*, P. De Rossi, G. Kotzalidis, G. Sani  
Sapienza University of Rome, Faculty of Medicine and Psychology,  
NESMOS Department Neurosciences, Mental Health and Sensory  
Functions, Rome, Italy

\* Corresponding author

**Background.**– Depression is the most important clinical factor associated with suicidality. Among psychopathological factors, hopelessness is reported most often and was found to be strongly associated with suicidal thoughts, but not attempts. Temperaments, childhood trauma, and aggression have been indicated as risk factors for suicidal acts and might explain the gap between suicidal ideation and suicidal attempt. We tested this hypothesis in a large sample of subjects with mood disorders.

**Methods.**– We assessed 306 patients with major depressive and bipolar disorders for a large number of clinical characteristics and for hopelessness, temperament, childhood trauma, and aggression. We tested their associations with suicidal ideation and acts using standard univariate/bivariate methods and multivariate logistic regression models.

**Results.**– Loss of expectations was a risk factor for suicidal ideation. Childhood emotional abuse, severity of depression, and female gender were risk factors for lifetime suicide attempts, whereas hyperthymic temperament was protective. Hyperthymic temperament was protective in committing suicide attempts with respect to only presenting suicidal ideation.

**Conclusions.**– Findings support the association of hopelessness with suicidal ideation and point to considering not only depression, but also childhood emotional abuse, hyperthymic temperament and gender in suicidal acts.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Novel triple opioid receptors antagonist ondelopran (LY2196044) for alcohol dependence phase III study: Female subjects subgroup efficacy and safety analysis**

E. Mukhametshina\*, F. Shagiakmetov, M. Samsonov  
JSC R-PHARM, Medical, Moscow, Russia

\* Corresponding author

Ondelopran is a novel potent antagonist/inverse agonist at kappa, mu and delta opioid receptors. Here we present some of the results from Phase III GCP-complied clinical study of ondelopran 125 mg QD in patients with alcohol dependence. The study has completed and analysis of the full dataset of information is ongoing. Here we present efficacy results in subgroup of female patients.

In combination with a psychosocial intervention aimed at reinforcement of motivation for sobriety ondelopran significantly reduced mean daily total alcohol consumption ( $P < 0.05$ ), and the number of heavy drinking days per month ( $P < 0.05$ ) versus placebo. Ondelopran also increased mean percentage of days of abstinence per month to 91.2% (almost complete abstinence) that was by 6.1% higher than in placebo group ( $P < 0.01$ ). The most significant superiority of ondelopran over placebo was found for the assessments of craving with Obsessive-Compulsive Scale ( $P < 0.001$ ) and Visual Analogue Scale ( $P < 0.01$ ). By the end of the study the proportion of patients with improvement in the overall clinical evaluation with CGI-I scale was significantly ( $P = 0.01$ ) higher in ondelopran group (91.6%) than in placebo group (72.5%). CGI-I scale performance index also was significantly ( $P < 0.01$ ) higher in ondelopran group. Ondelopran was well tolerated and safe. Gastrointestinal adverse events were the most frequent in ondelopran group (16.4% if compared to 8.4% in placebo group  $P < 0.01$ ). These preliminary results suggest ondelopran to be a novel and effective treatment for alcohol dependence.

### **Adherence to methadone maintenance treatment and associations with violent and non-violent offending: Results from a 17-year longitudinal cohort study of Canadian provincial offenders**

A. Russolillo\*, A. Moniruzzaman, L. McCandless, M. Patterson, J. Somers

Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

\* Corresponding author

**Introduction.**– Little is known about the long-term effectiveness of methadone maintenance treatment (MMT) in relation to the risk of violent and non-violent offending.

**Objectives.**– This study aims to estimate and test the difference in rates of violent and non-violent crime during medicated and non-medicated methadone treatment episodes.

**Methods.**– The study involved linkage of population level administrative data (health and justice) for all individuals ( $n = 14,530$ ) with a history of conviction and who filled a methadone prescription between January 1, 1998 and March 31, 2015. Rates of violent and non-violent offending during medicated periods were compared with rates during non-medicated periods.

**Results.**– During the first two years of treatment ( $\leq 2.0$  years), periods in which methadone was dispensed were associated with a 33% lower rate of violent crime [0.67 adjusted hazard ratio (AHR), 95% confidence intervals (CI) (0.59, 0.76)] and a 35% lower rate of non-violent crime [0.65 AHR 95% CI (0.62, 0.69)] compared to non-medicated periods. This equates to a risk difference of 3.6 [95% CI (2.6, 4.4)] and 37.2 [95% CI (33.0, 40.4)] fewer violent and non-violent offences per 100 person years (PYs), respectively. Significant but smaller protective effects of dispensed methadone were observed across longer treatment intervals (2.0 to  $\leq 5.0$  years, 5.0 to  $\leq 10.0$  years).

**Conclusions.**– Among a cohort of Canadian offenders, rates of violent and non-violent offending were lower during periods when

individuals were dispensed methadone compared with periods in which they were not dispensed methadone.

### **The association between act-belong-commit indicators and problem drinking among older irish adults: Findings from a prospective analysis of the Irish longitudinal study on ageing (TILDA)**

Z.I. Santini<sup>1</sup>, L. Nielsen<sup>1</sup>, C. Hinrichsen<sup>1</sup>, J.S. Tolstrup<sup>1</sup>, J.L. Vinther<sup>1</sup>, A. Koyanagi<sup>2</sup>, R.J. Donovan<sup>3</sup>, V. Koushede<sup>1</sup>

<sup>1</sup> The Danish National Institute of Public Health NIPH, Mental Health, Copenhagen, Denmark; <sup>2</sup> Parc Sanitari Sant Joan de Déu, Recerca, Barcelona, Spain; <sup>3</sup> University of Western Australia, School of Sport Science- Exercise, and Health, Perth, Australia

\* Corresponding author

The Act-Belong-Commit campaign is the world's first comprehensive, population-wide, community-based program to promote mental health. However, its potential for preventing substance use disorders is unknown. Further, a literature gap is evident concerning behavioral modification strategies to prevent such disorders. The aim of this study was to prospectively assess the association between indicators of the Act-Belong-Commit behavioral domains and the development of problem drinking.

Data from two waves of the Irish Longitudinal Study on Ageing (TILDA) were analyzed. The sample consisted of 3950 adults aged  $\geq 50$  years. A validated scale for problem drinking was used. The number of social/recreational activities engaged in was used as an indicator of Act, social network integration as an indicator of Belong, and frequency of participation in these social/recreational activities as an indicator of Commit. Multivariable logistic regression analyses were conducted to assess associations between baseline indicators of Act-Belong-Commit and the development of problem drinking at two-year follow-up.

Each increase in the number of social/recreational activities (Act) inversely predicted the onset of problem drinking. Similarly, being well integrated into social networks (Belong) was negatively associated with the development of problem drinking. Finally, frequency of participation in social/recreational activities (Commit) also inversely predicted the onset of problem drinking. These associations were apparent regardless of the presence of baseline common mental disorders.

Act-Belong-Commit indicators are shown to be associated with a reduced risk for problem drinking. This lends further support to the Act-Belong-Commit domains and has wide-ranging implications for preventing alcohol use disorders in the aging community.

### **Schizophrenia and pregnancy**

L. Simoila<sup>1</sup>, E. Isometsä<sup>1</sup>, M. Gissler<sup>2</sup>, J. Suvisaari<sup>3</sup>, E. Sailas<sup>4</sup>, E. Halmesmäki<sup>5</sup>, N. Lindberg<sup>6</sup>

<sup>1</sup> Helsinki University and Helsinki University Hospital, Psychiatry, Helsinki, Finland; <sup>2</sup> National Institute for Health and Welfare, Information Services Department, Helsinki, Finland; <sup>3</sup> National Institute of Health and Welfare, Mental Health Unit, Helsinki, Finland; <sup>4</sup> Kellokoski Hospital, Psychiatry, Kellokoski, Finland; <sup>5</sup> Femeda-clinic, Obstetrics and Gynaecology, Helsinki, Finland; <sup>6</sup> Helsinki University and Helsinki University Hospital, Forensic Psychiatry, Helsinki, Finland

\* Corresponding author

*Objectives.*– De-institutionalization and second-generation antipsychotics with less endocrine side-effects have enabled women with schizophrenia spectrum disorders to be more sexually active. However, research focusing on the reproductive health of women suffering from schizophrenia has been scarce.

*Methods.*– Using the Care Register for Health Care, we identified a national sample of Finnish women who were born between the years 1965 and 1980 and were diagnosed with schizophrenia. For each case, five age- and place-of-birth- matched controls were obtained from the Central Population Register of Finland. They were followed from the day when the disorder was diagnosed and coded in specialized health care until the individual moved abroad, died, or follow-up ended on 31.12.2013. Information about pregnancies was obtained from the Medical Birth Register.

*Results.*– We identified 1139 singleton pregnancies among exposed women and 4574 among unexposed ones. The exposed women were older and more often single at the end of the pregnancy, their body mass index before pregnancy was higher, and they smoked more often both in the beginning of pregnancy and after the first trimester than unexposed women. Exposed women showed a higher risk of pathologic oral glucose tolerance test, initiation of insulin treatment, and fast fetal growth. Maternal care for (suspected) damage to foetus from alcohol and/or drugs was fortunately rare, but it was more common among exposed women than among unexposed ones.

*Conclusions.*– Women with schizophrenia exhibit more pregnancy-related health problems and complications than their unexposed counterparts do. Close collaboration between gynecologists, obstetrics and psychiatrists are needed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Characteristics and risk factors for suicide among Japanese college students**

C. Uchida<sup>1</sup>\*, M. Uchida<sup>2</sup>

<sup>1</sup> Fukushima University, Human Development and Culture, Fukushima Child Mental Health Care Center, Fukushima, Japan; <sup>2</sup> Massachusetts General Hospital, Harvard Medical School, Psychiatry, Boston, USA

\* Corresponding author

Suicide is a leading cause of death for college students. The aim of this study was to identify risk factors of suicide among college students to prevent suicide.

*Methods.*– We conducted a 23-year (from 1989 through 2012 academic year) serial prevalence study of the prevalence and characteristics of death and suicide among 8.2 million Japanese college students. We analyzed rates of suicide and characterized suicide among this population, focusing on students' sex and psychiatric and academic backgrounds to identify risk factors for suicide.

*Results.*– Suicide rates increased throughout the 23 years, and suicide was the leading cause of death every year from 1996 onward. Male students, medicine majors, students in the final year of their program, and students who completed extra years of schooling or took academic leaves of absence were at higher risk for suicide. Only 16.4% had received a psychiatric diagnosis and 16.0% had received services through the university health center prior to the suicides. Results suggest the need for a stronger support system for college students, especially those majoring in medicine, and those who have taken leaves of absence or failed classes.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Relationship between suicidality and thyrotropic axis activity

S. Vuk Pisk<sup>1\*</sup>, E. Ivezić<sup>1</sup>, N. Ruljancic<sup>2</sup>, I. Filipic<sup>1</sup>

<sup>1</sup> *Psychiatric Hospital "Sv.Ivan", Acute female department, Zagreb, Croatia;* <sup>2</sup> *Psychiatric Hospital "Sv.Ivan", Laboratory, Zagreb, Croatia*

\* Corresponding author

**Introduction.**– Investigation of the relationship between suicidal-ity and the activity of thyrotropic axis is scarce and has yielded conflicting results.

**Objectives.**– The aim of this study was to examine the correlation between thyroid hormone levels and psychopathology (i.e. different mental disorders) and suicidality.

**Method.**– A total of 424 adult psychiatric inpatients (81.1% female; mean age 43.52 years) participated in this study. The occurrence of the predominant primary diagnoses were as follows: schizophrenia, schizotypal and delusional disorders (34.2%), mood disorders (29.7%), neurotic, stress-related and somatoform disorders (17.5%), personality disorders (8.3%), organic mental disorders (5.7%), and intentional self-harm (4.7%). Thyroid data was collected from medical records since January 2016 to March 2017.

**Results.**– Significant differences were obtained across different diagnostic categories (Kruskal–Wallis test) in relation to total T<sub>3</sub> and free T<sub>4</sub> hormones: patients with organic mental disorders had significantly lower values of T<sub>3</sub> hormone compared to other patients; patients with personality disorders had significantly lower values of free T<sub>4</sub> hormone (except when compared to patients with mood disorders), and patients with mood disorders had lower values of free T<sub>4</sub> hormone compared to patients with psychotic disorders, patients with organic mental disorders and those who attempted suicide. Additionally, patients who attempted suicide had lower values of TSH hormone compared to other patients.

**Conclusions.**– The findings showed different thyroid hormone levels in different mental disorders, including altered values of free T<sub>4</sub> hormone and TSH hormone in suicidal patients. Thus, the results suggest the possibility to determine these hormones as markers of suicidality in psychiatric patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– Predicting suicidal behaviors is one of the most complex challenges of daily psychiatric practices. Alterations of RNA

editing of neurotransmitter receptors and other proteins have been shown to be involved in etiology of different psychiatric disorders and linked to suicidal behavior.

**Objective.**– The objective of the present study was to test whether longitudinal measurement of RNA editing profile of disease-relevant blood biomarkers can be used to predict patients at greatest risk of relapse.

**Methods.**– A clinical study was performed to identify an RNA editing signature in blood of depressed patients with previous history of suicide attempts ( $n=28$ ) over a 6-month period. Patient's samples were drawn in PAXgene tubes at initial visit and 6 months later and analyzed on Alcediag's proprietary RNA editing platform using NGS. In parallel, clinical evaluations (Hamilton, MADRS and BDI) were performed.

**Results.**– During follow-up, 8 patients out of 28 have reattempted suicide (RSA). In the 20 patients that did not reattempt suicide (NRSA), the BDI score showed significant improvement during follow up. On the other hand, clinical evaluations in the RSA patients did not show any improvement and even showed worsening of the MADRS score. In addition, all phosphodiesterase 8A (PDE8A) mRNA editing sites showed significant changes in the NRSA patients over time whereas no PDE8A mRNA editing sites were modified in the RSA patients, suggestively signing improvement of their mental state.

**Conclusions.**– Longitudinal measures of RNA editing biomarkers in blood samples of patients can be useful for predicting future suicide attempts.

### Prevalence and predictors of social cohesion and its association with mental health in India

B. Ali

*International Institute for Population Sciences, International Institute for Population Sciences, Mumbai, India*

**Introduction.**– It is agreed that social cohesion plays a constructive role in the preservation of mental health and well-being. Social cohesion is well-connected phenomena with both vertical and the horizontal interactions among members of society. Methodology– Using the WHO-SAGE wave-1 data, which is a longitudinal and cross-sectional study on a sample of 11,230 adults, aged 18 years and older, this study investigated is there any association between social cohesion and mental health of people in India. Ordered logistic regression analysis has been used to understand the association between mental health and social cohesion. Social interaction, trust, safety, political participation and freedom of expression are used as indicators of social cohesion.

**Results.**– People those who had high social interaction in the society were 0.80 ( $P<0.001$ ) times less likely to have mental disorders. Further, People who had high trust in the society were 1.09 ( $P<0.05$ ) times and who had not any freedom of expression been 1.3 ( $P<0.001$ ) times more likely to have mental disorders. This study reveals that low social cohesion is significantly associated with poor mental health and vice-versa. Social interaction and freedom of expression are robust indicators, which strongly affect the

mental health. Results indicate that the high social cohesion leads to little mental health problems and increase the mental well-being of people in India.

**Conclusions.**– This study suggests that social cohesion in the society reduces mental disorders among people and people with high social interaction, trust, political participation and freedom of expression in the society have less mental disorders.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

OR0139

### **Prevalence and predictors of mental health disorder in India: A cross-sectional study**

B. Ali

*International Institute for Population Sciences, International Institute for Population Sciences, Mumbai, India*

**Introduction.**– The burden of mental illness has significant impacts on health and major social-economic consequences in India. The persistent socio-economic pressures are recognized risks to mental health for individuals and communities.

**Methodology.**– This study conducted using the WHO-SAGE wave-1 data which is a longitudinal and cross-sectional study on a sample of 11,230 adults aged 18 years and older. The logistic analysis is used to estimate the odds, and correlation matrix and Cronbach's alpha was used to understand the correlation and reliability of mental health symptoms.

**Results.**– The alpha value represents the acceptable internal consistency,  $\alpha = 0.83$ . This study indicated that those who were ages 60 years and above were 3.43 ( $P < 0.001$ ) times in Model-I, not currently working 1.56 ( $P < 0.001$ ) times in Model-II, Muslim 1.54 ( $P < 0.001$ ) times more likely to have mental disorders. About half of the population have severe mental disorders and mental illness is increasing with increment in age, and elderly, female and less educated people are more vulnerable than other.

**Conclusions.**– This study found that there was the severity of mental health problems in the Indian population. Mental health disorder is increasing with age, and older adults are more vulnerable compared to other. Female has the more severe mental disorder as compared to male while people lived in the rural area were suffering from the severe mental disorder. Education became a major determinant of mental disorder, and as educational status has been increasing, mental disorder is decreasing which shows the inverse relationship between them.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Cannabis use and clinical correlates in patients with an at-risk mental state and first episode of psychosis**

K. Beck<sup>1</sup>, L. Würsch<sup>1</sup>, E. Studerus<sup>1</sup>, C. Andreou<sup>1</sup>, U. Heitz<sup>1</sup>, S. Ittig<sup>1</sup>, L. Leanza<sup>1</sup>, L. Egloff<sup>2</sup>, S. Menghini-Müller<sup>1</sup>, M. Uttinger<sup>1</sup>, A. Riecher-Rössler<sup>1</sup>

<sup>1</sup> University of Basel Psychiatric Hospital, Center for Gender Research and Early Detection, Basel, Switzerland; <sup>2</sup> University of Basel Psychiatric Hospital, Department of Psychiatry, Basel, Switzerland

\* Corresponding author

**Introduction.**– Studies on cannabis use of patients with an at-risk mental state (ARMS) for psychosis and first-episode psychosis (FEP) patients have repeatedly found increased prevalence of cannabis consumption compared to healthy controls. There is evidence for an association of cannabis use and (subclinical) psychotic symptoms.

It is suggested that in ARMS patients' cannabis use increases the risk of transition to frank psychosis.

**Objectives.**– To investigate current cannabis use and its potential associations with clinical correlates in ARMS and FEP patients.

**Methods.**– Cannabis use was evaluated in 93 ARMS and 108 FEP patients recruited within the prospective Basel Früherkennung von Psychosen (FePsy) study. Positive and negative symptoms were assessed with the BPRS and SANS. Participants were followed for up to 5 years. Data on cannabis consumption of 2162 individuals of the Swiss general population (SGP) were used for comparison. All statistical analyses were adjusted for age and gender.

**Results.**– Prevalence of current cannabis use was significantly higher in ARMS and FEP patients (26.4%) compared to the SGP sample (4.6%;  $\beta = 1.172$ ,  $P < .001$ ,  $OR = 3.23$ ). ARMS and FEP patients with and without current cannabis use did not differ in regard to positive and negative symptoms. Presence and frequency of current cannabis use was not associated with transition.

**Conclusions.**– The high prevalence of cannabis use in ARMS and FEP patients indicates the need to integrate specific interventions in the treatment of these usually young patients. More research is needed to further elaborate the relationship of cannabis use and clinical correlates.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Comparison of long-term treatment outcomes in men and women with schizophrenic psychoses over a period of 20 years. Prospective study**

A. Cechnicki<sup>1</sup>, A. Bielanska<sup>2</sup>, K. Susz<sup>2</sup>, Ł. Cichocki<sup>1</sup>, D. Metel<sup>1</sup>, P. Błądziński<sup>1</sup>, I. Plencler-Bańczyk<sup>2</sup>, A. Daren<sup>1</sup>, A. Kalisz<sup>1</sup>

<sup>1</sup> Jagiellonian University Medical College, Chair of Psychiatry, Department of Community Psychiatry, Krakow, Poland; <sup>2</sup> Association for the Development of Community Psychiatry and Care, Schizophrenia Research Unit, Krakow, Poland

\* Corresponding author

**Background.**– Numerous studies on the differences in the course of schizophrenic psychoses in men and women produce contradictory results.

**Aims.**– The aim was to assess the long-term clinical and social outcomes and subjective quality of life among male and female patients over a 20-year period. Group and method: 57 patients: 34 (60%) women and 23 (40%) men diagnosed with DSM IV T-R schizophrenia were examined at index hospitalization and 7, 12 and 20 years later. Anamnestic and Katamnestic Questionnaire, GAF scales, BPRS-LA, social scale in DSM III, A. Lehman's Quality of Life Questionnaire were used.

**Results.**– Women average at index hospitalization was over 3.5 years later, with a lower incidence of schizoid and schizotypic personality disorders ( $P = 0.045$ ), they functioned better socially compared to men ( $P = 0.009$ ), they had more satisfying relationships ( $P = 0.008$ ), 50% started families, while only 17% ( $P = 0.014$ ) men did so, and after the second admission they displayed less severe symptoms ( $P = 0.045$ ). At 7, 12 and 20 follow-up no differences were found in any clinical and social outcome. In the subjective opinion of QoL, at 7, 12 and 20 follow-up women scored better than men by over one point, reaching a significant difference after twelve years ( $P = 0.50$ ).

**Conclusions.**– 1. Differences between sexes in favour of women observed before and at index hospitalization, disappear in long-term observations; 2. After the index hospitalization men are more likely to marry and thus raise their social status; 3. In the subjective

assessment of the QoL, women display higher general satisfaction with life.

### **Clinical and rehabilitation treatment outcomes of patients with severe schizophrenia in a comprehensive, case managed programme. A 7-year follow-up**

S. Diaz-Fernandez<sup>\*</sup>, J.J. Fernandez-Miranda, J. Diaz-Leiguarda  
AGC SM-V-HUCAB-SESP Asturian mental health service, Centro tratamiento integral, Gijón, Spain

\* Corresponding author

*Introduction.*– To increase treatment compliance is important to reach clinical and rehabilitation goals in people with severe schizophrenia

*Objectives.*– To know treatment (clinical and functional) outcomes and variables related of people with severe schizophrenia enrolled in a comprehensive case managed programme.

*Methods.*– A 7-year prospective, observational study of patients with severe schizophrenia undergoing case managed comprehensive programme in Spain ( $n = 200$ ). Assessment included the Clinical Global Impression severity scale, the Camberwell Assessment of Needs (CAN), the WHO Disability Assessment Schedule (WHO-DAS), reasons for discharge and medications prescribed at the beginning and after 3, 6, 12, 24, 36 and 84 months. Hospital admissions in the previous seven years and during the follow-up were measured.

*Results.*– CGI at baseline was 5.7 (0.7). After seven years 46% of patients continued treatment (CGI=4.1 (0.8);  $P < 0.01$ ); 33% were medical discharged (CGI=3.4(1.6);  $P < 0.001$ ) and continued non intensive treatment in mental health units; the WHO-DAS decreased in the four areas ( $P < 0.01$ ) and also the CAN ( $P < 0.01$ ) in both groups; 8% were voluntary discharges. Eight patients dead during the follow up; three of them committed suicide (1.5%). Hospital admissions decreased significantly ( $P < 0.001$ ). All patients had their own case manager, mainly a nurse. Forty-five percent of all of them were treated with atypical long-acting antipsychotics, with good tolerability and less voluntary discharges.

*Conclusions.*– Retention of patients with schizophrenia with severe symptoms and impairment in a case managed comprehensive programme was really high and helped to get remarkable clinical and functional improvement. Long-acting medication seemed to be useful in improving treatment adherence.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

<sup>1</sup> University of Miami Miller School of Medicine, Psychiatry and Behavioral Sciences, Miami, USA; <sup>2</sup> Sunovion Pharmaceuticals Inc., Medical Affairs, Marlborough, USA; <sup>3</sup> Sunovion Pharmaceuticals Inc., Statistics, Fort Lee, USA; <sup>4</sup> Sunovion Pharmaceuticals Inc., Medical Affairs, Fort Lee, USA

\* Corresponding author

*Introduction.*– Cognitive impairment significantly contributes to the functional impairment associated with schizophrenia.

*Objective.*– To evaluate the longer-term effects of lurasidone on cognition in children and adolescents with schizophrenia.

*Methods.*– Patients aged 13–17 years with schizophrenia who completed 6 weeks of double-blind (DB), placebo-controlled treatment with lurasidone were enrolled in a 2-year, open-label study in which patients were continued on lurasidone or switched from placebo to lurasidone. Cognitive function was assessed with the Brief CogState battery, which evaluates four cognitive domains: processing speed (detection task), attention/vigilance (identification task), visual learning (one card learning task), working memory (one back task, speed & accuracy). Based on normative data, an overall cognitive composite Z-score was calculated as the average of the standardized Z-scores for each of the four cognitive domains. These results are from a 52-week interim data analysis.

*Results.*– A total of 271 patients who completed the 6-week DB study entered the open-label extension study, and 75.6% completed 52 weeks of treatment (mean daily dose, 52.6 mg). The cognitive composite Z-score showed impairment at DB baseline ( $-1.09$ ). At week 28, overall improvement was observed in the cognitive composite Z-score (mean change,  $+0.16$ ). For CogState domains, mean change at week 52 in Z-scores was  $-0.02$  for processing speed,  $0.00$  for attention/vigilance,  $+0.45$  for visual learning,  $+0.24$  for working memory accuracy, and  $+0.23$  for working memory speed.

*Conclusions.*– In this study of adolescents with schizophrenia, lurasidone was not associated with cognitive impairment after 52 weeks of treatment; improvement was noted in selected cognitive domains.

### **Aminoacylase-1: A new potential biomarker for schizophrenia/a preliminary study**

D. Göverti<sup>1\*</sup>, R.N. Yüksel<sup>1</sup>, H. Kaya<sup>1</sup>, N. Özçelik<sup>1</sup>, Ç. Yücel<sup>2</sup>, T. Turhan<sup>2</sup>, E. Göka<sup>1</sup>

<sup>1</sup> Ankara Numune Education and Research Hospital, Psychiatry, Ankara, Turkey; <sup>2</sup> Ankara Numune Education and Research Hospital, Biochemistry, Ankara, Turkey

\* Corresponding author

*Introduction.*– Aminoacylase-1 (ACY1) is a cytosolic enzyme that deacylates the  $\alpha$ -acylated amino acids. ACY1 is strongly expressed in the human brain. Most individuals with ACY-1 deficiency present with neurological symptoms. Schizophrenia is also known to be a neurodegenerative disorder. Our aim was to investigate a possible correlation between schizophrenia and ACY-1 levels, a neural tissue marker.

*Methods.*– Overall, 47 acute schizophrenia patients who were diagnosed with DSM-V and 41 healthy controls, both groups between 18–60 years, without chronic diseases were included in this study for a period of 6 months. Serum levels of ACY-1 were measured in both groups. PANSS and the CGI-S were used to evaluate disease activity.

*Results.*– We found significant differences in serum levels of ACY-1 among the groups. We established that acute schizophrenia patients had significantly lower levels than healthy controls ( $12.8 + 16.9$  vs.

26.7 + 21.4;  $P < 0.001$ ). A negative correlation was found between total PANNS positive scores and ACY-1 serum levels. As total PANNS positive scores increased, ACY-1 levels decreased ( $P: 0.038$ ).

**Conclusions.**– To our knowledge, this is the first study that investigates serum levels of ACY-1 in patients with schizophrenia. Serum levels of ACY-1 were statistically significantly lower in the patient group. Although there is no study about the relation between ACY-1 and schizophrenia, the results of a study states that, lower ACY-1 was found in Huntington Disease which is described to be a neurodegenerative disease. So it can be assumed that, lower ACY-1 levels can be related to neurodegenerative process in schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Role of orexinergic neuron on ketamine-induced analgesia

K. Hirota\*, T. Kushikata

Hirosaki University Graduate School of Medicine, Anesthesiology, Hirosaki, Japan

\* Corresponding author

**Introduction.**– Although ketamine is an anesthetic agent, it is recently used as an antidepressant [1]. In addition, ketamine has also been used as an analgesic [2]. The orexin (OX) system is involved in a variety of physiological processes including pain modulation and modulation of the OX system is a new therapeutic approach to pain control [3]. We previously found the interaction of ketamine with OX system [4].

**Objectives.**– We have studied role of orexinergic neuron on ketamine-induced analgesia.

**Methods.**– After approval by our institutional committee on animal research, 16 OX neuron-deficient transgenic (orexin/ataxin-3: OX/AT-3 TG) rats and the wild-type rats weighing 300–400 g were used. Each rat was placed individually on a hot plate maintained at 50°C to measure the reaction time (cut-off latency: 60 sec), and then the reaction time was measured again after ketamine 15 mg/kg ip. After completion of the hot-plate tests, each rat was decapitated and the contents of noradrenaline and OX-A in the cerebrocortex, hippocampus, hypothalamus and pons were measured.

**Results.**– The area under the curve (AUC) of hot-plate latency-time after ketamine ip was significantly shorter in OX/AT-3 TG rats than that in the wild-type rats ( $P < 0.05$ ). There was a significant correlation between the AUC and OX-A content in the cerebrocortex, hippocampus and hypothalamus ( $P < 0.05$ ) whilst no correlation between the AUC and noradrenaline contents.

**Conclusion.**– The present data suggest that OX system may be involved in the mechanism of ketamine-induced analgesia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### PDE7B, NMBR and EPM2A variants and schizophrenia: A case-control and pharmacogenetics study

T.Y. Jun<sup>1</sup>\*, C.U. Pae<sup>2</sup>

<sup>1</sup> Yeouido St. Mary's Hospital, Psychiatry, Seoul, Republic of Korea; <sup>2</sup> Bucheon St. Mary's Hospital, Psychiatry, Seoul, Republic of Korea

\* Corresponding author

**Background.**– We investigated phosphodiesterase 7B (PDE7B), neuropeptide Y receptor (NMBR) and epilepsy progressive myoclonus type 2A (EPM2A) genes in schizophrenia (SCZ). To the best of our knowledge, these genes have been poorly investigated in studies of SCZ.

**Methods.**– Five hundred and seventy-three SCZ inpatients of Korean ethnicity and 560 healthy controls were genotyped for 2 PDE7B, 3 NMBR and 3 EPM2A polymorphisms. Differences in the allelic and genetic frequencies among healthy subjects and patients were calculated using the  $\chi^2$  statistics. Repeated measure ANOVA was used to test possible influences of single-nucleotide polymorphisms on treatment efficacy. In case of positive findings, clinical and demographic variables were added as covariates, in order to investigate possible stratification bias.

**Results.**– The rs2717 and rs6926279 within the NMBR gene and rs702304 and rs2235481 within the EPM2A gene were associated with SCZ liability. rs1415744 was also associated with Positive and Negative Symptom Scale negative clinical improvement. The results remained the same after inclusion of the covariates and were partially confirmed in the allelic and haplotype analyses.

**Conclusion.**– Our preliminary findings suggest a possible role of NMBR and EPM2A genes in SCZ susceptibility and, for the second one, also in antipsychotic pharmacogenetics. Nonetheless, further research is needed to confirm our findings.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Psychopathy, impulsivity and trait aggression as predisposing factors to violence in schizophrenia and in the general population: A profile analysis

M. Krakowski<sup>1</sup>\*, P. Czobor<sup>2</sup>

<sup>1</sup> Nathan S. Kline Institute, Psychiatry, Orangeburg, USA; <sup>2</sup> Semmelweis University, Department of Psychiatry and Psychotherapy, Budapest, Hungary

\* Corresponding author

**Introduction.**– To identify important predispositions to violence which are not restricted to the illness, violence in schizophrenia must be studied in the context of violent behavior in the general population.

**Objective.**– To investigate important trait predispositions to violence, including psychopathic and impulsive traits and trait aggression.

**Method.**– Participants included 40 violent (VS's) and 34 nonviolent (NV's) patients with schizophrenia, 35 healthy controls (HC's) and 35 non-psychotic violent subjects (NPV's). We used subscales of the Psychopathy Checklist (PCL-SV), Buss-Perry Aggression Questionnaire (BPAQ) and Barratt Impulsiveness Scale (BIS-11). History of childhood conduct problems was also assessed.

**Results.**– The violent groups presented with more severe psychopathy ( $F = 116.1$ ,  $df = 3, 141$ ,  $P < .001$ ), trait aggressiveness ( $F = 13.9$ ,  $df = 3, 141$ ,  $P < .001$ ) and impulsivity ( $F = 8.9$ ,  $df = 3, 141$ ,  $P < .001$ ) than the 2 non-violent groups. We further divided the 40 violent patients into 2 subgroups on the basis of childhood conduct problems; 22 presented with a history of childhood conduct problems (VS-CD),

and 18 without (VS-NCD). We compared these 2 subgroups to each other, to NPV's and HC's. We obtained significantly distinct multivariate profiles of traits for each group ( $F = 46.2, df = 3, 108, P < .001$ ), consisting of psychopathic traits (PCL-SV Factors 1 and 2), BPAQ Anger, BIS-11 Motor Impulsiveness and Self-Control. NPV's had the profile with the most severe impairments, followed by VS-CD's and then VS-NCD's. All the pairwise differences between profiles were significant ( $P < .001$ ).

**Conclusion.**– Specific traits form a core predisposition to violence in the general population and in patients with schizophrenia, particularly in patients with a history of conduct problems. This has important implications for treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Validation of a scale of autonomy in patients with schizophrenia in remission

M. Morozova<sup>1\*</sup>, A. Marchenko<sup>2</sup>, G. Rupchev<sup>2</sup>

<sup>1</sup> Mental Health Research Center, laboratory of psychopharmacology, Moscow, Russia; <sup>2</sup> Lomonosov Moscow State University, Faculty of Psychology, Clinical Psychology Department, Moscow, Russia

\* Corresponding author

**Introduction.**– During the last decades there's a marked rise of interest towards the questions of social functioning of patients. The most relevant line of research is evaluation of schizophrenia patient's conditions and ability of patients to independent existence (autonomy). The objective of this study was investigating of the construct validity a scale of autonomy.

**Method.**– A total of 200 patients, 112 men and 88 women (mean age = 39, 03) were assessed. New version of scale of autonomy (SA), comprising six items: activity, productive communication, social network, medical conventionality, care of themselves, social skills, PANSS, NSA, CGI, PSP, EQ-5D were administered.

**Results.**– The internal consistency: Cronbach's alpha = 0.93. Correlations of all items of the scale with a total score were found ( $P < 0.001$ ). Convergent validity was demonstrated by relatively high correlations between total score SA and related rating instruments, scales detecting the presence of negative symptoms: N4 ( $r = -.506^{**}$ ), PANSS Neg ( $r = -.573^{**}$ ), CGI Neg ( $r = -.573^{**}$ ) and four items of PSP: self-care ( $r = -.545^{**}$ ); personal and social relationships ( $r = -.526^{**}$ ), social useful activities ( $r = -.492^{**}$ ), level of functioning ( $r = 0.492^{**}$ ). Weak or rather weak correlations between AS and psychometric scales, assessing other constructs proved good discriminant validity of AS. Factor analysis separates distinct «autonomy» factor, comprised of all AS items plus several other variables.

**Discussion.**– SA has high internal consistency and good convergent and discriminant validity. SA has correlations with negative symptoms and several items of PSP scale and meets the basic psychodiagnostic requirements. SA is a new psychometric instrument for assessing one of the most important factors of social adjustment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Personality functioning and long-term results of treatment in remitted patients with schizophrenia

M. Morozova\*, G. Rupchev

Mental Health Research Center, laboratory of psychopharmacology, Moscow, Russia

\* Corresponding author

**Introduction.**– Schizophrenia is a complex neurobehavioral disorder. Due to this fact the effect of antipsychotic treatment cannot be attributed only to the biological factors.

**Aim.**– Determine the role of personality functioning (PF) in treatment outcomes in high compliant patients with schizophrenia.

**Method.**– A total of 130 patients with schizophrenia with sufficient treatment response were observed for no less than 4 years. PF was determined as the ability of patients to form a hierarchy of values, develop hobbies, have interests beyond the basic needs, live independently, care for important others, establish relations with the family members and outside the family, planning and implementation capacity. The ability to construct mental representation of the disease was assessed as one of the most important manifestations of PF. Three levels of PF were allocated.

**Results.**– Finally, the group of patients with the same diagnosis, stage of illness at the beginning of the observation, similar treatment, treatment response and good tolerability but different levels of the basic personality functioning fell into three subgroups. The subgroup with the moderate level of PF demonstrated gradually increased improvement both in symptoms severity and social adjustment. In the subgroups with low and high PF improvement in symptoms was not associated with increase of social adjustment.

**Conclusions.**– The ability of patients to utilize the treatment resource (“pharmacological credit”) in social adjustment depends on the level of PF. The patients with the low and high levels due to different reasons took less advantage from this “credit” than the patients with the moderately reduced level

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The effectiveness of the long-acting injections of second generation antipsychotics: A 54-month follow-up study of risperidone long-acting injection vs paliperidone palmitate one-month formulation

R. Navarro Pablo<sup>1\*</sup>, S.L. Romero Guillena<sup>2</sup>, F. Gotor Sanchez Luengo<sup>3</sup>, B.O. Plasencia García de Diego<sup>4</sup>, O. Santamaría Gómez<sup>3</sup>

<sup>1</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Sevilla, Spain; <sup>2</sup> U.G.C Salud Mental Virgen Macarena Hospital, Department of Psychiatry, Sevilla, Spain; <sup>3</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Sevilla, Spain; <sup>4</sup> De la Merced Hospital-Osuna, Department of Psychiatry, Sevilla, Spain

\* Corresponding author

**Introduction.**– Risperidone long-acting injection (RLAI) and Paliperidone Palmitate one-month formulation (PP1M) are a valuable strategy for the treatment of Schizophrenia. Long-term follow-up studies are required to assess the effectiveness to preventing relapse.

**Objective.**– To assess the long-term efficacy of PP1M vs. RLAI in preventing relapse in schizophrenia

**Methods.**– Overall, 58 patients with schizophrenia (ICD-10) that started treatment with PP1M (30) or RLAI (28). At the beginning and end of a follow-up period of 54 months were performed:

- Positive and Negative Syndrome Scale (PANSS);
- Patient Satisfaction with Medication Questionnaire (PSMQ);
- Percentage of patients who remained relapse free at the end of the study.

Relapse was defined as  $\geq 1$  of the following: Psychiatric hospitalization, or an increase of 25% from base line in the PANSS total score,) for two consecutive assessments.

**Results.**– Percentage of patients who remained relapse free at the end of the 54 months was 48% for RLAI and 72% for PP1M. Sixty

percent of patients in RLAI group reported to be “satisfied” or “very satisfied”, while 80% of patients in PP1M group reported that. Sixty-five percent of caregivers in RLAI group reported to be “satisfied” or “very satisfied”, while 80% of them in PP1M group reported that.

**Conclusions.**– We observed a higher percentage of relapse free patients in the PP1M group. PP1M appears to have greater acceptance in both patients and family members than RLAI

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

For ICD-11, the WHO’s Working Group on Sexual Disorders and Sexual Health recommended moving transgender condition to a more medical chapter, preserving related categories -Gender Incongruence in Adolescence and Adulthood (GIAA) and Gender Incongruence in Childhood (GIC)- in the classification to ensure access to health care.

**Objective.**– In this symposium we present with ICD-11 field studies intended to evaluate whether distress and dysfunction are more related to social rejection in adult transgender individuals from very diverse countries (GIAA studies); and to evaluate the need for an ICD-11 category of GIC (GIC study).

**Method.**– In the GIAA studies, 490 transgender adults (103 from Brazil, 72 from France, 28 from Lebanon, 250 from Mexico, and 57 from South Africa) completed a retrospective interview about their experiences of gender incongruence, distress, dysfunction and social rejection. In the GIC study, 12 transgender individuals participated in a qualitative interview to address the consequences of receiving a form of diagnosis of GIC, and the usefulness of the ICD-11 GIC guidelines.

**Results.**– In all GIAA studies, a high proportion of participants – but not everyone – reported having experienced distress and/or functional impairment, which were predicted by social rejection rather than by marked incongruence. In the GIC study, although diagnoses during childhood were experienced as negative, all participants considered the proposed ICD-11 GIC category as beneficial.

**Conclusion.**– The GIAA studies support ICD-11 proposal to move transgender condition out of mental disorders chapter, while the GIC study provides some support for retention of the category.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>1</sup> Seoul National University College of Medicine, Psychiatry, Seoul, Republic of Korea; <sup>2</sup> Seoul National University Hospital, Child and Adolescent Psychiatry, Seoul, Republic of Korea; <sup>3</sup> Seoul National University College of Medicine, Clinical Medical Sciences, Seoul, Republic of Korea

\* Corresponding author

**Introduction.**– Smart-toys based on ‘Internet of Things (IoT)’ can be used in many fields such as education and u-mental health care system for various purposes. In this study, the smart-toy (toy-robot) serves to provide appropriate feedback to children’s performances on cognitive behavioral tasks via bluetooth.

**Objectives.**– This study aimed to evaluate the efficacy of a smart tablet-based cognitive behavioral training (CCBT) program using a smart-toy for 5–7-year old children. The program aimed to enhance children’s attention (auditory attention, visual attention) and behavioral inhibition (attention shifting, impulse control) abilities.

**Methods.**– Sixty-four children were randomly assigned to three groups:

- ‘training group’ for the CCBT, using a smart toy;
- ‘comparison group’ for an existing CCBT, using a personal computer without smart toys;
- ‘waiting group’, which was the control group.

Participants in the training group and the comparison group were trained for eight sessions, each spanning 30–40 minutes over four weeks. We assessed participants’ cognitive abilities three times:

- pre-training;
- post-training;
- one-month follow-up.

**Results.**– Both of the training and the comparison groups showed significant improvement in auditory attention, visual attention and impulse control abilities, compared to the waiting group. Especially, the training group showed more prominent and long-lasting training effect on the behavioral inhibition task than did the comparison group.

**Conclusions.**– This study showed that computerized cognitive behavioral training using a smart-toy is effective for enhancing attention and behavioral inhibition abilities of young children.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– Lurasidone has demonstrated efficacy and safety in the short-term treatment of schizophrenia in adolescents.

**Objective.**– To evaluate long-term effectiveness and safety of lurasidone in adolescents with schizophrenia.

**Method.**– Patients aged 13–17 years with schizophrenia who completed 6 weeks of double-blind (DB), placebo-controlled treatment with lurasidone were enrolled in a 2-year study in which patients continued on (or switched to) open-label lurasidone. We present here the results of an interim analysis at week 52. Efficacy was assessed using the Positive and Negative Syndrome Scale (PANSS). **Result.**– A total of 326 patients were randomized to lurasidone (37 or 74 mg/d) or placebo. At week 6, significant improvement was observed for lurasidone vs. placebo in PANSS total score (37 mg/d: –18.6 and 74 mg/d: –18.3 vs. placebo: –10.5;  $P < 0.001$  for both comparisons). Overall, 271 patients entered the open-label (OL) study and 69.7% completed 52 weeks of treatment, including 3.3% who discontinued due to lack of efficacy and 8.5% who discontinued due to adverse events. For the combined lurasidone group ( $n = 271$ ), mean change in PANSS total score, from OL baseline was –15.6 at week 52 (observed case analysis), and –10.9 (LOCF-endpoint). During OL treatment, the most common adverse events were headache (21.8%), nausea (11.8%) and anxiety (11.8%). Minimal effects were observed on body weight, lipids, and glycemic indices.

**Conclusion.**– In adolescents with schizophrenia, long-term treatment with lurasidone was safe and generally well-tolerated, and was associated with continued improvement in symptoms of schizophrenia.

### Exploring the autonomic correlates of symptoms and functional difficulties in psychosis using wearables

M. Cella\*, H. Zhimin, T. Wykes

King's College London, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom

\* Corresponding author

**Background.**– Increasingly mobile digital devices are used to assess mental health symptoms. This method uniquely allows to assess illness related phenomena and their impact on people's lives. In people with psychosis autonomic deregulations have been hypothesised to influence symptom intensity and functional difficulties. Here we present the results of two studies using a wearable device measuring physiological parameters alongside a mobile assessment of psychotic symptoms and functioning difficulties.

**Method.**– Thirty-six people with schizophrenia and 33 healthy controls were assessed for social functioning (Study-1) and psychotic symptoms (Study-2) using a mobile device for six consecutive days at random times. During this period, participants were asked to wear a wrist worn wearable device recording movement, electrodermal activity (EDA) and heart rate variability (HRV). Participants were also assessed with measures of functioning and symptom severity.

**Results.**– Study-1: Participants with schizophrenia reported being more alone than controls. In people with schizophrenia EDA magnitude while reporting being with strangers was significantly higher. Study-2: When experiencing distressing hallucinations participants with SZ showed reduced HRV and increased EDA magnitude compared to when they reported no distressing hallucination experience. A similar pattern was observed for delusion but not for depression.

**Discussion.**– Increased physiological arousal alongside reduced HRV is associated with important clinical features of schizophrenia. Portable and wearables devices are acceptable and may become, when further validated, routine means of clinical assessment. These devices can allow regular active and passive clinical information gathering and are promising tools to improve relapse prevention and people's recovery prospect.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### First benzodiazepine prescription in relation to onset and duration of untreated illness in schizophrenia, mood and anxiety spectrum disorders

V. De Carlo\*, B. Grancini, M. Vismara, B. Benatti, L. Cremaschi, C. Arici, L. Oldani, C. Palazzo, A.C. Altamura, B. Dell'Osso  
Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico- via Francesco Sforza 35, 20122, Milan, Italy, Department of Psychiatry, University of Milan, Milano, Italy

\* Corresponding author

**Introduction.**– It is established that the delayed initiation of an effective pharmacotherapy plays a significant role in the overall burden of psychiatric disorders. Often, such conditions are treated with

symptomatic drugs, i.e. benzodiazepines (BZDs), in relation to their rapid onset of action and safety profile.

**Objectives.**– Our study aimed to assess the influence of treatment with BZDs on the duration of untreated illness (DUI); secondly, we assessed whether other socio-demographic and clinical factors could influence the choice of BZD as first treatment of patients affected by Schizophrenia, Mood and Anxiety spectrum disorders.

**Methods.**– Study sample consisted of 545 patients. One-way ANOVA for continuous variables and  $\chi^2$  test for dichotomous ones were performed for comparison between patients who used BZDs as first treatment (BZD w/) and those who did not (BZD w/o).

**Results.**– DUI resulted significantly longer in BZD w/vs w/o patients. Moreover, BZDs w/subjects experienced more frequently anxious/depressive symptoms at onset, and less frequently psychotic symptoms. Furthermore, BZDs w/patients more frequently had first therapist contact following a personal decision, while BZDs w/o subjects after receiving others' suggestion. BZDs w/patients were found to seek more frequently psychologists or general practitioners (GP) rather than psychiatrists as first therapists. Finally, BZDs w/subjects experimented more frequently phobias.

**Conclusions.**– BZDs may delay the overall DUI and their prescription seems to be influenced by specific socio-demographic and clinical factors. Further studies are needed to raise awareness of BZD first prescription.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0156

### **Clinical staging: Application in stable community-dwelling schizophrenia patients**

O. Godin<sup>1\*</sup>, M. Leboyer<sup>2</sup>, F. Berna<sup>3</sup>, F. Schurhoff<sup>4</sup>, P.M. Llorca<sup>5</sup>

<sup>1</sup> UPMC, Institut Pierre Louis d'épidémiologie et de santé publique, Paris, France; <sup>2</sup> Inserm U955, Créteil, France, équipe de psychiatrie translationnelle, Créteil, France; <sup>3</sup> Université de Strasbourg, Inserm U1114, Psychiatry, Strasbourg, France; <sup>4</sup> Inserm U955, université de Paris-Est Créteil, Psychiatry, Créteil, France; <sup>5</sup> CMP B, CHU, EA 7280, faculté de médecine, université d'Auvergne, Psychiatry, Clermont-Ferrand, France

\* Corresponding author

**Introduction.**– During the last two decades, a growing interest for clinical staging has increasingly emerged in psychiatric disease such as Schizophrenia, however most of the studies focused on the early phases of the illness and the transition from prodromal phase to psychosis.

**Objectives.**– The aim of this study is to apply this clinical staging framework in patients with chronic schizophrenia.

**Methods.**– The Structural Clinical Interview for DSM-IV was used to confirm the diagnosis of schizophrenia. Patients were assessed using the Positive And Negative Syndrome Scale and Global Assessment of Functioning scale. Depression was measured by the Calgary Depression Rating Scale for Schizophrenia. We performed a cluster analysis using the severity of the illness, number of lifetime episode and functioning as discriminating variables.

**Results.**– Seven hundred and seventy stable community-dwelling schizophrenia patients from the multicentric FACE-SZ cohort were included. Patients were classified into 5 clinical stages, defined as stages 2A ( $n=89$ ), 2B ( $n=272$ ), 3A ( $n=241$ ), 3B ( $n=112$ ) and 4 ( $n=56$ ), ranging from favorable functioning and no symptoms to unremitted illness and poor functioning, according to the Scott et al criteria (Scott et al., 2013). Multivariable analysis of covariance showed that the worst the grade is, the lower the education level, the higher the depressive symptoms, the lower the adherence to medication and the lower the cognitive performances.

**Conclusion.**– These findings provide further support to the clinical staging model in patients with Schizophrenia. Depressive symptoms seem to have a major contribution for discriminate patients in clinical staging.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0157

### **Clinical characteristics associated with benzodiazepines' use in mood disorders**

B.M. Grancini<sup>\*</sup>, V. De Carlo, V. Matteo, B. Benatti, L. Cremaschi, C. Arici, L. Oldani, C. Palazzo, A.C. Altamura, B. Dell'Osso  
Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, via Francesco Sforza 35, 20122, Milan, Italy., Department of Psychiatry, University of Milan, Milano, Italy

\* Corresponding author

**Introduction.**– Mood disorders are prevalent and burdensome diseases with a chronic course of illness. More often, especially for mild forms, patients are not treated in psychiatric services but they are managed by general practitioners (GPs). Among different medications, benzodiazepines (BDZ) are not recommended for the treatment of mood disorders, considering the lack of antidepressant effect and long-term side effects.

**Objectives.**– The present study aims to identify clinical variables related to BDZ use, to better characterize and recognize their misuse.

**Methods.**– Overall, 304 in- and out-patients with major depressive disorder (MDD), bipolar disorder (BD) and adjustment disorder (AD) were recruited. Their socio-demographical and clinical variables were collected and statistical analysis were conducted to compare patients with BDZ as first treatment (BDZ w/) and those without (BDZ w/o).

**Results.**– BDZ w/subjects were more frequently affected by AD and less frequently by BD compared to BDZ w/o ones. Moreover, BDZ w/patients reported more often anxious symptoms at onset and referred more frequently to psychologist or GPs rather than a psychiatrist. Furthermore, BDZ w/were less frequently treated as inpatients than BDZ w/o ones.

**Conclusions.**– The identification of clinical characteristics related to a more frequent use of BZD is necessary to better recognize their misuse. A more cautious prescription of BZD is recommended to prevent long-term side effects, abuse and withdrawal concerns.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Is there an association between theory of mind ability and biological rhythm disturbances in individuals with schizophrenia?**

C. Sahbaz, A. Kurtulmuş<sup>\*</sup>, İ. Kirpinar  
Bezmi Alem Vakıf University, Psychiatry, Istanbul, Turkey

\* Corresponding author

**Introduction.**– Theory of mind (ToM) deficits are widely recognized in schizophrenia and not limited to a particular stage of disorder and persist even after the remission. It has been found that desynchronisation of circadian rhythms negatively affects aspects of cognitive functions but there is not much data in the literature about association between biological rhythm disturbances and social cognition domains.

**Objectives.**– In this study we investigate the relationship between biological rhythm disturbances and ToM abilities in patients with schizophrenia.

**Methods.**– Fifty patients with schizophrenia and 48 healthy participants were recruited for the study. ToM was measured with the Reading the Mind in the Eyes Test (RMET). Biological Rhythms Interview of Assessment in Neuropsychiatry (BRIAN), Morningness-Eveningness Questionnaire (MEQ), Pittsburg Sleep Quality Index (PSQ) and Positive and Negative Syndrome Scale (PANSS) were applied.

**Results.**– In comparison to the control group, the schizophrenia group performed significantly worse on RMET task ( $P < 0.001$ ). PSQ and BRIAN scores were significantly higher and MEQ scores were significantly lower in schizophrenia group ( $P < 0.01$ ). In patient group, BRIAN scores were significantly negatively correlated with RMET scores ( $P = 0.02$ ;  $r = -0.34$ ). There was also a significant positive correlation between BRIAN scores and PANSS total and subscale scores ( $P = 0.001$ ).

**Conclusions.**– To our knowledge, this is the first study to investigate the relationship between biological rhythm disturbances and social cognitive functions in individuals with schizophrenia. These results suggest the effect of biological rhythm disturbances on social cognition impairments in schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Impact of childhood trauma on sensory gating in patients with first-episode schizophrenia**

X.B. Li

Capital Medical University, Beijing An Ding Hospital, Beijing, China

**Background.**– Childhood trauma (CT) has been found to contribute to the onset of schizophrenia, and auditory sensory gating deficit is a leading endophenotype for schizophrenia, however the association between the CT and sensory gating in first-episode schizophrenia remains an area that has not been explored.

**Methods.**– Fifty-six patients and 49 age and sex-matched healthy controls were assessed using the Childhood Trauma Questionnaire-Short Form (CTQ-SF) for childhood trauma and Positive and Negative Syndrome Scale (PANSS) for symptoms severity. Sensory gating was tested using the modified paradigm, perceived spatial separation-induced repulse inhibition (PSS PPI) as well as the perceived spatial co-location PPI (PSC PPI or classical PPI).

**Results.**– Associations between CT, PPI and symptoms were analyzed. Comparing with healthy controls, the patients had significantly higher score on sexual abuse ( $t = 2.729$ ,  $P < 0.05$ ), lower PSS PPI, % (ISI = 120ms and ISI = 60ms) ( $t = -3.089$ ,  $-4.196$ ,  $P < 0.05$ ). There was significant positive correlation between emotional neglect score, CTQ-SF total and positive symptomatology ( $r = 0.366$ ,  $P = 0.005$ ;  $r = 0.456$ ,  $P = 0.036$ , respectively). There was negative correlation between PSS PPI, % (ISI = 120 ms) and PANSS positive scale ( $r = -0.466$ ,  $P < 0.05$ ). There was significant negative correlation between emotional abuse, CTQ-SF total and PSC PPI, % (ISI = 60ms) ( $r = -0.519$ ,  $P = 0.006$ ;  $r = -0.495$ ,  $P = 0.026$ , respectively). Multiple linear regression analyses demonstrated the CTQ-SF total was negatively associated with PSS PPI (ISI = 120 ms) ( $P = 0.018$ ).

**Conclusions.**– The current study showed that the effects of CT on sensory gating in patients with first-episode schizophrenia, thus we hypothesize that CT may be risk factors to the occurrence of schizophrenia through its effects on sensory gating.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

\* Corresponding author

**Introduction.**– Cognitive deficits in psychotic patients can be observed already during prodromal phase. Moreover, cognitive impairments were found in unaffected relatives of patients, as well. **Objectives.**– Our study aim was to examine a cognitive profile of healthy siblings of patients with first episode of psychotic disorder and to compare it with the profile of patients and matching healthy subjects.

**Methods.**– Study sample consisted of 4 groups: (1) patients with first episode of psychosis, (2) – their healthy siblings, (3) control subjects matched according to age and education to patients, (4) controls matched to siblings. All study subjects were tested with a battery of neuropsychological tests measuring memory, executive functions, attention, visual-spatial skills, language skills, and psychomotor speed.

**Results.**– The total of 84 study subjects were included:

- patients  $n = 20$ ;
- siblings  $n = 22$ ;
- controls to patients  $n = 20$ ;
- controls to siblings  $n = 22$ , with even sex distribution.

The patients had significantly lower scores than their controls in all cognitive domains, the greatest difference was found in verbal memory ( $P = .000$ ) and abstraction ( $P = 0.002$ ). The siblings performed significantly worse than their controls in abstraction ( $P = 0.006$ ), non-significant trend was also observed in verbal memory. Interestingly, patients and siblings in these two domains did not differ.

**Conclusions.**– Our findings, cognitive deficits of healthy siblings in abstraction and verbal memory, comparable to those in first-episode patients, suggest that specific cognitive domains can be considered as an endophenotype of psychosis.

**Funding.**– Supported by the grant projects MH CR AZV 15-28998A, GACR 16-13093S, MEYS NPU4NUDZ: LO1611.

\* Corresponding author

**Introduction.**– Transition into parenthood is a demanding life phase and exposes becoming parents to vulnerability for depression and stress–postpartum depression is the most common complication after childbearing in Sweden. This in turn is associated with adverse

psychological and physiological outcomes for the infant, of great importance for population health in the long term.

**Objectives.**– To evaluate the effectiveness of Mindfulness Based Childbirth and Parenting during pregnancy in:

– reducing depression symptoms and perceived stress, from pre-to post-intervention and three months after birth among mothers and partners;

– normalizing levels of inflammatory and stress markers from pre-to post-intervention in the serum of pregnant mothers.

**Methods.**– Randomized Controlled Trial. In total, 195 participants and their partners have been included in the study. Depression symptoms have been assessed with the Edinburgh Depression Scale and Stress symptoms with the Perceived Stress Scale. Serum samples have been collected from the first 70 pregnant women and have been analyzed using a sensitive radioimmunoassay procedure.

**Results.**– Final data analyses among all participants, or analyses of serum samples have not yet been conducted, but will be completed in December 2017. Preliminary analyses among the first 87 pregnant women showed a significant within-group reduction of depression symptoms in the intervention group. With regard to perceived stress, no indications of the intervention superiority were found.

**Conclusions.**– So far, this study has given primary indications of a beneficial effect on depression symptoms from the mindfulness intervention. Full analyses of all data will provide more conclusive results.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The effects of psilocybin on brain EEG activity and connectivity in healthy volunteers – focus on the dynamics of the psychedelic state**

T. Palenicek\*, F. Tyls, M. Viktorinova, R. Androvicova, M. Brunovsky, P. Zach, A. Bravermanova, J. Korcak, J. Horacek  
National Institute of Mental Health, Research program on brain electrophysiology, Klecany, Czech Republic

\* Corresponding author

**Introduction.**– A serotonin 5-HT<sub>2A/C</sub> agonist, psychedelic drug psilocybin, is gaining attention as a potential therapeutic tool for anxiety and depression. Psilocybin induces desynchronization of the EEG during the peak of its effects, continuous data are lacking.

**Objectives.**– We focused on the dynamics of changes in neuropsychological parameters, brain activity and connectivity after oral administration of psilocybin.

**Methods.**– Twenty healthy volunteers (10 M/10F, 28–50yrs) were enrolled in this placebo controlled cross over double blind trial. A standard 19 channel EEG (registered before and 60, 90, 180 and 360 min after psilocybin (0.26 mg/kg) ingestion), brief psychiatric rating scale (BPRS), plasma levels of psilocin were collected several times over the session, a subjective scale “altered scale of consciousness scale (ASCs)” at the end of measurements. Current source density and connectivity were analysed by Low Resolution Brain Electromagnetic Tomography (LORETA).

**Results.**– Psilocybin induced psychotic-like symptoms, especially changes in perception and thought disturbances, peaking at 90 min after ingestion along with serum psilocin levels. Induced global decrease of the alpha current source density in the occipital cortex was negatively correlated with the intensity of effects. The overall connectivity decreased in the alpha band, but increased in all other frequency bands at peak, however, six hours after ingestion, the effects were inverted.

**Conclusions.**– The study shows that psilocybin dynamically shifts the brain from one connectivity state at baseline through a peak effect to reach another global connectivity state at the end. This work was supported by grants ED2.1.00/03.0078, LO1611/NPU I, MICR VI20172020056 and PROGRES Q35.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

Inserm U 1000, SHFJ CEA, neuroimaging and psychiatry, Orsay, France

\* Corresponding author

**Background.**– Immune system dysfunction is a hypothesis in the psychopathology of schizophrenia but the impact of antipsychotic treatment within this system is not clear. The aim of this meta-analysis was to investigate the impact of antipsychotic treatment on cytokine levels in in vivo studies on schizophrenia.

**Methods.**– After a systematic database search, original data were extracted with the help of authors. Means and standard deviations were extracted to calculate standardized mean differences (SMD). Cytokine levels were compared in vivo in schizophrenia patients, before and after antipsychotic treatment. Meta-regressions were performed to explore the influence of demographic and clinical variables on cytokine level SMDs.

**Results.**– Forty-seven studies were included in this meta-analysis. Pro-inflammatory cytokine level decreases were found for IL-1  $\beta$  levels ( $P < 0.0001$ ), IFN- $\gamma$  ( $P = 0.01$ ) and a statistical trend towards a decrease in IL-6 ( $P = 0.08$ ) and TNF- $\alpha$  ( $P = 0.07$ ) levels. An anti-inflammatory cytokine level increase was found for sTNF-R2 ( $P < 0.001$ ) and sIL2-R ( $P = 0.03$ ) levels. A meta-regression analysis found a correlation between IL-6 level SMD and positive schizophrenia symptom score SMD before and after treatment ( $P = 0.01$ ).

**Conclusions.**– The present meta-analysis provides evidence that antipsychotic treatment has an anti-inflammatory effect and could normalize immune balance dysfunction in schizophrenia. IL-6 level normalization could be a marker of illness equilibration, and thus used in clinical practice.

\* Corresponding author

Oculomotor dysfunction is one of the most replicated findings in schizophrenia. We studied saccadic performance in the group of clinical high risk of psychosis individuals (CHR) as a part of schizophrenia continuum. In this study, we have tested saccadic performance in different schizophrenia dimensions, according to the three-syndrome model of schizophrenia. The schizophrenia

patients were divided into three groups based on the sum of the global SAPS and SANS scores: patients with predominantly negative symptoms (NS); positive symptoms (PS) and disorganization symptoms (DS). Horizontal eye movements were recorded by using videonystagmograph. We measured peak velocity, latency and accuracy in prosaccade, antisaccade and predictive saccade tasks as well as error rates in the antisaccade task.

The study included 156 schizophrenia patients, 42 individuals at clinical high risk for psychosis and 61 healthy volunteers.

We found that the error rate in antisaccade task was significantly higher in CHR compared to controls. The performance on antisaccade task in CHR was close to the one of NS and PS groups of schizophrenia patients. The accuracy of reflexive saccade in CHR group was close to the results of NS group.

Latencies of predictive and reflexive saccades were longer in the NS than in controls. PS, DS and CHR did not differ in terms of latencies from controls. In reflexive saccades task accuracies in all schizophrenia groups and CHR group were worse than in controls. Our results support the idea that eye movement alterations are possible markers of clinical high risk of psychosis.

### Action-related language impairments in schizophrenia spectrum disorders

D. Smirnova<sup>1,2\*</sup>, M. Clark<sup>2</sup>, A. Jablensky<sup>2</sup>, J. Badcock<sup>2</sup>

<sup>1</sup> Samara State Medical University, Department of Psychiatry, Samara, Russia; <sup>2</sup> University of Western Australia, Centre for Clinical Research in Neuropsychiatry, Perth, Australia

\* Corresponding author

*Objectives.*– Action fluency deficit has been proposed as a potential endophenotypic marker for schizophrenia but its cognitive and language-related origins have not been examined.

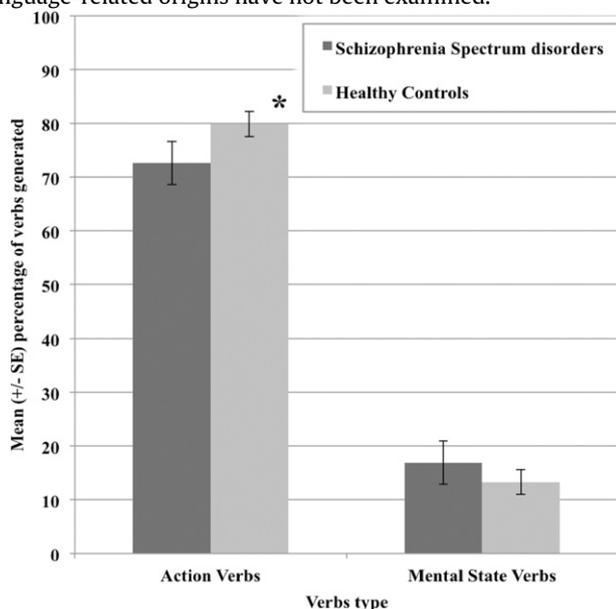

Fig. 1

*Methods.*– Action fluency task performance was studied in 46 patients with schizophrenia spectrum disorders and 76 healthy controls from the Western Australian Family Study of Schizophrenia. Verb responses ( $n=2219$ ) were classified as action or mental state verbs, using standard taxonomies. Lexical characteristics of the verbs were evaluated. Participants' clinical symptom, schizotypal personality traits and general cognitive abilities were also examined.

*Results.*– Independent inter-rater agreement on semantic categorization was high,  $k=0.905$  ( $P<0.001$ ), 95%CI (0.880,0.930). The proportion of action verbs was significantly lower in patients (Mean = 72.63,  $SD=6.73$ ) than in controls (Mean = 79.83,  $SD=3.81$ );  $t(120)=2.57$ ;  $P=0.011$ ; Cohen's  $d=-0.470$ . However, the proportion of mental state verbs produced by patients (Mean = 16.90,  $SD=13.57$ ) and controls (Mean = 13.30,  $SD=10.14$ ) did not differ,  $t(120)=1.67$ ;  $P=0.099$ ; Cohen's  $d=0.300$  (Figure 1).

Patients' action verbs were significantly less concrete (more abstract) (Median = 3.93,  $IQR=0.30$ ) than those produced by controls (Median = 4.03,  $IQR=0.19$ );  $U=1307.00$ ;  $z=-2.330$ ;  $P=0.020$ ; effect size  $r=0.203$ , reflecting a lower precision of encoding or reactivation of the sensory, motor and affective information associated with the core verb meaning. Action verbs fluency was positively correlated with memory and intelligence but not with executive function, medication dose or clinical symptoms. Conversely, fluency in action (but not mental state) verbs was negatively correlated with the interpersonal schizotypal traits denoting an increased sense of psychological distance from others.

*Conclusion.*– Impaired action verb, but intact mental state verb generation points to the neural separability of these processes and specific relationship between action-related language, memory deficits and poor interpersonal functioning in schizophrenia.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The place of VMAT-2 inhibitors for the treatment of tardive dyskinesia: A meta-analysis of randomized controlled trials

M. Solmi<sup>1\*</sup>, G. Pigato<sup>2</sup>, C. Correll<sup>3</sup>

<sup>1</sup> University of padua, Neurosciences Department, Padua, Italy; <sup>2</sup> University Hospital Padua, psychiatry, Padova, Italy; <sup>3</sup> University of Padua, Neurosciences, Padua, Italy

\* Corresponding author

*Purpose:* To summarize the characteristics, efficacy and safety of VMAT-2 inhibitors used for patients with tardive dyskinesia (TD).

*Patients and methods.*– Systematic review and meta-analysis. *Results.*– Altogether, two acute, 12-week, placebo-controlled trials with deutetrabenzine ( $n=413$ ) dosed at 12–48 mg/day and four acute, 4–6-week, placebo-controlled trials with valbenazine ( $n=486$ ) dosed at 12.5–100 mg/day were meta-analyzable, without meta-analyzable, high-quality data for tetrabenazine. Regarding reduction in total Abnormal Involuntary Movement Scale (AIMS) scores (primary outcome), both deutetrabenzine ( $k=2$ ,  $n=413$ , standardized mean difference (SMD) =  $-0.4$ , 95%CI  $-0.19$ ,  $-0.62$ ,  $P<0.001$ ; weighted mean difference (WMD) =  $-1.44$ , 95%CI  $-0.67$ ,  $-2.19$ ,  $P<0.001$ ) and valbenazine ( $k=4$ ,  $n=421$ , SMD =  $-0.59$ , 95%CI  $-0.26$ ,  $-0.91$ ,  $P<0.001$ ; WMD =  $-2.07$ , 95%CI  $-1.08$ ,  $-3.05$ ,  $P<0.001$ ) significantly outperformed placebo. Results were confirmed regarding responder rates ( $\geq 50\%$  AIMS total score reduction; deutetrabenzine: risk ratio (RR) = 2.13 (95%CI = 1.10–4.12,  $P=0.024$ , number-needed-to-treat (NNT) = 7, 95%CI = 3–333,  $P=0.046$ ; valbenazine: RR = 3.05, 95%CI = 1.81–5.11,  $P<0.001$ , NNT = 4, 95%CI 3–6,  $P<0.001$ ). Less consistent results emerged from patient global impression based response and clinical global impression for deutetrabenzine ( $P=0.15$ ,  $P=0.088$  respectively), and for clinical global impression change score for valbenazine ( $P=0.67$ ). Additionally, both deutetrabenzine and valbenazine acute efficacy trials were continued with open-label designs up to 159 (ongoing) and 48 weeks respectively with increased responder rates at endpoints ( $P=NA$ ), and symptom recurrence after valbenazine withdrawal. No increased cumulative or specific

adverse events vs placebo (acute trials), o vs acute phases of the trials (open-label extensions) were reported.

**Conclusion.**– The two recently FDA-approved VMAT-2 inhibitors, valbenazine and deutetrabenazine, are effective in treating TD, in acute and long-term treatments. No concerns about any increased risk of depression or suicide have arisen in the included stable psychiatric population with TD. No head-to-head comparison among VMAT-2 inhibitors and no high-quality, meta-analyzable data are available for tetrabenazine in TD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Is stress sensitivity a better marker of risk than ultra high risk (UHR) for psychosis criteria?

H. Stain<sup>1\*</sup>, L. Webster<sup>1</sup>, R. Wadman<sup>2</sup>, L. Mawn<sup>3</sup>, N. Akhter<sup>4</sup>, A. Kasim<sup>4</sup>

<sup>1</sup> Leeds Trinity University, School of Social and Health Sciences, Horsforth Leeds, United Kingdom; <sup>2</sup> University of York, Department of Health Science, York, United Kingdom; <sup>3</sup> Newcastle University, School of Psychology, Newcastle, United Kingdom; <sup>4</sup> Durham University, Wolfson Research Institute, Durham, United Kingdom

\* Corresponding author

**Background.**– Increased stress sensitivity has been associated with experiences of childhood adversity and ultra high risk (UHR) for psychosis status (Lardinois et al., 2011). A recent meta-analysis reported that greater stress sensitivity was associated with increased odds for psychotic experiences (DeVylder et al., 2016). There is evidence that stress sensitivity mediates the relationship between adversity and psychotic experiences (Gibson et al., 2014). We sought to explore these relationships in a university student population and include a focus on functioning and academic self-efficacy

**Method.**– An online survey was completed by 500 university students. The survey included measures of stress sensitivity, depressed mood, wellbeing, functioning (social and academic) and adversity (childhood and current). UHR status was measured by the threshold of the Prodromal Questionnaire-16 (PQ).

**Results.**– The majority of students were female (81%) and undergraduate (92%) with 102 meeting UHR threshold. Rates of childhood (50% vs 32%,  $P < .001$ ) and current adversity (82% vs 72%,  $P < .05$ ) were significantly higher for the UHR than non UHR participants. The UHR group had significantly higher stress sensitivity ( $P < .001$ ) and decreased functioning and wellbeing. A model exploring the possible predictive value of stress sensitivity for academic self-efficacy, wellbeing and UHR for psychosis will be presented.

**Conclusion.**– Stress sensitivity offers the opportunity for broad screening of vulnerable groups such as young people in transition periods. Importantly, it avoids the use of potentially stigmatising terms such as psychosis and personality disorder, and thus may have utility in screening for risk for the development of mental health problems.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Fully automated speech-based frontline screening for dementia

J. Tröger<sup>1\*</sup>, N. Linz<sup>1</sup>, A. König<sup>2</sup>, J. Peter<sup>3</sup>, J. Alexandersson<sup>1</sup>, P. Robert<sup>2</sup>

<sup>1</sup> German Research Centre for Artificial Intelligence DFKI, Intelligent User Interfaces, Saarbrücken, Germany; <sup>2</sup> IA CHU universit e C te d'Azur, Memory Center, CoBTeK, Nice, France; <sup>3</sup> University of Bern, Geriatric Psychiatry and Psychotherapy, Bern, Switzerland

\* Corresponding author

**Introduction.**– New telemedicine tools for effective frontline screening for dementia are needed. Automatic speech analysis can be a powerful solution to address this need as speech can be analysed via telephone.

**Objectives.**– To benchmark a fully automated dementia frontline screening based on automatic speech recognition and machine learning classification.

**Methods.**– A total of 166 elderly people diagnosed with either dementia (D; 79), Mild Cognitive Impairment (MCI; 47) or only subjective memory complaints (SMC; 40), were assessed at the memory clinic at the Institut Claude Pompidou in Nice, France. Within the scope of the Dem@care and ELEMENT projects participants performed a battery of speech-based cognitive tests. Speech was recorded and processed using automatic speech recognition (Figure 1). The experiment for this study is solely based on the recordings of the 60s semantic verbal fluency (SVF). Qualitative SVF features were extracted according to previous work (Linz et al., 2017; Using Neural Word Embeddings in the Analysis of the Clinical Semantic Verbal Fluency Task). For classification, Support Vector Machines with 10-fold cross validation were used.

**Results.**– Despite imperfect ASR – mainly misses in SVF correct responses – for the screening scenario (SMC vs. MCI & D) the approach achieves a sensitivity of .99 and a specificity of .74. Inter-group classification results were as follows (sensitivity/specificity): SMC vs. D (.91/.66), SMC vs. MCI (.85/.62) and MCI vs. D (.86/.49).

**Conclusion.**– The results show high ecological validity of the proposed automatic analysis for frontline screening of dementia. The high sensitivity in the screening scenario underlines its feasibility in telemedicine applications.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Angiotensin-converting-enzyme inhibitors (ACEI) as a repurposed treatment for a unipolar depression: Results of a 20-year follow-up study

D. Wincewicz<sup>1\*</sup>, T. Tolmunen<sup>2</sup>, A.K. Brem<sup>3,4</sup>, J. Kauhanen<sup>5</sup>, S. Lehto<sup>2,6,7</sup>

<sup>1</sup> Independent Public Mental Healthcare Centre, Department of Old Age Psychiatry, Choroszcz, Poland; <sup>2</sup> Kuopio University Hospital, Department of Psychiatry, Kuopio, Finland; <sup>3</sup> Max Planck Institute of Psychiatry, Department of Neuropsychology, Munich, Germany; <sup>4</sup> BIDMC Harvard Medical School, Berenson–Allen Center for Noninvasive Brain Stimulation, Department of Neurology, Division of Interventional Cognitive Neurology, Boston, USA; <sup>5</sup> University of Eastern Finland, Institute of Public Health and Clinical Nutrition, Kuopio, Finland; <sup>6</sup> University of Helsinki, Department of Psychology and Department of Psychiatry, Helsinki, Finland; <sup>7</sup> University of Eastern Finland, Institute of Clinical Medicine, Kuopio, Finland

\* Corresponding author

**Introduction.**– Comorbidity between psychiatric and cardiovascular disorders is a global public health priority. This bidirectional relationship is suggested to exist due to shared functional changes, understanding of which may lead to new or repurposed treat-

ment options for affective disorders. While CNS drug development has been underwhelming with RCTs not providing definitive evidence of antidepressant effectiveness, accumulating preclinical and clinical data consistently indicate the involvement of Angiotensin-Converting-Enzyme Inhibitors (ACEIs) and Angiotensin II Receptor Blockers (ARBs) in mood regulation.

**Objectives.**– To evaluate the mood-regulating capacity of orally delivered ACEI and ARB, the treatment-diagnosis association was examined using a prospective follow-up setting in the population-based Kuopio Ischemic Heart Disease Risk Factor Study.

**Methods.**– The study was conducted on a sample of 1774 subjects (920 females, 854 males; age range at baseline: 42–61 years) from Eastern Finland. A hospital discharge diagnosis of unipolar depression was used as outcome variable. Prospective analyses were conducted with the Cox proportional hazards model, adjusted for relevant background variables.

**Results.**– The risk of unipolar depression diagnosis ( $n=46$ ) was significantly reduced in ACEI-treated participants ( $HR=0.343$ , 95% CI 0.15–0.77,  $P=0.010$ ), but not in ARB-treated participants ( $HR=0.442$ , 95% CI 0.18–1.08,  $P=0.072$ ).

**Conclusion.**– ACEI treatment is associated with a statistically significant decreased risk for unipolar depression manifestation. However, our findings may not be generalizable to individuals below middle age.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Prediction of CYP3A metabolic phenotype in patients with ziprasidone by blood concentration measurement**

Y. Zhang<sup>1</sup>, Y. Li, J. Jiang, W. Zhu, F. Liu, X. Cui, Z. Dai, B. Wu, Q. Wu  
Xi'an Mental Health Center, Pharmacy Lab, Xi'an, China

\* Corresponding author

**Background.**– With the development of pharmacogenomics in recent years, more and more attention has been paid to the molecular genetic mechanism of pharmacokinetics among different individuals. Gene polymorphisms of drug metabolizing enzymes can affect the retention of drugs in vivo. However, the cost of gene polymorphism of drug metabolizing enzymes determination is high.

**Objective.**– The aim of this study was to investigate the relationship of CYP3A gene polymorphism and plasma concentration of ziprasidone injection

**Methods.**– The serum concentration of ziprasidone was determined by two-dimensional high performance liquid chromatography (HPLC) and the distribution proportion of CYP3A gene polymorphism in hospital database was calculated.

**Results.**– A total of 28 patients of ziprasidone blood concentration results showed that: 14 patients ziprasidone average half-life is 7.92, accounting for 53.57%; 8 patients average half-life is 5.37, accounting for 28.57%; 4 patients average half-life is 2.87, accounting for 14.29%; 1 patients half-life is 1.23, accounting for 3.57%. The CYP3A5 statistical data of 1327 patients in the center showed that the weak metabolic type accounted for 52.60%, the intermediate metabolic type accounted for 40.17%, and the fast metabolic type accounted for 7.23%.

**Conclusion.**– The metabolic characteristics of ziprasidone in 28 patients were closely related to the CYP3A5 gene polymorphism in 1327 patients. The plasma concentration could reflect the metabolic type of the patients in some extent.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

#### **The impact of childhood trauma on brain structure and stress response: Differences between first-episode psychosis patients and healthy controls**

S. Ciufolini<sup>1\*</sup>, M. Valeria<sup>2</sup>, K. Matthew<sup>1</sup>, M. Tiago<sup>1</sup>, M. Robin<sup>1</sup>, D. Anthony<sup>1</sup>, P. Carmine<sup>2</sup>, P. Dazzan<sup>1</sup>

<sup>1</sup> Institute of Psychiatry, Psychology and Neuroscience, King's College London, Psychosis Studies, London, United Kingdom;

<sup>2</sup> Institute of Psychiatry, Psychology and Neuroscience, King's College London, Psychological Medicine, London, United Kingdom

\* Corresponding author

**Introduction.**– The relationship between childhood trauma, brain alterations and dysfunctions of the stress response system, the Hypothalamic-Pituitary-Adrenal axis (HPA), remains unclear in patients with psychosis as well as in healthy population with history of significant abuse in childhood.

**Objectives.**– Investigate the impact of childhood abuse on the brain structure and stress response in individuals with and without psychosis.

**Methods.**– Initially, a vertex-by-vertex two-way ANCOVA analysis explored between-group differences in cortical thickness related to case (86 first episode psychosis patients; 49 with significant childhood abuse) and control (64; 30 with significant childhood abuse) status, and childhood abuse exposure. Finally a regression model investigated the relationship between Basal Cortisol Production (BCP) and cortical thickness of regions in which a significant association with abuse was identified.

**Results.**– The right medial-orbital-frontal gyrus and lingual gyrus showed thinning in individuals with childhood abuse (irrespective of being a case) and their cortical thickness negatively correlated with BCP. Furthermore the right cuneus, latero-orbital-frontal gyrus, post-central gyrus, pre-central gyrus, superior-frontal gyrus and inferior-parietal gyrus were thinner in cases and thicker in controls with abuse suggesting an interaction between group (patient/control) and abuse. Thickness of the right cuneus, latero-orbital-frontal gyrus, superior-frontal and the inferior-parietal gyrus negatively correlated with BCP in controls but not in cases.

**Conclusions.**– Childhood abuse has a long-term effect on the adult brain in areas involved in social adjustment, mood control and drive. Interestingly, this effect is divergent in cases and controls, suggesting a specific vulnerability in individuals who would eventually develop psychosis possibly implying an adaptive mechanism to environmental stress.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

#### **The role of spirituality in the care of older people with mental illness**

S. Curran

Fieldhead Hospital, Old Age Psychiatry, Waverley, United Kingdom

The role of spirituality in mental health care and older people is becoming increasingly recognised but it remains a misunder-

stood term and assessment and practice remains fragmented in the British NHS. This presentation will focus on spiritually competent practice in health care with an emphasis on mental health in older people. It will also examine the role of training and education in developing spiritually competent practitioners. Spirituality and spiritual competencies for practitioners will be defined. Service delivery that is designed to facilitate person-centred care is central to achieving high quality spiritually competent care for patients. Narrowly-defined spiritual competencies should be combined with compassionate motivation. Even when both are present, fragmented and pressured service delivery denies practitioners the time and opportunities to address the needs of the whole person and makes spiritually competent practice difficult if not impossible to achieve.

The presentation would increase interest and understanding in the three areas including:

- spiritual competencies;
- personal qualities and development of the practitioner;
- opportunities provided by the organisation of care.

As well as sharing ideas, I would hope to foster a discussion on these neglected areas from participants and generate innovative ideas through discussion [1].

### Brain health complications of diabetes mellitus: Awareness among individuals with diabetes and the general population in Ireland

C. Dolan<sup>1</sup>, R. Glynn<sup>2</sup>, S. Griffin<sup>3</sup>, G. McCarthy<sup>4</sup>, B. Lawlor<sup>5</sup>

<sup>1</sup> Sligo Mental Health Services, Psychiatry of Later Life, Sligo, Ireland;

<sup>2</sup> Health Service Executive, Public Health and Epidemiology, Dublin, Ireland;

<sup>3</sup> Psychiatry, Dublin, Ireland;

<sup>4</sup> Sligo Leitrim Mental Health Services, Psychiatry of Later Life, Sligo, Ireland;

<sup>5</sup> Trinity College Dublin, Psychiatry, Dublin, Ireland

\* Corresponding author

*Introduction.*– Awareness of the brain as vulnerable to adverse effects of diabetes resulting in depression, cognitive impairment and dementia, is growing among the research and clinical community. Such complications can adversely affect quality of life and diabetes outcomes. Research exploring translation of these findings into awareness among individuals with diabetes and the general population is lacking

*Objectives.*– To identify awareness of potential brain health complications of diabetes among patients and the public via an interviewer administered questionnaire.

*Methods.*– This observational, cross-sectional survey study recruited adults with diabetes attending a specialist diabetes clinic and representatives of the Irish general population. An interviewer-administered, study specific questionnaire gathered data on respondents' knowledge of:

- brain health complications of diabetes;
- modifiable risk factors for both dementia.

Data was also gathered on socio-demographic, personal health and lifestyle factors. Multivariable logistic regression was undertaken to identify variables independently associated with knowledge.

*Results.*– A total of 502 adult respondents: 250 in diabetes group (37.2% female, mean age 62.7 ± 14.23 years) and 252 in general population group (51.2% female, mean age 46.5 ± 16.58 years).

Respondent knowledge of (i) potential diabetes complications is outlined in Figure 1.

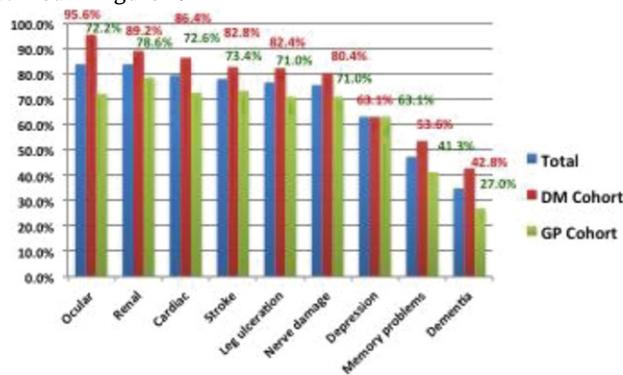

Fig. 1. and (ii) modifiable risk factors for dementia in Figure 2.

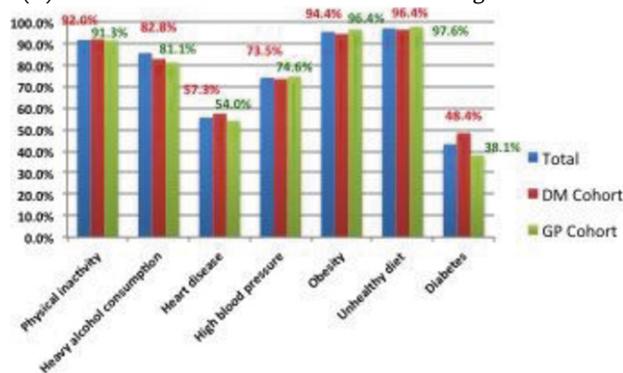

Fig. 2.

*Conclusions.*– This study demonstrates poor awareness of brain health complications of diabetes and modifiable risk factors for dementia among individuals with diabetes and general population in Ireland. Results suggest a need for expansion of public awareness campaigns to promote awareness of brain health complications of diabetes as part of a life-course approach to dementia prevention.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

<sup>2</sup> University of Saint-Étienne, Endocrinology, Saint-Étienne cedex 2, France;

<sup>3</sup> University of Saint-Étienne, Psychiatry & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France;

<sup>4</sup> University of Saint-Étienne, Psychiatry & Eating Disorders Reference Center & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France;

<sup>5</sup> University of Saint-Étienne, EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France

\* Corresponding author

*Introduction.*– Constitutional thinness (CT) is an underweight state characterized by normal menstruations and feeding behaviour. Thinness is the only resemblance between Anorexia Nervosa (AN) and CT. Removal of amenorrhea in the new DSM-5 definition of AN might lead to misdiagnosis between these populations.

**Objectives.**– The objective was to compare CT, AN and Controls in terms of biological, anthropometric, and psychological markers in order to better distinguish AN from CT subjects

**Methods.**– This retrospective study conducted from 2000 to 2015 included three groups of young women: 56 CT, 40 restrictive-type AN and 54 controls. Evaluation was made in all groups before any intervention: body composition, nutritional markers, pituitary hormones, bone markers and psychological scores. For every markers, a receiver Operator Characteristics (ROC) curve was calculated to evaluate the accuracy of differentiation between AN and CT.

**Results.**– For the majority of studied parameters, CT subjects were similar to controls but dramatically different from AN subjects. According to ROC data, while psychological scores were unsuccessful to differentiate AN from CT, except for DEBQ Restrained Eating item, free-T3 and Leptin were strong tools for AN and CT distinction with high sensitivities and specificities and low *P* values (<0.0001).

**Conclusions.**– Taking AN and CT distinction as a major objective, the exclusive use of psychological criteria is not sufficient and should be completed by at least free T3 determination, which is a cheap and an accessible laboratory testing for general practitioners. The final goal is to avoid social stigmatization and excessive useless therapies for CT women.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Hunger feeling in anorexia nervosa and ghrelin plasma level**

N. Germain<sup>1\*</sup>, T. Sigaud<sup>2</sup>, A. Duez<sup>3</sup>, F. Lang<sup>2</sup>, B. Estour<sup>1</sup>, B. Galusca<sup>1</sup>

<sup>1</sup> University of Saint-Étienne, Endocrinology & Eating Disorders Reference Center & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France;

<sup>2</sup> University of Saint-Étienne, Psychiatry & Eating Disorders Reference Center & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France;

<sup>3</sup> University of Saint-Étienne, Biochemistry & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France

\* Corresponding author

**Introduction.**– Self-food deprivation in Restrictive Anorexia nervosa (AN) contrasts with high but variable orexigenic ghrelin plasma level. As therapy one's aim is to bring the patient to overpass self-starvation in order to gain weight, hunger is one of the keys. Little is known about hunger in AN with very few publications that besides very often confuse hunger feeling, wanting and liking.

**Objectives.**– Therefore, this study was designed to evaluate simultaneously both hunger feeling and circadian ghrelin plasma level in AN patients compared to controls.

**Methods.**– Hunger feeling was recorded during 24 hours with a validated analogic visual scale (AVS). Ten AN patients with preserved hunger (ANH+) (AVS final 24 h score <sup>3</sup>15 and 3 pre-meal peaks (score 3)), 10 AN patients who lost hunger (ANH-) (AVS final 24 h score ≤ 5 and no peak (score ≤ 2)), 10 Constitutional Thinness patients (CT) (same BMI, no eating disorder, no undernutrition) and 10 normal-weight women (no eating disorder) as Controls were included. Ghrelin was evaluated at 12 points during the same 24 hours.

**Results.**– ANH-, CT and controls exhibited the same hunger scores and similar total and acylated ghrelin plasma levels. ANH+ showed significantly higher ghrelin level than the others.

**Conclusion.**– Ghrelin was high in AN with preserved hunger feeling and similar to controls in AN who lost it. This could modify the standard care in AN by adapting therapy to ghrelin level and promote ghrelin therapy in the group of patients who lost hunger feeling.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Restoring fertility to persistent amenorrheic weight-recovered anorexia nervosa patients: Benefice and risk**

N. Germain<sup>1\*</sup>, A. Fauconnier<sup>2</sup>, J.P. Klein<sup>3</sup>, F. Lang<sup>4</sup>, B. Estour<sup>1</sup>, B. Galusca<sup>1</sup>

<sup>1</sup> University of Saint Etienne, Endocrinology & Eating Disorders Reference Center & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France;

<sup>2</sup> University of Saint-Étienne, Endocrinology, Saint-Étienne cedex 2, France;

<sup>3</sup> University of Saint-Étienne, Reproduction Biology, Saint-Étienne cedex 2, France;

<sup>4</sup> University of Saint-Étienne, Psychiatry & Eating Disorders Reference Center & EA 7423 Eating Disorders Addictions and Extreme Bodyweight, Saint-Étienne cedex 2, France

\* Corresponding author

**Introduction.**– Anorexia nervosa (AN) is characterized by self-starvation-induced undernutrition leading to functional hypothalamic amenorrhea (HA). Weight recovery does not always restore menses despite no clinical and biological undernutrition residual signs. Pulsatile GnRH therapy is currently used to induce physiological ovulation, with effectiveness demonstrated in all types of HA, AN included. However, only few specific studies included AN, mostly with small number and under nourished patients. Besides lots of studies showed the high frequency of eating disorder among women who underwent such therapy.

**Objectives.**– This study was designed to evaluate hormonal and clinical responses to GnRH pump in two groups of HA patients: persistent amenorrheic weight-recovered AN patients (Rec-AN) and HA from other cause.

**Method.**– Twenty-two HA without any eating disorders patients and 19 Rec-AN (BMI > 18.5 kg/m<sup>2</sup> without menses recovery) were included in this study. Baseline Estradiol, LH and Progesterone plasma levels and their changes during induction cycles along with ovulation, follicular recruitment, pregnancies rate and eating disorders in AN were evaluated.

**Results.**– Rec-AN displayed higher basal Estradiol and LH plasma levels after both GnRH injection and during induction cycles compared to HA. Consequently follicular recruitment and ovulation rate were higher in Rec-AN. AN group exhibited 15% of reactivation of eating disorder.

**Conclusions.**– This study showed great clinical and hormonal response to GnRH therapy in persistent amenorrheic weight-recovered AN, suggesting this treatment is the first one to propose to patient. It raises also the importance to carefully monitor eating disorder and mainly to evaluate psychological state before proceeding.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Exposure to trauma, post traumatic stress disorder and depression symptoms in eritrean refugees living in Ethiopia**

B. Getnet<sup>\*</sup>, G. Medhin, A. Alem  
Addis Ababa University, Psychiatry, Addis Ababa, Ethiopia

\* Corresponding author

**Background.**– There is a paucity of research evidence about the mental health of Eritrean refugees.

**Objectives.**– To identify the differential association between exposure to pre-migration and post-migration trauma with PTSD, depression or both symptoms among Eritrean refugees in Ethiopia.

**Methods.**– A cross-sectional survey method was employed in this study in which 562 participants were randomly selected from Eritrean refugees living in Mai Aini refugee camp, Ethiopia. The needed information were collected using pre and post-migration living difficulties checklist, Primary Care PTSD screener (PC-PTSD), Center for Epidemiologic Studies Depression Scale (CES-D), Oslo Social Support Scale (OSS-3), Sense of Coherence Scale (Soc-13) and Coping Style Scale. Multiple linear regression, independent sample t-test, and partial correlation were used as methods of statistical analysis.

**Results.**– PTSD and depression symptoms do not vary across major demographic variables such as: gender, age and marital status. After adjusting for demographic factors, sense of coherence and social support, exposure to pre-migration trauma is significantly associated both with symptoms of PTSD ( $\beta=0.11, P<.05$ ) and depression ( $\beta=0.29, P<.001$ ). Exposure to post-migration trauma is associated with depression ( $\beta=0.21, P<.001$ ). However, sense of coherence ( $\beta=-0.17, P<.001$ ) and social support ( $\beta=-0.08, P<.05$ ) are inversely associated with PTSD symptoms; sense of coherence ( $\beta=-0.32, P<.001$ ) and social support ( $\beta=-0.11, P<.001$ ) have also demonstrated inverse association with symptoms of depression.

**Conclusions.**– While depression is associated with both pre and post-migration trauma, PTSD is associated with pre-migration trauma. Sense of coherence and social support are associated with reduced symptoms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cardio-metabolic monitoring in patients on antipsychotics in an inner city New York city adult outpatient clinic: What have we learned so far**

S. Gunturu

ICAHN School of Medicine at Mt. Sinai, Bronx Lebanon Hospital Center, Psychiatry, New York, USA

Patients with serious and persistent mental illness (SPMI) have frequent concurrence with heart disease, diabetes, and other cardio metabolic risk factors. Clinical Anti-psychotic Trials of Intervention Effectiveness (CATIE) schizophrenia trial estimated 43 percent prevalence (54% in Females; 36% in Males) of metabolic syndrome in patients with schizophrenia at baseline. This warrants an urgent need of cardio metabolic risk monitoring for early detection and intervention to reduce mortality.

**Methods.**– Phase one of our study involved retrospective chart review of 2826 patients during the one-year study period (2014–2015). Phase 2 involved interventions including provider education on cardiovascular practice guidelines and improvement in the electronic medical record such as alerts for the provider and the development of a cardio metabolic screening order set. Phase 3 involves pre-post interventional data analysis.

**Results.**– Baseline data of 2826 patients showed 55% ( $n=1563$ ) of our patients were on antipsychotics and had a high prevalence of cardio metabolic risk factors such as hypertension (39%), obesity (35%), smoking (34%), diabetes mellitus (25%), hyperlipidemia (25%). Our baseline data results showed that cardio metabolic monitoring was below par as per standard of practice guidelines with following monitoring results: fasting glucose monitored (52%), HbA1c (30%), LDL (37%), Cholesterol (38%), Weight and BMI (67%).

**Conclusion.**– The baseline data showed that in our routine clinical practice, patients on antipsychotics did not have sufficient cardiometabolic screening. Post intervention review of our data will show the effect of the intervention on cardiometabolic screening and will provide insights on how EMR based strategies can be integrated into out-patient clinics.

### **National model for mental health work among refugees and asylum seekers in Finland**

J. Mäki-Opas, A. Castaneda, S. Jokela\*

National Institute for Health and Welfare THL, Department of Welfare, Helsinki, Finland

\* Corresponding author

**Introduction.**– Mental health is a crucial part in refugees' overall wellbeing. According to Finnish surveys, migrants with a refugee background are more prone to experience severe symptoms of depression and anxiety compared to the general Finnish population. Traumatic experiences in the former home country and discrimination in Finland explain some of the refugees' mental health problems.

**Objectives.**– A need existed to improve the mental health work done among refugees and asylum seekers in Finland.

**Methods.**– Information on existing problems and good practices and treatment models was gathered in 2016–2017 in several ways: qualitative interviews of professionals ( $n=157$ ) and refugees ( $n=32$ ) were conducted all over the country and service levels, literature was reviewed, and seminars were held and participated. The PALOMA model for refugees' better mental health was built in 2017 with a large expert group, also including refugees, and implemented in 2018.

**Results.**– The PALOMA model for refugees' mental health is targeted for professionals on different levels of administration and contexts. The model covers the whole field of mental health work from preventive work outside of health and social services (e.g. school, police, etc.) to primary and specialized care of health and social services. The PALOMA model gives detailed recommendations for prevention, recognition and treatment of mental health problems among refugees and asylum seekers in Finland.

**Conclusions.**– Concrete recommendations of the PALOMA model enable the professionals to promote mental health and improve services in a culturally sensitive way. As a result, refugees' mental health and overall wellbeing will be improved.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Building a prognosis model for anorexia nervosa: A machine learning approach**

C. Kan<sup>1</sup>\*, J. Leppanen<sup>1</sup>, J. Adamson<sup>2</sup>, K. Tchanturia<sup>1</sup>, C. Lewis<sup>3</sup>, J. Treasure<sup>1</sup>

<sup>1</sup> King's College London, Psychological Medicine, London, United Kingdom;

<sup>2</sup> South London and Maudsley NHS Foundation Trust, Eating Disorders, London, United Kingdom;

<sup>3</sup> King's College London, MRC Social, Genetic, Developmental and Psychiatry Centre, London, United Kingdom

\* Corresponding author

**Background.**– Anorexia nervosa has the highest mortality rate of all psychiatric disorders, with approximately 50% of individuals devel-

oping a severe and enduring form of illness. Low weight is a major concern and weight restoration is a common goal for inpatient treatment. However, the degree of weight gain varies considerably across individuals and at present it is unclear what factors contribute to this variability.

**Objectives.**– An exploratory study to examine predictors of change in BMI following inpatient treatment.

**Methods.**– The sample consisted of 292 patients admitted to the inpatient eating disorder unit at South London and Maudsley NHS Foundation Trust between 2004 and 2016. Three domains of predictors were considered: (i) demographic characteristics, (ii) clinical history prior to admission and (iii) clinical features on admission including eating psychopathology. Elastic net regularized regression with nested cross-validation was used to optimise the prognosis model.

**Results.**– A combination of demographic and clinical variables explained 13.6% of variance in BMI change following treatment. As expected, the strongest predictors were those related to weight (BMI on admission) and severity of illness (previous hospital admissions and the use of voluntary admissions). Interestingly, social factors (living with others) and ethnicity (Asians) also emerged as important predictors.

**Conclusion.**– Our findings support the notion that easily accessible demographic and clinical variables can explain a proportion of therapeutic response to inpatient treatment for anorexia nervosa. Machine learning can be a useful method to identify factors that contribute to poor treatment response and can potentially be developed into a decision-support tool for clinicians.

**Disclosure of interest.**– We would like to thank all participants in the study and Deborah Agbedjro for her statistical support. This project and JA are funded by the Health Foundation (Bridging Transitions from Hospital to Home: Collaborative Skill Sharing Intervention with Carers). CK, KT, CML and JT are currently part funded by the National Institute for Health Research Mental Health Biomedical Research Centre for Mental Health at South London and Maudsley NHS Foundation Trust and King's College London. CK had received salary support from Novo Nordisk UK Research Foundation. The views expressed are those of the author(s) and not necessarily those of the NHS, the NIHR or the Department of Health.

### **Automated analysis of verbal fluency ability for detection of cognitive impairment in elderly people**

A. König<sup>1</sup>\*, N. Linz<sup>2</sup>, J. Tröger<sup>2</sup>, J. Alexandersson<sup>2</sup>, P. Ro<sup>1</sup>

<sup>1</sup> University Côte d'Azur, Cobtek Cognition, Behavior, Technology Research Lab, Centre de Mémoire de Ressources et de Recherche, Centre Hospitalier Universitaire, Nice, France;

<sup>2</sup> German Institute for Artificial Intelligence, Computer Science, Saarbrücken, Germany

\* Corresponding author

**Introduction.**– Verbal fluency (VF) tests are commonly used assessments of cognitive functioning. Due to time constraints, clinicians usually measure task performance manually only by the total number of correct words and errors.

**Objectives.**– To investigate whether automated analysis of semantic measures such as the amount of clusters and switches could be useful for clinical assessment.

**Methods.**– Overall, 179 older persons performing the VF tests were recorded from which 90 were diagnosed with dementia, 47 were diagnosed with Mild cognitive impairment (MCI) and 42 were healthy controls (HC). Participants were given 60s to name as many animals as they can. All performances have been recorded and transcribed. Speech signal processing techniques and automatic speech recognition for computation of semantic clusters/chains

were applied and compared to manual annotations. Automatically extracted features were tested in their power to correctly distinguish between these groups.

**Results.**– We found that the automatically extracted information from the speech recordings is as reliable as manual annotations with a correlation of 0.89 for word count, 0.92 for cluster size and 0.92 for the amount of switches. Classifiers based on automatic extracted features outperformed with 73.6% accuracy between HC and MCI those trained with manual annotations with an accuracy of only 71.3%.

**Conclusions.**– Our results demonstrate the feasibility of using automated semantic analytics and the additional value of vocal features, for the assessment and monitoring of cognitive impairment in elderly people through VF tests. This time saving automated tool could provide clinicians with reliable data immediately, based on non-invasive, simple and low-cost methods.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

OR0182

### **The effectiveness of psychosocial interventions for survivors of natural disasters: A systematic review**

S. M Selveindran\*, C. Campbell

University of Edinburgh, School of Molecular, Genetic and Population Health Sciences, Edinburgh, United Kingdom

\* Corresponding author

**Introduction.**– Natural disasters are becoming increasingly more common, with significant psychosocial impact on survivors, that can lead to psychosocial disorders and chronic psychopathology. Effectiveness of currently available interventions is uncertain, although the evidence-base is emerging with more primary studies evaluating these, and which remains to be synthesized.

**Objective.**– To identify, critically appraise and synthesize the current evidence base on the effectiveness of psychosocial interventions in preventing or treating PTSD, MDD and/or GAD in adult and child survivors of natural disasters.

**Methods.**– Guided by a protocol, a systematic search of eight international electronic databases, other grey literature databases and relevant websites, as well as bibliographic and citation searching of eligible articles was done. Papers meeting the specific inclusion criteria underwent quality assessment using the Downs and Black checklist. The extracted data was analysed by way of narrative synthesis.

**Results.**– Searches returned 3777 papers where 31 met the criteria for inclusion. Two papers were obtained through bibliographic and citation searching. Methodological quality of most papers was fair, and evaluated psychological interventions. All studies, reported post-intervention reductions in symptom scores for PTSD, depression and anxiety and where assessed, reduced diagnosis of PTSD and MDD. Statistically significant results were seen in 22 studies. However, three studies demonstrated that the evaluated interventions may not have been very beneficial.

**Conclusions.**– The overall positive results suggest that psychosocial interventions are favourable over no interventions. Yet, heterogeneity and methodological shortcomings of the current evidence-base makes it difficult to draw definite conclusions. Further rigorously conducted research in this area is needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Alcohol use and dependence among older adults in canadian home care: Is it getting better or worse over time?

E. Neufeld

Laurentian University, Centre for Rural and Northern Health Research, Sudbury, Canada

**Introduction.**– The risk-relationship between alcohol consumption and poor mental health has been well established. The objective of this study was to examine alcohol use and mental health among older adults receiving home care (HC) services in Canada, with the goal of informing mental health promotion policy and practice.

**Methods.**– Canadian HC data were retrieved from the Home Care Reporting System (HCRS) database. Information in the HCRS is based on the Resident Assessment Instrument–Home Care (RAI-HC), an assessment tool used to identify the strengths, preferences and needs of HC clients. The sample included HC clients across five provinces, aged 60 years and older assessed with the RAI-HC between 2004 and 2014 ( $n=692,353$ ). The main outcome measure was alcohol consumption and dependence (i.e. alcohol use), measured with two items:

- the person's alcohol consumption concerns others;
- needing a drink first thing in the morning.

Descriptive and multivariate analyses were performed.

**Results.**– There was a slow and steady increase in rates of alcohol use over time. In total, alcohol use was present in 19.0 cases/1000 Canadian HC clients. These clients were younger on average, aged 60 to 74 years and more likely male. Main drivers of alcohol use included smoking ( $OR=5.17$ ,  $CI: 4.96-5.40$ ), younger age ( $OR=2.11$ ,  $CI: 1.99-2.24$ ), and depressive symptoms ( $OR=1.63$ ,  $CI: 1.55-1.72$ ). Social involvement and medication use lowered odds of alcohol use.

**Conclusion.**– These findings provide evidence for policy and practice surrounding alcohol use and mental health promotion in the Canadian home care sector.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Adult attachment styles and cortisol awakening response in eating disorders

F. Pellegrino<sup>1\*</sup>, A.M. Monteleone<sup>1</sup>, G. Fico<sup>1</sup>, V. Ruzzi<sup>1</sup>, M. Cimino<sup>1</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> University of Campania "Luigi Vanvitelli", Psychiatry, Naples, Italy;

<sup>2</sup> University of Salerno, Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Neuroscience, Salerno, Italy

\* Corresponding author

**Introduction.**– Adverse early experiences are considered a major risk factor for Eating Disorders (EDs). Repeated interactions with caregivers in childhood affect emotion regulation development. Therefore, Adult Attachment Styles (AAS) may be associated with an altered stress response through differences in subjective feelings of distress and in physiological responses, including the Hypothalamic-Pituitary-Adrenal (HPA) axis functioning. A dysregulation of HPA axis activity as a function of AAS has been found in healthy women but it has never been investigated in people with EDs.

**Objectives.**– This study aimed to explore the possible association between AAS and HPA axis activity, as assessed by the saliva Cortisol Awakening Response (CAR) in ED patients.

**Methods.**– Overall, 78 ED patients (43 with AN, 35 with BN) were recruited. Participants filled in the Experiences in Close Relationships (ECR) questionnaire in order to assess the AAS. Then they

were instructed to collect saliva sample at awakening and 15, 30 and 60 minutes after awakening, in order to measure cortisol levels. **Results.**– A three-way ANOVA with repeated measures showed a statistically significant effect for AAS and for the interaction between AAS and time. Indeed, people with avoidant AAS exhibited a CAR significantly higher than those with secure AAS with a different time pattern.

**Conclusions.**– These findings indicate that AAS, but not the ED categorical diagnosis, influence the CAR in EDs. This would confirm that early life experiences might modulate not only affect regulation strategies but also stress systems response. Overall, our study suggests the importance to focus on attachment issues in the assessment of ED pathophysiology.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### An analysis of pharmaceutical interventions in a psychiatric hospital: A 5-month retrospective study

P. Rhodes<sup>1\*</sup>, J.L. Longuefosse<sup>1</sup>, B. Foucher<sup>2</sup>

<sup>1</sup> Centre hospitalier Maurice Despinoy, Pharmacy, Le Lamentin, France;

<sup>2</sup> Centre hospitalier Maurice Despinoy, Psychiatry, Le Lamentin, France

\* Corresponding author

**Introduction and objectives.**– Analysis and validation of hospital prescriptions are issued by our pharmacy which has developed an initiative to register these pharmaceutical interventions (PI) on the SFPC website (French Society of Clinical Pharmacy). The aim of this study is to characterize possible areas of improvement in the prescription validation process.

**Methods.**– A prospective 20-week study (April–September 2017) was conducted in order to collect pharmaceutical interventions, which included the following informations: drug involved, type of problem, type and results of intervention (accepted/not accepted/not described).

**Results.**– A total of 261 PI were recorded (27% of the total drug prescriptions). Dose adjustment account for 43% of the interventions, drug interactions for 41%, repositories non compliance for 10%. Seventy-nine percent of the involved drugs were psychotropic drugs, mainly neuroleptics (90%). General PI acceptance by prescribers was 34%. This low PI acceptance is mainly due to the lack or answers with cardiac problems. Excluding this type of intervention, general PI acceptance reach 46%. Eighty-eight percent of the interventions were considered to have a significant clinical impact. Four PI were considered to have been able to avoid a vital damage. One hundred and ninety-five PI (75%) have a positive economic impact, 96% were coded as positive for organizational impact.

**Conclusion.**– This analysis of pharmacist's interventions allow to characterize the drugs involved, the low rate of acceptance of our interventions. It constitute supports to achieve improvement and adequacy between pharmacists and prescribers in order to increase the acceptance of PIs by prescribers. This could be used as indicator of pharmacist's performance.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Social cognition as a hub between creative thinking and affective-cognitive dysfunction in subjects with traits of the psychotic spectrum

H. Santamaría García\*, D. Giraldo, M.D.P. Otero, J.F. Blanco, J. Castro  
Pontificia Universidad Javeriana, Psiquiatría, Bogotá, Colombia

\* Corresponding author

Social cognitive processes seem to be at core of behavioral and cognitive impairments in mental disorders including schizophrenia, affective disorders, autism spectrum disorders and frontotemporal degeneration. Besides, social cognition modulation goes beyond of those aspects as it has been reported that theory of mind is also involved in the generation and modulation of creative thinking.

Assuming a double inference, namely social cognitive processes involved in cognitive alterations of mental disorders, and the role of social cognition in creative thinking, we explored the extent in which social cognition serves as a link between psychotic spectrum and creative thinking, a classical link still not fully understood. Against this background, we run two studies exploring this relationship. In the first study a group of 60 subjects, we have used a more general and subjective methodology for exploring the link between personality traits, creative thinking and theory of mind by using standardized scales. In a second study, a group of 60 subjects participated in more objective measures of the aforementioned dimensions including experimental paradigms and standardized scales focus in subjects with traits of the psychotic spectrum.

Those results support the relevance of social cognitive processes as a point of convergence between behavioral and cognitive dysfunctions mental disorder and in generating creative thinking. Results were also discussed to the light of importance of social cognition as a resource to produce creative ways of facing daily life challenges even in conditions where behavior, cognition and autonomy are sensibly affected as is the case of mental disorders.

\* Corresponding author

*Background.*– Neurotrophic properties of lithium have been suggested but its effects at a microstructural scale are largely unknown in humans. Our aim was to in vivo assess grey matter ultrastructure in patients with BD undergoing lithium therapy.

*Methods.*– We included 28 patients with BD. All subjects had an MRI examination including 3 shells diffusion acquisition (30 directions at  $b=200\text{ mm}^2/\text{s}^2$ , 60 directions at  $b=1500\text{ mm}^2/\text{s}^2$  and 60 directions at  $b=2700\text{ mm}^2/\text{s}^2$ ) with an isotropic resolution of  $1.25\text{ mm}^3$  and a millimetric 3DT1 acquisition. Intracellular fraction was estimated using an in-house MCMC algorithm (Microscopist software, Neurospin) based on the Neurite Orientation Dispersion and Den-

sity Imaging model. T1 anatomical segmentations with FreeSurfer 5.0 were used to investigate intracellular fraction in grey matter regions of interest. Means between groups were compared using linear models after adjustment for age and gender.

*Results.*– We found higher intracellular fraction values in the left frontal and left parietal cortices in patients with BD taking lithium medication when compared those without lithium treatment ( $P=0.045$  and  $P=0.039$ , Bonferroni corrected), reflecting a higher dendritic density in these two cortical regions.

*Discussion.*– This study reports for the first time ultrastructural differences in grey matter in patients with BD. Considering our data, lithium may expand dendritic ramifications in the frontal and parietal cortices in accordance with animal studies. Further work is needed to investigate longitudinally the temporal dynamics of microstructural changes associated with lithium in bipolar patients.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### A randomised sham-controlled feasibility trial of repetitive transcranial magnetic stimulation in outpatients with severe and enduring anorexia nervosa

U. Schmidt\*, B. Dalton, S. Bartholdy, J. McClelland, I. Campbell  
King's College London, Psychological Medicine, London, United Kingdom

\* Corresponding author

*Introduction.*– Anorexia nervosa (AN) is a disabling and deadly disorder. Treatment innovations are needed, especially for those with severe and enduring illness (SE-AN). Repetitive transcranial magnetic stimulation (rTMS) is a noninvasive brain stimulation method which has shown promise in AN and other eating disorders.

*Objectives.*– The aim of the present study was to conduct a randomised controlled double-blind feasibility trial in adult outpatients with SE-AN and previous unsuccessful treatment, comparing real rTMS with sham treatment, as an add-on to treatment-as-usual (TAU).

*Methods.*– Thirty-four participants with SE-AN (mean illness duration 14 years) were allocated by chance to receive 20 sessions of either real or sham high frequency rTMS in addition to their usual treatment. A range of outcomes (body mass index, eating disorders symptoms, mood, quality of life) were assessed at pre-treatment, post-treatment (1 month post-randomisation) and follow-up (4 months post-randomisation). We also asked participants about their experience of this treatment.

*Results.*– Two patients were withdrawn for safety reasons post-randomisation, 32 started and 30 completed treatment and all research visits. There were small group differences in BMI and eating disorder symptoms at both post-treatment and follow-up. At 4 months post-randomisation, there were between-group differences in depression, stress and obsessive compulsive symptoms of medium to large effect size, favouring real rTMS over sham. rTMS was well tolerated and considered to be an acceptable treatment.

*Conclusions.*– This study provides evidence for the therapeutic potential of rTMS in adults with SE-AN. It also supports the need for future larger-scale studies.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Perception and satisfaction of patients versus staffs in psychiatry wards

S.M. Zamir

Qazvin university of medical sciences, Psychiatry, Qazvin, Iran

**Introduction.**– Patients and staffs experience different aspects of work environment in psychiatry wards, although they spend time in the same place, and it is lead to several difficulties in relationship between patients and staff.

**Objective.**– Evaluate the perception and satisfaction of patients versus staffs in three psychiatric wards in Tehran.

**Methods.**– A total of 219 participants (patients and staffs) in three hospitals were evaluated using Ward Atmosphere Scale (WAS), Working Environment Scale (WES-10), Moos and Verona Service Satisfaction Scale- 32 (VSSS) questionnaires.

**Results.**– Overall, 217 participants including 121 patients (55.2%), 58 staffs (26.4%) (Nurses and assistant nurses) and 38 doctors (17.3%) (psychiatrist and residents) were evaluated. The highest mean score in WAS for patients was in order and organization ( $0.57 \pm 0.13$ ) and for staffs was in anger and aggressive behavior ( $0.58 \pm 0.13$ ) items, moreover the lowest mean score in patients and staffs was in autonomy. The mean scores for patients regarding order and organization, staff control and clarity items were higher than staffs and in other items the staffs scored higher than patients. Involvement with therapy strongly correlated with Verona (+0.75). MOOS showed direct significant correlation with self-realization and indirect significant correlation with nervousness, conflict and work load in WES-10.

**Conclusion.**– Staff and patients perceive the treatment environment differently, moreover staff consider ward atmosphere more suitable than patients, but staff satisfaction did not correlate with their perception from treatment environment.

**Keywords:** Ward Atmosphere Scale (WAS), Verona Service Satisfaction Scale-32 (VSSS), Work environment and job satisfaction (WES-10), Patient and staff satisfaction

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Effects of maternal stress during different gestational periods on the emotion development in adult rat offspring

F. Zhen<sup>1</sup>, C. An

The first hospital of Hebei Medical University, Department of Psychiatry, Shijiazhuang, China

\* Corresponding author

Prenatal stress (PS) is associated with deficits of emotions in adult offspring. However, the critical timing of the impairment is little known. So we studied the effect of single-prolonged stress (SPS) at three different periods during the first (PS1), third (PS3) and first plus third (PS1-3) of pregnancy on depression-like behavior. The Sprague-Dawley pregnant rats were exposed to SPS on gestational day 7,15 or 7–15. SPS contains immobilization for 2 h, forced swim for 20 min in 24°C water, and loss of consciousness by diethyl ether. The offspring were grown to adulthood and forced swim test (FST) and sucrose intake (anhedonia) were performed. In the anhedonia, there was a significant effect among PS ( $F = 57.552, P = 0.000$ ), but sex ( $F = 0.000, P = 0.993$ ) was no significant effect. PS3 offspring were reductive on anhedonia than control while PS1 inductive in anhedonia compared to the control group. In the FST, there was a significant effect of PS ( $F = 17.287, P = 0.000$ ) and sex ( $F = 4.745, P = 0.033$ ) on time spent immobile. PS3 females spending more time than PS3 males. PS3 females were immobile for longer than control female while PS1 and PS1-3 shorter than control. In males, PS1 and PS1-3 males were immobile for shorter than control male. PS has the effects on depression-like behavior in adult offspring. PS3 offspring increased depression-like behavior, while PS1 offspring decreased depression-like behavior. Females were more depress. These results suggested that the time window of the PS and the sex of the offspring were critical to determine the outcome.

### Disruptive mood dysregulation disorder in offspring of parents with ADHD

M. Abouzed\* A. Elawady

Al-Azhar university, faculty of medicine, psychiatry department, Cairo, Egypt

\* Corresponding author.

**Background.**—Emotion dysregulation, is common in ADHD and may arise from deficits in orienting toward and processing emotional stimuli. Disruptive mood dysregulation (DMDD) in the offspring of parents with ADHD under estimated and this but the specificity of this association has not been established.

**Aims.**— We examined the specificity of DMDD to family history by comparing offspring of parents with ADHD WITH a control group without psychiatric disorders.

**Method.**— 112 children who are offspring of parents with ADHD and 100 children for normal parents without ant psychiatric disorders and age and sex matched. We diagnose DMDD using the Schedule for Affective Disorders and Schizophrenia for School Aged Children for DSM-5 in 180 youth aged 6–18 years (KSADS-PI).

**Results.**— Diagnostic criteria for DMDD were met in 21 (18.75%) of the offspring of parents with bipolar disorder, 6 (6%) of the control offspring. With  $P$ -value  $< 0.001$ .

**Conclusions.**— Our results suggest that Disruptive mood dysregulation (DMDD) is may be associated with a family history of ADHD.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

### Prevalence and severity of social anxiety symptoms and its relationship with body dysmorphic disorder symptoms among adults

A. Alhadi<sup>1,2\*</sup>, M.A. Alageel<sup>3</sup>, A.A. Alfaifi<sup>3</sup>, T. Ben Duraihem<sup>3</sup>, H.M. Alkaff<sup>3</sup>, F.A. Alsuhaibani<sup>3</sup>, M.S. Albawardi<sup>3</sup>

<sup>1</sup> King Saud university, department of psychiatry, Riyadh, Saudi Arabia; <sup>2</sup> King Saud university, SABIC psychological health research & applications chair SPHRAC, Riyadh, Saudi Arabia; <sup>3</sup> King Saud university, college of medicine, Riyadh, Saudi Arabia

\* Corresponding author.

**Introduction.**— Social anxiety disorder (SAD) is a subtype of anxiety. It's characterized by fear, avoidance, and hyperarousal symptoms. SAD has a prevalence of 13% in western countries. Body dysmorphic disorder (BDD) is appearance defect and obsession about the looking. Both diseases share similar symptoms. However, the relationship between SAD and BDD is ambiguous.

**Objectives.**— We measured the prevalence of SAD symptoms and the associated socio-demographic factors and tried to determine if a relationship between SAD and BDD is present or not.

**Methods.**— The study is quantitative, observational and cross-sectional that was conducted by administrating translated Arabic version of Severity Measure for Social Anxiety Disorder scale and BDD scales in five places in Riyadh which are King Khaled University Hospital, King Abdulaziz University Hospital, and three shopping malls.

**Results.**— A total of 752 responses, most of the sample were female 509 (68.32%), single (51%), educated (56% university graduate) and have low-moderate family income (64% family income was less than 2555 \$ per month). The study also shows 233 subjects (30.98%) had the moderate-severe form of SAD. Among the 233 (30.98%) participants who showed the moderate-severe form of SAD, 86 (36.9%) had the moderate-severe form of BDD. The correlation of SAD to BDD is significant ( $r = 0.496$ ,  $P$ -value  $\leq 0.001$ ).

**Conclusion.**— The prevalence of SAD was higher compared to other countries. Low Family income, education and female gender have a role in the disease condition. Moreover, there was a clear association between SAD and BDD.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

### The effectiveness of psychoanalytic psychotherapy in the somatoform disorders treatment

I. Belokrylov\*, A. Bryukhin, S. Semikov

Peoples' friendship university of Russia, RUDN university, department of psychiatry and medical psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– The problem of differentiated use of individual psychotherapeutic methods in patients with somatoform disorder (SFD) remains insufficiently studied. Psychoanalytic psychotherapy, which has become relatively common in Russia, is no exception.

**Aims.** A study of the psychoanalytic psychotherapy effectiveness in SFD treatment with the definition of its psychopathological and personality predictors.

**Methods.**– Patients with somatoform disorders (F45 according to ICD-10,  $n=60$ , 34 men, 26 women, mean age  $32.4 \pm 7.6$  years, the average duration of the disease is  $5.2 \pm 3.1$  years) were randomly assigned to 2 groups (30/30); in the main group, patients received a 3-month course of short-term individual psychoanalytic psychotherapy (2 sessions per week), in the control group – identical non-psychotherapeutic sessions (psychoeducation)... Psychopathological and psychological parameters were compared before and after treatment.

**Results.**– The effectiveness of psychoanalytic psychotherapy has been proven significantly by the best results of treatment in the main group according to clinical data, as well as the results of pathopsychological testing ( $P < 0.05$ ). The highest results are observed in the absence of signs of somatoperceptive constitution and hypochondria. The most sensitive test of the personal prediction of the effectiveness of psychotherapy was “The Illness Perception Questionnaire-Revised” (IPQ-R, correlation coefficient  $r=0.63$ ,  $P < 0.05$ ).

**Conclusion.**– Psychoanalytically oriented psychotherapy can be successfully used in the treatment of SFD, especially patients who can reason about the symptoms of the disease in the context of past life experiences.

**Disclosure of interest.**– The publication was prepared with the support of the “RUDN University Program 5-100”.

### Psychological impact of acne on anxiety, depression and self-esteem symptoms before and after treatment with isotretinoin

P. De Jaime Ruiz<sup>1</sup>, F.J. Navarro Triviño<sup>2</sup><sup>1</sup> Campus de la Salud, Psychiatry, Granada, Spain; <sup>2</sup> Hospital Santa Ana Motril, Dermatology, Granada, Spain

\* Corresponding author.

Acne is a common skin disorder, which affects mainly adolescents. It appears at a key moment in human development, the dynamics of which need to be properly understood. It can cause anxiety, depression and low self-esteem. Effective treatment of acne can reduce some of those symptoms and significantly improve other physiological parameters and quality of life. The aim of this study was to determine the psychological status and quality of life of acne patients before and after treatment with oral Isotretinoin.

The prospective study included a total of 30 patients suffering from acne. To assess the psychological status and quality of life we performed the following standard psychometric questionnaires before and after the treatment with Isotretinoin: Hamilton Depression Rating Scale (HAM-D), Rosenberg's Self-esteem Scale and Sheehan Disability Scale (SDS).

We also took into account if patients needed psychotropic drugs or special assistance of Mental Care Specialists.

Our results indicate that there is no increase in depressive and anxiety symptoms in patients treated with oral isotretinoin. What concerns to self-esteem and quality of life we observed an improvement after treatment. There were few patients with severe psychological affection and most of them did not require specialized psychological interventions.

Summarizing we confirmed that far from worsening affective symptoms, treatments for acne can improve them. We should also target that there is an influence in patients' personal well-being when physicians care not only about the external affection, but also about the internal. Not to mention that a proper psychiatric intervention may also contribute.

### Anxiolytic fabomotizol improve quality of life in patients with anxiety disorders

O. Dorofeeva\*, M. Metlina, T. Syunyakov, G. Neznamov

FSBI “Zakusov institute of pharmacology”, laboratory of clinical psychopharmacology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Quality of life (QOL) improvement is very important in patients with anxiety disorders from both clinical and social view. Atypical anxiolytic  $\sigma 1$ -, MT3- and MT1-receptors agonist and MAO-A inhibitor fabomotizole with its favorable tolerability can improve QOL.

**Objectives.**– This study aimed to evaluate changes in QOL during fabomotizole treatment in patients with anxiety disorders and its association with symptomatic changes.

**Methods.**– 30 drug-free patients (16 women and 14 men) aged from 21 to 55 years (mean  $33.8 \pm 8.87$  years) with generalized anxiety disorder (F41.1), panic disorder (F40.0) and nosophobia (F45.2) per ICD-10 criteria without somatic and mental disorders entered the study.

Study design included 7-day screening and 14-day treatment period with fabomotizole 30 mg daily. The World Health Organization Quality of Life Instruments (WHOQOL-BREF), Psychiatric Symptoms Severity Evaluation Questionnaire (PSSEQ) were used in the study. Data analyzed using Wilcoxon test and Spearman correlations. Confidence level  $P < 0.05$  was used.

**Results.**– QOL scores changes are presented in the Table 1. Changes in QOL “Psychological” domain scores significantly correlated with “anxiety” and “insomnia”, “affective lability” and “headache” PSSEQ scores (Spearman's  $R$ : 0.373, 0.378, 0.436 and 0.359, respectively, all  $P < 0.05$ ). “Social support” domain changes correlated with “asthenia” PSSEQ scores changes ( $r=0.331$ ,  $P < 0.05$ ).

**Conclusion.**– Fabomotizole treatment of patients with anxiety disorders associated with QOL and symptomatic improvement. QOL improvement were associated with fabomotizole effects on anxiety, asthenia, affective lability, insomnia and autonomic symptoms.

Table 1 QOL score changes during fabomotizole treatment.

QOL Domain	Background		Endpoint		p-level (Wilcoxon test)
	M	$\sigma$	M	$\sigma$	
Physical Health domain	51.43	10.21	54.52	11.33	p>0.05
Psychological domain	49.03	9.52	49.31	11.48	p>0.05
Social support domain	51.67	18.88	56.94	21.78	p<0.05
Environment domain	52.29	10.48	56.88	11.73	p<0.01
Total score domain	73.10	6.29	76.13	8.70	p<0.01

M: mean;  $\sigma$ : standard deviation.

### Is acceptance and commitment therapy (ACT) effective on academic resilience of children with anxiety?

A. Keshavarz<sup>1</sup>, M. Erfanian<sup>2\*</sup>, M. Ranjbar Golestani<sup>3</sup>

<sup>1</sup> Azad university, psychology and brain sciences, Torbat-e-Jam, Iran;

<sup>2</sup> Maastricht university, faculty of psychology and neuroscience, Maastricht, The Netherlands; <sup>3</sup> Azad university, Torbat-e-Jam, Iran

\* Corresponding author.

Academic resilience is the ability to positively adapt with educational environment that accounts for success despite the significant adversity. The intrapersonal and extrapersonal characteristics moderate the academic resilience. In this regard, Acceptance and Commitment Therapy (ACT) is an interventional approach using acceptance and mindfulness strategies as well as commitment and behavior-change strategies to build psychological flexibility and enhance resilience. This study aims to investigate the effect of ACT on academic resilience in students with anxiety. The current study with quasi-experimental design was conducted with pre-test and post-test, including two groups of experimental ( $n = 10$ ) and control ( $n = 10$ ). Twenty young participants (age range of 5 to 10 years old) were randomly selected from the database of our clinic, among the children who were already diagnosed with school-related anxiety. We evaluated the academic resilience of the selected participants with Academic Resilience Scale (ARS-30). Acceptance and Commitment Therapy was given in 8 sessions of 90 minutes to the experimental group and the control group did not receive any treatment. Pre-test and post-test scores of ARS-30 were analyzed using analysis of covariance (ANCOVA). The results indicate a statistically significant difference between the two groups of experimental and control in terms of the academic resilience ( $P = 0.1$ ). Our findings highlight the effectiveness of ACT on improving the academic resilience in children with school-related anxiety. ACT is a therapeutic modality with validated effectiveness on anxiety related disorders which can be regularly applied in educational system to improve the success rate in students' populations.

### Effectiveness of forgiveness skill in reducing anxiety and depression among women victims of sexual abuse in childhood

S. Ghahari<sup>1,2</sup>

<sup>1</sup> Department of mental health, school of behavioral sciences and mental health Tehran institute of psychiatry, Iran university of medical sciences IUMS, Tehran, Iran; <sup>2</sup> Psychiatry and behavioral sciences research center, addiction Institute, Mazandaran university of medical sciences, Sari, Iran, Tehran, Iran

*Background and purpose.*– Sexual abuse has irreversible physical and mental health on the person. This study was conducted to determine effectiveness of forgiveness skill in reducing anxiety and depression among women victims of sexual abuse in childhood.

*Materials and methods.*– This is a semi-experimental study with pretest-posttest as well as control and experimental groups. Statistical population of study consisted of 30 depressed and anxious women who reported a sexual abuse in childhood and referred to several a psychological clinic in Tehran. They were selected randomly and signed into two 15-member test and control groups. Sample members of test group were under treatment individually within 12 sessions with forgiveness skill and control group members were in waiting list. Both groups filled out Beck's anxiety and depression inventory in baseline and after intervention. The data were analyzed using covariance analysis through SPSS22 software.

*Findings.*– Results of this study indicate difference between anxiety and depression level of women victims of sexual abuse among control and test groups after intervention to forgiveness skill ( $P < 0.05$ )

*Conclusion.*– Forgiveness skill is effective in reducing anxiety and depression among women victims of sexual abuse in childhood.

*Keywords:* Forgiveness; Anxiety; Depression; Women; Sexual abuse

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### Comparison the efficiency of play and narrative therapy on decreasing depression, anxiety and aggression of sexually abused children in Tehran

M. Amirzadegan<sup>1</sup>, S. Ghahari<sup>2,3\*</sup>, A.A. Asgharnejad Farid<sup>4</sup>

<sup>1</sup> Clinical psychology, Islamic Azad university, Tehran, Iran;

<sup>2</sup> Department of mental health, school of behavioral sciences and mental health Tehran institute of psychiatry, Iran university of medical sciences IUMS, Tehran, Iran; <sup>3</sup> Psychiatry and behavioral sciences research center, addiction institute, Mazandaran university of medical sciences, Sari, Iran, Tehran, Iran; <sup>4</sup> Iran university of medical sciences, center of excellence in psychiatry, school of behavioral sciences and mental health, Tehran, Iran

\* Corresponding author.

*Aims and context.*– Child sexual abuse is one of the most common psycho-social health problem which bring so many negative consequences for the child. The current study is aimed on comparison the efficiency of play and narrative therapy on decreasing depression, anxiety and aggression of sexually abused children.

*Methodology.*– The current study is an experimental research along pre-test, post-test and a control group. The statistical group was included all the children between 7 to 12 years old who visited Rooyesh Nahal Tehran Institute in 2017. Among this group, 45 victim children (sexually abused) were selected by means of available sampling method and divided into the two experimental groups: 1-

play therapy 2-narrative therapy, and one control group randomly (Each group was included 15 people). Experimental groups was intervened by play and narrative therapy separately during 10 sessions, and control group was put on the waiting list. Both groups filled these questionnaires at the baseline and after treatment: Children and Adolescent Depression Scale (C.A.D.S), Multidimensional anxiety scale for children (M.A.S.C). The data analyzed through the descriptive and deductive statistical analysis (covariance analysis. ANCOVA).

**Findings.**– The results of multivariable covariance analysis were referred to a significant differences between two experimental groups with the control group. The Comparison of experimental groups pointed that the narrative therapy in compare with play therapy had more efficiency on decreasing the level of anxiety and aggression among sexually abused children ( $P < 0.05$ ) while the play therapy was more effective than narrative therapy in reducing depression of sexually abused children ( $P < 0.05$ ).

**Conclusion.**– Narrative therapy has more efficiency than the play therapy on decreasing level of anxiety and aggression of sexually abused children, and play therapy is more effective than narrative therapy on reducing depression of sexually abused children.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The role of secrets in psychopathology of individuals and their relationship with internal and external shame**

C. Barmpouta<sup>1</sup>, K. Gourgouliani<sup>1</sup>, C. Hatzoglou<sup>1</sup>, M. Gouva<sup>2</sup>  
<sup>1</sup> University of Thessaly, Graduate Program “Primary Health Care”, university of Thessaly, Greece, Larisa, Greece; <sup>2</sup> TEI of Epirus, research laboratory psychology of patients families and health professionals, T.E.I. of Epirus, Greece, Ioannina, Greece

\* Corresponding author.

**Introduction.**– Due to the complexity of the phenomenon of secrets both in everyday life and in the health sector, several issues raise through their study.

**Purpose:** The purpose of this research was to investigate the relationship of secrets with psychopathology as well as with the internal and the external shame.

**Method.**– The sample of this study was people from the Greek normal population, aged 18 to >65. The research tools used were the following: (a) the Symptom Checklist 90-R - SCL-90), (b) the Other As Shamer Scale (OAS), and (c) Experience of Shame Scale (ESS), and even a questionnaire of socio-demographics and attitudes of questions and representations of human secrets.

**Results.**– Persons who have secrets from their families and come from families that kept secrets have higher levels than people without secrets and that do not come from families who kept secrets in scales: Feeling of inferiority (.008), feeling of emptiness (.010), perception of the person regarding to the reaction of others when he/she make mistakes (.015), characterological shame (.000), behavioral shame (.013), bodily shame (.001), somatization (.002), interpersonal sensitivity (.021), depression (.000), anxiety (.000), phobic anxiety (.031), paranoid ideation (.000) and psychoticism (.000).

**Conclusions.**– The results of our study found high levels of psychopathology in people who keep secrets from their family, their friends, their partners, and come from families that keep secrets not only among their members and also from other relatives.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Mitochondrial DNA copy number is reduced in psychosis and inversely correlated with anti-psychotic prescription dosage**

P. Kumar<sup>1</sup>, P. Efstathopoulos<sup>1</sup>, C. Lavebratt<sup>1</sup>, V. Millischer<sup>1</sup>, C. Villaescusa<sup>1</sup>, E. Olsson<sup>1</sup>, B.W. Ya<sup>1</sup>, U. Ösby<sup>1</sup>, M. Schalling<sup>1</sup>, O. Brüstle<sup>2</sup>

<sup>1</sup> Karolinska Institutet, molecular medicine and surgery, Solna, Sweden; <sup>2</sup> University of Bonn, institute of reconstructive neurobiology, Bonn, Germany

\* Corresponding author.

Accumulating evidence has linked impaired mitochondrial biogenesis and telomere shortening to psychotic disorders. However, studies, which investigated mitochondrial DNA copy number (mtDNAcn) and leukocyte telomere length (LTL) in BD and SZ, have not considered the effect of anti-psychotic treatment (AP) and have arrived at discrepant conclusions on the alteration of these markers. In the present study, leukocyte mtDNAcn and TL analysis was performed on 594 chronic psychosis patients. Regression analysis was carried out using leukocyte mtDNAcn and TL as dependent variables with clinical information and drug treatment as independent variables. MtDNAcn, when corrected for age, metabolic health and lifestyle factors, was associated with age ( $\beta = -0.171$  and  $P < 0.001$ ), psychosis severity ( $\beta = -0.123$  and  $P = 0.005$ ) and AP, in particular, clozapine ( $\beta = -0.098$  and  $P = 0.025$ ) and risperidone ( $\beta = -0.124$  and  $P = 0.004$ ). MtDNAcn was significantly associated with prescribed oral doses of clozapine ( $\rho = -0.342$  and  $P = 0.007$ ) and risperidone ( $\rho = -0.230$  and  $P = 0.028$ ). We also investigated the effect of the drugs, clozapine and risperidone on mtDNAcn of stem-cell derived human neurons in vitro. Clozapine ( $P = 0.0004$ ) and risperidone ( $P = 0.0126$ ) had a reducing effect on the mtDNAcn of human neurons in vitro at typical plasma doses. Our study shows that leukocyte mtDNAcn is associated with AP treatment and psychosis severity. Additionally, we have first evidence of leukocyte mtDNAcn being associated linearly with prescribed oral doses of AP.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Clinical influences of anxiodepressive disorders on irritable bowel syndrome through the Gut-brain axis**

L.A. Mazelin

University of Nice-Sophia Antipolis, psychiatry, Nice, France

**Objective.**– The interaction of anxiodepressive syndromes (SAD) and irritable bowel syndrome (IBS) through the gut-brain axis is an example of a holistic physiological loop. SAD and IBS are part of the spectrum of civilization diseases whose prevalence has increased in recent decades and in which low-grade inflammation plays a central role (Fig. 1).

The aim is to estimate the proportion of digestive disorders in severe anxiodepressive patients.

**Methods.**– 46 individuals recruited through six self-questionnaires: epidemiological data, Beck depression inventory (BDI), hospital anxiety and depression scale (HAD), digestive vulnerability questionnaire (QVD), Rome IV criteria (R4) and discomfort intestinal scale (SII). Average age 48.9 years (EC: 14.9) and sex ratio 1/2. If SII  $\geq 20$ , the result is suspect. If SII  $\geq 40$ , the discomfort is severe. In QVD, patients with a leaky gut have an average score of 7.1 (unlike the healthy subjects who have 2.1).

or Parkinson Disease and healthy controls were enrolled. They completed the Snaith-Hamilton Pleasure Scale (SHAPS) and the Temporary Experience of Pleasure Scale (TEPS) to assess anhedonia and its anticipatory and consummatory facets, respectively. Depressive symptoms were evaluated too.

**Results.**– According SHAPS cut-off, half of the anhedonics were in the depressive subgroup whereas there were no differences among the others' rates. When comparing the groups for the anhedonic gap, defined as the difference between the mean scores at the anticipatory and consummatory TEPS' subscales, the controls ( $F=4.941$ ;  $P=.001$ ) were the only ones without a significant difference ( $t=-.705$ ;  $P=.488$ ). This was held true even when controlling for possible confounding variables ( $P=.129$ ). This means that their abilities to foresee a pleasure and experience it are more balanced.

**Conclusion.**– Our results suggest that a more fine-grained evaluation of anhedonia, rather than a dichotomous approach, might help clinicians in a better understanding of patient's needs and subsequent therapeutic targets.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0015

### **The Italian Version of the 16-item Prodromal Questionnaire (Ipq-16): Field-test and psychometric features**

L. Pelizza<sup>1\*</sup>, S. Azzali<sup>1</sup>, F. Paterlini<sup>1</sup>, S. Garlassi<sup>1</sup>, I. Scazza<sup>1</sup>, A. Raballo<sup>2</sup>

<sup>1</sup> Reggio Emilia public health service, Reggio Emilia department of mental health, Reggio Emilia, Italy; <sup>2</sup> Norwegian university of science and technology, department of psychology, Trondheim, Norway

\* Corresponding author.

**Objective** – Among current early screeners for psychosis-risk states, the 16-item Prodromal Questionnaire (PQ-16) is often used. We aimed to assess reliability and validity of the Italian version of the PQ-16 in a young adult help-seeking population.

**Methods.**– We included 154 individuals aged 18–35 years seeking help at the Reggio Emilia outpatient mental health services in a large semirural catchment area (550,000 inhabitants). Participants completed the Italian version of the PQ-16 (iPQ-16) and were subsequently assessed with the Comprehensive Assessment of At-Risk Mental States (CAARMS). We examined diagnostic accuracy (sensitivity, specificity, positive and negative predictive values, and positive and negative likelihood ratios) and content, convergent, and concurrent validity between PQ-16 and CAARMS using Cronbach's alpha, Spearman's rho, and Cohen's kappa, respectively. We also tested the validity of the adopted PQ-16 cut-offs through Receiver Operating Characteristic (ROC) curves plotted against CAARMS diagnoses and the 1-year predictive validity of the PQ-16.

**Results.**– The iPQ-16 showed high internal consistency and acceptable diagnostic accuracy and concurrent validity. ROC analyses pointed to a cut-off score of  $\geq 5$  as best cut-off. After 12 months of follow-up, 22.4% of participants with a PQ-16  $\geq 5$  cut-off at the baseline, showed a psychotic disorder and 29.3% an Ultra-High Risk (UHR) status.

**Conclusions.**– Psychometric properties of the iPQ-16 were satisfactory.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

Studies in adolescents on Ultra-High Risk (UHR) and Basic Symptoms (BS) criteria for psychosis prediction are scarce. In Italy, early interventions in psychosis are less widespread than in other countries. In this study, we (1) assessed the clinical relevance of a UHR diagnosis (according to the Comprehensive Assessment of At-Risk Mental States [CAARMS] criteria) in order to promote the implementation of specific services for UHR adolescents into the Italian health care system; (2) described severity of positive, negative, general, and basic symptoms in UHR adolescents compared to adolescents with First-Episode Psychosis (FEP) and non-UHR adolescents (i.e. those above CAARMS criteria for UHR or FEP); and (3) investigated the predictive validity of UHR criteria in relation to BS criteria. Seventy-nine adolescents (aged 13–18 years) were assessed with the CAARMS, the Positive and Negative Syndrome Scale (PANSS), and the Schizophrenia Proneness Instrument, Child and Youth version (SPI-CY). Both UHR ( $n=25$ ) and FEP ( $n=11$ ) had significantly higher PANSS subscales scores compared to non-UHR ( $n=43$ ). UHR had significantly lower PANSS positive symptoms scores than FEP, but similar global functioning and PANSS negative symptoms and general psychopathology scores. Compared to non-UHR, both FEP and UHR had more severe thought and perception BS disturbances, and significantly more often met BS criteria. After 12 months, 2 of 20 (10%) UHR had transitioned to psychosis. They also met both BS criteria. Future research is needed to determine whether the combined assessment of BS with UHR symptoms can improve the accuracy of psychosis prediction in adolescence.

\* Corresponding author.

This phase III, multicentre, international, randomised, double-blind, comparative trial assessed the 12-week efficacy and safety

of agomelatine 25–50 mg versus venlafaxine XR 75–150–225 mg in non-depressed Asian outpatients with generalized anxiety disorder (GAD). The study was prematurely stopped due to a sponsor's strategic decision. 187 patients were randomized into two parallel groups: agomelatine ( $n=96$ ), or venlafaxine XR ( $n=91$ ). Dose adjustment was possible at Week 4 (for both treatments) and Week 6 (for patients on venlafaxine 150 mg/day).

All randomized patients fulfilled DSM-IV diagnostic criteria for GAD, 51% of them were female and the mean age was  $39 \pm 11.6$  years. The mean HAM-A total score at baseline was  $28.5 \pm 4.5$  and did not significantly differ between treatment groups.

In the Full Analysis Set ( $n=167$ ), at week 12 (LOCF), the mean HAM-A total score decrease was  $-15.8 \pm 8.3$  on agomelatine and  $-17.7 \pm 7.6$  on venlafaxine XR without statistically significant difference between groups.

The response rate (decrease in HAM-A total score  $\geq 50\%$  from baseline) was 70% on agomelatine and 74% on venlafaxine XR.

The three most frequent emergent adverse events in the agomelatine group had a lower frequency on agomelatine than on venlafaxine XR (nausea: 7.5% versus 18.2%, constipation: 6.5% versus 12.5% and dizziness: 5.4% versus 10.2%, respectively).

One agomelatine-treated patient had transaminases increase  $>3\text{ULN}$  after 6 weeks on treatment and recovered 7 days after the treatment cessation.

In these GAD Asian patients, the symptoms of anxiety improved in both treatment groups. Agomelatine was better tolerated than venlafaxine XR.

### **Dysfunctional schema modes and co-morbidity of psychiatric symptoms in people with epilepsy (PWE)**

N. Shafique\*, M.T. Khalily

International Islamic University, Psychology, Islamabad, Pakistan

\* Corresponding author.

The current study aimed at exploring the predicting relationship between dysfunctional schema modes and psychiatric symptoms. Furthermore, also examine the role of various demographics in epilepsy and dysfunctional modes. A total sample of 108 people with epilepsy comprised of 54% was female with a mean age ( $M=24.91$ ,  $SD=7.42$ ) recruited from the neurology ward of hospitals located in Islamabad and Rawalpindi. The respondents completed the Schema Mode Inventory, and SCL-90, also the demographic and clinical variables were taken from the semi-structured interview. Regression analyses showed that Detached Protector, Punishing Parent and Vulnerable child significantly predicting Depression (DEP), Anxiety (ANX), Hostility (HOS), Interpersonal Sensitivity (INT), Phobia (PHOB), Paranoid (PAR), Psychoticism (PSY), Obsessive Compulsive Disorder (OCD) and Somatization (SOM). Whereas Angry protector significantly predicted DEP, ANX, HOS. The Angry child was found to be the only predictor of OCD, Compliant surrender and Enraged child significantly predicted HOS and the Bully and Attack predicted PHOB. A One-way variance analysis revealed the significant differences between the lower, middle and upper socio-economic class on Dysfunctional Modes. The lower middle class had significantly utilized the modes detached protector, bully, and attack, angry protector, angry child, enraged child, impulsive child, undisciplined child and punishing the parent. However, Hostility found in the lower class as compared to upper or middle class. Moreover, Gender differences indicated the significantly higher mean of males on Self-aggrandizer, Bully and Attack, Impulsive child and Undisciplined child. Thus, findings sug-

gestively highlight that maladaptive coping response significantly contribute in psychiatric comorbidities in PWE.

\* Corresponding author.

*Introduction.*– In order to aid clinicians in the early identification of patients with an anxiety disorder in need of highly specialized care, we developed the Decision Tool Anxiety Disorders (DTAD).

*Objectives.*– The aim of this study was to assess the feasibility, reliability and validity of the DTAD in patients with a DSM-IV-TR anxiety disorder.

*Methods.*– A total of 454 outpatients who were referred for treatment to a general psychiatric or highly specialized treatment centre were studied. The duration of completion and content clarity of the DTAD were used as indicators of feasibility. Inter-rater reliability was assessed using pairs of independent ratings ( $n=87$ ). To assess convergent validity, the five-level EuroQol five-dimensional questionnaire (EQ-5D-5L) was administered. A receiver operator characteristic curve was constructed to assess criterion validity.

*Results.*– The average completion time of the DTAD was 4.62 min ( $SD=2.62$ ), and the content of the total set of items was judged as clear in 93.0% of all evaluations. Krippendorff's alpha values of the items ranged from 0.427 to 0.839. The pattern of correlations between the total DTAD score and EQ-5D-5L index ( $-0.413$ ,  $P<0.001$ ) and EQ-5D-5L visual analogue scale ( $-0.296$ ,  $P<0.001$ ) score supported convergent validity. A maximum Youden index ( $J=0.471$ ) was obtained at a cut-off score of  $\geq 4$  (sensitivity 70.0%; specificity 77.1%).

*Conclusions.*– The DTAD provides an easily used, moderately reliable and sufficiently valid tool for the identification of patients with an anxiety disorder in need of highly specialized care. Its use in clinical practice will guide in selecting the most appropriate treatment setting.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Racing thoughts in adults with ADHD: A neglected symptom associated with mood instability and insomnia

L. Weiner<sup>1</sup>, P. Ossola<sup>2</sup>, J.B. Causin<sup>1</sup>, C. Kraemer<sup>3</sup>, G. Bertschy<sup>1</sup>, S. Weibel<sup>1</sup>

<sup>1</sup> INSERM, 1114, university hospital of Strasbourg, Strasbourg, France; <sup>2</sup> University of Pisa, Pisa, Italy; <sup>3</sup> University hospital of Strasbourg, psychiatry department, Strasbourg, France

\* Corresponding author.

**Introduction.**— Attention deficit with or without hyperactivity disorder (ADHD) is characterized by inattention, impulsivity and hyperactivity. To our knowledge, racing thoughts, usually described in manic episodes of bipolar disorder (BD), have never been quantitatively assessed in patients with ADHD, although patients often complain of 'mental hyperactivity' and thought pressure. We investigated racing thoughts in patients with ADHD compared to healthy controls and manic patients with BD, and assessed the relationship between racing thoughts, ADHD symptoms, mood instability, and insomnia.

**Methods.**— 37 unmedicated adults with ADHD, 89 controls, and 42 manic BD patients filled out the Racing and Crowded Thought Questionnaire (RCTQ), a 34 item self-report scale (range 0 to 136). Circadian variability of racing thoughts was assessed via a Likert scale.

**Results.**— RCTQ score was higher in ADHD patients compared to controls (83.84 vs. 11.14;  $P < .001$ ), but also manic patients (52.38,  $P < .05$ ). ADHD patients reported that racing thoughts were more severe in the evening and at bedtime. In ADHD patients, RCTQ score was positively correlated with insomnia scores ( $r = .35$ ,  $P < .05$ ), inattentive and impulsivity/hyperactivity symptoms (respectively,  $r = .67$  and  $r = .46$ ,  $P < .01$ ) and mood instability ( $r = .39$ ,  $P < .05$ ).

**Discussion.**— Racing thoughts are an important clinical feature of ADHD. Compared to mania, increased self-reported racing thoughts in ADHD suggests that they are perceived as more distressing. Moreover, in ADHD racing thoughts are associated with more severe symptoms, mood instability and sleep disorders. Future studies should focus on the characteristics of racing thoughts in ADHD, as they might be related to poorer clinical outcomes.

### Prevalence of obsessive-compulsive disorder in adolescent with high functioning autism

M. Abouzed\*, A. Meshref

Al-Azhar university, faculty of medicine, psychiatry department, Cairo, Egypt

\* Corresponding author.

**Background.**— Obsessive compulsive behaviors are common and disabling in autistic-spectrum disorders (ASD) but the prevalence of OCD is variable.

**Aim of the work.**— To estimate prevalence and characteristic features of obsessive-compulsive behaviors in adolescents with high functioning autism (HFA), in comparison with a normal developing control group.

**Patient and methods.**— 130 adolescents (70 HFA; 60 controls), aged 12–18 years, matched for age, gender and IQ were compared. AS

and OCD patients were diagnosed according to the DSM-V criteria. The Autism Diagnostic Observation Schedule and the Autism Diagnostic Interview-Revised were used to assist in the AS diagnosis; the WISC-R was administered to assess IQ. Obsessive and compulsive symptoms were evaluated by using the Children's Yale-Brown Obsessive-Compulsive Scale (CY-BOCS), OCD symptoms were carefully distinguished from stereotype behaviors and interests usually displayed by those with ASD.

**Result.**— The HFA group reported a mean of (7.4) obsessions and (4.8) compulsions compared with a mean of (6.6) obsessions and (4.3) compulsions in the control group. Somatic obsession with significant high in HFA group 24% versus 5% in control group and  $P$ -value  $< 0.001$ . and ritual 17% in HFA group versus 8% in control group with  $P$ -value  $< 0.001$ .

**Conclusion.**— The high functioning autism (HFA) had higher frequencies of obsessive-compulsive disorder, but without statistical significance although sub threshold obsessive symptoms as somatic obsessions and repeating rituals being more frequent in the HFA group and statistically significant.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

PW0022

### Prevalence of hoarding in adolescents with high functioning autism

M. Abouzed\*, A. Elsherbiny

Al-Azhar university, faculty of medicine, psychiatry department, Cairo, Egypt

\* Corresponding author.

**Background.**— Hoarding is characterized by the persistent inability or failure to discard possessions independent of actual value, the accrual of which results in debilitating clutter. As a result of these symptoms, individuals with clinically significant hoarding symptoms show impairments in social, family, economic and occupational functioning.

**Aim of the study.**— To estimate the prevalence and specificity of hoarding among youth with high functioning Autism (HFA).

**Patient and methods.**— 153 adolescent with ASD were examined to assess presence of hoarding syndrome and co morbid other psychiatric disorders. Parents completed questionnaires related to child hoarding behaviors, child behavior checklist/8 (CBCL), The Autism Diagnostic Observation Schedule and the Autism Diagnostic Interview-Revised were used to assist in the AS diagnosis and Schedule for Affective Disorders and Schizophrenia for School Aged Children for DSM-V (K-SADS-PL).

**Result.**— Sample means age was 13.8 sd  $\pm$  1.4. Male 102 (66.6%). Prevalence of hoarding syndrome among (HAF) was 26.7% (41 person) co-morbid OCD 60.9% anxiety disorders 41.4% ADHD 12.1%.

**Conclusion.**— Hoarding is a frequent co-morbid disorders in autism associated with anxiety disorders and ADHD, detection of this comorbidity may help in improve the outcome of behavior management of autism.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

<sup>2</sup> General hospital of Santorini, anesthesiology, Santorini, Greece;

<sup>3</sup> University hospital of Ioannina, psychiatric, Ioannina, Greece;

<sup>4</sup> Psychiatric Hospital of Thessaloniki, Psychiatric, Thessaloniki,

Greece; <sup>5</sup> General hospital of Santorini, general medicine, Santorini, Greece

\* Corresponding author.

**Background.**– Memantine is an N-methyl-D-aspartate (NMDA)-receptor antagonist. It is used to reduce abnormal activation of glutamate neurotransmission. Memantine is used in Alzheimer's disease improving cognitive function. Impulsivity and compulsivity characterize many psychiatric disorders. These behaviors may be caused in a problem in cortical circuits. There is the hypothesis that impulsivity can be triggered by the ventral striatum and compulsivity by the dorsal striatum and a different area of prefrontal cortex probably suppresses these behaviors. Memantine has good efficacy and tolerability therefore is increasingly being studied in a variety of non-dementia psychiatric disorders.

**Objective.**– According to the NMDA hypothesis we used memantine in 3 cases of comorbid Pervasive developmental disorder with impulsive aggression, non-responding to usual pharmaceutical practice.

**Material.**– Case 1: Patient with pervasive developmental disorder with multiple hospitalizations in psychiatric clinics due to serious domestic violence and impulsive behavior. Impulsive aggression and affective instability were present. Violence incidences were controlled with 10 mg of aripiprazole and 20 mg of memantine. Case 2: Patient with Asperger syndrome, with compulsive buying demands which lead progressively to impulsive aggressive behavior. The behavior was controlled with 4 mg of risperidone and 10 mg of memantine. Case 3: Patient with autism and comorbid psychosis, non-responder to medications, multiple hospitalizations due to serious domestic violence. Violence incidences were significantly reduced with the adjunction of 10 mg of memantine to the anti psychotic treatment.

**Results.**– Significant improvement of Violence incidences observed, with good tolerability, indicating that there may be a potential for an adjunctive treatment strategy for pervasive developmental disorders. Further research is needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0024

### Parenting styles and social skills of school-aged children with attention-deficit hyperactivity disorder (ADHD)

W. Charoenwongsak<sup>1</sup>, K. Wangtrakul, K. Luangbumroong, C. Kwunrod, P. Promchuy

Southern institute of child and adolescent mental health, Surat Thani, Thailand

\* Corresponding author.

**Background.**– Social impairment is not part of diagnostic criteria of attention-deficit hyper activity disorder (ADHD), but is strongly associated with the condition and still often persists after treatment of primary symptoms through medication and behavioral therapy. Interactions between parents and child, particularly par-

enting styles, have been found to be associated with wide-range of outcomes in child's life, but very few studies have been conducted in investigating its association with child's social impairment.

**Objective.**– To examine the association between parenting styles of primary caregivers and social skills of children with ADHD.

**Methods.**– We investigated the association in a sample of children (6–12 years of age), who were diagnosed with ADHD and have received treatment at Southern Institute of Child and Adolescent Mental Health in Surat Thani, Thailand, through questionnaires. Cross-sectional statistical analyses, including Pearson correlation, were used to examine the association between parenting styles and social skills of children with ADHD.

**Results.**– Total of 221 participants were analyzed; There are a negative correlation between neglectful parenting style and participant's self-control, problem-solving skill, and conflict resolution skill ( $P < 0.05$ ) and a positive correlation between authoritative parenting style and participant's self-confidence ( $P < 0.05$ ) while controlling for primary caregiver sociodemographic factors (marital status, education level, and income), participant's length of received treatment, and medication adherence.

**Conclusions.**– Neglectful parenting style has been found to be negatively associated with participant's self-control, problem-solving skill, and conflict resolution skill, while authoritative parenting style has been found to be positively associated with participant's self-confidence.

### Boredom proneness and its correlation with internet addiction and internet activities in adolescents with attention-deficit/hyperactivity disorder

W.J. Chou

Chang Gung Memorial Hospital, Kaohsiung medical center and college of medicine, department of child and adolescent psychiatry, Kaohsiung, Taiwan R.O.C.

**Objective.**– This study examined the associations of boredom proneness with Internet addiction and activities as well as the moderators for such associations in adolescents with attention-deficit/hyperactivity disorder (ADHD).

**Methods.**– In total, 300 adolescents who received a diagnosis of ADHD and were 11 to 18 years old participated in this study. Their Internet addiction, the scores for lack of external and internal stimulation on the Boredom Proneness Scale-short form (BPS-SF), ADHD, and parental characteristics were assessed. The types of Internet activities that the participants engaged in were also examined. The associations of boredom proneness with Internet addiction and Internet activities and the moderators of the associations were examined using logistic regression analyses.

**Results.**– Higher scores for lack of external stimulation on the BPS-SF were significantly associated with a higher risk of Internet addiction (Odds ratio [OR]=1.103; 95% confidence interval [CI]: 1.049–1.159). Maternal occupational socioeconomic status moderated the association of lack of external stimulation with Internet addiction. Higher scores for lack of external stimulation were significantly associated with a high tendency to engage in online gaming (OR=1.109, 95% CI: 1.043–1.180), whereas higher scores for lack of internal stimulation were significantly associated with a low tendency to engage in online studies (OR=.962, 95% CI: .926–.999).

**Conclusion.**– Lack of external stimulation on the BPS-SF should be considered a target in prevention and intervention programs for Internet addiction among adolescents with ADHD.

**Keywords:** Attention-deficit/hyperactivity disorder; Boredom proneness; Internet addiction; Internet gaming

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Intrauterine exposure to pre-eclampsia and the risk of autism spectrum disorder in offspring: A meta-analysis**

B. Dachew\*, A. Mamun, J. Maravilla, R. Alati

*The university of Queensland, institute for social science research, Brisbane, Australia*

\* Corresponding author.

**Introduction.**– Evidence on the effect of intrauterine exposure to preeclampsia on offspring Autism spectrum disorder (ASD) is not well-established.

**Objectives.**– To examine the association between preeclampsia and ASD.

**Methods.**– PubMed, EMBASE, and PsycINFO databases were searched. Pooled relative risks (RR) with 95% confidence interval (95% CI) were calculated. Subgroup and sensitivity analysis were performed. Heterogeneity was assessed using Cochran's Q and I<sup>2</sup> test statistics. The presence of publication bias was evaluated by Egger's test and visual inspection of the symmetry in funnel plots.

**Results.**– Ten studies meet the inclusion criteria. The pooled RR was 1.32 (95% CI; 1.20–1.45). Sensitivity analysis revealed consistent pooled estimates ranging from 1.30 (95% CI 1.17–1.44) to 1.37 (95% CI, 1.26–1.48). We found no significant heterogeneity or evidence of publication bias.

**Conclusion.**– Intrauterine exposure to pre-eclampsia increased the risk of ASD in offspring. The finding suggests need for early screening for ASD in offspring of women with preeclampsia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0027

### **Mental health among private high school students in Hanoi, Vietnam**

L. Dang

*Institute of population, health and development, research, Hanoi, Vietnam*

**Introduction.**– Mental health problems are common among Vietnam adolescent. However, studies focus on private high school students are limited.

**Objectives.**– Examine mental health status and related factors among private high school students in Hanoi, Viet Nam.

**Methods.**– 342 students in a private school completed a self-administered structure questionnaire in 2016. Strengths and Difficulties Questionnaire was used to screen 5 domains: (1) emotional symptoms; (2) conduct problems; (3) hyperactivity, (4) peer relationship problems; and (5) prosocial behaviors. The first four domains were added together to screen mental health problems and total score range is 0–40. We used the cut-off point of 15 to assess mental health problem. Statistical analyses were performed using STATA.

**Results.**– Mean age of participant is 16.79 ± 0.88 and 62.2% are boys. With the cut-off point of 15, 27% have mental health problems, not significantly higher in girls (30.2%) than boys (25%). Prevalence of participants with conduct and peer relationship problems are similar (24.7%) and higher than emotional problem (19.7%), hyperactivity problem (14.3%). 27% have prosocial behaviors. Bivariable analysis indicated various factors associated with mental health

problems among students such as: academic, athletic, social, and personal behaviors. Multinomial logistic regressions showed that studying time and frequency of playing game have significant association with mental health problems ( $P < 0.05$ ).

**Conclusion.**– The prevalence of students with mental health problems in our study is higher than some previous studies in Vietnam and shows the need of developing and implementing intervention programs at school to improve mental wellbeing of student.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0028

### **Self-evaluation of negative symptoms: A transdiagnostic observational study in first episode young patients, using the Self-evaluation of Negative Symptoms (SNS) Scale**

S.B. Guessoum<sup>1,2,3\*</sup>, F. Brunet<sup>1,2,3</sup>, L. Avenet<sup>1,2,3</sup>, A.L. Garnier<sup>1,2,3</sup>, C. Dubertret<sup>1,2,3</sup>, J. Mallet<sup>1,2,3</sup>

<sup>1</sup> INSERM u894, department of psychiatry, Paris, France; <sup>2</sup> Paris 7, Paris Diderot university, department of psychiatry, Paris, France;

<sup>3</sup> Louis Mourier university hospital, department of psychiatry, Colombes, France

\* Corresponding author.

**Background.**– Negative symptoms (NS) can be separated into two factors: diminished expressivity, including blunted affect and poverty of speech, and avolition/anhedonia/asociality. Since Schneider first rank symptoms of schizophrenia were spread, NS have been insufficiently studied and treated; despite they are factors of handicap and a public health burden. Moreover, NS are transdiagnostic symptoms found among patients without schizophrenia. We found no NS transdiagnostic study in early psychiatric disorders. The Self-evaluation of Negative Symptoms (SNS) scale is a new self-evaluation tool for NS.

**Aims.**– To compare NS among psychiatric diagnosis in first episode young patients with no psychiatric history.

**Method.**– In this observational prospective study, hospitalized patients were aged 15 to 26 and had no previous psychiatric history. Patients fulfilled the SNS scale, the Prodrome Questionnaire (PQ-16) for psychotic prodromes and other questionnaires for addiction and sleep disorders. Depression was evaluated with the Hamilton Depression Scale.

**Results.**– 23 patients were included. Average SNS score was 21.8 in the 9 patients with schizophrenia (confirmed 6 months later) whereas it was 17.5 in the 14 other patients, particularly 18.4 in the 10 depressive patients. The difference of SNS score between patients with schizophrenia and patients with depression was higher in diminished expressivity factor than in avolition/anhedonia/asociality factor. No correlation was observed between SNS score and depressive symptoms or prodroma.

**Conclusion.**– Both patients with schizophrenia and depression had negative symptoms but the SNS score was higher in patients with schizophrenia. NS could be a specific prognosis factor in first episode patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The utilization of a creative strategy in the prevention of the use of psychoactive substances with children and adolescents**

J. Jaber<sup>\*</sup>, S. Humel, S. Leite, A. Tomé, A. Hollanda, B. Reys  
Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

\* Corresponding author.

*Introduction.*– The work describes a successful experience in the utilization of art as a tool to work the prevention of the use of drugs. The experience was developed with children and adolescents between the ages of 3 and 17 who reside in a risky area near Latin America's biggest dump, located in the city of Taguatinga, FD, Brazil.

*Objectives.*– Create a therapeutic space to make possible the dialog with the children and adolescents, promoting the prevention and the consciousness about the harm of the use of psychoactive substances, providing clarification on the theme, through art, being the use of formal language and terms like “illicit drugs”, unnecessary.

*Methods.*– The children, who participated in the project, used, as expression tool, several painting items. The public was divided by age in two groups: the children received ludic approach, allowing the team nearness and interaction with them, in such a way that the former transmitted information and guidance about the harm on the use of psychoactive substances.

*Results.*– The results were satisfactory. All the children and adolescents involved in the project demonstrated adhesion to the use of the offered tools and established a communication link which allowed the receptivity of information about prevention in the use of psychoactive substances.

*Conclusions.*– Through the developed activities, it was observed that the strategy utilization of art as a language had better efficiency than a formal approach since the children and adolescents could have a learning space in a spontaneous way, demonstrating interest.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The relationship between parents' child rearing style and emotion-regulation skills in adolescents: The moderating role of parenting stress**

M. Kheradmand<sup>\*</sup>, S. Ghahari

Addiction institute, psychology, Tehran, Iran

\* Corresponding author.

*Background and objectives.*– Adolescence is one of the most challenging periods in people's life during which the individual is faced with personal, social, occupational and family problems on the one hand, and extensive physical and cognitive changes on the other; dealing with these problems and changes requires emotional regulation and management. Parents have a major role in fostering these skills. The present study aims to investigate the moderating role of parenting stress in the relationship between child rearing style and emotion regulation skills in adolescents.

*Materials and methods.*– The study population consisted of all the adolescents in Tehran in 2016, 400 of whom were selected from different districts of the city through multistage cluster sampling. The participants completed the Parenting Styles Questionnaire, the Parenting Stress Index and the Emotion Regulation Checklist. Data were analyzed in SPSS software.

*Results.*– The results showed that parenting stress has a moderating role in the relationship between authoritative parenting styles and emotion regulation in adolescents ( $P < 0.0001$ ); that is, an authoritarian child rearing style fosters emotion regulation in adolescents, but parents with stress cannot bring up children with emotion regulation abilities despite their authoritarian parenting style.

*Conclusion.*– Parenting stress can moderate the relationship between child rearing style and emotion regulation skills.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Potential barriers in the therapeutic relationship in unaccompanied refugee minors in mental health**

P. Majumder<sup>1\*</sup>, P. Vostanis<sup>2</sup>, K. Karim<sup>2</sup>, M. O'Reilly<sup>2</sup>

<sup>1</sup> University of Nottingham, medicine and health sciences, Nottingham, United Kingdom; <sup>2</sup> University of Leicester, psychology, Leicester, United Kingdom

\* Corresponding author.

*Introduction.*– Even though refugee children, particularly unaccompanied refugee minors, present with disproportionately high prevalence of emotional and psychological morbidities, this group of vulnerable but marginalised young people's access to utilize mental health service has been consistently shown to be significantly poorer than the general population. However, so far there has not been much research to explore the possible underlying reasons or barriers for them to access mental health service in their host countries.

*Objectives.*– This research aims to understand unaccompanied refugee minors' barriers to access and utilize specialist mental health services and to explore any specific issues that are perceived to be related to this poor engagement with the services.

*Methods.*– The study was conducted by using semi-structured interviews with fifteen unaccompanied refugee young persons and their carers to elicit their views, perceptions and beliefs based on their experience of receiving treatment from a specialist mental health service in the UK.

*Results.*– Thematic analysis was used to analyse the interview transcripts. After analysing the interview data, main findings were categorised into two broad themes, the participants' perceptions of the intervention received, and the professionals involved. The different elements and pertinent issues within these two broad areas were discussed.

*Conclusions.*– The findings will help stimulate further research into gaining better understanding of the barriers for these young people to access help, and contribute in developing services that are more efficient in engaging this vulnerable group and suitable to meet their specific needs.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Clinical use of long acting antipsychotic injection in an adolescent inpatient unit**

V. Muñoz Martínez, L. Asensio Aguerra, L. Nuevo Fernandez, C. Rodriguez Gomez-Carreño, B. Mata Saenz, E. Lopez Lavela  
Ciudad Real university hospital, psychiatry, Ciudad Real, Spain

\* Corresponding author.

*Introduction.*– Nowadays, mental health clinicians are treating children and adolescents with atypical antipsychotics at increasing

rates for a range of psychiatric illnesses, despite limited data on their efficacy in this age group. Age is clearly an important consideration when treating patients with different pathologies and treatment selection and outcome expectations have to be taken into account. But, when working with adolescents, other areas related to life quality also have to be taken into account. As a consequence, the use of long-acting injectable antipsychotic drugs is increasing in the treatment of adolescents.

**Objectives.**– To establish the effects of different long-acting antipsychotic drugs in an adolescent hospitalization unit.

**Methods.**– The review was made in order to study the numbers of relapse during one year after the prescription of a long-acting antipsychotic drug.

**Results.**– 49 patients were admitted in the unit. From those, 26 were treated with long-acting antipsychotic drugs (57.69% with Paliperidone Palmitate, 3.84% with Zuclophenthixol; 26.92% with Risperidone, and 11.53% with Aripiprazole. Patients' diagnoses: Schizophrenia 68.5%, bipolar disorder 17.3%, Autism Spectrum Disorders 0.6%, Disruptive Behaviour 7.3%, Drug Abuse 4.5%, and schizoaffective disorder 1.8%. Only three of those patients relapsed and had to be admitted again. We also reported a decrease in the number of bed days from 28.2 to 20.6 over the study duration.

**Conclusion.**– After the study, we concluded that physicians must clearly consider the use of long-acting antipsychotic drugs because of the low incidence of secondary effects, and also because of the increased treatment adherence and the decreased number of relapses.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Prevalence of sensory disturbances in an early autism diagnostic outpatient unit**

V. Muñoz Martínez\*, L. Mella Dominguez, L. Nuevo Fernández, B. Mata Saenz, M. Vela Romero, G.S. Adrian, V. Romero Vela, L. Asensio Aguerri

Ciudad Real university hospital, psychiatry, Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– In addition to the core features of autism, researchers have reported that children and adolescents with autism spectrum disorders (ASD) respond to sensory experiences differently from peers without disabilities. Impairments with modulating incoming sensory input have been widely reported in the literature describing autism characteristics.

**Objectives.**– To explore the sensory profile of young children with ASD compared to young children with other developmental delays (DD) at first ASD assessment in order to investigate the prevalence of sensory disturbances in each group.

**Methods.**– A total of 15 participants were collected from May 2017 to August 2017. The diagnosis were: Autistic traits 20%; Autism 40%; stereotypic movement disorder 6.6%, Communication, speech and language disorders 6.6% and no Neurodevelopmental disorder 26.6%.

**Results.**– 73.4% of the participants with ASD obtained significant scores in sensory processing. The results in the other groups were: for the stereotypic movement disorder 0.01%, for the communication, speech and language disorders 23.4%; autism traits 57.8% and for those children without a developmental disorder 5.5%. Scores at the ASD group at the SP were: taste and smell sensitivity (22.5%), auditory filtering (43.6%), underresponsive/seeking sensation (56.3%), tactile sensitivity (51.9%), taste and smell sensitivity (44.1%). The other scores at the SP items had not significant differences.

**Conclusions.**– Children with a neurodevelopmental disorder reported significant scores at the SP, related with sensory processing impairments.

Sensory processing skills play a role in the variable developmental performance of people with ASD. Recognizing these sensory processing contributions as a vital component of the complex developmental presentation in ASD.

### **Technology of diagnostic anxiety and depressive disorders in children with somatic diseases**

E. Mykhailova\*, T. Proskurina, D. Mitelov, T. Matkovska, N. Ryabokon

State institution "institute for children and adolescents health care of the NAMS of Ukraine", psychiatry, Kharkiv, Ukraine

\* Corresponding author.

**Background and aims.**– The study considers the problem of the anxiety–depressive disorders (ADD) in children with somatic diseases in the context of the search for effective methods of diagnostics.

**Materials and methods.**– The study included 160 children of 6–14 years with somatic diseases with the anxiety–depressive disorders. Design comprised: clinic psychopathological, somatoneurological, neurophysiological, psychological (Children's Depression Rating Scale Revised - CDRS-R; the Spielberg scale to estimate personal and reactive anxiety as well as "Me and my illness" and "Man in the Rain" projective drawing tests).

**Results.**– An alternative method of anxiety diagnosis in children with depression has been developed and approved. The method is based on determining of the intensity of anxiety and depression symptoms, integration of the information obtained in projective drawing tests ("A test on the ability to adapt to critical situations", Star-Wave Test), reflecting personality disturbances, depressive tendencies; anxiety index indicator according to the data of electroencephalography of heart rate variability (EEG HRV). In order to identify the severity of anxiety and depression symptoms a diagnostic index has been proposed – "The Coefficient of Anxiety and Depression Severity".

**Conclusion.**– The ability to determine the informative markers of the risk of anxiety and depression disorders development in children, prediction of unfavorable course of the disease, the timely differential treatment and secondary prevention of progression of depression in children with somatic diseases.

**Keywords:** Children; Anxiety and depression disease; Somatic diseases; Diagnostic index

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0035

### **The problem of rehabilitation of children with anxiety and phobic disorders**

E. Mykhailova\*, T. Proskurina, T. Matkovska, D. Mitelov, T. Ryabokon

State institution "institute for children and adolescents health care of the NAMS of Ukraine", psychiatry, Kharkiv, Ukraine

\* Corresponding author.

**Background and aims.**– Nowadays, there are almost no works on the mechanisms of anxiety and phobic disorders formation in child-

hood; therefore, there are no highly effective, pathogenetically founded methods of their treatment.

**Materials and methods.**– 108 children aged 7–14 with anxiety and phobic disorders were included in the study. Used techniques: Clinical psychopathological, the method of multidimensional assessment of children anxiety, structured psychological interviewing, questionnaires for children and parents about the presence of fears – the questionnaire by A.I. Zakharov, projective drawing tests, “Me in the Past”, “Me in the Present”, “Me in the Future”; “A Person in the Rain.”

**Results.**– On the basis of clinical features of anxiety and phobic disorders in pediatric practice there is a rehabilitation vector, which is based on the implementation of the 2 modules. Diagnostic module includes: finding out the sequence of occurrence of anxiety spectrum of complaints, considering phobias and symptoms of depression; definition of graphic signs of anxiety, of phobias and depression; analysis and integration of information obtained in projective drawing tests. The rehabilitation module includes: behavioral psychotherapy, mastering the techniques of muscle relaxation and a further systematic desensitization, in the presence of psychosocial problems providing a cognitive therapy, cognitive remodelling.

**Conclusion.**– Psychoeducation and psychotherapeutic effect contribute to the specific disclosure of a psychogenic situation, prevention of fixation and imprinting of anxiety and phobias, finding psychologically adequate ways to change the pathologically rigid attitudes and restoring a child’s adaptation and his ability to counteract stressful effects.

**Keywords:** Children; Anxiety and phobic disorder

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Screening for psychosis risk among help-seeking adolescents: Application of the 16-item Version of the Prodromal Questionnaire (PQ-16) in Italian neuropsychiatry services**

L. Pelizza<sup>1</sup>, S. Azzali<sup>1</sup>, F. Paterlini<sup>1</sup>, I. Scazza<sup>1</sup>, S. Garlassi<sup>1</sup>, A. Raballo<sup>2</sup>

<sup>1</sup> Reggio Emilia public health service, Reggio Emilia department of mental health, Reggio Emilia, Italy; <sup>2</sup> Norwegian university of science and technology, department of psychology, Trondheim, Norway

\* Corresponding author.

Among current screeners for psychosis-risk states, the 16-item Prodromal Questionnaire (PQ-16) is used. In order to implement a routine screening for identifying at-risk adolescents, we assessed psychometric properties of the Italian version of the PQ-16 in adolescent help-seekers. We included 72 individuals aged 13–17 years attending child and adolescent neuropsychiatry services of the Reggio Emilia Department of Mental Health. Participants completed PQ-16 and were subsequently assessed with the Comprehensive Assessment of At-Risk Mental States (CAARMS). We examined diagnostic accuracy (sensitivity, specificity, positive and negative predictive values, positive and negative likelihood ratios) and concurrent validity between PQ-16 and CAARMS using Cronbach’s alpha and Cohen’s kappa. We also tested the validity of the adopted PQ-16 cut-offs through Receiver Operating Characteristic (ROC) curves plotted against CAARMS diagnoses and the 1-year predictive validity of the PQ-16. The Italian version of the PQ-16 showed high internal consistency and acceptable diagnostic accuracy and concurrent validity. ROC analyses pointed to score of  $\geq 6$  on the total PQ-16 as best cut-off. After 12 months of follow-up, 14.3% of ado-

lescents with a PQ-16  $\geq 6$  cut-off at the baseline showed a psychotic disorder and 31.4% an Ultra-High Risk (UHR) status. Psychometric properties of the Italian PQ-16 were satisfactory.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Sleep-wake cycle instability as endophenotype of bipolar disorder: An actigraphy study**

A. Sebel<sup>1</sup>, E. Farkova<sup>2</sup>, M. Goetz<sup>3</sup>, T. Novak<sup>1</sup>

<sup>1</sup> National institute of mental health, diagnostics and treatment of mental disorders, Klecany, Czech Republic; <sup>2</sup> National institute of mental health, sleep medicine and chronobiology, Klecany, Czech Republic; <sup>3</sup> Charles university in Prague, department of child and adolescent psychiatry, Motol university hospital, Prague, Czech Republic

\* Corresponding author.

**Introduction.**– Bipolar disorder (BD) is defined by phasing of pathological elevated and depressed mood. Stable alternation of sleep and wake periods is essential for the regulation of emotions and stable mood. The sleep-wake cycle is regulated by circadian rhythms. Circadian rhythms, the same as BD, are genetically determined. Instable sleep-wake cycle therefore might be an endophenotype of BD.

**Objectives.**– This study compares the sleep-wake cycle and sleep characteristics in offspring of bipolar parents (BD-off) and controls.

**Methods.**– Case-control cross-sectional study. 30 days of actigraphic assessment controlled with sleep diaries. We analyzed interim data of 27 BD-off and 22 controls.

**Results.**– Samples did not differ in sex (11 females vs. 8 females; Fisher’s exact test;  $P = .77$ ) and age ( $10.1 \pm 2.3$  vs.  $9.7 \pm 2.3$ ;  $t = 0.23$ ;  $P = .77$ ). No significant between-group differences were found in sleep-wake rhythm parameters (stability;  $t = 0.74$ ;  $P = .46$ ; and variability;  $t = -1.36$ ;  $P = .18$ ). Total activity score was higher in BD-off than in controls ( $Z = 3.42$ ;  $P < .001$ ). Approximated daily sleep time was shorter in BD-off than in controls ( $7.7 \pm 1.3$  vs.  $8.1 \pm 0.5$  hours;  $Z = -2.21$ ;  $P = 0.03$ ). More poor sleepers (sleep efficacy  $< 80\%$ ) were found in BD-off (16/24 vs. 4/13; Fisher’s exact test;  $P = .047$ ).

**Conclusion.**– Although BD-off do not have dysregulated sleep-wake cycle, they have lower sleep quality than controls.

**Funding.**– Study was funded by the projects GA UK no. 476417 and AZV 17-32478A.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Specific interrelations between metabolites in the left dorsolateral prefrontal cortex of patients in remising state after first episode of schizophrenia. Single voxel 1H-MRS study**

M. Ublinskiy, N. Semenova, T. Akhadov, P. Menshchikov\*, A. Manzhurtsev

Clinical and research institute of emergency pediatric surgery and trauma, radiology, Moscow, Russia

\* Corresponding author.

**Object.**– We tested the hypothesis on metabolic abnormalities of dorsolateral prefrontal cortex (DLPC) in male patients with schizophrenia.

Table 1 Mean values ( $\pm$ SD) of signal intensities in 1H-MR spectra of left and right DLPC in patients (p) and controls (c).

		NAA/H <sub>2</sub> O	Cr/H <sub>2</sub> O	Cho/H <sub>2</sub> O	ml/H <sub>2</sub> O	Glx/H <sub>2</sub> O
Left_DLPC	Patients	0.83 $\pm$ 0.12	0.54 $\pm$ 0.11	0.35 $\pm$ 0.07	0.20 $\pm$ 0.10	0.20 $\pm$ 0.06
Left_DLPC	Controls	0.87 $\pm$ 0.09	0.58 $\pm$ 0.08	0.36 $\pm$ 0.09	0.24 $\pm$ 0.10	0.22 $\pm$ 0.08
Right_DLPC	Patients	0.83 $\pm$ 0.08	0.53 $\pm$ 0.07	0.34 $\pm$ 0.07	0.18 $\pm$ 0.07	0.19 $\pm$ 0.04
Right_DLPC	Controls	0.87 $\pm$ 0.07	0.53 $\pm$ 0.09	0.31 $\pm$ 0.06	0.19 $\pm$ 0.05	0.20 $\pm$ 0.08

Statistically significant correlation coefficients between variables, obtained in schizophrenia (left DLPC).

Variables pairs	Cr-Cho	Cr-NAA	Cr-ml
R	0.63	0.58	-0.51

**Materials and methods.**– The study was done in accordance to the Code of Ethics of the World Medical Association (Declaration of Helsinki) for experiments involving humans. All participants signed an informed consent.

22 young (16–28) male patients with schizophrenia (F20, ICD-10) and 26 mentally healthy age- and sex-matched subjects were analyzed. The 1H spectra were obtained on Phillips Achieva 3 T MRI scanner with PRESS (TE = 35 ms, TR = 2000 ms). The voxel was placed to the middle part of the middle frontal gyri (an area of DLPC) in both hemispheres. The signal intensities of NAA, Cho, Cr, ml, Glx were normalized to unsuppressed water. The intergroup differences and linear correlations were analyzed.

**Results.**– Although there were no intergroup differences by the tested metabolites, the correlations NAA-Cr and ml-Cr in the DLPC of left hemisphere were significant ( $P < 0.05$ ) only in the patient group ( $R = 0.58$ ,  $R = -0.51$ , respectively) (Table 1).

**Conclusion.**– The findings seemingly reflect the schizophrenia-associated abnormalities in the energy metabolism in atrocities and neurons of the DLPC.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Characteristics of diffusion in the corticospinal tract of patients with early stage of schizophrenia: Diffusion tensor magnetic resonance imaging

M. Ublinskiy<sup>1</sup>, N. Semenova<sup>1</sup>, T. Akhadov<sup>1</sup>, P. Menshchikov<sup>1</sup>, A. Manzhurtsev<sup>1</sup>, I. Melnikov<sup>1</sup>, I. Lebedeva<sup>2</sup>

<sup>1</sup> Clinical and research institute of emergency pediatric surgery and trauma, radiology, Moscow, Russia; <sup>2</sup> Psychiatry, national mental health research centre of the Russian Academy of medical sciences, psychiatry, Moscow, Russia

\* Corresponding authors.

**Object.**– Among various neurobiological models of schizophrenia, much attention is paid to structure and microstructure disturbances in brain white matter. The aim of this study is to research the most important pyramid pathway of the brain responsible for impulse transduction during motion regulation – corticospinal tract (CST) – using method of diffusion tensor imaging (DTI)

**Materials and methods.**– The study was done in accordance to the Code of Ethics of the World Medical Association (Declaration of Helsinki) for experiments involving humans. All participants signed an informed consent.

13 young (17–27) male patients with schizophrenia (F20, ICD-10) and 15 mentally healthy age- and sex-matched subjects were analyzed. MRI data were obtained on Achieva 3.0T scanner (Philips) with DualQuasar gradient system and 8-channel radio-frequency receiver coil for the head. DT-images were acquired in the axial

plane using echoplanar impulse sequence. Diffusion gradient were applied in 32 non-collinear directions.

Functional anisotropy (FA) and diffusion coefficient (DC) were measured in the following parts of CST in left and right hemispheres: motor area, radiate crown, posterior limb of internal capsule, cerebral peduncle, pyramids of the medulla oblongata (Tables 1 and 2).

**Results.**– A decrease in the coefficient of fractional anisotropy in the posterior limb of the internal capsule and an increase in diffusion coefficient in the radiate crown and motor cortex were observed.

**Conclusion.**– The results reflect different mechanisms of changes in water diffusion in various areas of the corticospinal tract: changes in nerve fiber microstructure in internal capsule (left hemisphere) and density decrease in motor cortex and radiate crown.

Table 1 FA Level in Various Areas of CST and Results of Between-Group Comparison (M  $\pm$  SD).

### Relaxation kinetics in the study of neurobiological processes using functional magnetic resonance imaging and spectroscopy

M. Ublinskiy, N. Semenova, T. Akhadov, P. Menshchikov\*, A. Manzhurtsev, I. Melnikov

Clinical and research institute of emergency pediatric surgery and trauma, radiology, Moscow, Russia

\* Corresponding author.

Biochemical reactions in normal living cells are multistage chemical processes that take place in a stable steady state. Study of the dynamic system behavior and kinetics of system return to the initial stable steady state provides ample information on the process mechanism. The aim of this study is to combine the method of localization dynamic spectroscopy we developed with relaxation kinetics techniques using MRI methods (fMRI and NMR).

9 mentally and neurologically unimpaired men comprised test group (mean age was  $22.1 \pm 1.9$ ).

MRI data were performed on Achieva Philips 3.0 T scanner. The fMRI audio-stimuli (tone, 1 kHz frequency, 70–80 dB) were presented to the test subjects. The test subjects were instructed to press a special button with the right hand index finger upon the stimulus presentation. The paradigm of the study consisted of 210 dynamics, the number of target stimuli was 30. A spectroscopic voxel measuring  $20'10'15 \text{ mm}^3$  was placed in the activation area.

Statistical analysis demonstrated that without a load all measured values are constant. The load effect is observed for two parameters:  $[\text{Hb}]/[\text{dHb}]$  (BOLD) and NAA. For  $[\text{Hb}]$  we observed three kinetically discriminable processes involving at least four kinetic stages. The variation of the NAA concentration follows similar kinetics.

Analysis has revealed six kinetically discriminable stages. The oxygen consumption activation processes are kinetically related to the concentration dynamics of the NAA as a neuronal marker. The developed approach reveals the multi-substrate character of the process and makes it possible to formulate hypotheses of the molecular response mechanisms (Figs. 1–3).

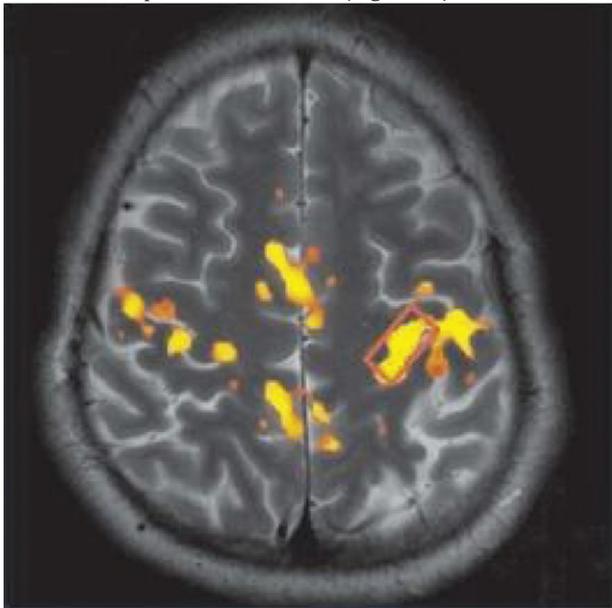

Fig. 1 Position of the spectroscopic voxel in the axial T2-weighted brain images.

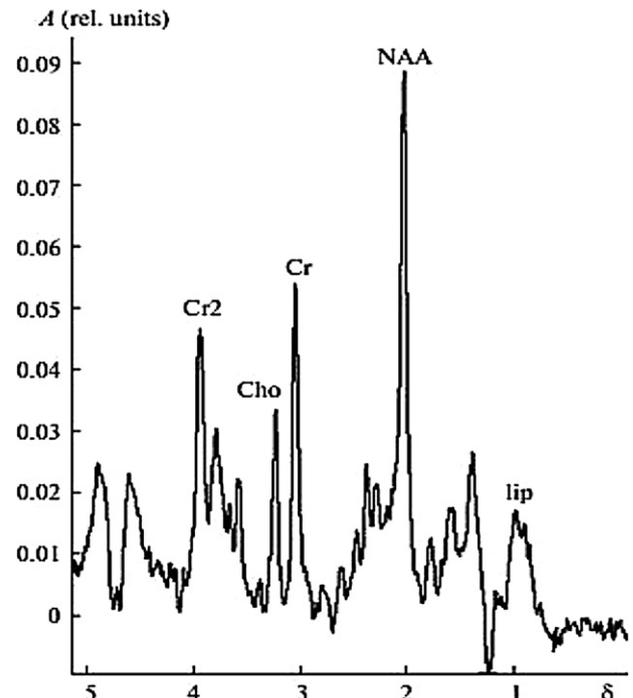

Fig. 2 1 h NMR spectrum of a human brain motor cortex sample.

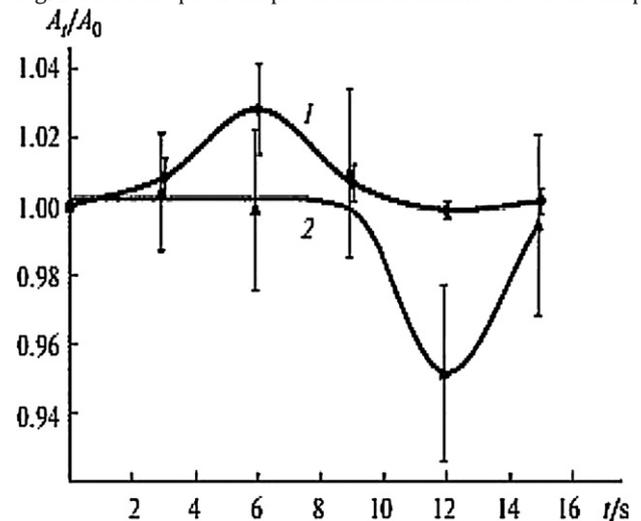

Fig. 3 BOLD signal (1) and dynamics of the averaged NAA signal amplitudes (2) in the  $^1\text{H}$  NMR spectra of the premotor cortex for time  $t$  ( $A_t$ ) normalized to the amplitude of NAA signal for  $t=0$  ( $A_0$ ).

### Clinical application of transcranial electrical stimulation in the treatment of cognitive and functional impairments of the autism spectrum

A. Subbotkina<sup>1\*</sup>, A. Uspenskiy<sup>2</sup>

<sup>1</sup> Rehabilitation center "Ogonek", rehabilitation department, Moscow, Russia; <sup>2</sup> Moscow establishment of social protection No. 31, rehabilitation department, Moscow, Russia

\* Corresponding author.

The severity of cognitive and functional impairments of the autism spectrum correlates with moving of activity focus and phenotypic

hemispheric asymmetry of basic cerebral rhythms (BEA, brain bio-electric activity). BEA variations are represented by hemispheric asymmetry > 50%, moving of activity focus of alpha-rhythm from occipital and parietal areas to frontal area of the brain, increased activity of slow (delta- and theta-) rhythms. The practical purpose was to correct the location of foci of basic cerebral rhythm and hemispheric asymmetry using method of transcranial electrical stimulation (ES) with feedback based on parameters of electroencephalography (EEG).

Two groups of patients were selected for the study. Inclusion criteria was the presence of hemispheric asymmetry > 50% and Childhood Autism Rating Scale (CARS) score > 37 points. The control group ( $n = 46$ ;  $CARS = 47 \pm 2.5$ ) received the standard treatment: drug therapy, speech therapy, educational and neuropsychological correction. Patients of the main group ( $n = 48$ ;  $CARS = 48 \pm 3.0$ ) received the standard treatment plus ES.

Patients of main group underwent ES session as follows: EEG analysis - ES - EEG. BEA registration and stimulation performed sequentially using the same device with the same leads. The brain stimulation parameters were determined using EEG. One of the schemes of stimulation was chosen: Bitemporal or Frontal-Occipital.

The main group showed 20% reduction of hemispheric asymmetry. CARS score after ES session was  $40 \pm 2.5$  ( $P \leq 0.05$ ). In control group BEA asymmetry persisted at the same level; CARS score after standard course was  $45 \pm 1.5$  ( $P \leq 0.05$ ). No reliable moving of focus activity was reached.

### Internet-delivered cognitive behavior therapy for OCD: A randomized controlled trial

R. Aly

*Egyptian association of cognitive behavior therapy, Cairo, Egypt*

*Introduction.*– During the last 45 years, cognitive behavior therapy (CBT) has gone from being a promising new treatment to the most well-established psychological treatment for obsessive compulsive disorder. In several hundreds of randomized controlled trials (RCTs), CBT has been shown to be effective in treating these disorders and is a first-line treatment for this condition.

*Objectives.*– Several forms of remote CBT have been developed, the general idea is that CBT delivered through the Internet or using telephone communication reflects the content of conventional CBT, but is administered as a form of therapist-guided treatment protocol using remote communication methods e.g. the Internet. Remote CBT consists of modules for therapy, each corresponding to a session in conventional CBT, which the patients practice as they progress through the treatment.

*Methods.*– A group of patients suffering from Obsessive compulsive disorder was randomized into two groups; one received CBT as usual & the intervention group received CBT using telephone &/or the Internet. Both groups were assessed pre- & post treatment.

*Results.*– Both groups of patients were committed to the treatment program & no differences in drop-out rates were detected between the two groups. Pre- & post study measures indicated a statistical & clinically relevant changes in patients of two groups.

*Conclusion.*– Delivering CBT for patients suffering from OCD in Egypt using remote communication methods (e.g. telephone &/or the Internet) appears to be effective in alleviating symptoms & improving the Quality of Life.

### Nosology of psychosis. A critical appraisal

A. Comparelli\*, M. Pompili

*Sapienza Università di Roma, Sant'Andrea hospital, neuroscience, Roma, Italy*

\* Corresponding author.

*Introduction.*– Despite the amount of emerging data from neuroscience and clinical research, new acquisitions continue to be ineffective on conceptualizing psychosis in a valid nosography.

*Objectives.*– The present reflection aims at critically evaluating whether or to which extent new information may be accommodated in an updated nosology of psychosis, with an advantage in the real world of the mental healthcare.

*Methods.*– We searched in MEDLINE/PubMed databases for articles published up to September 2017.

*Results.*– In the last two decades research reports have emphasized dimensional aspects of psychosis. According to the concept of extended psychosis phenotype, deriving from high-risk clinical studies, psychosis is a trans-diagnostic dimension, and schizophrenia only represents the poor outcome fraction of a much broader spectrum of psychotic disorders. At the same time, neurodevelopmental and genome wide association studies suggest that psychoses, rather than being etiologically discrete entities, could better be conceptualized as lying on an etiological and neurodevelopmental spectrum.

*Conclusions.*– Both dimensional and spectrum constructs of psychosis, though very appealing, set theoretical and pragmatic limits. The trans-diagnostic dimension of psychosis is not sufficiently supported by the available scientific data. The concept of spectrum – as promoted in the most recent edition of DSM – increases the problem of the blurred boundary between schizophrenia and other major psychoses, if it is not supported by thorough psychopathological and neurobiological knowledge that allows differentiating primary phenomena from secondary or compensatory ones. Research strategies may actually improve nosological issues of psychosis with a philosophic realistic position on the nature of psychiatric disorders.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Applying tetrad test to depression-specific symptoms, is there a latent trait?

R. García-Velázquez<sup>1\*</sup>, M. Jokela<sup>1</sup>, T.H. Rosenström<sup>1,2</sup>

<sup>1</sup> *University of Helsinki, psychology and logopedics, Helsinki, Finland;*

<sup>2</sup> *Norwegian institute of public health, Psykiske lidelser, Oslo, Norway*

\* Corresponding author.

*Introduction.*– Major Depression Disorder (MDD) is considered to be a latent trait that causes a particular set of symptoms. MDD is a heterogeneous disease with cognitive, affective and somatic complaints. The somatic criteria in MDD are unspecific and observed also in a number of other mental and physical conditions, so they may be caused by other comorbid diseases besides depression.

Affective-cognitive symptoms (low mood, anhedonia, feelings of worthlessness and thoughts of death or self-harm) are specific to MDD. It is unclear whether latent MDD causes the symptoms (reflective model) or whether MDD emerges from its symptoms (formative model).

**Objectives.**– To examine whether the model of MDD provides an adequate fit to the data when analyzing the four specific diagnostic criteria.

**Methods.**– We used data from the National Health and Nutrition Examination Survey (NHANES), a nationally representative sample of the US consisting of repeated cross-sectional measurements of adults ( $n = 29,228$ ). Depressive symptoms were measured with the PHQ-9 scale on a four-point Likert scale, and correspond to the DSM diagnostic criteria. We implemented bootstrapped tetrad tests to distinguish causal from effect indicators.

**Results.**– The analyses did not fully support the reflective model.

**Conclusions.**– The measurement model of MDD has direct implications for its diagnosis and treatment. Further evidence is needed on how MDD symptoms operate with respect to outcomes such as impairment, persistence, or duration of the disease; and with respect to each other (e.g., in network models).

### The new epidemic of the 21st century

M. Gómez García<sup>1</sup>, L. Gallardo Borge, H. De la Red Gallego, R. Hernández Antón, N. De Uribe Vitoria, M. De Lorenzo Calzón  
Hospital Clínico Universitario de Valladolid, psychiatry, Valladolid, Spain

\* Corresponding author.

**Introduction.**– Absenteeism of patients to the specialized consultation has a direct and negative impact on their quality of care and the economy of hospitals.

**Objectives.**– To estimate the frequency of absences in a psychiatric clinic of a mental health center in Valladolid, as well as its epidemiological and clinical variables, from January to August 2017.

**Material and methods.**– Descriptive prospective study of patients who did not attend their appointment at the psychiatric clinic.

**Results.**– Of the total number of patients cited, the percentage of absences was 18.98%, and 80% did not warn that they were not going to attend. In the sample analyzed ( $n = 216$ ) the mean age was  $50.48 \pm 16.79$  years, the percentage of women being 68.5%.

There was a greater number of faults when patients came for successive visits (86.6%), compared to first visits (13.4%). Analyzing the diagnoses according to the DSM-V code, it was observed that most of the absences corresponded to trauma-related disorders and other stressors (29.4%), followed by depressive disorders (23%) and by disorders related to the spectrum of schizophrenia, other psychotic disorders (12.8%) and Personality Disorders (7%).

In addition, it was observed that in the previous and subsequent month, only 2.8% needed emergency psychiatric care and 2.3% required hospitalization.

**Conclusion.**– Absenteeism generates unproductive and economic inefficiencies, observing that the highest percentage of absences are associated with patients who do not suffer severe mental illness.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Effect the influence of environment capacity (affordances) on motor development of 6–9 years old children with intellectual disorders

M. Homayounnia Firoozjah<sup>1</sup>, M. Sheikh<sup>2</sup>, R. Hemayattalab<sup>3</sup>, S. Shahrbanian<sup>4</sup>

<sup>1</sup> University of Tehran, physical education and sport science, Tehran, Iran; <sup>2</sup> University of Tehran, physical education, motor development, Tehran, Iran; <sup>3</sup> University of Tehran, physical education, Tehran, Iran; <sup>4</sup> University of Boali Sina, physical education, Hamedan, Iran

\* Corresponding author.

**Purpose.**– Affordance is the tendency to the development or encouragement of growth changes. It includes critical helps, encouragement, and/or directed training. This study aims at determining the influence of environment capacity (affordances) on motor development of 6–9 years old children with intellectual disorders.

**Methods.**– This study is empirical type with pre-test and post-test phases and control group. The statistical population of this research included all 6–9 years old children having IQ abnormalities from Babol city in 1396 who were 175. For evaluating children's motor development skills, Bruininks-Oseretsky test of motor proficiency was used. The obtained data were analyzed with multivariate covariance method.

**Results.**– The obtained results indicated that the affordances are influential in improving motor development skills such as the coordination of upper limb, agility, balance, speed of response and power, which their statistical power are 0.48, 0.39, 0.51, 0.19, and 0.49, respectively ( $P < 0.01$ ). Also, findings showed that affordances had no impact on controlling sight-motor, speed, and vivacity of the upper limb variables ( $P < 0.01$ ).

**Conclusion.**– Given the achieved results of the study, it could be concluded that there should be special attention to the environment and environmental capabilities, and using appropriate methods of affordance for enhancing motor development capabilities of children with IQ abnormalities. By using affordance methods and taking advantages of environmental capabilities, many medical procedures and their side effects could be avoided.

### Opinions of polish psychiatrist on psychiatry and their own professional role

A. Kochański<sup>1</sup>, A. Bielańska<sup>2</sup>, A. Cechnicki<sup>3</sup>

<sup>1</sup> Ex *CORDIS*, community psychiatry and psychotherapy unit, Lublin, Poland; <sup>2</sup> Association for the development of community psychiatry and care, schizophrenia research unit, Kraków, Poland; <sup>3</sup> Chair of psychiatry Jagiellonian university Collegium Medicum, department of community psychiatry, Kraków, Poland

\* Corresponding author.

**Aim.**– To analyze the opinions of Polish psychiatrists regarding perception of psychiatry by Polish society, by doctors in other fields and by the psychiatrists themselves.

**Method.**– 232 questionnaires were collected from psychiatrists and analysed.

**Results.**– 47% of the respondents think that the average citizen considers psychiatric treatment not very effective or ineffective, and

according to 54% a large proportion of the society associates psychiatric treatment with violence. 8.6% psychiatrists believe that over 60% of the population is convinced that psychiatry is used to protect those who have broken the law. 57% respondents believe that the prestige of psychiatry in the opinion of doctors of other specialties is low or very low and 62.5% think that those doctors judge the effectiveness of psychiatric treatment as low. 87.5% of the respondents often notice discrimination of psychiatric patients by doctors of other branches of medicine. 96% psychiatrists expressed satisfaction with having selected psychiatry and 67% believe that most of their colleagues share this satisfaction. 77% assess that the level of emotional stress in their profession is high or very high and 64% believe that the level of legal responsibility is above average. 87% psychiatrists believe that funding for psychiatry is lower than for other fields of medicine.

*Conclusions.*– Many surveyed psychiatrists believe that a large part of the population considers psychiatric treatment rather ineffective and linked with violence, that its prestige is low among somatic doctors and it is discriminated against financially, however they are satisfied with their career choice.

### **Prevalence of mental health problems among isolated indigenous youth from Amazonian forest**

D. Londe Rabelo Taveira<sup>1\*</sup>, P. Verlaine Borges e Azevêdo<sup>1</sup>, L. Ferreira Caixeta<sup>2</sup>

<sup>1</sup> Pontifical University Catholic of Goiás, medical department, Goiania, Brazil; <sup>2</sup> Federal University of Goiás, medical department, Goiania, Brazil

\* Corresponding author.

*Introduction.*– Indigenous populations worldwide exhibit higher expectancy of mental disorders compared to non-indigenous populations. Disintegration of the socio-cultural environment, acculturation process and territory loss contribute to the increased prevalence of psychiatric disorders. Although there is an important segment of indigenous population in Brazil, little is known about their mental health.

*Objectives.*– To estimate the prevalence of mental health problems in children and adolescents from indigenous people living in isolated tribes in the Brazilian Amazon Basin.

*Methods.*– A cross-sectional, population-based study was conducted with 214 native indigenous children and adolescents, aged between 7–14 years, of Karajá ethnicity. Prevalence of mental health problems were measured using the parent, teacher and self-reported versions of the Strengths and Difficulties Questionnaire (SDQ).

*Results.*– The prevalence of mental health problems (total problems) in children and adolescents was 22.17% according to parents (SDQ-P), 15.27% according to teachers (SDQ-T) and 5.19% according to adolescents (SDQ-S). Similar to literature data, males scored higher for hyperactivity and conduct problems, and females obtained higher punctuation for emotional and peer problems. Contrary to literature data, younger children (7–10 years) showed higher prevalence of mental disorders (26.83%) than adolescents (11–14 years) (15.73%).

*Conclusions.*– The prevalence of mental health problems was significant suggesting that, even in an ancestral culture that maintains habits from over 10,000 years, mental disorders exist with the same presentation that is found in industrialized societies and populations worldwide, although cultural context may influence its

manifestations. Prevention policies and mental health services are needed to address the unmet demand of the indigenous youth.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Classification of behaviors in dementia based on theories of information processing**

A.S. Luthra

Homewood health, program for older adults, Guelph, Canada

\* Corresponding author.

*Objective.*– There is vast heterogeneity in use of terminology and classification of behaviors in dementia with no universally accepted classification system. The objective is to classify behaviors in dementia based on impairment in theories of information processing.

*Methods.*– Criteria proposed by Davis, Buckwalter and Burgio (1997) were identified as the basis for classification of behaviors in dementia. A review of the literature was done to identify the “Specification of the Theoretical Construct” (STC) to justify aggregation of similar behavioral symptoms into clinically meaningful categories.

*Results.*– STC identified for these behavioral categories are those based in theories on information processing (TIP). Two behavioral categories emanating from pathological changes in TIP are: Disorganized Behaviors (DOB), and Misidentification Behaviors (MiB).

*Conclusions.*– DOB is the result of an alteration in the physiological status of the patient. This result in changes in arousal and attentiveness and this, in turn, leads to impairment of the sequential organization of information processing thereby giving way to fragmentation of the process at many different levels of the brain. MiB are the result of a specific breakdown in two specific steps of TIP; schema identification and pattern recognition. This result in the failure of the usual pairing of old and new information with an altered sense of relatedness between self and persons, places, objects and events.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **The DSM-ICD diagnostic approach as an invaluable bridge between the patient and the “Big Data”**

G. Mitropoulos

Psychiatric hospital of Attika, 4th department, Kifisia, Greece

\* Corresponding author.

Criticism towards DSM-ICD diagnosis traditionally regards such problems as hyponarrativity, biologism, “death of phenomenology”, and a questionably valid overfragmentation of diagnosis among others. Lately, criticism has shifted to such issues as lack of validity, having failed to adopt a dimensional stance, not adequately relying on genetics and neurobiology, and impeding research into the etiopathogenesis of mental disorders. The former problems seem to derive from the fact that the operationalist criteria have been uncritically accepted as the ultimate authority in diagnosis, instead of being merely guides, as intended explicitly; the latter problems have been made more evident since the emergence of the American RDoC research initiative, which not only points to an alternative, more valid, classification of mental disorders, but also aspires to signal a move of psychiatry towards precision medicine.

We examine the historical and epistemological context of the emergence of DSM, and its remarkable achievement in terms of diagnostic reliability as well as clinical utility. Then we consider the potential of the new era of genetics, neurobiology and analysis of the “big data” for generating a novel approach to psychiatric diagnosis and classification. We also discuss the particularity of the psychiatric object and the clinical significance of the categorical approach to diagnosis.

We conclude that the DSM-ICD approach continues to have a place in psychiatry as a bridge/interface between clinic and research data, as a common clinical language, and as an epistemic hub.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Singing about suicidal behaviours: An analysis of Spanish Punk Music (1981–2010)**

F. Pavez<sup>1\*</sup>, G. Jenkin<sup>2</sup>, P. Marset<sup>3</sup>, S. Collings<sup>2</sup>

<sup>1</sup> University of Murcia, Escuela Internacional de Doctorado, Murcia, Spain; <sup>2</sup> University of Otago, suicide and mental health research group, Wellington, New Zealand; <sup>3</sup> University of Murcia, Departamento de Ciencias Sociosanitarias, Murcia, Spain

\* Corresponding author.

*Introduction and objectives.*– The exploration of popular attitudes to suicide by investigating its depictions in art has been defended in literature on the grounds that suicide is not simply “a medical problem”. The complex nature of suicide is deeply embedded and mirrored in social, cultural, and historical narratives. This study describes the frequency of allusions to suicidal behavior in the song lyrics of Spanish punk bands, between 1981–2010. The results are compared with published studies of other musical genres.

*Methods.*– Discographies of the most representative punk bands in Spain, between 1981 and 2010, were reviewed. Instrumental songs and those sung in languages other than Spanish were excluded. Contents of song lyrics were analyzed looking for references to suicidal behaviors, defined as: non-suicidal self-injuries, suicidal thoughts, suicide attempts and suicide. Main outcome measures: Frequency of references over the entire period.

*Results.*– Of 2995 songs studied (2.64%,  $n = 79$ ) alluded to suicide-related behavior (only one reference to non-suicidal self-injuries).

*Discussion.*– Depictions of suicide in music are scarcely studied. Frequency of allusions to suicidal behavior in lyrics of Spanish punk songs are far below those described in a previous study addressing depictions of completed suicides, non-fatal suicide and suicidal thought in 337 Western operas written between 1607 and 2006 (2.64% vs 33%). Our understanding of the social meanings of suicide in music would be greatly facilitated by the replication of these studies to other musical genres and languages. This would allow for comparisons to illuminate common themes and nuanced differences between genres and languages.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0052

### **Portrayals of mental disorders in music: How are they studied?**

F. Pavez<sup>1\*</sup>, E. Saura<sup>2</sup>, G. Pérez<sup>3</sup>, P. Marset<sup>4</sup>

<sup>1</sup> University of Murcia, Escuela Internacional de Doctorado, Murcia, Spain; <sup>2</sup> Private practice, Psychology, Murcia, Spain; <sup>3</sup> University of Granada, Departamento de Historia y Ciencias de la Música, Granada, Spain; <sup>4</sup> University of Murcia, Departamento de Ciencias Sociosanitarias, Murcia, Spain

\* Corresponding author.

*Introduction and objectives.*– The importance of the study of social representations of mental disorders and psychiatry in music, and particularly in songs lyrics, have been discussed in previous communications. It is a small-explored topic, and most published articles do not exhibit a rigorous research methodology. In this communication, we review the methods used in published studies addressing depictions of mental disorders or mental health concerns in music (advantages and limitations); in order to propose a framework for the study of the social representations of psychiatry and mental disorders in song lyrics.

*Methods.*– Descriptive study. Methods used in thirty-seven articles addressing the depictions of mental disorders or mental health issues in music were reviewed. Frequencies of the research methods used are provided. Finally, a theoretical review of the advantages and limitations of different research strategies was performed.

*Results/Conclusion.*– Research designs are heterogenous between studies. Despite Content Analysis was the most frequent research strategy identified, there is a high representation of opinion articles or essays. Quantitative methods are rarely used (if we consider Content Analysis as a Qualitative Strategy). Content analysis is frequently used in studies addressing exposition to risk factors (mostly, depictions of substance use). We propose a mixed method by using descriptive statistics (frequency measures of allusions to mental disorders in song lyrics), followed by content analysis and thematic analysis. This strategy allows a deeper approximation to the contents, favoring the access to the social meanings of psychiatry or mental disorders expressed through music.

### **ICD-11 ecological implementation field studies: Inter-rater reliability and perceived clinical utility of diagnostic guidelines for common mental disorders applied to real patients by Mexican clinicians**

R. Robles<sup>1\*</sup>, M.E. Medina-Mora<sup>2</sup>, T. Rebello<sup>3</sup>, T. Domínguez<sup>4</sup>, N. Martínez<sup>5</sup>, F. Juárez<sup>1</sup>, P. Sharam<sup>6</sup>, G. Reed<sup>7</sup>

<sup>1</sup> National Institute of Psychiatry “Ramón de la Fuente Muñiz”, Direction of Epidemiological and Psychosocial Research, Mexico City, Mexico; <sup>2</sup> National Institute of Psychiatry “Ramón de la Fuente Muñiz”, General Direction, Mexico City, Mexico; <sup>3</sup> Columbia University Medical Center, Global Mental Health Program, New York, NY, USA; <sup>4</sup> Consejo Nacional de Ciencia y Tecnología, Cátedras CONACYT, Mexico City, Mexico; <sup>5</sup> National Institute of Psychiatry “Ramón de la Fuente Muñiz”, Subdirection of Clinical Research, Mexico City, Mexico; <sup>6</sup> All India Institute of Medical Sciences, Psychiatry, New Delhi, India; <sup>7</sup> World Health Organization, Department of Mental Health and Substance Abuse, Geneva, Switzerland

\* Corresponding author.

Ecological Implementation Field Studies were designed to evaluate the diagnostic guidelines proposed for the Chapter on Mental and Behavioural Disorders in the forthcoming Eleventh Revision of the International Classification of Diseases and Related Health Problems (ICD-11) in real patients.

*Objectives.*– To examine inter-rater reliability and clinical utility (goodness of fit, ease of use, and adequacy) of proposed ICD-11 diagnostic guidelines for psychotic, mood, anxiety and stress-related disorders applied to Mexican patients.

*Methods.*– A total sample of 153 patients participated in a psychiatric evaluation by an interviewer-observer pair selected from a pool of 23 psychiatrists / fourth or fifth-year psychiatry residents, who are actively engaged in clinical work for at least 10 hours per

week, and completed a brief training on ICD-11 guidelines under study. After that, the two clinicians assigned a diagnosis independently and evaluated the clinical utility of the ICD-11 diagnostic guidelines as applied to the particular patient.

**Results.**– The agreement between interviewer and observer across all diagnostic groupings was high. Sensitivity varied between .64 for anxiety disorders and .94 for stress related disorders, and specificity ranged from .84 for affective disorders to .98 for anxiety disorders. Kappa scores were significant for all groupings, ranging from .78 for psychotic disorders to .63 for stress-related disorders. A high proportion of clinicians considered that all diagnostic guidelines evaluated are quite to extremely useful.

**Conclusions.**– ICD-11 diagnostic guidelines for psychotic, mood, anxiety and stress-related disorders allow high inter-rater consistency between Mexican clinicians, who consider them also as very useful for routinely clinical work.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0054

### **Perfectionism as a systemic destructive factor of para-suicidal and suicidal behavior in cultural and clinical contexts**

E.T. Sokolova, L.S. Pechnikova, A. Ryzhov\*

Lomonosov MSU, faculty of psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Destructive forms of abuse (including abuses of eating, alcohol and psychoactive substances, work, digital technologies, sex, esthetic surgery, and practices of body and spiritual enhancement) are widespread in contemporary culture, characterized by pressure towards perfection in every aspect of one's life.

**Objectives.**– The clinical psychology aspect of the perfectionism study is supported by empirical evidence of its linkage to borderline type of personality disorder and predisposition to parasuicidal behaviors. It is assumed that systemic quality of destructive perfectionism would also lead to specific distortions of cognitive processes.

**Methods.**– 40 patients with F32 (depressive episode) and F43.2 (adjustment disorder) diagnoses and suicidal attempts were compared to 40 controls using: (1) The Multidimensional Perfectionism Scale (Hewitt, Flett, 1989; Gracheva, 2006), (2) a battery of cognitive tasks directed to reasoning evaluation (sorting test, etc.), (3) a modified proverb interpretation task, with the inclusion of strive for perfection content to study the reasoning processes in the ambiguous and emotion-charged situations.

**Results.**– (1) Significant differences ( $P < .05$ ) in number of cognitive distortions in high and low-level perfectionism groups (in both clinical and control subjects) were found in emotion-charged but not in neutral tasks. (2) Clinical group differentiated from controls by deficiency of symbolical thinking, extremity, flatness and subjectivity of reasoning, tendency to devaluation and idealization and incapacity to account for one's limitations.

**Conclusions.**– Perfectionism as a systemic factor of parasuicidal behavior is mediated by a complex of dysfunctional cognitive traits disabling constructive resolution of the critical or ambiguous life situations that require meaning-making and symbolization.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0055

### **Transgenderism in Poland**

D. Sendler

Felnett health research foundation, laboratory of forensic sexology, legal medicine, and digital ethnography, Staten Island, USA

**Introduction.**– Transgender lives continue to be understudies, especially in terms of understanding legal boundaries limiting access to specialized medical care. This study investigates the lives of transgender women and men living in Poland.

**Methods.**– A semi-structured interview study of 46 individuals (25 M, 21 F – by birth-assigned gender) was conducted throughout 2016 and 2017. Each meeting lasted about thirty minutes and participants responded to questions related to their experiences of changing gender in Poland.

**Results.**– Participants reported several issues concerning sex reassignment process in Poland. First, there is overwhelming bureaucratic bias against transgender petitioners seeking to legally change gender. In course of legal proceedings, transgender people are usually required to receive expert evaluation by a psychiatrist. Examination involves inappropriate touching of the genitals as indication of readiness for sex reassignments. Second, bureaucratically, most judges are not trained to handle cases of transgender petitions. As such, many have to hire a lawyer which puts them in difficult financial situation. Third, there are biases within the medical community where physicians often misinterpret transgenderism as a disease, potentiating maltreatment of transgender patients.

**Conclusions.**– Our data show that transgender individuals seeking to legally change gender in Poland are required to go through complicated and biased legal and medical assessments of fitness for change of gender. These processes often require medical examinations that are not based on scientific evidence, and increase stigmatization of this vulnerable sexual minority group.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **A peculiar case of Alice in Wonderland syndrome**

S. Tunc<sup>1</sup>, H.S. Basbug<sup>2</sup>

<sup>1</sup> Kafkas university, department of psychiatry, KARS, Turkey; <sup>2</sup> Kafkas university, department of cardiovascular surgery, KARS, Turkey

\* Corresponding author.

The term Alice in Wonderland syndrome (AIWS) was initially coined by John Todd in 1955 to describe some weird somesthetic aura involving the shape or size of the objects and body parts. The name of this disorder was inspired by the novel of Lewis Carroll and his novel hero Alice. Alice appeared to experience many body size changes throughout the course of the story. Alice even feels her body shrink (microsomatognosia) or growing unexplainably taller (macrosomatognosia) than she actually is. Such visual perceptual distortions may occur in epileptic seizures, encephalitis, drug intoxication, and may be described in patients with schizophrenia or brain lesions. However, migraine and epilepsy are highly involved diseases that cause this type of aural symptoms. In this paper, a unique presentation of a young AIWS patient who has been depressed by experiencing an intermittent perceptual disturbance of seeing her cat as a huge tiger was reported. AIWS is an important condition associated with various psychiatric and medical comorbidities and complications. The AIWS has not been classified yet in the International Classification of Diseases (ICD-10) and the Diagnostic and Statistical Manual of Mental Disorders (5th ed.; DSM-5). Therefore, this unique and fascinating disorder may be consid-

ered to be mentioned in the forthcoming issues of DSM under the heading of perceptual disturbances. On the other hand, the pathophysiology and the etiological mechanisms still remain unclear and the most probable etiopathological scenario seems to be the common neuropsychiatric impairments, these mechanisms should further be explained with detailed researches.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0057

### **Child abuse, psychopathology and cultural differences – Comparison of Hungarian and Norwegian general population**

V. Voros<sup>\*</sup>, P. Osvath, C. Skeisvoll, S. Fekete  
University of Pecs, department of psychiatry and psychotherapy, Pecs, Hungary

\* Corresponding author.

*Introduction.*– The association of child abuse and suicidal behaviour is indicated by several studies. However, the frequency of child abuse in the general population, the psychopathological consequences (depression, suicide intention) and cultural differences have not been systematically investigated.

*Methods.*– 100 (50 Norwegian and 50 Hungarian) age and gender controlled subjects completed questionnaires regarding child abuse (CATS), suicidal behaviour (MINI-SI) and general health status, including depression (PHQ-9). Chi<sup>2</sup> test, logistic analysis and Pearson's correlation were performed.

*Results.*– The rate of child abuse was higher in the Hungarian sample (50% vs. 30%; OR: 6.2), especially emotional abuse (40% vs. 18%; OR: 10.9), while sexual abuse was more common in the Norwegian sample (14% vs. 6%). Among Hungarians mild depression, low suicide risk (12% vs. 4%) and the rate of previous suicide attempts/gestures (6% vs. 4%) were higher however, there was no difference in more severe psychopathology (moderate or severe depression, significant suicide risk) between the two groups. In the correlation analysis suicide intentions were associated with sexual abuse (0.665), while depression was correlated with neglect (0.366).

*Conclusions.*– Child abuse is common in the general population. Our results strengthen the correlation between sexual abuse and suicide risk. Although, there were major differences in the rate of different abuses in the Norwegian and the Hungarian sample, there was no significant difference in psychopathology and depression. Beside cultural differences, this may also reflect differences in coping with traumas.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Comorbidity/Dual Pathologies - Part I**

PW0058

### **Prevalence of comorbid psychiatric disorder among children and adolescents with attention deficit hyperactivity disorder**

M.R. Mohammadi<sup>1</sup>, N. Ahmadi<sup>2\*</sup>, A. Shakiba<sup>1</sup>

<sup>1</sup> Psychiatry and psychology research center, Tehran university of medical sciences, Tehran, Iran; <sup>2</sup> Yazd cardiovascular research center, Shahid Sadoughi university of medical sciences, Yazd, Iran

\* Corresponding author.

*Introduction.*– Attention-deficit hyperactivity disorder is one of the most common psychiatric disorders among children and adolescents. Several studies have reported higher rates of other psychiatric disorders among affected children and adolescents that may complicate diagnosis, therapeutic interventions and prognosis.

*Objectives.*– In this study, the frequency of comorbidity in children and adolescents with attention deficit/hyperactivity disorder and its patterns according to gender and age is examined.

*Methods.*– In across-sectional community based study, 9636 children and adolescents aged 6–18 years were selected from five provinces in Iran. After screening with the Strengths and Difficulties Questionnaire (SDQ), then further evaluation was done using Persian version of Kiddie-SADS-Present and Lifetime Version (K-SADS-PL).

*Results.*– Among 9636 participants, 381 (3.96%) were diagnosed with ADHD. The overall prevalence of psychiatric comorbidity was 69.8%. The highest rate of comorbid disorder was for oppositional defiant disorder (44.1%), followed by anxiety disorders (35.4%), depressive disorders (13.9%), obsessive compulsive disorder (7.9%) and enuresis (7.3%). No significant difference was found between females and males in respect to the prevalence of comorbidities, and among specific disorders only depressive disorders had higher comorbidity in girls.

*Conclusion.*– We found high rate of comorbid psychiatric disorders among children and adolescents with ADHD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0059

### **The prevalence of attention deficit hyperactivity disorder symptoms and impairment of executive functions in a cohort of patients with schizophrenia**

I. Arican<sup>\*</sup>, A. McQuillin, G. Giaroli

University College London, molecular psychiatry, London, United Kingdom

\* Corresponding author.

*Introduction.*– The dearth of literature on adulthood attention deficit hyperactivity disorder (ADHD) as a persistent, comorbid condition in schizophrenia (SCZ), has resulted in a lack of recommended pharmacological treatments for the symptomatology the subgroup display. We have conducted a systematic review utilising the PRISMA statement criteria into the prevalence of child or adulthood ADHD in patients with SCZ. Of the 5 articles within our inclusion criteria, only 2 measured adulthood ADHD.

*Objectives.*– To examine the prevalence of childhood and adulthood ADHD symptoms in a cohort of patients with SCZ, and measure how executive functions (EF) are affected.

*Methods.*– Self-report questionnaires were used to investigate adult and childhood ADHD symptoms, and impairments of EF in 126 patients with ICD-10 diagnoses of SCZ. Using regression models the severity of ADHD symptoms were examined in relation to EF.

*Results.*– Nearly half of patients reported some lifetime ADHD symptoms. Twenty-nine patients (23%) reported symptomatology consistent with both childhood and adulthood ADHD, 14 (11%) reported only childhood and 16 (13%) only adulthood ADHD symptoms. Sixty-eight patients (54%) reported impairments in EF. Univariate analyses showed a strong association between higher scores for ADHD symptomatology and severity of EF impairments. Patients with only adulthood or childhood ADHD symptoms did not differ significantly by EF.

**Conclusions.**– The study suggests that the covariation between ADHD symptoms and SCZ is higher than that reported for the general population in literature and that ADHD symptoms predict a greater impairment of EF. The subgroup affected highlight the necessity of correct diagnosis and management.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0060

### **Age of onset of substance use disorder in patients with dual diagnosis and its association with clinical characteristics, risk behaviours, course and outcome**

D. Basu<sup>\*</sup>, S. Sahoo, B.N. Subodh, S.K. Mattoo  
PGIMER, psychiatry, Chandigarh, India

\* Corresponding author.

**Introduction.**– Do patients with dual diagnosis (DD) with an early onset of substance use disorders (EOS) differ from those with late onset substance use disorders (LOS) regarding characteristics, sex-related risk behaviour, course and outcome?

**Objectives.**– To study EOS and LOS groups of patients with DD attending an addiction treatment centre with regard to clinical characteristics, type of psychiatric disorders, sex-related risk behaviours and short-term outcome.

**Methods.**– Retrospective chart review of patients diagnosed with DD ( $n = 307$ ) with regard to the above variables. Diagnoses of both substance use disorders (SUD) and psychiatric disorders were made by direct interview of the patients according to ICD-10 criteria.

**Results.**– Among 307 subjects with DD, 100 were in EOS group (onset of SUD before 18 years of age as assessed clinically) and 207 in LOS group. Cannabis as the primary substance was more prevalent in the EOS (30%) than the LOS group (12%). Psychotic disorders were more prevalent in the EOS group (41%) followed by mood disorders (30%), while the reverse was true in the LOS group (27.5% and 56.5% respectively). Compared to the LOS group, the EOS group had higher number of psychiatric admissions, reported higher prevalence of risky sexual behaviours (unprotected sexual intercourse, multiple sexual partners and history of sexual intercourse with commercial sex workers), showed poorer treatment adherence, and worse outcome regarding both psychiatric disorder and SUD (all differences significant at  $P < 0.05$ ).

**Conclusions.**– DD patients differ significantly based on age of onset of SUD. These may have therapeutic and management implications.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction.**– Trait anger and anger attacks are common in psychiatric patients. However, there is a lack of research investigating the relationship between anger and types of psychiatric disorders.

**Objectives.**– The aim is to explore the prevalence of anger and its correlates in order to better understand how anger should be viewed in a clinical context.

**Methods.**– Using data from the Netherlands Study of Depression and Anxiety (NESDA) cohort study, anger (anger trait and anger attacks) was analysed in patients with anxiety ( $n = 263$ ), depressive ( $n = 141$ ), comorbid anxiety and depressive disorders ('comorbid',  $n = 155$ ), remitted participants ( $n = 1262$ ), and healthy control subjects ( $n = 470$ ).

**Results.**– High trait anger and anger attacks were present in respectively 28.4% and 42.6% of patients with a comorbid disorder compared to 2.6% and 5.1% of controls ( $P < 0.001$ ). Patients with anger attacks showed significantly higher mean of total trait anger scores across all diagnoses groups. Psychiatric diagnoses, male gender and depression severity (IDS) were significantly associated with both trait anger and anger attacks. Also alcohol abuse and BAI score were associated with higher trait anger score, whereas the use of benzodiazepines and other antidepressants than SSRIs or TCAs were associated with lower trait anger. Younger age was a significant determinant of anger attacks.

**Conclusion.**– Anger is a prevalent emotional state and trait in patients suffering from psychiatric disorders. Anger is most prevalent in male patients suffering from comorbid disorders and is strongly associated with depression severity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Evaluation of psychosocial factors and cognitive disturbances in patients with arterial hypertension of high cardiovascular risk**

N. Garganeeva<sup>1\*</sup>, M. Belokrylova<sup>2</sup>, I. Kartashova<sup>3</sup>, Y. Rakhmatullina<sup>1</sup>

<sup>1</sup> Siberian state medical university, department of general practice and polyclinic therapy, Tomsk, Russia; <sup>2</sup> Mental health research institute, Tomsk national research medical center, Russia, Borderline States Department, Tomsk, Russia; <sup>3</sup> Mental health research institute, Tomsk National research medical center, Russia, Clinics, Tomsk, Russia

\* Corresponding author.

**Objective.**– To evaluate influence of psychosocial factors and cognitive disturbances on the course of arterial hypertension (AH) in patients of high and very high cardiovascular risk.

**Methods.**– 150 patients (aged  $56.5 \pm 4.6$  years) with AH of 1–3 degrees were examined. CHD ( $n = 30$ ), type 2 DM or disturbance of glucose tolerance ( $n = 38$ ), an excess body weight, obesity ( $n = 40$ ), dislipidemia ( $n = 45$ ) were revealed. HADS and MMSE were used.

**Results.**– Anxiety and depressive disorders were revealed in 45% of AH patients. Within the last 6 months patients experienced a psychosocial stress which caused development of mental and psychological disadaptation. Stressful factors included stress at work, in the family, loss of the nearest one. According to HADS the average level of depression was  $10.5 \pm 1.2$  points, anxiety –  $12.5 \pm 1.5$  points. Anxiety level in women was higher ( $P = 0.001$ ). In patients with very high cardiovascular risk level of depression was higher ( $11.2$  to  $14.5$ ;  $P < 0.05$ ). Level of points according to MMSE was  $25.5 \pm 1.5$ . Men with depression differed by a heavier course of AH combined with CHD ( $P < 0.05$ ). Fear of death, frequent critical states, tachycardia, irritability were typical for AH patients with a high level of anxiety. AH patients with depression had a low mood, fixing on the psychoinjuring situation, a sleep disorder. Decreases in concentration of attention, quick exhaustibility, forgetfulness were observed.

**Conclusion.**– In AH patients of high and very high cardiovascular risk who experienced a psychosocial stress, course of AH was complicated by development of anxiety and depressive disorders and mild cognitive disturbances.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The effectiveness of mindfulness-based stress reduction (MBSR) in anxiety and depression in patients with multiple sclerosis (MS) in Iran**

S. Ghahari<sup>1</sup>, A.S. Ebrahimi<sup>2</sup>

<sup>1</sup> Iran university of medical sciences, mental health, Tehran, Iran;

<sup>2</sup> Islamic Azad university, Tonekabon Branch, Tehran, Iran

\* Corresponding author.

**Goal.**– Multiple sclerosis (MS) can be along with anxiety and depression. Then, the aim of this study is to investigate effectiveness of mindfulness-based stress reduction in anxiety and depression in patients with multiple sclerosis.

**Method.**– This study is in kind of semi-experimental research in form of pretest posttest with control group. All of patients with multiple sclerosis referred to Iran MS Association by 2016 were selected by available sampling method and based on having inclusion criteria. 30 depressed and anxious patients were selected and randomly classified in two groups (15 people in each group). Experimental group was under mindfulness-based training on stress reduction for 8 sessions with 2 h per session. Control group was in waiting list. All patients in experimental and control groups fulfilled depression and anxiety inventories before and after intervention. The data was analyzed using MANCOVA and in SPSS22 software.

**Finding.**– There is significant difference between the two groups in terms of anxiety and depression after intervention ( $p < 0.001$ ).

**Conclusion.**– Mindfulness-based stress reduction can reduce symptoms of anxiety and depression in patients with MS.

**Keywords:** Mindfulness-based stress reduction; Anxiety; Depression; Multiple sclerosis (MS)

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Does targeted coping skills training enhance the efficacy of motivational interviewing (MI) among young people with alcohol related-injuries accessing emergency department and crisis support care?**

L. Hides<sup>1\*</sup>, D. Kavanagh<sup>2</sup>, M. Daghli<sup>3</sup>, J. Connor<sup>4</sup>, S. Cotton<sup>5</sup>

<sup>1</sup> University of Queensland, school of psychology, Brisbane, Australia;

<sup>2</sup> Queensland university of technology, centre for youth substance abuse treatment, Brisbane, Australia; <sup>3</sup> Queensland health, hospital alcohol and drug service, Brisbane, Australia; <sup>4</sup> University of Queensland, centre for youth substance abuse treatment, Brisbane, Australia; <sup>5</sup> University of Melbourne, Orygen Youth health research centre, Melbourne, Australia

\* Corresponding author.

It is unclear which type of brief intervention (BI) for alcohol use in young people is most effective and there is significant scope to increase their impact. This randomized controlled trial determined if motivational interviewing (MI) enhanced with coping

skills training targeting the risk factors underlying alcohol use (MIC) was more efficacious than MI alone or an assessment feedback/information (AFI) only control. Participants were 394 young people (16–25 years) accessing an emergency department or crisis support service with an alcohol related injury/illness. Young people received (i) 2 sessions of MI; (ii) 2 sessions of MIC or (iii) a 1-session AFI. Participants (56% Female;  $M_{age} = 20.3$  years) were drinking on a mean of 1.4 days ( $SD = 1.5$ ) per week and consuming 10.7 ( $SD = 7.2$ ) drinks per drinking occasion at baseline and were followed up at 1, 3, 6 and 12 months (80% retention). Mixed effects model repeated measures analyses of variance found all groups achieved significant reductions in the frequency, quantity (standard drink units (SDU) and SDU/drinking day and alcohol-related problems. However, significantly larger reductions in the frequency and quantity of alcohol use were found in the MIC group compared to the MI and AFI groups. Moderators and mediators of treatment response will be reported. Telephone-delivered BIs provide a youth-friendly, accessible and easily disseminated treatment. All three types brief interventions resulted in reductions in alcohol use and related harm in young people. However, the addition of coping skills training targeting the risk factors underlying alcohol use enhanced the impact of MI.

### **Neurological soft signs in tunisian patients with first-episode psychosis and relation with cannabis use**

A. Mhalla<sup>\*</sup>, M. Gharmoul, B. Amamou, S. Boubaker, L. Gassab,

A. Mechri, L. Gaha

Faculty of medicine of Monastir, university of Monastir, department of psychiatry, Monastir, Tunisia

\* Corresponding author.

**Introduction.**– Neurological soft signs (NSS) are minor non-localizing neurological abnormalities that are conceptualized as neurodevelopmental markers that mediate the biological risk for psychosis.

**Objectives.**– We aimed to explore the relationship between NSS and cannabis use, an environmental risk factor of psychosis.

**Methods.**– This was a cross-sectional study in consecutively admitted patients hospitalized for first-episode psychosis in Fattouma Bourguiba Hospital, Monastir (Tunisia). NSS were assessed by the NSS scale. Presence of NSS was defined as a NSS scale total score  $\geq 9.5$ . Cannabis use was ascertained with the cannabis subsection in the Composite International Diagnostic Interview.

**Results.**– Among 61 first-episode psychosis patients (mean age =  $28.9 \pm 9.4$  years; male = 86.9%, antipsychotic naïve = 75.4%), the prevalence of current cannabis use was 14.8%. NSS were present in 83.6% of the sample (cannabis users = 66.7% versus cannabis non-users = 85.5%,  $P = 0.16$ ). The mean total NSS score was  $15.3 \pm 6.7$ , with a significant lower total NSS score in cannabis users ( $11.2 \pm 5.6$  versus  $16.0 \pm 6.7$ ,  $P = 0.048$ ). The linear regression model showed that this association remained significant after adjustment for two potentially confounding factors that have been associated with NSS: negative symptoms and neurological side effects of antipsychotics.

**Conclusions.**– This study demonstrated a negative association between cannabis use and NSS, especially regarding motor dyscoordination. This finding supports the hypothesis that a strong environmental risk factor, such as cannabis, may contribute to the onset of psychosis even in the presence of lower biological and genetic vulnerability, as reflected indirectly by lower NSS scores.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Psychological factors associated with glycemic control and adherence in type 2 diabetes

A. Mhalla<sup>1\*</sup>, H. Mhalla<sup>2</sup>, K. Ounaissa<sup>2</sup>, B. Amamou<sup>1</sup>, F. Zaafrane<sup>1</sup>, L. Gaha<sup>1</sup>

<sup>1</sup> Faculty of medicine of Monastir, university of Monastir, department of psychiatry, Monastir, Tunisia; <sup>2</sup> National institute of nutrition, external consultations and functional investigations department, Tunis, Tunisia

\* Corresponding author.

The relationship between diabetes and mental disorders and in particular depression has been widely established in the literature. The objective of this study was to determine the psychological factors associated with glycemic control and adherence to treatment in type 2 diabetes.

*Methods.*– This is a cross-sectional study of 102 outpatients with type 2 diabetes. Adherence was assessed by the Morisky et al. scale. Depression symptoms were assessed by the Beck scale, self-esteem was assessed by the Rosenberg scale. The evaluation of the satisfaction of the treatment was carried out by the “Diabetes Treatment Satisfaction Questionnaire”, the evaluation of the quality of life by “the Audit of Diabetes Dependent Quality of Life scale”, the evaluation of the affective temperaments by “the Tunisian Temperament Scale”.

*Results.*– The mean age was 53.4±8.5 years old. The glycated hemoglobin was positively correlated with depression score ( $r=0.26$ ;  $P=0.009$ ) and negatively correlated with adherence score ( $r=-0.23$ ;  $P=0.02$ ), quality of life score ( $r=-0.23$ ;  $P=0.02$ ) and treatment satisfaction score ( $r=-0.46$ ;  $P<0.001$ ).

Adherence score was positively correlated with age ( $r=0.21$ ;  $P=0.03$ ), self-esteem score ( $r=0.20$ ;  $P=0.04$ ) and satisfaction score ( $r=0.26$ ;  $P=0.02$ ) and was negatively correlated with the depression score ( $r=-0.26$ ;  $P=0.009$ ), cyclothymic temperament score ( $r=-0.21$ ;  $P=0.03$ ), irritable temperament score ( $r=-0.28$ ;  $P=0.005$ ) and the anxious temperament score ( $r=-0.19$ ;  $P=0.05$ ).

*Conclusions.*– Glycemic control and adherence to treatment in type 2 diabetes are associated with psychological factors such as depression, temperament and self-esteem.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Adult ADHD and bipolar disorder: The impact of ADHD co-occurrence on clinical features of bipolar inpatients

F. Oliva<sup>1\*</sup>, A. Portigliatti Pomeri<sup>2</sup>, P. Ferreri<sup>2</sup>, S. Bramante<sup>2</sup>, G. Nibbio<sup>1</sup>, C. Mangiapane<sup>1</sup>, M. Boero<sup>1</sup>, C. Pirlo<sup>1</sup>, G. Maina<sup>2</sup>

<sup>1</sup> University of Turin, biological and clinical sciences department, Orbassano TO, Italy; <sup>2</sup> University of Turin, neurosciences “Rita Levi Montalcini” department, Torino, Italy

\* Corresponding author.

*Introduction.*– The aim of the present study was to evaluate the prevalence of adult attention-deficit/hyperactivity disorder (ADHD) in inpatients affected by bipolar disorder, focusing on the impact of ADHD diagnosis on clinical features of bipolar disorder.

*Methods.*– A consecutive sample of patients admitted in the psychiatry ward for acute affective episode of bipolar disorder were assessed for adult ADHD by Adult Attention Deficit and Hyperactiv-

ity Self-Report Scale (ASRS-V1.1) and Diagnostic Interview for Adult ADHD (DIVA 2.0). The other comorbidities and the suicidal risk were evaluated using the Mini-International Neuropsychiatric Interview (MINI). Moreover, retrospective data about the onset and the course of bipolar disorder were collected by an ad-hoc questionnaire.

*Results.*– Twelve out of 44 bipolar patients (27%) were diagnosed with adult ADHD according to DSM-IV-TR criteria. Patients with comorbid ADHD showed a higher rate of previous suicidal attempts (25% vs. 13%,  $P=0.02$ ) and a greater suicidal risk (33% vs. 6%,  $P=0.02$ ). As regards the other comorbidities, the agoraphobia was more prevalent among patients with both bipolar disorder and ADHD (33% vs. 3%,  $P=0.005$ ).

*Conclusions.*– The prevalence of undiagnosed adult ADHD among our sample of bipolar inpatients was ten times higher than in general population (27% vs. 2.8%, Fayyad et al., 2017). Moreover, this comorbidity was tied to some of most severe features of bipolar disorder such as suicidal attempts and other comorbidities. Together these findings support the relevance of screening and assessment of ADHD in bipolar patients.

PW0068

### Training in substance abuse/dual disorders for psychiatric residents in the world: An international survey

V. Pereira Sánchez<sup>1\*</sup>, C. Gomez Sanchez-Lafuente<sup>2</sup>, E. Lopez de Munain<sup>3</sup>, H. Saiz<sup>4</sup>, T. Gomez Alemany<sup>5</sup>, C. Llanes<sup>6</sup>, M.A. Alvarez de Mon<sup>1</sup>

<sup>1</sup> Clinica Universidad de Navarra, psychiatry and medical psychology, Pamplona, Spain; <sup>2</sup> Hospital Universitario Virgen de la Victoria, Servicio de Psiquiatria, Malaga, Spain; <sup>3</sup> Hospital Universitario Ramon y Cajal, Servicio de Psiquiatria, Madrid, Spain; <sup>4</sup> Complejo Hospitalario de Navarra, Servicio de Psiquiatria, Pamplona, Spain; <sup>5</sup> Hospital Benito Menni, Servicio de Psiquiatria, Barcelona, Spain; <sup>6</sup> Complejo Asistencial de Zamora, Servicio de Psiquiatria, Zamora, Spain

\* Corresponding author.

*Introduction.*– Substance abuse and dual disorders (substance abuse + another psychiatric disorder) represent a challenge for early-career psychiatrists. An overview of training schemes around the world is important in order to encourage policies of improvement, and to strengthen international collaborations.

*Objective:* To conduct a survey comparing training schemes for psychiatric residents in substance abuse and dual disorders across countries from all over the world.

*Methods.*– National delegates from the countries included in the European Federation of Psychiatric Trainees (EFPT) and Young Psychiatrists' Network (YPN) were e-mailed with a 6-question survey about training and working opportunities for early-career psychiatrists in their countries regarding substance abuse and dual disorders. Questions asked for: length of psychiatric residency, specific training in substance abuse/dual disorders, specific training on adolescent populations, and facilities used for those disorders.

*Results.*– 60 countries were contacted, providing 13 responses: Nigeria, Iran, India, Azerbaijan, Turkey, Spain, Poland, Denmark, Czech Republic, Argentina, Mexico, Canada and USA. Great heterogeneity was found among training schemes. Only North American countries reported specific training on dual disorders and specific training in adolescent populations. Duration of training in substance abuse disorders is 1–4 years in North American countries and 1–7 months in the others. The most common kind of facilities are community-based centres, frequently coexisting with other public and private resources.

*Conclusion.*– Training in substance abuse and dual disorders seems heterogeneous around the world. North America counts with

longer and more specific training programmes. Further research, including more quantifiable data and countries, would provide policy-making results.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Are there differences between patients admitted into a dual diagnosis unit due to suicide attempt/ideation and patients admitted due to other causes?

E. Ribera-Bassols<sup>1\*</sup>, G. Mateu-Codina<sup>1,2,3</sup>, A. Farré-Martínez<sup>1,2,4</sup>, R. Sauras-Quetcuti<sup>1,3</sup>, J. Martí-Bonany<sup>2,5</sup>, M.T. Campillo-Sanz<sup>6</sup>, M.G. Hurtado-Ruiz<sup>6</sup>, R. Sánchez-González<sup>7</sup>, C. Castillo Buenaventura<sup>3</sup>, M. Torrens-Mèlich<sup>1,2,3,4</sup>

<sup>1</sup> Dual Diagnosis Unit, Institut de Neuropsiquiatria i Addiccions, Centre Emili Mira, Parc de Salut Mar, Psychiatry, Barcelona, Spain; <sup>2</sup> IMIM Hospital del Mar Medical Research Institute, Psychiatry, Barcelona, Spain; <sup>3</sup> CAS Fòrum, Institut de Neuropsiquiatria i Addiccions, Centre Fòrum, Parc de Salut Mar, Psychiatry, Barcelona, Spain; <sup>4</sup> CAS Barceloneta, Institut de Neuropsiquiatria i Addiccions, Hospital del Mar, Psychiatry, Barcelona, Spain; <sup>5</sup> Partial Hospitalization Program, Institut de Neuropsiquiatria i Addiccions, Centre Emili Mira, Psychiatry, Barcelona, Spain; <sup>6</sup> Acute Psychiatric Hospitalization Program, Institut de Neuropsiquiatria i Addiccions, Centre Emili Mira, Psychiatry, Barcelona, Spain; <sup>7</sup> Institut de Neuropsiquiatria i Addiccions, CSMA Sant Martí Nord, Parc de Salut Mar, Psychiatry, Barcelona, Spain

\* Corresponding author.

*Introduction.*– The probability of suicide in patients with substance use disorders is three to four times higher than in general population.

*Objectives.*– To describe the different characteristics between subjects with severe mental illness and co-morbid substance use disorders whether the reason of admission on a dual diagnosis unit was suicide attempt/ideation or not.

*Methods.*– We assessed all patients admitted into a dual diagnosis unit along three years by collecting sociodemographic and clinical data. We grouped them into two categories based on whether they were admitted due to suicide ideation/attempt or not. Comparisons between groups were carried out using chi-square test for categorical variables and T-test for continuous variables. Subsequently a multivariate analysis was performed using logistic regression.

*Results.*– There were 975 patients, of whom 71.7% were men. The mean age was 39.24 years (17–71). In 189 cases (19.4%), the reason of admission was suicide attempt/ideation. A significant relationship was found between suicide ideation/attempt and the following variables: female sex, married status, disability, pathology of axis I and II, and history of suicide attempts. In the logistic regression, a significant relationship was maintained with the variables female sex, married status, disability, pathology of axis II and history of suicide attempts.

*Conclusion.*– We found significant differences between the patients admitted due to suicide ideation/attempt and patients admitted due to other causes. These findings can help us to improve the treatment of those patients in the future.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Depressive symptoms in Parkinson's disease and recurrent depressive disorder

A.M. Romosan<sup>\*</sup>, L. Dehelean, M. Simu, A.C. Bredicean, I. Papava, R.S. Romosan

University of medicine and pharmacy "Victor Babes", neurosciences, Timisoara, Romania

\* Corresponding author.

*Introduction.*– Psychopathological symptoms, especially mood disturbances, are common in patients with Parkinson's disease. It has long been considered that the onset of depressive symptoms is secondary to motor symptoms (a reaction to the disability), but newer studies have shown that depressive symptoms can occur even before the onset of motor symptoms, suggesting that depressive symptoms are in themselves a possible neurological sign.

*Objectives.*– To identify differences between depressive symptoms in Parkinson's disease (PD) and recurrent depressive disorder (RDD)

*Methods.*– Eighty-four patients were included in this study. The first study group included 41 patients diagnosed with PD according to ICD-10 criteria and that had moderate or severe depressive symptoms upon study entry. The second group comprised of 43 patients with RDD according to ICD-10 criteria, who had either a moderate or a severe depressive episode upon study entry. The two patient groups were comparatively assessed by using the MINI Interview, the SCL-90, MADRS and HAM-D scales both upon study entry and after 1 month.

*Results.*– We found no statistically significant results regarding depressive symptom severity at baseline (study entry) between the two patient groups. At follow-up (1 month after study entry), patients with RDD had significantly lower HAM-D and MADRS total scores than patients with PD.

*Conclusions.*– Depressive symptoms in PD and RDD are similar in regards to severity, but not duration. Patients with RDD seem to have a quicker improvement of depressive symptoms than patients with PD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0071

### Clinical outcomes of the DA VINCI (Depression and Alcoholism: Validation of an Integrated Care Initiative) Project

A.V. Samokhvalov<sup>1\*</sup>, S. Awan<sup>2</sup>, C. Probst<sup>1</sup>, P. Voore<sup>3</sup>, J. Rehm<sup>1</sup>

<sup>1</sup> Centre for addiction and mental health, institute for mental health policy research, Toronto, Canada; <sup>2</sup> Centre for addiction and mental health, integrated care pathways program, Toronto, Canada; <sup>3</sup> Centre for addiction and mental health, acute care program, Toronto, Canada

\* Corresponding author.

*Background.*– Major Depressive Disorder (MDD) and Alcohol Use Disorder (AUD) are highly prevalent, comorbid and have significant impact on morbidity, mortality and socioeconomic burden in Canada. At the Centre for Addiction and Mental Health, Toronto, Canada, we developed and implemented an Integrated Care Pathway (ICP) specifically for treatment of concurrent MDD and AUD, which was then further implemented at 8 other sites across Ontario, Canada (the DA VINCI project). The goal of this study was to summarize the main clinical outcomes of the project.

*Methods.*– Prospective non-randomized cohort design. 246 patients included, 58.8% males. Statistical tests: t-test, Chi<sup>2</sup>, ANOVA, generalized linear models.

**Results.**– Overall completion rate was 70.7% with no significant variation between settings ( $\chi^2 = 3.35$ ,  $df = 2$ ,  $P = 0.19$ ). There was a statistically significant and clinically meaningful reduction in the number of drinking days per week ( $-1.81$ ,  $t = 8.78$ ,  $P < 0.001$ ). The cohort overall demonstrated significant and meaningful reduction in severity of cravings (PACS:  $-4.42$ ,  $t = 8.63$ ,  $P < 0.001$ ) and depressive symptoms (QIDS:  $-4.25$ ,  $t = 11.26$ ,  $P < 0.001$ ). While the baseline patient characteristics and treatment parameters varied between the settings, the variation in clinical outcomes was mostly insignificant, though more pronounced changes were observed in academic setting and with individual therapy.

**Conclusions.**– The study demonstrated that the ICP is a feasible and effective treatment for concurrent AUD and MDD that delivers meaningful clinical improvement in a variety of settings. Controlled study is needed to properly compare the treatment outcomes between ICP model and treatment as usual and to further explore the role of various factors on treatment outcomes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Barratt impulsivity and severity in gambling disorder

P. Sanchez Paez<sup>1</sup>, A. Ibañez Cuadrado, J. Saiz Ruiz  
Hospital Universitario Ramon y Cajal, Psychiatry, Madrid, Spain

\* Corresponding author.

**Background.**– Given the role of impulsivity on severity of substance use disorders [1] and gambling disorder [2]), the aim of this study was to determine the association of impulsivity and severity in a sample of gamblers.

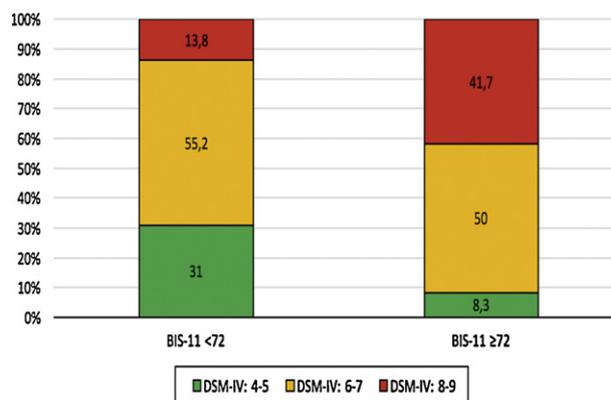

**Methods.**– The sample consisted of fifty-five men with gambling disorder. Trait impulsivity was measured by Barratt Impulsiveness Scale version 11 (BIS-11). The sample was categorized into highly and low impulsive by establishing the cut-off point at 72 [3]. Severity of gambling was evaluated by DSM-IV, considered to be mild if it complied with 4–5 items, moderate 6–7 items, and severe 8–9 items (APA, 1987).

**Results.**– The results showed a statistically significant positive correlation between BIS-11 and DSM-IV scores (Table 1).

Also, a statistically significant association ( $P < 0.05$ ) between impulsivity and severity was observed. Thus, 41.7% of highly impulsive gamblers had a severe DSM-IV score (8–9), compared to 13.8% of low impulsive gamblers (Fig. 1).

Fig. 1 Association between BIS-11 and DSM-IV severity in gambling disorder ( $P = 0.027$ ).

**Conclusions.**– These results show that impulsivity assessed by BIS-11 has prognostic implications in gambling disorder, given its association with severity. This is consistent with outcomes of recent studies [4].

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Bipolar disorder and comorbidity with drug use in hospitalized patients from a mental health unit from the South of Spain

O. Santamaria<sup>1\*</sup>, B.O. Plasencia<sup>2</sup>, S.L. Romero<sup>3</sup>, R. Navarro<sup>1</sup>, F. Gotor<sup>1</sup>

<sup>1</sup> Nuestra Señora de Valme university hospital, psichiatria, Seville, Spain; <sup>2</sup> La Merced hospital, psichiatria, Osuna Seville, Spain; <sup>3</sup> Virgen Macarena university hospital, psichiatria, Sevilla, Spain

\* Corresponding author.

**Introduction.**– Bipolar Disorder is the Psychiatric Disorder more frequently associated with Drug Dependence. This co-morbidity results in more hospitalizations, slower recovery and a poorer prognosis.

**Objectives.**– To analyze the variations in the number of admissions and average hospital stays in bipolar patients who meet diagnostic criteria for substance abuse or substance dependence and those non-users.

A comparative analysis of sociodemographic characteristics in bipolar patients in relation to toxic consumption.

**Method.**– A descriptive epidemiological and retrospective study that analyzed the medical histories of all hospitalized patients in the Mental Health Unit in the period between March 2016 and March 2017 with the following diagnoses: Type I and II Bipolar Disorder, Schizoaffective Disorder and Bipolar Disorder induced by substance or medical condition.

**Results.**– 1. Out of a total of 2137 admissions, 12% had a diagnosis of the referral diagnostics. Of these, 21% met criteria for substance abuse or substance dependence.

2. The following differences were statistically significant ( $P < 0.05$ ) in relation to variables studied: The average of admissions in consumers was higher than in non-users (5.5 vs. 3.2), with higher hospital stay (18.3 vs. 15.2).

Table 1 BIS-11 and DSM-IV correlations.

		Correlations		
		Rho Spearman		
		N	Correlation coefficient	p value
DSM-IV	Total BIS-11	53	0,441	0,001
	Attention impulsivity	53	0,461	0,000
	Motor impulsivity	53	0,340	0,012
	Non planning impulsivity	53	0,335	0,013

3. Sociodemographic Characteristics: Consuming patients: 82.3% men. Average age of 34.3 years\*. Rural sector: 58.2%. \* $P < 0.05$ .

4. There were statistically significant differences between toxic consumption and the variables sex and age ( $P < 0.05$ ).

**Conclusions.**– Toxic consumption, when is presented in comorbidity with Bipolar Disorder, results in more admissions and longer hospital stays. These patients are represented mostly by young men from the rural sector.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Purpose.**– To examine whether psycho-social variables are associated with increased activity of Crohn's disease (CD) and ulcerative colitis (UC).

**Methods.**– Cross sectional study design. Patients with active UC or CD completed demographics, economic status (ES), medical history, Brief Symptom Inventory (GSI, stress measure), List of Threatening Experiences Questionnaire (LTE, major stress events), Brief COPE Inventory (disease coping), Satisfaction with Life Scale (SWLS), SF-36.

**Results.**– The cohort comprised 122 patients with UC (mean age 38.6 (SD 14.0) years, 60.0% women) and 305 with CD (age 45.2 (15.1) years, 60.1% women). Psychological scores were higher in UC vs. CD: GSI 1.24 (0.8) vs. 0.9 (0.8),  $P < 0.001$ ; emotion-focused-strategies 24.5 (5.7) vs. 23.0 (5.7),  $P < .03$ ; problem-focused-strategies 16.4 (4.5) vs. 15.4 (4.2),  $P < .04$ ; dysfunctional-strategies 23.7 (5.7) vs. 22.0 (5.0),  $P < .01$ . LTE, SWLS, SF-36 and ES scores were similar in both diseases. UC activity was associated with gender, age, ES, GSI, LTE, all coping strategies, SWLS and SF-36 ( $P < 0.02$ – $0.001$ ). CD activity was associated with work status, ES, GSI, LTE, dysfunctional-strategies, SWLS and SF-36 ( $P < 0.05$ – $0.001$ ). In a multiple linear regression model UC activity was predicted by GSI (9.1% of variance), ES (6.9%), problem-focused-strategies (4.2%) and LTE (1.3%), and CD activity by LTE (5%), GSI (4%) and age (1%). The path analysis showed that GSI and problem-focused-strategies mediated the effects of ES, age and LTE on disease activity, with significant differences between UC and CD.

**Conclusions.**– Psychological stress impacted differently on active UC and CD. Therefore, psychological intervention should be different in the two diseases.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– Comorbidity between Bipolar Disorders (BD) and Eating Disorders (ED) is common. The incidence of ED in patients with BD varies from 9.9% to 28.8%. If the comorbid ED worsens BD, the effect of comorbid BD on the severity of ED remains unclear. The aim was to investigate whether the comorbid BD in patients with eating disorders was related to more severe ED behaviors.

**Method.**– 261 patients with ED defined by the DSM-5 criteria were consecutively recruited in an evaluation center of eating disorders from February 2012 to October 2014. The severity of ED symptoms was assessed using EDE-Q and EDI-2. Screening of the BD was carried out by the M.I.N.I with confirmation of the diagnosis in a center specialized in the evaluation of BD. **Results.**– After screening we found 47/353 suspicions of BD, the diagnosis was confirmed in 30 patients. Comorbid BD was associated with more anxiety disorders ( $P = 0.004$ ), substance use disorders ( $P = 0.002$ ), tobacco consumption ( $P = 0.03$ ), history of suicide attempts ( $P = 0.005$ ), history of hospitalization for ED ( $P = 0.02$ ). After adjustment, Eating Concern, Shape Concern and Weight Concern, Body dissatisfaction, Perfectionism, Interoceptive awareness, Impulse regulation were significantly higher for patients with comorbid BD.

**Conclusion.**– This study highlights (1) that comorbid BD increases eating disorders severity, (2) that comorbid BD must be evaluated by specialists to limit over diagnosis, (3) that ED which are the most associated with comorbid BD are bulimia nervosa, binge eating disorder and eating disorder not otherwise specified.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Mechanical restraint in the acute psychiatric unit of hospital del Mar, Barcelona

M. Angelats<sup>1\*</sup>, L. Pujol<sup>1</sup>, A. Brown<sup>2,3</sup>, A. Mas<sup>4</sup>, V. Pérez<sup>1,5,6</sup>, P. Salgado<sup>1</sup>, D. Bergé<sup>1,5,6</sup>

<sup>1</sup> Instituto de Neuropsiquiatria y Adicciones INAD, Parc de Salut Mar, Psiquiatria, Barcelona, Spain; <sup>2</sup> CISS-Chaudière-Appalaches, Centre hospitalier affilié universitaire, Hôtel-Dieu de Lévis, Psychiatry, Lévis Québec, Canada; <sup>3</sup> Université Laval, Chargé d'enseignement clinique, Québec, Canada; <sup>4</sup> Hospital de Palamós, Serveis de Salut Integrats Baix Empordà, Medicina de Família, Palamós, Spain; <sup>5</sup> CIBERSAM

Centro de Investigación Biomédica en Red de Salud Mental, Mental Health, Barcelona, Spain;<sup>6</sup> Institut Hospital del Mar d'Investigacions Mèdiques-IMIM, Parc de Salut Mar, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Mechanical restraint is an intervention used for the agitation management and to decrease fall risk. However, it is a procedure that implies ethical issues and adverse effects. According to bibliography, psychotic, manic and geriatric patients are the most restrained.

**Aims.**– To describe demographic characteristics of patients that have been under mechanical restraint in Hospital del Mar in 2016. We also want to know if factors as age, gender or diagnostic might have an impact on frequency and time spent under mechanical contention.

**Patients and methods.**– During 2016, there were 164 patients under mechanical restraint in the brief psychiatric hospitalization unit. We have collected retrospective data: age at the moment of contention, gender, principal diagnosis affecting the patient, among others.

A descriptive analysis and a logistic regression have been performed to study the relation between these variables.

**Results.**– Age varied between 19 and 89 years old; the mean was 40.48 years (SD 15.68). Men represented 56.7% of our sample, and women 43.3%. The three more frequent diagnoses were psychotic disorders (44.3%), bipolar disorders (26.8%) and schizoaffective disorder (12.8%).

Older age ( $P=0.01$ ) and masculine gender ( $P=0.03$ ) seem to be factors increasing the total hours that patients remained restrained. The diagnostic category seems to have no-influence on this outcome.

**Conclusions.**– According to our study, factors that influenced the most the total time of mechanical restraint are age and gender. We did not have found concrete diagnostic representing a physical restraint higher risk.

More research is needed to promote new measures of prevention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>3</sup> Hopital militaire d'instruction Mohamed V Rabat, psychiatry, Rabat, Morocco;

<sup>4</sup> Hopital militaire Moulay Ismail Meknes, psychiatry, Meknes, Morocco

\* Corresponding author.

As a part of a humanitarian mission and Following royal orders, The Health Military Department deployed a medico-surgical multidisciplinary hospital since august 2012 in Jordan close to Syrian-Jordanian border. The main of this mission is to give a medical and social support to Syrian refugees in the Zaatari refugee's camp. The psychiatric support given to Syrian refugees, who suffer from psychic traumatism or from known mental disorders, is given by a medico-psychological team: a military psychiatrist and a specialist nurse. They give psychiatric consultations; they also practice liaison psychiatry for the benefit of injured and patients who carry psychiatric pathologies with somatic complaints. In our work we faced that anxiety disorders are dominated by post traumatic stress disorder, which affect 15% of a population of refugees estimated at over 120 000, this prevalence of 15% is lower than what

was found within the civilian victims of armed conflicts in Kosovo (34%) and Gaza (38%), this low rate is related to the fact that the Syrian refugees have left conflict areas. Moroccan health department provided support and medico-psychological assistance for the benefit of a population of destitute refugees who left their country for fear of losing their lives after losing everything.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A model of home-based crisis intervention: A preliminary follow-up study**

J. Denis<sup>1\*</sup>, S. Hendrick<sup>1</sup>, A. Maisin<sup>2</sup>, A. Pecher<sup>2</sup>

<sup>1</sup> University of Mons,

systemic and psychodynamic clinical psychology department, Mons,

Belgium;

<sup>2</sup> CHP Chêne-aux-Haies, mobile psychiatric team, Mons,

Belgium

\* Corresponding author.

**Introduction.**– Home-based crisis intervention (HBCI) is an intensive clinically service designed to immediately (max. 24 hours) assist patients in crisis in their real life environment. Our mobile psychiatric team also integrates families in the treatment. We offer care delivery based on the needs of people with mental health problems and relational or emotional disorders.

**Objectives.**– The present preliminary study examines the effect of our HBCI model on health-related quality of life, symptom distress (depression, anxiety), interpersonal relationships (conflict with others), suicidal ideation or behavior and continuity of care in patient in crisis.

**Methods.**– Thirty patients experiencing an acute crisis, aged between 19 and 71 years, were assessed before and after our home-based treatment. The Nottingham Health Profile (NHP), the Hospital Anxiety and Depression scale (HAD), the Outcome questionnaire (OQ-45), the Scale for Suicide Ideation (SSI), and the Alberta Continuity of Services Scale for Mental Health (ACSS-MH) were used in a 9-month preliminary follow-up study.

**Results.**– Our results showed a significant decrease in distress symptoms and suicidal ideation after between three to 6 weeks of treatment with a large effect size. The dimensions related to the quality of life assessment also improved during the intervention. At the end of treatment, a majority of patients had a total OQ-45 score below clinical significance.

**Conclusion.**– This study suggests that our home-based crisis intervention may benefit for patient in crisis with improvement on several outcomes measures. However, the lack of comparison group entails caution when drawing conclusion.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Psychiatric presentations of anti-NMDA receptor encephalitis in adults and children**

R. Gurrera

VA Boston healthcare system, mental health/psychiatry, Brockton, USA

**Introduction.**– Anti-NMDA receptor encephalitis (anti-NMDARe) is caused by auto-antibodies binding to the NMDA receptor. Most cases occur in females with ovarian teratomas, but often no tumor is found and the trigger appears to be a virus or is never identified.

Given its strong association with ovarian pathology, an important question is whether the clinical presentation varies with age or sex. *Objectives.*– To identify salient clinical features of this disorder in male and female adults and children.

*Methods.*– EMBASE and PubMed databases were systematically searched in January 2017 to identify published anti-NMDArE cases in which behavioral symptoms were prominent.

*Results.*– The search yielded 200 adults (37M, 163F; mean(S.D.) age 32.1(12.4) years) and 175 children (47M/128F; mean(S.D.) age 11.6(5.5) years). There were proportionately more male children than adults (26.9% vs 18.5%); tumors other than teratoma were more common in men (13.5% vs. 2.1%), and viral prodromes were more common in boys (31.9% vs 21.6%). Most men and boys had unknown precipitants (61.2% vs 66.0%). Among females, teratoma was more frequent in women (38.0% vs 20.3%), as were other tumors (6.1% vs 0%). The trigger was unknown in 17.8% of women, compared to 39.1% of girls. Seizures, dyskinesias, or a speech/language disturbance were common across groups (78.4–95.7%).

*Conclusions.*– The clinical presentation of anti-NMDArE is minimally influenced by sex and age. Females are more likely to be pregnant or have reproductive organ tumors, whereas males are more likely to have unidentified triggers. Behavioral symptoms rarely present without seizures, dyskinesias or a speech/language disturbance.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

PW0080

### **Differentiating anti-NMDA receptor encephalitis from psychiatric disorders and neuroleptic malignant syndrome**

R. Gurrera

VA Boston healthcare system, mental health/psychiatry, Brockton, USA

*Introduction.*– Anti-NMDA receptor encephalitis (anti-NMDArE) is the most common form of autoimmune encephalitis. Symptoms including auditory and/or visual hallucinations, paranoia, grandiose or religious delusions, anxiety, depression, insomnia, aggression and hyperactivity can mimic primary psychiatric disorders, and consequently most cases are initially evaluated by a psychiatrist and treated with antipsychotic medications. This compounds the risk of misdiagnosis because fever, autonomic dysregulation and muscle rigidity occur in anti-NMDArE and can be confused with neuroleptic malignant syndrome (NMS). Without prompt treatment anti-NMDArE can cause severe long-term neurological and cognitive disability.

*Objectives.*– To analyze presenting signs and symptoms in published cases of anti-NMDArE to identify potentially distinctive patterns of features that may facilitate rapid diagnosis.

*Methods.*– Systematic computerized searches of EMBASE and PubMed databases conducted in January 2017 identified published anti-NMDArE cases in which behavioral symptoms were reported.

*Results.*– The search yielded 200 (37M, 163F) adult patients (mean (S.D.) ages 38.2 (16.4) and 30.7 (10.8) years, respectively). Seizures were observed in 28 (75.7%) men and 138 (84.7%) women. Ten (27.0%) men and 62 (38.0%) women manifested orofacial dyskinesias; 14 (37.8%) men and 80 (47.9%) women evidenced some form of dyskinesia. Eleven (29.7%) men and 45 (27.6%) women were dysarthric or had impaired language ability. At least one of these clinical signs was present in 29 (78.4%) of men and 153 (93.9%) of women.

*Conclusions.*– A first episode of psychosis or mood disorder, when accompanied by new onset seizures, dyskinesias, or speech or language disturbance, should prompt immediate consideration of an anti-NMDArE diagnosis.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Asylum seeker, refugee and migrant mental health and gender in Australia**

K. Jenkins

The Royal Australian and New Zealand College of Psychiatrists, OPCEO, Melbourne, Australia

*Introduction.*– Migrants and refugees in Australia have poorer mental health outcomes and poor access to health services compared to the general population. Women in general often face greater challenges to access of health care; this is especially true for migrant and refugee women.

*Objectives.*– This paper seeks to address how issues of asylum seeker, refugee and migrant mental health are being addressed and some initiatives being undertaken within the Australian context.

*Methods.*– The Royal Australian and New Zealand College of Psychiatrists (RANZCP) is concerned about the mental health of migrants and refugees. The RANZCP Asylum Seeker and Refugee Mental Health Working Group has developed a Position Statement that advocates for improved mental health outcomes for refugees and asylum seekers.

The RANZCP is part of the national Migrant and Refugee Women's Health Partnership (the Partnership), which brings together health professionals and community leaders to address systemic health barriers.

*Results.*– Through its Position Statement and membership to the Partnership, the RANZCP maintains that asylum seekers, refugees and migrants should have access to health care at a level comparable to the general population.

The RANZCP's involvement in the Partnership has helped to ensure that mental health care for migrant women is a priority across Australia.

*Conclusion.*– This paper highlights some of the work being done in Australia to improve mental health care access and outcomes for asylum seeker, refugee and migrant populations. However, more needs to be done, and psychiatrists should continue to advocate for the necessary supports and services for migrant and refugee populations.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Personality and cultural intelligence as factors of coping with stress of recent relocation and adaptation in multicultural environment in Russia**

S. Chigarkova<sup>1</sup>, G. Soldatova<sup>1</sup>, S. Khrushchev<sup>2\*</sup>, E. Rasskazova<sup>3</sup>, A. Tkhostov<sup>4</sup>

<sup>1</sup> Lomonosov Moscow State university, department of psychology, Moscow, Russia; <sup>2</sup> National research center for hematology, laboratory studying mental and neurological disorders in hematology, Moscow, Russia; <sup>3</sup> Lomonosov Moscow state university/mental health research center, Associate Professor, Senior Researcher, Moscow, Russia; <sup>4</sup> Lomonosov Moscow state university, the head of the clinical psychology department, Moscow, Russia

\* Corresponding author.

**Introduction.**– Studies of psychological factors of adaptation of migrants are important in multicultural countries with high migration level like Russia.

**Objectives.**– The aim was to reveal the role of personality and cultural intelligence in the adaptation in multicultural environment in those who recently moved.

**Methods.**– 1545 adults from 8 Russian regions were interviewed and filled NEO Five-Factor Inventory (McCrae, Costa, 1997), Expanded Cultural Intelligence Scale (Van Dyne et al., 2012), Hardiness Test (Maddi, 1998), Tolerance to Ambiguity Scale (Kornilova, 2009).

**Results.**– 16.7% moved less than 5 years ago and for 13.1% Russian language was not native. According to MANOVA, people who moved less than 5 years ago demonstrated higher openness and tolerance to ambiguity ( $F=3.98-5.19$ ,  $P<.05$ ,  $\eta^2=.01$ ) while those with other native languages reported higher extraversion, agreeableness, consciousness, motivational and behavioral cultural intelligence, intolerance to ambiguity ( $F=3.90-21.07$ ,  $P<.05$ ,  $\eta^2=.01-.02$ ) and felt more successful in multicultural environment ( $F=35.53-158.72$ ,  $P<.01$ ,  $\eta^2=.04-.14$ ). Hardiness commitment and control were lower in those moved less than 5 years ago only if Russian was not their native language ( $F=3.17-3.37$ ,  $P<.01$ ,  $\eta^2=.01$ ). In those moved less than 5 years ago cultural intelligence predicted better success in intercultural communication ( $\beta=.23$ ,  $R^2=11.3%$ ,  $P<.05$ ) while extraversion and emotional stability predicted hardiness commitment, control and challenge ( $\beta=.15-.44$ ,  $R^2=22.0-30.9%$ ,  $p<.01$ ).

**Conclusions.**– Results suggest that recently moved and speaking other languages people are vulnerable to stress feeling uncommitted and out of control but they could be more successful in multicultural interactions. Extraversion and emotional stability seem to compensate for negative effects of recent migration.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Determinants of mobility and migration trends of psychiatric trainees in Turkey: The role of gender**

O. Kilic<sup>1</sup>\*, G. Erzin<sup>2</sup>, M. Pinto da Costa<sup>3</sup>

<sup>1</sup> Koç university hospital, department of psychiatry, Istanbul, Turkey;

<sup>2</sup> Ankara Diskapi training and research hospital, department of psychiatry, Ankara, Turkey; <sup>3</sup>Hospital de Magalhães Lemos, Porto, Portugal institute of biomedical sciences Abel Salazar ICBAS, university of Porto, Porto, Portugal unit for social and community psychiatry WHO Collaborating centre for mental health services development, Queen Mary University of London, London, United Kingdom, Department of psychiatry, Porto, Portugal

\* Corresponding author.

**Introduction.**– Brain drain, the migration of skilled human resources from “donor countries” has an impact on health systems across countries. Particularly, Turkey in the last 50 years has suffered from emigration of skilled professionals such as medical doctors, although it is unclear how frequent such phenomenon is across medical specialities in the country.

**Objective:** This work aimed to present the views about migration among psychiatric trainees in Turkey.

**Method.**– Data from Turkey collected in 2013–2014 through a European cross-sectional study (the EFPT Brain Drain study) has been analysed.

**Results.**– 107 psychiatric trainees in Turkey responded to this study. Importantly, 74.5% of psychiatric trainees in Turkey have “ever” considered leaving the country, and the majority were adult psychiatric trainees. Male trainees were more likely to express intention

to leave the country compared to females ( $P=0.04$ ). Considering leaving the country was not found to be correlated with being adult or child psychiatric trainee, marital status or number of years spent in the training ( $P=0.386$ ,  $P=0.782$ ,  $P=0.903$ ).

**Conclusions.**– The majority of psychiatric trainees in Turkey considered leaving the country and most of these expressions were done by male trainees. Reasons behind this gender variation of mobility trends may be related with more frequent family concerns in women making them more willing to stay in Turkey, whereas for men, working abroad could bring the chance of postponing or avoiding doing the compulsory military service, which may be appealing for some.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Tolerability and patient satisfaction with inhaled loxapine for the treatment of acute agitation**

A. Porras Segovia<sup>1</sup>\*, M.Á. Arenas<sup>2</sup>, M.Á. Rosales-Muñoz<sup>3</sup>, B. Vela-Sánchez<sup>3</sup>, A. Oria<sup>3</sup>, P. De Jaime Ruiz<sup>1</sup>, J. Cervilla<sup>4</sup>, M. López-Pérez<sup>3</sup>, M. Reyes-Nadal<sup>2</sup>

<sup>1</sup> University hospital San Cecilio, mental health services, Granada,

Spain; <sup>2</sup> University hospital San Cecilio, mental health service,

Granada, Spain; <sup>3</sup> Hospital Virgen de las Nieves, mental health

service, Granada, Spain; <sup>4</sup> University of Granada, psychiatry

department, Granada, Spain

\* Corresponding author.

**Introduction.**– Traditional management of agitation includes intramuscular medication and, sometimes, physical restraint. These measures may be perceived as highly invasive by patients, thus hindering the therapeutic relationship.

Loxapine is a dibenzoxazepine tricyclic antipsychotic agent whose inhalatory administration was recently approved for the treatment of acute agitation in the context of schizophrenia or bipolar disorder.

**Objectives.**– We aim to explore the tolerability and satisfaction with inhaled loxapine in agitated patients.

**Methods.**– Patients suffering from agitation in an acute inpatient psychiatry unit were recruited to participate in the study. Only patients with a minimum level of cooperation were considered. Group assignment was performed using an alternate sequence. Cases received inhaled loxapine, while controls were administered intramuscular antipsychotic medication, mainly olanzapine or haloperidol.

Treatment Satisfaction Questionnaire for Medication (TQSM) and UKU side effect rating scale were administered after the agitation episode had resolved.

**Results.**– Our sample consists on 30 patients who were diagnosed either with schizophrenia or with bipolar disorder. Patients in the case group showed a significantly higher score on the Treatment Satisfaction Questionnaire for Medication. Inhaled treatment was generally well tolerated, with a low score on the UKU scale.

**Conclusions.**– The pain-free inhaled administration that Loxapine offers is well tolerated and it is perceived as a less invasive treatment than injected medication.

The use of inhaled loxapine in inpatient psychiatry units, where agitation is a common phenomenon, could help patients from feeling that the treatment they are receiving is actually a “punishment” for their inadequate behaviour, a misperception that often comes with intramuscular medication.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0085

### **Audit of demographic and diagnostic variables influencing psychiatric intensive care length of stay**

A. Raffi<sup>1</sup>, A. Bann-Khellaf

Priory hospital Cheadle Royal, psychiatric intensive care, Cheadle, United Kingdom

\* Corresponding author.

**Background.**– Psychiatric Intensive Care (PICU) is for patients detained in secure conditions in acutely disturbed phases of serious mental illness. Department of Health (DoH) Guidelines state PICU stay should not exceed 8 weeks. There is limited data on factors affecting PICU stay including demographics and diagnosis of patients.

**Aim.**– The Audit compared length of stay (LoS) in a private PICU service across a 6 month period and examined ethnicity /diagnosis of patients.

**Methodology.**– 6 months of patient data across PICU service from March to August 2017 ( $n=124$ ) using electronic patient records and analysed.

**Results.**–

Sample size = 124 (27 female/97 male).

Mean LoS was 29.4 days (male 28.7, female 31.8).

Mean LoS females, diagnosis Schizophrenia was 80.9 days ( $n=7$ ).

Mean LoS males, diagnosis personality disorder (PD) was 45.8 days ( $n=5$ ).

15 patients exceeded 8 week DoH guidance for LoS (Male 12, female 3).

3 patients exceeded LoS by 7 weeks all had primary/secondary diagnosis of PD.

Mean LoS for non-white patients was 56.2 days ( $n=24$ ).

**Conclusions.**–

Mean LoS 29.4 days is consistent with other studies (26.5–34.3 days).

Female PICU attracts difficult to treat cases which reflects higher LoS in those with Schizophrenia.

Male PICU has attracted larger number of referrals pertaining to recidivism which reflects longer LoS in PD and in those patients who exceed DoH guidelines significantly.

A call for improved cultural understanding of patient needs may assist reduction of LoS in non-white patients (56.2 days).

The audit highlights the need for further understanding into demographic and diagnostic factors in PICU services.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0086

### **Highly frequent users at the psychiatric emergency services: What are their differential characteristics?**

B. Reneses<sup>1\*</sup>, G. Seara<sup>2</sup>, A. Del Rey<sup>2</sup><sup>1</sup> Hospital Clinico San Carlos, institute of psychiatry, Madrid, Spain;<sup>2</sup> Hospital Clinico San Carlos, institute of research, innovation unit, Madrid, Spain

\* Corresponding author.

**Background.**– The phenomenon of high frequentation in the psychiatric emergency services may be an indicator that some subjects are not receiving adequate care in outpatient and/or inpatient mental health services. In countries with a National Health Service, with a universal coverage, as in the case of Spain, this phenomenon requires special attention because it would indicate a gap in the expected care pathways.

**Methods.**– Retrospective study of 15,045 patients who received care at the Psychiatric Emergency Service of a University General Hospital in Madrid (Spain) from 2006 to 2016. Subjects were classified as “highly frequent users” or not, considering that those who have received emergency psychiatric care more than 3 times with periods shorter than 6 months between them are “highly frequent users”. 924 subjects were found to be “highly frequent users” and 14,121 were found not to be. Both groups were compared according to their socio-demographic and clinical characteristics and the emergency care resolution in their last attendance.

**Results.**– Highly frequent users were younger (25 to 49 years, range age more represented), they had a significant major proportion of suicide attempts, diagnosis of schizophrenia and psychotic disorders, bipolar or personality disorders (specifically BPD). Highly frequent users were more frequently admitted in the inpatient psychiatric units and had more voluntary emergency service discharges.

**Conclusions.**– Highly frequent users of psychiatric emergency services should be studied with the objective to identify possible gaps in their care pathway. Attention should be focused on psychotic, bipolar and personality disorders and in patients who committed suicide attempts.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0087

### **Prevalence of psychiatric diagnoses among torture survivors globally: A systematic review protocol**

H. Turner

NHS Shetland, general medicine, Aberdeen, United Kingdom

**Introduction.**– While we would like to think torture belongs to the past, it is unfortunately very relevant to modern European medicine, particularly psychiatry. Mental health service providers may frequently come into contact with survivors, although this might not be recognised at the time. An understanding of prevalence rates of psychological illness following torture could aid recognition and management. A review of the literature in this area has not been published since 1988 [1].

**Objectives.**– To determine the prevalence of anxiety, depression and PTSD diagnoses among survivors of torture worldwide.

**Methods.**– Databases MEDLINE, PsychINFO and EMBASE were searched using terms relating to psychological disorders, prevalence and torture. Studies were appraised using the JBI Critical Appraisal Checklist, and data extracted using a modified JBI Data Extraction Tool. Data was then synthesized as a narrative summary with graphs and tables as heterogeneity prevented meta-analysis. Subgroup analysis took place to investigate heterogeneity.

**Results.**– Results varied widely for each outcome, ranging between 4% to 100% for depression, 10% to 91% for anxiety and 18% to 90% for PTSD.

**Conclusions.**– It was concluded that a range of factors such as migration, asylum seeking and experience of war may affect prevalence of psychological illness in torture survivors, leading to the variation in the literature. Further research is needed into the causes of variation. The need for high quality research was also highlighted.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Differences between Syrian refugee patients from an outpatient clinic who wants to migrate to Europe and stay in Turkey

E. Uygun<sup>1\*</sup>, Ş. Başar<sup>2</sup>, M. Kızıdoğan<sup>2</sup>, A.T. Aker<sup>3</sup><sup>1</sup> Prof. Dr. Mazhar Osman psychiatric and neurological diseases training and research hospital, psychiatry, İstanbul, Turkey;<sup>2</sup> İstanbul Bilgi university, psychology, İstanbul, Turkey; <sup>3</sup> İstanbul Bilgi university, trauma and disaster mental health, İstanbul, Turkey

\* Corresponding author.

**Introduction.**– The growing number of refugees and inadequate level of support for the basic needs of immigrants lead them to search and try different ways to move on places where the better living conditions can be provided.

**Objective:**The aim of this study is comparing the social and mental health parameters of refugees who wants to immigrate to Europe and plans to stay in Turkey in the irrational refugees who applied for immigrant/refugee mental health.

**Method.**– Data forms were created by researchers to be applied to people who have been applied to the BRSHH immigrant and refugee mental health outpatient clinic and some scales were given to asses PTSD, Depression, Perceived Stress, Well Being and Quality of Life. **Results.**– In total 70 people were included in this study with an average age of 34.4 and 38 of them were women. It was founded that the higher the level of education ( $P=0.05$ ),the lower mental well-being status scores ( $P=0.04$ ),higher male gender ( $P=0.02$ ), the presence of a friend or relative in Europe ( $P=0.04$ ) and higher the PTSD score levels ( $P=0.05$ ) were statistically significant when we compared two groups.

**Conclusion.**– There is no other study to compare our data because of the reason that it's the first one that addresses this topic and also there is a need for qualitative studies to define the relationship between the significant findings that we found and the claim to migrate to Europe. Firstly we should understand refugees to prevent their migration from illegal ways.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Migration and duration of untreated psychosis in first-episode patients

S. Vilas Boas Garcia<sup>\*</sup>, R. Mateiro, I. Pinto, T. Filipe, T. Teodoro, M.J. Avelino, M. Martins, J. Salgado

Centro Hospitalar Psiquiátrico de Lisboa, Clínica 1, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– A higher risk for psychosis is estimated to be present in migrants. An extended duration of untreated psychosis (DUP) is associated with worse outcome in first-episode psychosis (FEP). Several factors contribute to DUP. Current findings regarding DUP's relation to migrant background are inconsistent.

**Objectives.**– The aim of this study is to understand the relationship between migration and DUP in FEP. Firstly, it seeks to determine if migrants FEP patients have different DUP than native patients. Secondly, this study also investigates sociodemographic characteristics of migrant and native groups and its association to DUP.

**Methods.**– A total of 52 FEP patients were included. The 10th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD-10) was used for diagnosis. Data relating to DUP and clinical and sociodemographic characteristics were collected retrospectively from case notes.

**Results.**– Mean DUP was 36.9 weeks (median 12, SD = 73) in migrant group and 45.5 weeks (median 16, SD = 65.7) in native group. There

was no statistically significant difference between DUP in both groups. Mean age was 39 for migrant group and 35 for native group. There was a weak positive correlation between age and DUP in migrants ( $\rho=0.300$ ). Migrant group had more female patients (65%) than native group (34%).

**Conclusions.**– Despite DUP was shorter in migrant than in native patients, a comparison of FEP patients from both groups revealed no significant difference in DUP. More studies are needed to better understand FEP patients in migrant population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Emergency patients with mental crisis accessing emergency medical services in Thailand

P. Wachiradilok<sup>1\*</sup>, T. Sirisamutr<sup>1</sup>, A. Somton<sup>2</sup><sup>1</sup> National institute for emergency medicine, research and development unit, Nonthaburi, Thailand; <sup>2</sup> National institute for emergency medicine, technology and information, Nonthaburi, Thailand

\* Corresponding author.

**Introduction.**– Emergency responders face an increasing number of calls involving people with behavioral and mental crisis issue. They must be able to recognize signs of mental distress, apply proven techniques for dangerous situations and referrals for them to obtain mental health care.

**Objectives.**– To study the situation, characteristics, issues, and accessibility to the emergency medical services (EMS) and appropriate treatment for emergency patients with a mental crisis in Thailand.

**Methods.**– The sample included 26,511 mental crisis patients using EMS from the Information Technology for Emergency Medical System between 2014–2016 and stakeholder from four provinces distributed regionally using focus group and in-depth interview. The data were analyzed using descriptive statistics and content analysis.

**Results.**– The number of mental crisis patients with EMS is increasing for the past 5 years. Most patients are male in working age group from the Northeastern during the raining and cold season, especially between September and October. During patients with maniacal attacks, assistance will be requested from the police and the emergency units. The response depends on the experience and community capability. The operation teams have insufficient knowledge and skills. Emergency rooms in most hospitals lack specific caring unit. Psychiatric hospitals have different criteria for admitting patients. Most had not fast track system and even refuse admittance.

**Conclusion.**– Accessibility to appropriate service centers was still an issue. Most staffs had insufficient knowledge and skills. Cooperation among the police, emergency operation team and the psychiatric team is still a challenge.

PW0091

### Comparison of outcomes of a crisis stabilization unit compared to an emergency department

L. Zun<sup>1\*</sup>, L. Downey<sup>2</sup><sup>1</sup> Mount Sinai hospital, emergency medicine, Chicago, USA;<sup>2</sup> Roosevelt university, school of public health, Chicago, USA

\* Corresponding author.

**Background.**– The primary objective of this study was to examine and identify methods of assessing levels of agitation in psychiatric patients presenting to the ED, which are not commonly involved with ED triage of psychiatric patients.

**Objective.**– The purpose of this study was to assess psychic pain on a similar rating system as somatic pain, assess levels of agitation (self-reported and observed), and compare measured psychic pain to levels of agitation.

**Methods.**– The sample population included patients, 18 years or older, presenting with a psychiatric illness to a level one inner-city Emergency Department. Patients were surveyed immediately upon arrival to ED and every 30 minutes, for a total of 2 hours using both observational or self-reported surveys. Patients were enrolled and surveys were administered by a research fellow. This study was IRB approved.

**Results.**– A total of 151 participants were enrolled and 93 completed at least 1 hour. Upon arriving to the ED, among patients who self-reported moderate/marked levels of agitation 87.3% were given agitation scores of none/mild with PANSS-EC agitation survey, and 84.4% were given none/mild by ACES calmness evaluation. Self-reported psychic pain showed significant differences from self-reported levels of agitation.

**Conclusions.**– The results show significant differences between the observational surveys and self-reported surveys and amongst the self-reported surveys. The results suggest the use of both observational and varying self-reported surveys to obtain a complete picture of patient levels of agitation and psychic pain on arrival to the ED.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0092

### Comparison of an suicide assessment tool to usual care

L. Zun<sup>1</sup>, L. downey<sup>2</sup><sup>1</sup> Mount Sinai hospital, emergency medicine, Chicago, USA;<sup>2</sup> Roosevelt University, Healthcare Policy, Chicago, USA

\* Corresponding author.

**Purpose.**– The primary objective of this study is to compare the SPRC Risk Assessment Tool (Decision Support Tool) to the current suicide assessment for patients who present to the emergency department.

**Method.**– A convenience sample of patients that presented to the ED with a psychiatric complaint who consented to be part of the study was utilized. The SPRC responses and subsequent disposition were compared to those elicited by the current evaluation tool used by the mental health worker. These assessments were obtained retrospectively.

**Results.**– A total of 70 patients were enrolled in the study. When patients answered yes to question 1 (they had considered a suicide plan), crisis workers noted a plan in 52.9% (18) of these patients. However, when patients answered yes to question 2 (they had suicidal intent), crisis workers noted suicide ideation in 79.3% (23) of these patients. Of the patients who answered yes to question 3 (they had previously attempted suicide), crisis workers reported previous attempts in 58.5% (24) of these patients. Despite this difference between crisis worker assessment and Decision Support Tool data, the recommended disposition and actual disposition of patients were similar. Recommended admission was 40.7% (22) of cases, while actual admission was 46.3% (25). Recommended transfer and actual transfer were equal at 31.5% (17) of cases. Recommended discharge was 25.9% (14) of cases, while actual discharge was 22.2% (12).

**Conclusion.**– The results of the Decision Support Tool and the crisis workers' assessments differed in individual qualitative measurements but not in patient dispositions.

### Impact of opioid receptor genes on anticipatory and consummatory pleasure in schizophrenia

M. Alfimova<sup>\*</sup>, T. Lezheiko, N. Kondratiev, M. Gabaeva

Mental health research center, clinical genetics, Moscow, Russia

\* Corresponding author.

**Introduction.**– Anhedonia is a prominent feature of schizophrenia. A comprehensive understanding of neurobiological processes contributing to anhedonic symptoms may help in developing their effective treatments. Two phases of pleasure experience have distinct neurochemical mechanisms. The anticipatory phase is driven by the dopaminergic pathway, while the consummatory phase involves dopamine and opioid receptor activation. In contrast to dopamine receptor genes, opioid receptor genes have not been much studied in relation to schizophrenia.

**Objectives.**– We investigated associations of hedonic capacity of schizophrenic patients with genes encoding delta (OPRD1) and mu (OPRM1) opioid receptors.

**Methods.**– 248 inpatients with schizophrenia spectrum disorders (mean age 38 (SD 13) years, 62% women) and 208 healthy controls (33(14) years, 53% women) donated blood for DNA extraction and completed the Temporal Experience of Pleasure Scale (TEPS). OPRD1 rs618886 and/or OPRM1 rs1799971 were genotyped.

**Results.**– When sex and age were taken into account, patients showed lower TEPS scores than controls ( $P=0.0001$ ). Both anticipatory and consummatory pleasure were decreased ( $P=0.002$  and  $P=0.0001$ , respectively). The differences were more pronounced in men. None of the genes had main effects on the TEPS scores. For OPRD1, an interaction effect of the gene with sex and diagnosis on anticipatory pleasure was found ( $P=0.03$ ). Schizophrenic men carrying the OPRD1 minor allele had the lowest scores and differed significantly from healthy men ( $P<0.003$ ). The same trend was seen for consummatory pleasure ( $P<0.04$ ).

**Conclusions.**– The OPRD1 gene polymorphism may modify severity of anhedonia in men with schizophrenic disorders.

**Funding.**– This study was funded by the RFBR grant no. 16-06-00100.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0094

### Genetic polymorphisms of endothelin-1 (Lys198Asn) and E-selectin (Leu544Phe, Ser128Arg) in patients with alcoholism in Russia

A. Sakharov<sup>1\*</sup>, S. Golygina<sup>1</sup>, A. Emelyanov<sup>2</sup><sup>1</sup> Chita State Medical Academy, Faculty of Psychiatry, Narcology and Medical Psychology, Chita, Russia; <sup>2</sup> Chita State Medical Academy, Laboratory of Molecular Genetics, Chita, Russia

\* Corresponding author.

**Objective.**– The study aims to explore the prevalence of alleles and genotypes of the polymorphisms of Endothelin-1 (Lys198Asn) and

E-selectin (Leu544Phe, Ser128Arg) in patients with alcoholism and healthy people in Russia.

**Methods.**– 157 patients with alcohol dependence and 72 healthy people were included in the study. For analysis of polymorphisms – Endothelin-1 (Lys198Asn) and E-selectin (Leu544Phe, Ser128Arg) method was used allele-specific polymerase chain reaction with electrophoretic detection. Standard series of reagents for the study of mutations were used “Litech” (Russia).

**Results.**– In the study the mutation of Endothelin-1 in homo- and heterozygous condition were identified; mutation Leu544Phe E-selectin were presented only with genotypes Leu/Leu and Leu/Phe mutation Ser128Arg is determined solely by the genotype Ser/Ser in the control group. All studied polymorphisms conformed to Hardy-Weinberg balance. Were no differences between genotypes and alleles for the END-1 (Lys198Asn) and SELE (Leu544Phe) in patients with chronic alcoholism and healthy. Among patients with alcohol dependence were more likely to be carriers of the Ser/Arg genotype polymorphism of SELE (Ser128Arg). For this patient the risk of developing the disease was only 29.22 [CI 95%:1.75–486.58]. Homozygotes for Arg/Arg-genotype was determined only in patients with alcoholism. Carriers of the wild type genotype in homozygous state among healthy residents was predominant.

**Conclusion.**– For patients with normal allele Ser mutation SELE (Ser128Arg) OR equal to 0.03 [CI 95%: 0.00–0.49], carriers of the mutant allele Arg risk of alcohol dependence was 33.25 [CI 95%: 2.02–546.90]. Consequently, the carriage of the mutant allele polymorphism of E-selectin (Ser128Arg) contributes to the pathogenesis of alcoholism.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Interaction between fat mass and obesity-associated gene (FTO), adverse life events, and psychopathology in eating disorders patients**

G. Castellini<sup>1</sup>, M. Franzago<sup>2</sup>, L. Lelli<sup>1</sup>, L. Stuppia<sup>2</sup>, V. Ricca<sup>1</sup>, G. Stanghellini<sup>2</sup>

<sup>1</sup> University of Florence, department of neuroscience, psychology, drug research and child health, Florence, Italy; <sup>2</sup> University G D'Annunzio Chieti Pescara, department of psychological, health and territorial sciences, school of medicine and health sciences, Chieti, Italy

\* Corresponding author.

**Introduction.**– The multifactorial etiopathogenesis of Eating Disorders (EDs) encompasses environmental, psychological and biological predictors.

**Objective.**– To evaluate the interaction between the fat mass and obesity-associated gene (FTO), early adverse life conditions (such as overweight during childhood, childhood neglect and abuse) and the psychopathology in a group of patients with eating disorders.

**Methods.**– The distribution of a polymorphism of the FTO (rs9939609 T>A) was evaluated in a series of 200 EDs patients and in a group of 119 healthy control subjects. Clinical data were collected through a face-to-face interview and several self-reported questionnaires were applied, including the Emotional Eating Scale and the IDentity and EAting disorders (IDEA) questionnaire for bodily disorders and self-identity. The assessment was repeated at three year follow up.

**Results.**– The presence of the A-allele was associated with binge eating behavior, higher emotional eating and higher IDEA scores. Finally, the FTO rs9939609 SNP was found to be a moderator of the

association between early adverse life events and the stability of the psychopathology in the long term.

**Conclusions.**– The experimental approach adopted in the present study provides an integrative perspective based on the assumption that eating disorders are caused by a sequence or combination of risk factors rather than a single influence. Our results suggested that the FTO polymorphism moderated the association between adverse life events, eating psychopathology and its stability across time.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Assessing the shared genetic overlap between congenital heart disease and neurodevelopmental disorders using large-scale population data**

A. Cordova-Palamera<sup>\*</sup>, J. Priest  
Stanford University, Pediatrics, Stanford, USA

\* Corresponding author.

**Introduction.**– Congenital heart disease (CHD) is the most common birth defect in newborns and the leading cause of death in infancy, affecting nearly 1% of live births. Along with the common health issues directly derived from cardiac disruptions in CHD, around 10% of children with this condition also exhibit neurodevelopmental alterations usually affecting motor, neurocognitive and social impairments. Novel findings suggest that the link between CHD and neurodevelopmental disorders can be informed by the analysis of shared genetic pathways.

**Objectives.**– By leveraging publicly available genome-wide association study (GWAS) results and data on ~500,000 individuals from the UK Biobank, this large-scale population analysis is aimed at eliciting the putative genetic overlap between cardiac and brain development alterations prenatally.

**Methods.**– Multiple statistical tools are used to analyze genotype data at both the global genome level (e.g., LD Score Regression; Mendelian Randomization, polygenic risk scores) and on a marker-by-marker basis (e.g., GWAS of the UK Biobank).

**Results.**– The results expand on the previous CHD/neurodevelopment literature to inform on genome-wide patterns of overlap, as well as on additional genomic loci throughout a broad set of neurodevelopmental outcomes.

**Conclusions.**– The data provide novel insights into the shared genetic architecture of CHD and neurodevelopmental disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Catatonia and mutism: Neurotic, psychotic or paraneoplastic disorder? About a case**

P. De Jaime Ruiz<sup>1</sup>, J.L. García-Fogeda Romero<sup>2</sup>, B.M. Girela Serrano<sup>1</sup>, A. Porras Segovia<sup>1</sup>

<sup>1</sup> Campus de la Salud, Psychiatry, Granada, Spain;

<sup>2</sup> Campus de la Salud, Internal Medicine, Granada, Spain

\* Corresponding author.

Catatonia is caused by a variety of psychiatric and organic conditions. The onset, clinical profile, and response to treatment may vary depending on the underlying cause. Catatonia is more likely to be associated with Neurotic and Psychotic Disorders, but some Psychiatric symptoms are key components in the clinical presentation of paraneoplastic encephalitis. This uncommon presentation

could lead to a late diagnosis and treatment initiation increasing significantly the morbidity and mortality.

We report a 57-year-old female who started showing paroxysmal recurrent episodes for the last two years, characterized by surrounding disconnection, disorientation and muscle spasm (myoclonus), followed by a postictal state. These episodes frequently occurred after stressful situations.

After performing neurological and psychiatric assessments the patient was started on anticonvulsants, antidepressants, benzodiazepines and antipsychotic drugs, but no response was found. The clinical orientation was conversion/dissociative disorder.

In the following months the symptoms evolved to akinetic mutism, catatonia, rapidly progressive vision and audition loss and almost surrounding disconnection.

She was hospitalized and underwent a battery of tests, performed by Internal Medicine, Neurology and Psychiatry clinicians: blood tests, head CT scan and MRI, and lumbar puncture. Abnormal findings in MRI and cerebrospinal fluid suggested that those behavioural and motor disorders could be due to a paraneoplastic meningoencephalitis. The patient died 3 months later.

Albeit catatonia and akinetic mutism are commonly related to psychiatric diseases, numerous medical conditions can mimic psychiatric disorders. A differential diagnosis with infectious, autoimmune and paraneoplastic encephalitis should always be carried out. We encourage everyone to keep it in mind to ensure better interventions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Involvement of nicotinamide phosphoribosyltransferase in both amyloidogenic and non-amyloidogenic pathways**

J.H. Ha\*, E. Kim, J. Jeong, H. Kim, J. Lee, S.Y. Cho  
Yonsei university severance hospital, department of psychiatry,  
Seodaemun-gu, Republic of Korea

\* Corresponding author.

AMP-activated kinase (AMPK) and silent mating-type information regulator 2 homolog 1 (SIRT1) are representative enzymes in energy homeostasis. The concomitant action of AMPK and SIRT1 suppress Alzheimer's (AD) pathologies. Metformin; the most widely prescribed antidiabetic drug, has been shown to exert neurotoxic effects through AMPK activation; however little is known for SIRT1 activation. Therefore, we investigate the effect of metformin on the activity of SIRT1 as well as AMPK.

Metformin-induced AMPK activation simultaneously induces SIRT1 activation by activating the AMPK / nicotinamide phosphoribosyl transferase (Namt) / nicotinamide adenine dinucleotide (NAD) pathway. However, we have found that metformin cannot activate neuronal SIRT1 despite AMPK activation. Rather, it reduced the levels of Namt and NAD. Metformin-induced AMPK activation increased the levels of beta-site amyloid precursor protein cleavage enzyme 1 (BACE1) and secreted beta-amyloid (A $\beta$ ). In addition, metformin-induced Namt suppression was associated with decreased expression of tumor necrosis factor alpha converting enzyme (TACE) which promotes non-amyloidogenic pathway. These adverse effects of metformin were also identified in the brains of diabetic db/db mice. Overexpression of Namt rescued metformin-induced neurotoxicity in vitro. In addition, donepezil treatment reversed metformin-induced TACE suppression via Namt/NAD/SIRT1 in vitro and in vivo by activating Namt. Our results suggest the important role of Namt in regulating amyloid production. AMPK activation by metformin might be neu-

rotoxic because it fails to induce concomitant action of AMPK and SIRT1. Co-treatment of donepezil could be a proper measure to protect the brain from potential risk of AD pathogenesis in diabetic patients taking metformin.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Russian original benzodiazepine phenazepam's safety during alcohol withdrawal syndrome treatment: Pharmacogenetics associations with ABCB1 3435C>T**

D. Ivashchenko<sup>1\*</sup>, K. Ryzhykova<sup>2</sup>, Z. Sozaeva<sup>2</sup>, E. Grishina<sup>2</sup>, M. Zastrozhin<sup>3</sup>, B. Eugenyi<sup>4</sup>, D. Sychev<sup>5</sup>

<sup>1</sup> Russian medical academy of continuous professional education, department of applied problems of personalized medicine, Moscow, Russia; <sup>2</sup> Russian medical academy of continuous professional education, department of molecular biological research, Moscow, Russia; <sup>3</sup> Russian medical academy of continuous professional education, department of narcology, Moscow, Russia; <sup>4</sup> Moscow research practical center of narcology, administration, Moscow, Russia; <sup>5</sup> Russian medical academy of continuous professional education, department of clinical pharmacology and therapeutics, Moscow, Russia

\* Corresponding author.

*Introduction.*– ABCB1 (multidrug resistance gene 1 - MDR1) gene which coding transport protein glycoprotein P. Glycoprotein P share its' substrates with CYP3A4 isoenzyme. Consequently, glycoprotein P activity can influence on benzodiazepine tranquilizers' pharmacokinetics.

*Aim.*– To study associations of ABCB1 3435C>T polymorphism with bromdihydrochlorphenylbenzodiazepine safety in patients with alcohol withdrawal syndrome.

*Materials and methods.*– 102 male patients with non-complicated alcohol withdrawal syndrome (F 10.3 by ICD-10) were involved into the study in 24 hours after their admission to hospital. During 6 days of dynamic observation each participant was prescribed bromdihydrochlorphenylbenzodiazepine (Phenazepam). 5 ml of venous blood was collected from each participant for genotyping. Blood samples were analyzed to detect the ABCB1 3435C>T (rs1045642, C – dominant allele) polymorphism by real-time polymerase chain reaction. Safety of therapy was evaluated with UKU Side Effects Rating Scale. Data analysis was performed with SPSS Statistics 21.0.

*Results.*– Association analysis of adverse effects (AE) in the whole sample ( $n = 102$ ) revealed that CT>TT genotypes carriers had higher rate of "Other adverse effects" UKU subscale:  $0.36 \pm 0.78$  vs  $0.0 \pm 0.0$  scores ( $P = 0.033$ ). Comparison of several adverse effects showed that allele T was associated with "Increased dream activity" ( $P = 0.026$ ) and "Depression" ( $P = 0.046$ ), but allele C – with "Concentration Difficulties" ( $P = 0.031$ ), "Polyuria/polydipsia" ( $P = 0.048$ ).

*Conclusion.*– There were significant relationships of C and T alleles with adverse effects according to UKU Side effects rating scale. However, these associations were not specified. Consequent analysis will include addition biomarkers – CYP3A4 isoenzyme's activity factors: genetic polymorphisms and phenotyping.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Psychological stress causes relative infertility through direct change in the frequency pattern of GnRH release from the hypothalamus

R. Khodabakhsh Pirkalani<sup>1</sup>\*, K. Khodabakhshi Pirkalani<sup>2</sup><sup>1</sup> Alzahra university and Mehr medical group, internal medicine/clinical psychology, Tehran, Iran; <sup>2</sup> Mehr medical group, internal medicine, Tehran, Iran

\* Corresponding author.

*Introduction.*– Effect of mentality on fertility is not fully clarified.*Objectives.*– Evaluation of oscillation pattern of GnRH release by the hypothalamus in different mental states.*Methods.*– Twenty eight patients were evaluated by a computer algorithm to find oscillation of LH/GnRH pulsation measured on four sessions (day 6 and 14) every 10 minutes within two consecutive cycles in addition to the MCMI-III.*Results.*– The pattern of oscillation was showed statistically significant lowering of frequency during anxiety and depression states. Besides, the slope of GnRH between two consecutive sessions ( $d_0\text{GnRH}_0/\text{GnRH}_1\text{dt}$ ) showed also a prominent reduction and even flattening. In addition the time to ovulation was also postponed in cycles with prominent anxiety.*Conclusion.*–

1. Psychological stress exerts its effect through a reduction of pulsation frequency in GnRH release.
  2. Pattern of GnRH pulsation changes due to external stimuli in the range of ¼ to 1/15 of the baseline.
  3. MCMI-III is an excellent tool for evaluating psychological state of the patient.
  4. Patients with borderline, schizoid, dependent, depressed and passive aggressive personality suffer most from irregularity of menstruation cycles.
  5. Patients with chronic major depression are subject to menstrual irregularity highest during stabilization of disease and in the early phases of recovery after treatment with SSRI.
  6. Treatment of depression/anxiety causes a reduction of menstrual cycle length.
  7. Measurement of GnRH, FSH, LH and Estradiol on two sessions one week apart is a nice marker for regularity and ovulation.
- The global functioning of bipolar patients between attacks is not fully delineated.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0101

### Specific patterns of high cognitive functions in children with cerebellum tumors

M. Kovyazina<sup>1,2\*</sup>, A. Trofimova<sup>1</sup>, N. Varako<sup>1,2</sup>, E. Rasskasova<sup>1,3</sup>, I. Taranova<sup>4</sup>, Y. Chaplygina<sup>5</sup>, O. Dobrushina<sup>6</sup><sup>1</sup> Lomonosov Moscow State University, psychology, Moscow, Russia;<sup>2</sup> Research center of neurology, neurorehabilitation and physiotherapy, Moscow, Russia; <sup>3</sup> Mental health research center, psychosomatics and psychotherapy, Moscow, Russia; <sup>4</sup> Psychology Institute of Russian Academy of Sciences, developmental psychology and acmeology, Moscow, Russia; <sup>5</sup> Mental health research center, clinical psychology, Moscow, Russia; <sup>6</sup> Research center of neurology, neuroscience, Moscow, Russia

\* Corresponding author.

*Introduction.*– Medulloblastomas are the most common prejudicial tumors of childhood. This disease affects not only vestibular system,

but also such cognitive functions as language, attention, verbal and non-verbal memory and intellectual capacity.

*Objectives.*– To study peculiar features of high cognitive functions in children with cerebellum tumors; to elicit cognitive function which correction can accelerate cognitive rehabilitation process.*Methods.*– The study included 9 children (age 2–10 years) with cerebellum tumor in the fourth ventricle who underwent neurorehabilitation course. Cognitive sphere was diagnosed by Luria-Nebraska Neuropsychological Battery (LNNB) on the first and the last sessions.*Results.*– Two types of cognitive syndromes were fetched out through the neuropsychological diagnostics: 1 – semi-frontal lobe syndrome (defects in serial movement organization, stagnancy, memory disorders, special pathological features of thinking, especially attention disorders); 2 – disorders in spatial functions (projective errors in visual gnosis and visual presentation).*Conclusions.*– Assessment of the defect structure and of the whole rehabilitation process reduce the main element of high cognitive function which is important firstly to start work with – it is attention. Galperin P.Y. said that attention is an independent psychical function which provide control over content of pattern, thought and operation. Development of the rehabilitation process around the correction of attention allows reduction of the duration of the rehabilitation period and the degree of defect in cognitive functions in children with cerebellum tumor.*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Paving the way for precision medicine in psychiatry – Design and implementation of a unified rare genetics curriculum

D. Moreno De Luca<sup>1\*</sup>, D.A. Ross<sup>2</sup><sup>1</sup> Bradley hospital, Alpert medical school, Brown university, division of child and adolescent psychiatry, department of psychiatry and human behavior, Providence, USA; <sup>2</sup> Yale university, psychiatry, New Haven, USA

\* Corresponding author.

*Background.*– For the last few years, we have been witnessing an accelerated pace of genetic discoveries that are redefining our understanding of mental health disorders. However, psychiatry residency and fellowship programs have not yet integrated this new information into their curricula. Current challenges include determining and implementing unified content areas using principles of adult learning.*Methods.*– As a joint effort between the Education Taskforce of the International Society of Psychiatric Genetics (ISPG) and the National Neuroscience Curriculum Initiative (NNCI), we have identified key knowledge areas in genetics that every psychiatrist should have, and developed tools for their implementation. As an example, we designed a module on rare genetics of autism using the NNCI standards, and included supporting media material and guidance for facilitators. We administered this exercise to 300 psychiatry residents, fellows, and psychiatry program directors, and obtained pre and post knowledge assessments, as well as qualitative data on impressions and utility of the module.*Results.*– We observed an overall low genetic literacy among surveyed groups in the pre-assessments, followed by a high retention of content after the exercise, with detailed analyses underway. We also obtained positive qualitative feedback, which included an increased appreciation for the clinical relevance of this knowledge and satisfaction with the method of delivery.

*Discussion.*— Our results highlight the importance of blending key content with sound pedagogical methods and maintaining the clinical grounding of exercises, an approach that could easily be adapted and broadly generalized for other core competencies in genetics.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

<sup>2</sup> Hôpital Robert Debré, psychiatrie de l'enfant et de l'adolescent, Paris, France; <sup>3</sup> McGill university, Montreal neurological institute, Montreal, Canada; <sup>4</sup> CHU de Montpellier, hôpital Lapeyronie, Montpellier, France; <sup>5</sup> Inserm U1061, neuropsychiatry, epidemiological and clinical research, Montpellier, France; <sup>6</sup> Hôpital Sainte-Anne, clinique des maladies mentales et de l'encéphale CMME, Paris, France

\* Corresponding author.

*Introduction.*— Anorexia nervosa (AN) is a severe psychiatric disorder resulting of several factors including, genetic, biological, psychological and social events. Many investigations converge to the involvement of the brain derived neurotrophic factor (BDNF) in AN. Thus, low circulating concentrations of BDNF are associated with a higher risk of AN, as well as genetic association with its variant Val66Met. The epigenetic regulations are also strongly suggested in AN. Thus, the DNA methylation level of *BDNF* gene could modify its circulating concentration.

*Objectives.*— Our work was to measure the DNA methylation level of *BDNF* gene in current AN patients, remitters and controls in the goal to identify a specific profile in AN.

*Methods.*— We extracted DNA from blood samples of 24 AN patients, 24 remitters and 48 controls. Methylation of DNA was measured for 73 CpGs encompassing *BDNF* gene by using the Infinium Human Methylation 450 Bead Chip technology.

*Results.*— Analysis showed significant decreases of methylation levels of CpGs encompassing *BDNF* gene in AN compared to controls. Furthermore, remitters present an intermediate methylation profile between AN and controls.

*Conclusions.*— We are currently replicating this observation in an independent cohort and searching for confirming the impact of the difference of DNA methylation level of *BDNF* gene in its RNA and protein expression between AN patients, remitters and controls.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

In patient with advanced cancer, not only physical symptoms, but also symptoms related to mental health or the meaning of life are becoming important subject of treatment. This study investigated the efficacy of meaning-centered psychotherapy (MCP), a psychotherapeutic intervention known to be helpful in situations of great suffering on pancreatobiliary cancer patients.

119 patients with pancreatobiliary cancer were recruited from 3 centers, and patients who wanted to receive psychotherapy were assigned to four sessions of meaning-centered psychotherapy. Patients were assessed before treatment and 2 months after treatment. The outcome measures assessed anxiety, depression, mental adjustment to cancer, and quality of life, as well as the degree of stress and physical symptoms.

Sixteen patients completed the MCP and completed the assessment 2 months later. In the initial assessment, the patients receiving MCP showed higher levels of stress, anxiety, and depression than patients were not receiving MCP, and the quality of life was also lower in terms of role function, emotional function, and social function. At the 2-months follow-up assessment, the MCP group showed a significant improvement than the non-MCP group in depression and anxiety. In addition, the quality of life was maintained at a similar level in the MCP group, while it was worse in the non-MCP group.

MCP has clear benefits for emotional distress and quality of life in patients with pancreatobiliary cancer. It is necessary to continue the research on psychological interventions with patients who have advanced cancer to reduce the emotional distress and enhance quality of life.

*Disclosure of interest.*— This project was supported by the research Funds of Korean Society of Surgical Oncology (2015).

### Changes in the psychological state and quality of life among women with newly diagnosed malignant neoplasms in the course of psychotherapy

N. Semenova<sup>\*</sup>, P. Chernov, I. Lysenko, S. Lyashkovskaya, A. Chubrikova

The V.M. Bekhterev National medical research center of psychiatry and neurology, Saint-Petersburg, Russian Federation, Scientific-organizational department, St. Petersburg, Russia

\* Corresponding author.

The aim of research was to investigate the results of a special medical and psychological rehabilitation program for the women with newly diagnosed malignant tumors. The program included cognitive-behavioral psychotherapy (10 individual and 10 group meetings in 12-week period). To objectify emotional and psychosocial changes and to determine the quality of life, complex psychological assessment, including a SCL-90-R, Integrative Anxiety Test, Ways of Coping Questionnaire, Irrational Belief Scale, EORTC-QLQ-C 30, interview with patients and treating doctors has been carried out twice throughout the study. 37 women underwent the program and 38 were included in the control group (average age  $49.4 \pm 1.3$ ).

According to the psychological assessment data, all the studied patients suffered from the pronounced symptoms of anxiety, depression and adaptation difficulties on baseline. Post-treatment psychological assessment has revealed the complete reduction of those symptoms in 52.8% of patients (main group). Nonrational cognitive patterns that cause stress became less common. Demandingness, awfulizing and frustration intolerance level has decreased ( $P < 0.001$ ). The attitude towards the disease has become more conscious and responsible. Quality of life (emotional, social and cognitive functioning) and compliance has improved ( $P < 0.05$ ). Fatigue, pain and side effects of treatment (nausea and vomiting, appetite loss, constipation) was significantly decreased. No spontaneous skips or refusals from treatment's sessions were registered. Such changes were not registered in the control group.

Thus, the psychotherapeutic experience had importance for the patients. They have developed the effective ways to overcome depression, anxiety, learned to distinguish the first signs of these symptoms and to prevent them.

### **Anxiety and depressive disorders in breast cancer women – Data from a psycho-oncology clinic, at hospital Pedro Hispano, Oporto, Portugal**

J. Silva<sup>1</sup>, M. Nazha<sup>2</sup>, D. Fontanete<sup>3</sup>

<sup>1</sup> Hospital de Magalhães Lemos, Porto, C Service, Custoias, Portugal;

<sup>2</sup> Hospital Pedro Hispano, Matosinhos, Psychiatry Unit, Matosinhos, Portugal; <sup>3</sup> Hospital Pedro Hispano, Psychiatry Unit, Matosinhos, Portugal

\* Corresponding author.

**Introduction.**– Mental health conditions are associated with poorer clinical outcomes and increased costs of care among cancer patients (Fox 2013). Anxiety and depressive symptoms are often assessed together and referred to as psychological distress, and their approach is crucial as they may lead to adverse effects on quality of life, not only of the patients but also of their caregivers. Around 25–50% of cancer patients experience clinically elevated psychosocial distress for which professional care is needed. For breast cancer patients this rate seems higher: 44.5–66%, compared to 40% of the control group (Jadoon 2010) (Gold 2015). What is less clear, particularly in primary care settings, is the percentage of individuals who have anxiety or depression disorders in breast cancer patients **Objectives.**– To clarify the prevalence of depression and anxiety disorders, in a psycho-oncology clinic, at Hospital Pedro Hispano, Oporto, Portugal.

**Methods.**– Present data of prevalence of depression or anxiety disorder in breast cancer woman, in a psycho-oncology clinic.

**Results.**– In the presented study 85% of patients admitted in the psycho-oncology clinic had depressive symptoms, of which 86.2% were an adjustment disorder and 13.7% were a major depression disorder. Anxiety and sleep disorders were presented in 4% of cases, 8.8% were mentally healthy. Psychiatry consultations was needed in 67.6% of patients, while 32.4% of patients improved only with psychology support.

**Conclusions.**– A careful approach and diagnosis of anxiety and depressive disorders in breast cancer patients is important as it leads to more specific choices in terms of treatment, whether pharmacological or psychotherapeutic.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Genetic polymorphism of CYP2C19 and clinical response to antidepressants – A literature review**

O. Vasiliu

“Dr. Carol Davila” central military hospital, psychiatry, Bucharest, Romania

**Background.**– The concept of individualized treatment is very important for improving the chances of recovery in patients diagnosed with major depression.

**Objective.**– To analyze the current status of research regarding the impact of CYP2C19 polymorphism in the antidepressants response.

**Methods.**– A systematic literature analysis was performed for detecting available applications of pharmacogenomics in cases of depressive disorder treatment. We searched medical databases

(MEDLINE, PubMed, Cochrane, EMBASE, Google Scholar) for clinical trials focused on the pharmacological implications of CYP2C19 polymorphism.

**Results.**– Importance of CYP2C19\*17, which represents an ultrarapid metabolizer isoform, is still under investigation from clinical perspective, but several studies report reduced concentration of escitalopram by 50%, and deletion of this gene with 5.7-fold increase of escitalopram concentration. Several recommendations were found related to the need to avoid tertiary amines like amitriptyline in patients with depression due to sub-optimal response in cases of \*17/\*17 genotype, or if these drugs are used then monitoring of the drug concentration should be included in the protocol. If combinations of \*2 and \*3 alleles are detected, then a 50% reduction of tertiary amines at the beginning of the treatment could be recommended. CYP2C19\*2 was associated with higher bupropion plasma concentrations, but CYP2C19 genotype was not associated with smoking cessation outcomes.

**Conclusions.**– Pharmacogenetics could offer a quantifiable way to identify the population at risk for non-response (due to lower blood concentration through metabolic enzymes hyperactivity), toxic reactions (based on higher concentrations, secondary to lower action CYP enzymes) and other types of adverse events during antidepressant treatment.

**Disclosure of interest.**– The author was speaker for Servier, Eli Lilly and Bristol-Myers, and participated in clinical trials funded by Janssen Cilag, Astra Zeneca, Otsuka Pharmaceuticals, Sanofi-Aventis, Sunovion Pharmaceuticals.

## **Mental Health Care / Prevention of Mental Disorders**

### **Characterization of Patients assessed in community mental health clinics in an oil sands city in Canada: Patient profile, sex differences, and follow-up referral**

V. Agyapong<sup>1</sup>, M. Juhás<sup>1</sup>, O. Igwe<sup>1</sup>, J. Omeje<sup>2</sup>, A. Ritchie<sup>3</sup>, O. Ogunsina<sup>3</sup>, L. Ambrosano<sup>3</sup>, S. Corbett<sup>3</sup>

<sup>1</sup> University of Alberta, department of psychiatry, Edmonton, Canada;

<sup>2</sup> Alberta health services, department of public health, Fort McMurray, Canada; <sup>3</sup> Northern lights regional health centre, department of psychiatry, Fort McMurray, Canada

\* Corresponding author.

**Aims.**– To characterize the sex-specific differences in the demographic and clinical profile as well as psychiatric antecedents, and follow-up referral for new outpatient psychiatric patients in Fort Mc Murray.

**Methods.**– Information on a data assessment tool designed by the psychiatric team in Fort McMurray as part of a service improvement initiative to assist the psychiatrists gather all relevant demographic and clinical characteristics of patients assessed was compiled as part of a clinical audit process between 1st January 2014 and 31st December 2014.

**Results.**– Overall, 677 patients were assessed by the four psychiatrists over the 12 month period, comprising 261 (38.6%) males. The mean age for all the patients was 35.67 (SD = 13.02) and 563 (83.2%) of the patients were referred by Family Physicians. There were statistically significant differences between male and female patients in respect of all the demographic and social characteristics as well as psychiatric antecedents. Primary diagnosis included: Depressive disorders 249 (36.8%), Anxiety disorders 133 (19.6%),

Trauma related Disorders 96 (14.2%), Substance related disorders 66 (9.8%), Bipolar and related disorders 31 (4.6%), Personality disorders 20 (3.0%) and Schizophrenia spectrum disorders 14 (2.1%). Outpatients diagnosed with substance related disorders, personality disorders and trauma related disorders were about 4.5, 5.5, and 7 times respectively less likely to be offered follow-up appointments after their initial assessments compared to patients with depressive disorders.

**Conclusion.**– By better understanding the outpatient profile, we are able to better understand not only the mental health needs but also the potential antecedents associated with greater need for psychiatric services.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0109

### **Job stress outcomes among Iranian emergency room nurses: A literature review**

N. Amanat<sup>1\*</sup>, S. Bahrapouri<sup>1</sup>, M. Hosseini<sup>2</sup>, Z. Abbasi Dolatabadi<sup>3</sup>, A. Dalvandi<sup>2</sup>

<sup>1</sup> University of social welfare and rehabilitation sciences, health in emergency and disaster, Tehran, Iran; <sup>2</sup> University of social welfare and rehabilitation sciences, nursing department, Tehran, Iran;

<sup>3</sup> Tehran university of medical sciences, department of critical care nursing, school of nursing & midwifery, Tehran, Iran

\* Corresponding author.

**Introduction.**– Nursing is a stressful job originally. Nurses experience more job stress in emergency department, because there are workplace with excessive workload, unsure range and severity of patient, verbal and physical aggression by patient's companions, shortage of resources and many other problems.

**Objective.**– The aim of the study is the review of studies that assessed outcomes job stress among nurses, who are working in the Iranian emergency department.

**Methods.**– This literature review generated based on Prisma guideline. The searched keywords were included base on: stress, nurse and emergency in PubMed, Scopus and Iranian database such as SID, Magiran, Irandoc and Noormags. The research included all of original researches that were done in Iran and published between 2000–2017. In primary search 139 articles were found and, after exerting inclusion and exclusion criteria and eliminated the repeated articles, 10 full articles were reviewed.

**Results.**– Results shown; interpersonal problems, aggression, PTSD, burnout, skeletal diseases, mental workload and human errors are main impacts of nurses' job stress that assessed in Iranian articles. Nurses' job stress outcomes usually discussed in three main domains includes impact on staff, patient and organization. The findings showed that, patients' related outcomes neglected in Iranian researches.

**Conclusions.**– Nurses' job stress, especially in emergency room were treated nurses' health, their organization, and quality of services rendered for patients. Therefore, we recommend assessment of job stress' factors in workplace and using stress relief strategies for emergency room nurses for improving the quality of work and services for patients and nurses.

**Keywords:** Nurse; Job stress; Emergency

### **Relationship between gluten sensitivity, celiac disease and mood disorders**

M. Arts<sup>1\*</sup>, S. Petrykiv<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> Mental Health Western Northern Brabant, geriatric psychiatry and neuropsychiatry, Halsteren, The Netherlands; <sup>2</sup> University of Groningen, university medical center Groningen, department of clinical pharmacy and pharmacology, Groningen, The Netherlands;

<sup>3</sup> Mental health care – Friesland GGZ Friesland, department of geriatric psychiatry, Leeuwarden, The Netherlands; <sup>4</sup> Leonardo scientific research institute, department of geriatric psychiatry and neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

**Introduction.**– Gluten is a glycoprotein consisting of two other glycoproteins, namely gliadin and glutenin. It can be found in many types of food (like bread, pasta, cookies) and its function is acting as a glue that helps food to maintain their shape or texture. Celiac disease (CD) is a lifelong gluten-sensitive autoimmune disease that is present in 0.8–1.9% of the general population and is characterized by serious gastrointestinal complaints. Gluten sensitivity (GS) is a disease distinct from CD with a prevalence up to 13%. It is known that GS and CD may present with psychiatric disorders, but it is still unclear to what extent GS and CD plays a role in the pathophysiology of mood disorders.

**Objectives and aims.**– To report and discuss the possible role of GS and CD in the pathophysiology of mood disorders.

**Methods.**– An literature search was conducted using Pubmed, EMBASE searching for studies reporting GS, CD, and its possible role in the pathophysiology of mood disorders.

**Results.**– Several studies reported an association between CD, GS, and mood disorders. Especially the older population with comorbid GS had a significant increase of depressive symptoms or late-life depression (LLD) compared to elderly subjects without GS. It was also reported that gluten-free diets improved symptoms of LLD.

**Conclusions.**– We found a clear relationship between CD, GS and mood disorders. There is also sufficient evidence to recommend gluten-free diets in patients with mood disorders. However, further research is needed to disentangle the mechanisms of gluten-associated psychiatric conditions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Intervention for aversive memory reconsolidation – A critical review**

L. Bolsoni<sup>\*</sup>, A. Zuardi

FMRP-USP, department of neurosciences and behavioral sciences, Ribeirão Preto, São Paulo, Brazil

\* Corresponding author.

**Introduction.**– Memories may be modified or interrupted because of the administration of drugs over a period called the “reconsolidation window”. In contrast to animal studies, reports on interventions during the process of memory reconsolidation in humans are scarce.

**Objective.**– To analyze studies on fear memory modifications in humans through pharmacological interventions during reconsolidation and to analyze the methodological difficulties associated with these studies.

**Method.**– PubMed, Scopus, Web of Science and SciELO were searched from inception to July 2016 in accordance with the PRISMA guidelines. The following keywords were used: [(memory) AND (consolidation OR reconsolidation) AND (pharmacological

manipulation OR pharmacological intervention)]. Studies were included if they were original articles reporting on pharmacological interventions during aversive memory reconsolidation in humans. *Results.*– Eight randomized, double-blinded clinical trials were included. Two studies used a protocol involving autobiographical aversive memories, and in the other six, the aversive memories were induced in the laboratory. The most commonly used drug was propranolol. In six studies pharmacological intervention occurred after memory reconsolidation. In one study it occurred before and after reconsolidation, while in another, intervention occurred after reconsolidation; however, the optimal timing of pharmacological interventions is a controversial issue in the field.

*Conclusion.*– Our results suggest that some pharmacological interventions can affect the reconsolidation of aversive memory. However, methodological difficulties are involved in this type of study. The issues raised in this review remain open given the small number of human studies. Therefore, there is urgent requirement for studies evaluating the issues discussed here.

*Disclosure of interest.*– Support: FAPESP (grant 2016/01801-5).

<sup>1</sup> Montefiore medical center, psychiatry, Bronx, USA; <sup>2</sup> Bronx Lebanon hospital center, department of psychiatry and behavioral sciences, Bronx, USA; <sup>3</sup> NYC health and hospitals/gouverneur health, behavioral health, New York, USA; <sup>4</sup> Icahn school of medicine at Mount Sinai, child and adolescent psychiatry, New York, USA; <sup>5</sup> Weill Cornell medical college, psychiatry, New York, USA

\* Corresponding author.

Mental disorders are common worldwide and can impact all aspects of life. The World Health Organization ranks anxiety and depression among the most disabling conditions in terms of Years Lived with Disability, leading to high health care costs and loss of productivity. Meanwhile, there is a large gap in psychiatric care. In the United States only 1 in 5 adults with mental illness receives specialist treatment, with up to 60% of psychiatric care provided by Primary Care Physicians (PCPs). Integrated Care models, which are increasingly used for both medical and psychiatric conditions, attempt to bridge this gap. Behavioral Health Integration places mental health providers in primary care settings, with PCPs treating common mental disorders with support from case managers and psychiatrists. Given the global shortage of providers and the stigma around mental illness, Integrated Care can improve access to screening and treatment and reduce health care costs.

The American Psychiatric Association (APA) recognizes the importance of Integrated Care at a national and international level, and supported a panel presentation on Integrated Behavioral Health at the United Nations (UN) in June 2017. We build on this knowledge dissemination by describing Integrated Care models implemented in New York City, including in low resource and transcultural settings. We will discuss global applications of Integrated Care, and describe a collaboration with Afghani providers to improve recognition and treatment of mental disorders, arising from our presence at the UN. Finally, we will present our collective perspective on future directions for Global Mental Health.

### **A novel SCL-90-R 6-item factor to identify subjects at risk of early adverse outcomes in public mental health settings**

M. Curto<sup>1\*</sup>, C. Silvestrini<sup>2</sup>, E. Pompili<sup>2</sup>, P. Bellizzi<sup>2</sup>, S. Navari<sup>2</sup>, P. Pompili<sup>2</sup>, A. Manzi<sup>2</sup>, V. Bianchini<sup>2</sup>, S. Ferracuti<sup>1</sup>, G. Nicolò<sup>2</sup>, R.J. Baldessarini<sup>3</sup>

<sup>1</sup> Sapienza university, neurology and psychiatry, Rome, Italy; <sup>2</sup> ASL Rome 5, department of mental health, Rome, Italy; <sup>3</sup> Harvard medical school, department of psychiatry, Boston, MA, USA

\* Corresponding author.

*Introduction.*– To increase access to treatment, Italy made access to community mental health centers (CMHCs) independent of medical referral, resulting in greatly increased in numbers of patients to be triaged efficiently.

*Objectives.*– To support this process, we evaluated ratings of SCL-90-R items to identify factors that predicted adverse outcomes by 3 months in a large CMHC sample.

*Methods.*– We evaluated all persons seeking first-time CMHC care in a 24-month sample. A psychiatric nurse screened all entering subjects with a brief clinical interview, CGI rating, and self-administered SCL-90-R and provided an ICD-9 diagnosis. We recorded their risk of suicide attempts and hospitalization over the following 3 months.

*Results.*– Of 832 screened subjects, 32 (3.85%) were hospitalized or attempted suicide within 3 months. Six initial SCL-90 items (#15, 41, 55, 57, 78, 88) scored much higher in these subjects. The 6-item sum is proposed as a new predictive measure. In multivariable logistic modeling, this factor, but not age, sex, or diagnosis was a strong predictor of adverse outcomes. By ROC-analysis, an SCL-6 cut-off score of  $\geq 7.5$  identified adverse outcomes with sensitivity of 72% and specificity of 73%.

*Conclusions.*– To supplement general clinical assessment, a novel 6-item factors derived from the SCL-90 was found to be a powerful predictor of severely adverse early outcome among psychiatric patients newly evaluated in a Roman CMHC. This simple, rapid screening tool may support timely identification of patients who require especially close follow-up.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0114

### **Child health clinical outcome review programme: Health care utilisation, care pathways and educational status in children and young people with mental health disorders**

A. John<sup>1</sup>, S. Demougin<sup>2\*</sup>, S. Rees<sup>3</sup>, T. Wang<sup>3</sup>, A. Akabri<sup>3</sup>

<sup>1</sup> Swansea university medical school, population psychiatry, suicide and informatics, Swansea, United Kingdom; <sup>2</sup> Cardiff university school of medicine, division of population medicine, Cardiff, United Kingdom; <sup>3</sup> Swansea university medical school, the secure anonymised information Linkage Databank, Swansea, United Kingdom

\* Corresponding author.

*Introduction.*– The diagnosis, management and services available for mental disorders are of growing concern and a source of controversy in the UK. Transitional care between child and adult services and the interface between primary and secondary/ specialist services is often disjointed. Thresholds for referral to Child and Adolescent Mental Health Services are high and many adolescents are treated, at least initially, in primary health care systems.

**Objectives.**– To use routinely collected healthcare datasets and data linkage to identify patterns of healthcare utilisation by children and young people with mental health disorders across the four UK Nations. We will determine the extent to which routinely collected datasets can contribute to an assessment of the health needs and the quality of care that children and young people with mental health disorders receive.

**Methods.**– Data has been requested from the national data providers in each country. A series of descriptive analyses were performed and methods were developed for cross-national comparisons to be made (e.g. Four Nation Person Spell).

**Results.**– It is feasible to explore healthcare utilisation across the four countries of the UK using routine data. However the recording, availability and access varied considerably between countries, making meaningful comparisons challenging.

**Conclusions.**– Routine data has the potential to make a difference to care. However collection and access needs to be standardised in order to improve efficiency and effectiveness in improving the care for children and young people with mental health disorders. MQ has funded an Adolescent Data Platform to facilitate this.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0115

### **Hospitalized schizophrenics: Insight view**

S. Ennaifer\*, S. Ellini, W. Cherif, R. Damak, M. Cheour  
Hospital Razi, psychiatrie E, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Insight became an important field for research and practice in psychiatry. Its improvement is an important prognostic factor and allows better care.

**Objectives.**– Evaluate insight and determine the predictors of good or impaired insight in patients hospitalized for schizophrenia.

**Methods.**– This is a cross-sectional study conducted in patients hospitalized for schizophrenia in a department of psychiatry of the Razi hospital in Tunisia. Diagnosis based on the DSM 5 diagnostic criteria. The insight was assessed using the Q8 scale and then assessed its correlation with various socio-demographic and clinical factors, collected from patients' medical records Results: our population was made of 25 male schizophrenics. The average age was 39.68 years. 20% of the cases had a university level. 84% of the patients were single. 20% was living alone. 64% was without a profession. Socioeconomic conditions were poor in 80% of the cases. 40% consumed toxic products. 65% of them were admitted according to the mode of office. The average duration of psychiatric stay was 79.55 days. 16% had no prior history of hospitalization. 28% had a history of attempted suicide. Follow-up was regular in 26% of patients. The insight scores were low with an average of 1.62. Factors that would increase the insight score include: free hospitalization, higher education, family support, history of hospitalization or attempted suicide, long hospital stay and regular follow-up.

**Conclusions.**– It seems important to work the awareness of the disorder in patients. Psychoeducation targeting the improvement of insight is useful but must be accompanied by supervision and care.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>1</sup> INSERM, UMR-S 1123, Eceve, Paris, France; <sup>2</sup> EPSM Lille Métropole, centre collaborateur OMS, Lille, France

\* Corresponding author.

In order to reduce the mental health treatment gap, additional knowledge should be gathered on factors associated with mental healthcare use.

This study aims to identify individual and environmental correlates of mental healthcare use among people suffering from mental disorders.

Our study is based on a cross-sectional survey called "Mental Health in the General Population" undertaken in France between 1999 and 2003. Among the 39,617 individuals included in the survey, 13,565 (34%) were identified as suffering from mental disorders through the MINI. Mental healthcare use was assessed considering GP, psychiatrists, nurses and psychotherapist consultations as well as day hospital visits and full-time hospitalizations. Potential correlates taken into account included clinical and subjective need-of-care, employment status, education, income, migration, social support, mental health literacy, stigma as well as religiosity and informal healthcare use. At environmental level, were considered (mental) healthcare characteristics of the psychiatric sector, as well as socioeconomic territorial variables and urbanicity. Factors associated with mental healthcare use were identified using a multi-level logistic regression model following the conceptual framework of Andersen's health service use model.

Results showed no mental health use disparities based on income and educational attainment. However, not using healthcare was associated with being male, young, not feeling sick, being from an extra-European origin or living in French overseas territories, being Muslim, using religious care, having poor social support, stigmatizing mental health and poor mental health literacy.

Results will be completed by a research of moderators and mediators within the correlates.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Prevalence of stress in junior doctors during their internship training: A cross-sectional study of two Tunisia medical colleges' hospitals**

A. Kchaou<sup>1</sup>, M. Hajjaji<sup>1</sup>, R. Masmoudi<sup>2</sup>, N. Kotti<sup>1</sup>, M.L. Masmoudi<sup>3</sup>, J. Masmoudi<sup>2</sup>, K. Jmal<sup>4</sup>

<sup>1</sup> Hospital Hédi Chacker, Sfax, department of occupational medicine, Sfax, Tunisia; <sup>2</sup> Hospital Hédi Chacker, Sfax, department of psychiatry, Sfax, Tunisia; <sup>3</sup> Hospital Hédi Chacker, Sfax, department of occupational medicine, Sfax, Tunisia; <sup>4</sup> Hospital Hédi Chacker, Sfax, department of occupational medicine, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Medical science is perceived as a stressful educational career and medical students experience monstrous stress during their internship and residency training, which affects their cognitive function, practical life, and patient care.

**Objectives.**– This study wanted to examine the prevalence of self-perceived stress among new medical graduates during their internship training.

**Methods.**– Interns of the Hédi Chaker and Habib bourguiba University hospitals in Sfax- Tunisia were invited to complete the Perceived Stress Scale (10-item form). Also, the questionnaire collected personal data (age, sex and marital status) in addition to information relevant to hospital training, assigned duties, and clinical training rotations.

**Results.**– A total of 216 (males = 60; females = 66) residents trainees participated in this study. The mean age of the study population was 27.30 years. Nearly 65% of the participants considered themselves in very good health. Most of the interns were affected by a severe level of stress (78.6%), followed by mild (19%) and moderate (2.4%) levels of stress. The stress level was significantly higher (83%) among female doctors in comparison with male doctors (65%) (Odds ratio = 1.64; confidence interval = 1.74–3.87;  $P < 0.0002$ ). The highest stress level was reported by interns during the clinical rotations of medicine (78%), followed by surgery (75%), pediatrics (70%), and emergency (60%). High levels of perceived stress were significantly associated with general health problems of residents trainees ( $P < 0.000$ ).

**Conclusion.**– We found a significantly high level of stress among the medical interns. Hence, medical interns need support and subsequent interventions to cope with stress.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Prevention program workshops are evaluated for their long term effectiveness

S. Kocijančič\*, V. Švab

Faculty of medicine, university of Ljubljana, department of psychiatry, Ljubljana, Slovenia

\* Corresponding author.

**Introduction.**– The project in reflection is a prevention program with anti-discriminatory workshops that are performed by medical students for high-schoolers to inform them about mental disorders, de-stigmatization and for raising mental health awareness.

**Objectives.**– The goal was to evaluate the anti-discriminatory effect of the workshops on adolescents attitudes towards mental disorders at several different times.

**Methods.**– The workshops were performed in different schools in Slovenia, where 288 high-schoolers participated. The questionnaire was handed out before and after the workshop and a year later in order to determine the change in the attitude of the participants towards mental disorders with a Likert scale. Peer to peer method of education was used in a classrooms of approx. 30 high-schoolers each. Standard paired *T*-test was used, with a value of  $P < 0.05$ .

**Results.**– 288 high-schoolers participated in the workshops and answered in the before and right after the workshop questionnaire. 1 year later, the assessment was repeated in the same sample group. Standard *t*-test comparison before the workshop and 1 year later showed a large improvement towards less stigmatizing attitude. Comparison between the workshop assessment at conclusion and a year later showed also a small improvement, without a booster session in between.

**Conclusion.**– The results show improved attitudes of adolescents at the conclusion of the workshops towards a less stigmatizing attitude. A year later the improvements are still seen on a smaller scale.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Pathway to care in mental health settings: First contact in treatment seeking and mode of referral to a tertiary care psychiatric facility in Islamabad

S. Mansoor<sup>1</sup>\*, T. Mansoor<sup>2</sup>

<sup>1</sup> Senior Registrar, department of psychiatry, foundation university medical college, Islamabad, Pakistan; <sup>2</sup> National university of medical sciences, behavioral sciences team, multidisciplinary department, Rawalpindi, Pakistan

\* Corresponding author.

**Introduction.**– The understanding of pathway to care helps to improve the utilization of mental health services.

**Objective.**– To assess the factors associated with the first contact of patients and the mode of referral to a private tertiary care psychiatric facility in Islamabad, Pakistan.

**Methods.**– Through convenience sampling, 246 patients making their first contact with a psychiatric facility in Islamabad from June to Dec 2016 were made part of the sample. For each patient, the age, gender, educational status, marital status, locality of residence, monthly family income, first contact in treatment seeking and mode of referral to psychiatric service were recorded. Data was analyzed using SPSS 20.0.

**Results.**– Out of 246 patients (61.4% females and 38.6% males), the majority of patients (38.2%) consulted faith healers as their first contact for mental health care, followed by general practitioners (23.2%), medical specialists (14.6%) and traditional medical practitioners (14.2%). Only 9.8% patients reported to a psychiatrist directly. Local general practitioners were the primary source of referral to psychiatric services in majority of patients (40.7%). The educational status, monthly family income and locality of residence were significantly associated with the choice of first contact; patients from rural background with no formal education and low monthly income were more likely to seek care from faith healers.

**Conclusion.**– Strategies to improve pathways to mental health care must aim to foster collaboration between key community-based providers and specialist mental health services, particularly in rural areas with low literacy rates and poor socio-economic settings.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

Popa” university of medicine and pharmacy, general medicine, Iasi, Romania; <sup>3</sup> University of medicine and pharmacy “Grigore T. Popa”, career counseling, Iasi, Romania;

<sup>4</sup> University of medicine and pharmacy “Grigore T. Popa”, general medicine, Iasi, Romania

\* Corresponding author.

**Introduction.**– Alexithymia is a multidimensional construct that is responsive to depression and situational stressors.

**Objectives.**– The aim of this study is to investigate the relationship between alexithymia and depression among medical students enrolled in the pre-clinical years of study.

**Methods.**– A number of 155 medical students (43 males, 112 females) took part in this study, 97 in 1st year and 58 in the 2nd year. The students were asked to fill a questionnaire containing socio-

demographic information. Two instruments were used: Toronto Alexithymia Scale (measuring the level of alexithymia) and Beck Depression Inventory (measuring the level of depression). Spearman correlations for the correlational analysis and Independent Samples *T*-Test for the comparative analysis were used.

**Results.**– A strong positive correlation between the total score for depression and the total score for alexithymia ( $r=0.442$ ,  $P=0.000$ ) was identified, the more depressed the subjects are, the higher their alexithymia score will be. No significant differences were found between the subjects in the 1st year and the subjects in the 2nd year regarding the total score for the alexithymia, and for two of its factors (difficulty describing feelings and difficulty identifying feelings). Externally oriented thinking dimension produces significant differences ( $t(151)=-3.584$ ,  $P=0.000$ ), the students from the 2nd year ( $M=19.45 \pm 4.89$ ) proving being more externally oriented thinking than their freshman colleagues ( $M=16.76 \pm 4.24$ ).

**Conclusions.**– It is important to identify the causes of depression among medical students in order to create effective psychological strategies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Mental health use in a group of patient with committed suicide**

N. Noorani<sup>1\*</sup>, A.H. Jalali Nadoushan<sup>2</sup>, K. Alavi<sup>3</sup>, S.K. Malakouti<sup>3</sup>

<sup>1</sup> Private sector, psychiatry, Tehran, Iran; <sup>2</sup> IMUS, psychiatry, Tehran, Iran; <sup>3</sup> IUMS, psychiatry, Tehran, Iran

\* Corresponding author.

**Objectives.**– Suicide victims frequently have had contact with the mental health services before they died. In this study, the rate of mental health care system contact during the last year before suicide commission was evaluated.

**Methods.**– Utilization of mental health care facilities during the last 12 months of 231 individuals who committed suicide was assessed by the questionnaire.

**Results.**– Of the suicide victims, 62% had been used mental health services at least once. The mean age of the patients was 29.7 years ( $SD=4/11$ ). There wasn't significant difference in age between men and women who had used mental health services ( $P=0.077$ ). There was a significant relationship between the two groups using and not using of mental health services and suicide more than once ( $P=0.008$ ). There was also a significant relationship between psychiatric illness and mental health services ( $P<0.0001$ ).

**Conclusion.**– Increasing utilization of mental health care facilities should be considered a particularly profound suicide risk assessment and post discharge treatment planning. Continued and more serious follow-up of these patients with strategies such as social workers or through methods such as telemedicine (Continuous and right communication through phone, email, etc.) is necessary to prevent from their suicide.

**Keywords:** Suicide; Mental health services; Demographic data

### **Psychiatric home hospitalization unit of the hospital Del Mar (HADMar). A crisis resolution and home treatment team in Barcelona**

L. Alba Palé<sup>\*</sup>, D. Sanagustin Bosqued, J. León Caballero, D. Córcoles Martínez, A. Gonzalez Díaz, M. Bellsolà Gonzalez, L.M. Martin Lopez

Hospital del Mar, Inad, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Although home hospitalization has begun to develop widely in recent years there is a notable lack of studies. The following study includes data from the Psychiatric Home Hospitalization Unit of the Hospital del Mar (HADMar). This program has been running for two years and takes place in a socio-demographically depressed area in Barcelona. It receives patients from community and hospital services. Monitoring is limited in time and at discharge patient are referred to the ambulatory unit.

**Methods.**– All patients visited from 2015 to the present time were selected. A total of 135 patients were included in the sample. A qualitative descriptive study was carried out in order to define the socio-demographic characteristics. The severity of symptoms, suicidal risk and changes in the functionality were considered as clinical outcomes.

**Results.**– The mean age of patients was 44.6 years and there were no gender differences. 26 patients had a history of autolytic attempts and 11.1% lived alone. 51.1% were diagnosed with a psychotic disorder. The mean GEP score for the severity of the psychiatric symptoms was 2.39 and the mean risk of suicide was 0.49. There is an increase in the GAF score from admission to discharge, which means an improvement in the functionality of patients.

**Conclusion.**– The results obtained in our study are consistent with previous results. Home crisis intervention teams have proved to be an alternative to traditional hospitalization. However, more studies are needed to support these results.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Are patients with mental disorder who address a primary care doctor in Greece slipping through the cracks?**

I. Papachristopoulos<sup>1\*</sup>, A. Konstantopoulou<sup>1</sup>, M. Leotsinidis<sup>1</sup>, P. Gourzis<sup>2</sup>, E. Jelastopulu<sup>1</sup>

<sup>1</sup> University of Patras, department of public health, medical school, Patras, Greece; <sup>2</sup> University Hospital of Patras, department of psychiatry, Patras, Greece

\* Corresponding author.

**Introduction.**– A patient with mental disorder will first approach a primary care physician who should recognize, treat and manage the mental illness. In Greece, doctors of primary care are considered the general practitioner (GP) as well as the internist who has an office-based practice, acting as a gatekeeper.

**Objectives.**– To investigate the diagnostic skills and management of patients with mental disorders in a primary care setting.

**Methods.**– A standardized questionnaire with 6-point Likert scale was designed addressing GPs and internists. 521 primary care doctors anonymously completed the 24-item questionnaire nationally. SPSS 24 software was used for the data analysis.

**Results.**– GPs attend psychiatric conferences and small-group clinical tutorials more often than the internists (53.2% and 38.3% vs 27.3% and 18.4%). Only the 43.9% of GPs and the 30% of internists consider their training in psychiatry sufficient. GPs are feeling more

confident to diagnose a mental disorder (68.6%) and are more aware of the medication they must follow (77.9%) than the internists (46.5% and 44%, respectively). GPs are more reluctant to directly refer a patient with mental disorder to a psychiatrist than the internists (32% vs 76.2%).

**Conclusions.**– The training of a primary care doctor seems to minimize the referrals to specialized care thus mitigating the risk of a patient to quit or delay the visit to the psychiatrist. Nevertheless, physicians' sense of inadequate literacy underlines the need for their further and continuous training in mental health problems, especially for the internists, as to ensure the proper management of such patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Predicting factors of an acute hospitalization from a mobile psychiatry unit**

L. Pujol Canadell<sup>1\*</sup>, M. Angelats Martin<sup>1</sup>, J. León<sup>1,2</sup>, Á. Malagón<sup>1</sup>, M. Bellsolà<sup>1</sup>, A. González<sup>1</sup>, A. Brown<sup>3</sup>, L.M. Martin<sup>1</sup>, V. Pérez<sup>1,2,4</sup>, D. Córcoles<sup>1</sup>

<sup>1</sup> *Instituto de Neuropsiquiatria y Adicciones INAD, Parc de Salut Mar, Psychiatry, Barcelona, Spain;* <sup>2</sup> *Institut Hospital del Mar d'Investigacions Mèdiques, IMIM, Psychiatry, Barcelona, Spain;*

<sup>3</sup> *CISSS, Chaudière-Appalaches, Centre hospitalier affilié universitaire, Hôtel-Dieu de Lévis, Psychiatry, Lévis Québec, Canada;* <sup>4</sup> *CIBERSAM, Centro de Investigación Biomédica en Red de Salud Mental, Barcelona, Spain*

\* Corresponding author.

**Introduction.**– The main assistance method during an acute decompensation of mental illness is the hospitalization and it is often used as the first step to enter in the mental health system. Studies describing mobile psychiatry unit (MPU) were first made during the 1970s but, until today, determinants of income on MPU patients have not been assessed.

**Aim.**– To determine which factors can help a MPU to predict the hospitalization of a patient.

**Methods.**– A total of 1672 visits made by MPUs were analyzed from 2007 to 2016. Sociodemographic and clinical variables were collected. Other parameters, such as severity, disability and aggressiveness were also assessed according to different scales. We performed a multivariate logistic regression using SPSS 20.0 package to determine the relative contribution of each variable.

**Results.**– The sociodemographic and clinical variables including mean age, low education level, treatment non-adherence, previous linkage to mental health care, reason of consultation, diagnosis and scales such as AVAT, WHO/DAS, Total SPI, mean CGI and GAF were statistically significant ( $P < 0.05$ ). The best logistic regression model showed that age, drug use and higher scores on the GAD scale were protective factors while higher scores on GEP, AVAT and CGI were risk factors of hospitalization.

**Conclusions.**– Psychiatric hospitalizations from a MPU seems to be guided by symptom severity. Substance abuse, previous treatment adherence, aggressive behavior and low level of functioning are important factors. Differences detected between other psychiatric units suggest that more studies should be performed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Family rooms in psychiatric hospitals**

T. Ranjan<sup>\*</sup>, N. Jovanovic, N. Hakim

*Bart's and London school of medicine and dentistry, Queen Mary University of London, London, United Kingdom*

\* Corresponding author.

**Introduction.**– Up to half of all patients discharged from psychiatric hospitals have dependent children. Parental hospitalisation can have devastating impact on children. How can inpatient services support families during hospitalisation?

**Objectives.**– To evaluate the role of off-ward family room at psychiatric hospital in East London, UK during 2014–2016.

**Methods.**– Frequency of use of the room during was analysed using the electronic booking system. To obtain staff and patient thoughts and experiences on the family room, a 15-minute semi-structured interviews were conducted. Data was analysed using descriptive statistics and thematic analysis.

**Results.**– The room was booked almost every day (on average 225 bookings per year), more commonly on weekends and in the afternoon, and mainly by female patients. On average, the room was booked for 1 hour per patient. A total of 15 patients and 19 staff members were interviewed. Both staff and patients felt positive about using the room. Staff saw time spent with families in the room useful for diagnostic purpose as well as treatment. Patients found it useful to remain close to their families and feel that the room provides a sense of privacy which is not always the case on the wards. However, most patients want more flexibility during family visits and less staff supervision. Both agreed that the room should be bigger and better furnished.

**Conclusion.**– Family-friendly rooms are essential to the provision of family-friendly mental health services. They can improve experience of inpatient care as well as support parents and children during this critical period.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Evolution of addressability for psychiatric services in a rural area of Romania**

M. Sarpe<sup>1\*</sup>, B. Mihai<sup>2</sup>, L. Maria<sup>2</sup>

<sup>1</sup> *Psychiatry, outpatient care unit, Sarpe Marcel, psychiatry, Focsani, Romania;* <sup>2</sup> *University of medicine and pharmacy "Carol Davila", psychiatry, Bucharest, Romania*

\* Corresponding author.

**Introduction.**– Fear of stigma related to psychiatric disorders is still strong in Romanian rural areas.

**Objectives.**– The paper evaluates the evolution of the addressability of rural population for psychiatric outpatient treatment over two years.

The perception of Romanian rural patients regarding the opportunity and usefulness of psychiatric treatment is evaluated, based on statistical analysis.

**Methods.**– The population of a large rural area was monitored and the addressability was measured. The psychiatric disorders of the presenting outpatients were analyzed, so that the main reasons for presentation could be identified.

**Results.**– Vrancea County's area is of 4857 km<sup>2</sup>, and a population of about 350,000 people. From them, the rural population is about 220,000 people, about 66% of the people from the county.

The results showed that about 45% of the patients suffered from Major Depressive Disorder, about 40% suffered from Anxiety Disorders, about 10% presented with other Psychiatric problems, like

Somatoform Disorders, and the rest, about 5% with Psychotic Spectrum Disorders.

**Conclusions.**– Although stigma related to psychiatric disorder is still important in rural areas, due to psycho-education and the means that raise the awareness in population, this fear is decreasing.

We also want to stress out about the fact that about 30,000 people from this county works abroad our country, especially in Italy and in Spain, and their addressability to Romanian medical services are more important in the summer months, when they return home, for holiday.

As a conclusion, people begin to be more educated and the number of patients who reach out for psychiatric treatment is increasing.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0127

### **The relationship between personality traits and burnout among medical students from preclinical years**

M. Iorga<sup>1</sup>, C. Dondas<sup>2</sup>, S. Socolov<sup>3\*</sup>, I.M. Gavrilescu<sup>4</sup>, T. Pantilimonescu<sup>4</sup>

<sup>1</sup> University of medicine and pharmacy “Grigore T. Popa”, Behavioral Sciences, Iasi, Romania; <sup>2</sup> University of medicine and pharmacy “Grigore T. Popa”, Career Counselling, Iasi, Romania; <sup>3</sup> “Gr. T. Popa” university of medicine and pharmacy, general medicine, Iasi, Romania; <sup>4</sup> University of medicine and pharmacy “Grigore T. Popa”, general medicine, Iasi, Romania

\* Corresponding author.

**Introduction.**– There is a high risk of burnout among medicals students with a negative impact on their psychological well-being and academic performance.

**Objectives.**– The aim of this study is to investigate the relationship between personality traits and the level of burnout among students enrolled in the pre-clinical years of study.

**Methods.**– A number of 155 medical students (97 from 1st year and 58 from 2nd year) answer to two instruments: Big Five Inventory – to identify the personality traits and Maslach Burnout Inventory to measure the level of burnout. Socio-demographic data were also registered.

**Results.**– Emotional exhaustion correlated with extraversion ( $r = -0.271$ ,  $P = 0.001$ ), agreeableness ( $r = -0.232$ ,  $P = 0.004$ ), neuroticism ( $r = 0.425$ ,  $P = 0.000$ ) and openness ( $r = -0.291$ ,  $P = 0.001$ ). Depersonalization correlated with conscientiousness ( $r = -0.185$ ,  $P = 0.023$ ), agreeableness ( $r = -0.249$ ,  $P = 0.002$ ), and extraversion ( $r = -0.291$ ,  $P = 0.000$ ) and personal achievement correlated with extraversion ( $r = 0.226$ ,  $P = 0.005$ ), agreeableness ( $r = 0.194$ ,  $P = 0.016$ ) and openness ( $r = 0.187$ ,  $P = 0.020$ ). Students from 2nd year seem to be more emotionally exhausted and obtained higher scores for depersonalization.

**Conclusions.**– A strong interdependence between personality factors and the burnout dimensions was identified. Students from 2nd year of study are more emotionally exhausted and have higher level of depersonalization comparing to freshman students, academic strategies should be reconsider in order to prepare them for the clinical years of their medical formation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Patterns of mental health morbidity in primary health care**

M. Xavier<sup>1,2\*</sup>, P. Mateus<sup>2</sup>

<sup>1</sup> Health Directorate General, Mental Health, Lisbon, Portugal;

<sup>2</sup> NOVA Medical School, Mental Health, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– In Portugal, main mental health care providers are Local Mental Health Services, located in departments belonging to general NHS hospitals. These work articulated with the primary health care centres in the same geographic area. The country already had one of the highest rates of mild and moderate mental health disorders prevalence when a long and challenging economic crisis putted primary health care to the test.

**Objectives.**– To evaluate the use of primary health care (PHC) services in Portugal, due to common mental health disorders, at the peak of the economic crisis negative effects.

**Methods.**– PHC services use was assessed through indicators available in the Regional Health Authority Information System (SIARS), using the International Classification of Primary Care, Second edition (ICPC-2) codification system.

**Results.**– Results show an increase in the number of PHC users with depression and anxiety disorders between 2011 and 2014, in all five Portuguese health regions. The increase was higher in the Alentejo region for Anxiety disorders (from 4.14% in 2011 to 6.70% in 2014), and Depression (from 6.05% in 2011 to 9.62% in 2014).

**Conclusion.**– Results show an increase in the number of users in the PHC services, during the worst period of the economic crisis. Mental health care in primary care must be considered a top priority in times of economical crisis. PHC services should work together along with liaison programmes, both with specialised services and other community institutions, such as schools and social care agencies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## **Mental Health Policies / Promotion of Mental Health**

### **Relationships between youth sports participation and mental health in young adulthood among Finnish males**

K. Appelqvist-Schmidlechner<sup>1\*</sup>, J. Vaara<sup>2</sup>, A. Häkkinen<sup>3</sup>, T. Vasankari<sup>4</sup>, J. Mäkinen<sup>2</sup>, M. Mäntysaari<sup>5</sup>, H. Kyröläinen<sup>6</sup>

<sup>1</sup> National institute for health and welfare, mental health unit, Helsinki, Finland; <sup>2</sup> National defence university, the department of leadership and military pedagogy, Helsinki, Finland; <sup>3</sup> University of Jyväskylä, health sciences, Jyväskylä, Finland; <sup>4</sup> UKK institute for health promotion, UKK institute for health promotion, Tampere, Finland; <sup>5</sup> Centre for military medicine, centre for military medicine, Helsinki, Finland; <sup>6</sup> University of Jyväskylä, department of biology of physical activity, Jyväskylä, Finland

\* Corresponding author.

There is a growing body of evidence that higher level of physical activity is associated with a better state of mental health. Less is known about the relationships between youth competitive sports and mental health in the adulthood. The aim of the study was to examine whether retrospectively assessed sports participation (SP) and competitive sports (CS) at the age of 12 years is associated with

mental health (mental well-being as well as mental distress) and health behaviour in young adulthood among males.

The study sample consisted of 680 males aged between 20–35 years. The data were gathered with self-administered questionnaires in 2015 in Finland. Mental well-being was measured with SWEMWBS and mental distress with five items of SF-36 scale. SP at the age of 12 is associated with better mental health in young adulthood, with both mental well-being (OR=1.86, 95% CI 1.11–3.11) as well as mental distress (OR=0.61, 0.41–0.90). Age, years of education and current physical activity were controlled. Higher level of intensity of SP or the level of CS in childhood was associated with lower level of mental distress in adulthood. No association was found between the level of CS in childhood and mental well-being in adulthood. Further, the study showed that youth SP can present a higher risk for increased alcohol consumption and use of snuff and tobacco in adulthood.

Despite negative outcomes related to health behaviour, the findings provide support for the association between youth sports participation and mental health outcomes in adulthood among males.

### **Critical review of psychiatric advance directives globally and its implications in LAMIC countries**

A. Balakrishnan\*, S. Moirangthem, C. Naveen Kumar, S. Bada Math, P. Murthy

*National institute of mental health and neurosciences NIMHANS, psychiatry, Bangalore, India*

\* Corresponding author.

*Introduction.*– Psychiatric Advance Directives are legal instruments for competent persons to state their preferences regarding future mental health treatment in the event of a loss of capacity to make healthcare decisions. These are seen as a landmark step in the shift from a charity – based to a rights – based approach. PADs have largely been implemented in the developed countries. Little is known about implementation in the LAMIC regions where resources are limited.

*Objectives.*– The present study aims to review existing reports on the implementation of PADs and examine implications in the Indian subcontinent

*Methodology.*– A systematic search of articles published in the English language was conducted. Ten experts in the field of mental health were interviewed.

*Results.*– PADs have been found to enhance treatment engagement and the perceived sense of control of the patient, leading to greater autonomy. Barriers such as lack of awareness of both providers and consumers, issues of determination of competency, have been discussed.

In the developing countries, PADs face financial, legal and cultural barriers. Cultural explanations of mental illness, the perceived autonomy of the mentally ill, poor awareness of legal provisions, perception of the doctor- patient relationship, and huge financial costs were seen as important challenges.

The differences in laws that have incorporated PADs and the individual challenges in the different countries will be discussed

*Conclusion.*– A large gap between legislation and implementation exists. Strategies to overcome this include awareness programs, legal assistance programs and a cultural paradigm shift in the doctor-patient relationship.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Talking about suicide: Reaching our community with the “Setembro Amarelo” campaign**

P. Barbosa\*, S. Farinha-Silva, A. Matos-Pires  
*ULSBA, Serviço de Psiquiatria, Beja, Portugal*

\* Corresponding author.

*Introduction.*– “Setembro Amarelo” (translation: “Yellow September”) is a Suicide Prevention campaign created in Brazil in 2015. September, 10th is World Suicide Prevention Day and the campaign extends the activities across the whole month to raise awareness for this problem. In Portugal, Beja has one of the country's highest suicide rates. This fact made the local hospital's Psychiatry Department and Aris da Planície association promote the “Setembro Amarelo” campaign for the first time in Portugal on September 2017.

*Objective:* To review the activities held during the “Setembro Amarelo” campaign.

*Method.*– Interviewing organizers, participants and collecting information from the campaign materials.

*Results.*– The first edition of “Setembro Amarelo” campaign in Beja consisted of several activities for the community. Four conferences were held with psychologists and psychiatrists, who also gave weekly interviews on a local radio station. Two booklets on suicide awareness were distributed in the city with help of college students. On World Suicide Prevention Day there was a bike ride linked to the “Cycle around the globe” campaign from International Association for Suicide Prevention. Four gyms also contributed to this activity. There was also a workshop on suicide risk assessment for health-care professionals.

*Conclusion.*– Suicide awareness campaigns are very important in a region who is specially affected by this problem. The campaign “Setembro Amarelo” was very well received by the local authorities, business and media. These partners were found to be very helpful and important allies when promoting mental health in the community.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **From self-centered services to user-centered services: An Italian experience of services system change**

P. Carozza

*Mental Health Authority, mental health department, Ferrara, Italy*

\* Corresponding author.

*Introduction.*– In the Italian Health Reform, despite the existence of the law 180/78, many services' systems are mainly oriented to “stabilize” the symptoms and to “replace” permanently many clients in the psychiatric residential facilities, often reproducing a marginalized way of living, instead fostering recovery processes. Other critical points:

- families involvement in their relatives' treatment plan not delivered on regular basis;
- increased number of clients placed into public and private psychiatric residential facilities with increased health care costs;
- low monitoring of treatments' effectiveness (outcomes evaluation);
- lack of recovery oriented competence curricula.

*Objective.*– It became clear that the traditional treatments, medication and crisis interventions, had shown themselves inadequate to meet the different needs of people with psychiatric disabilities/substance abuse and insufficient to increase role functioning

in the real world. So, we should have paid a greater attention to the tools and the methods with which to counteract the disabling effects of mental illness and substance abuse.

**Method.**– It will be described how to develop a services system's change, adopting an holistic approach (people, before being defined as diagnosis, are persons, with three closely connected dimensions: biological, psychological, social), with the purpose to increase the social functioning and subjective well-being of users.

**Results and conclusion.**– The results of a Italian system services process of change are reported and acquisitions gained about system sustainability to transfer EB and recovery principles in the practice are highlighted.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>1</sup> The University of Texas at Austin, Latino Research Initiative, Austin, USA; <sup>2</sup> Latino Research Initiative, Mexican American and Latino Studies, Austin, USA; <sup>3</sup> Columbia University, Sociomedical Sciences, New York City, USA; <sup>4</sup> Substance Abuse and Mental Health Services Administration, Center for Mental Health Services, Rockville, USA; <sup>5</sup> MHMR of Tarrant County, Paving the Way, Fort Worth, USA;

<sup>6</sup> University of California at Riverside, Public Policy and Sociology, Riverside, USA

\* Corresponding author.

**Introduction.**– Aggressive behaviors are a concern among youth particularly to the extent that they relate to mental health (MH). We evaluated changes in perpetrated aggressive behaviors following the implementation of a school-based intervention aimed at reducing mental illness stigma.

**Objectives.**– To evaluate the short- and long-term impact of a school-based anti-stigma intervention on physical, verbal, and relational aggressive behaviors among youth with MH symptoms.

**Methods.**– Diverse sixth-graders were randomized to receive an anti-stigma curriculum. A pre-posttest survey assessed self-reported MH symptoms and frequency of aggressive behaviors. Longitudinal follow-up was administered at 6-, 12-, 18-, and 24-months post-intervention. Generalized estimating equations assessed the effect of the curriculum compared to control on perpetrated physical, verbal, and relational aggression among youth with high-level MH symptoms ( $n = 260$ ).

**Results.**– Highly symptomatic youth who received the curriculum compared to those who did not had consistently decreased odds of perpetrating physical, verbal, and relational aggressive behaviors from pre- to post-test. Although longitudinal effects were non-significant, predicted probabilities of perpetrating these behaviors were explored over the two-year follow-up. The patterns for each aggressive behavior type were consistent: youth who received the curriculum as compared to youth in the control demonstrated a declining trend in aggressive behaviors up to 18-months. After the 18-month follow-up, aggressive behaviors began to increase for those in the curriculum group.

**Conclusions.**– The anti-stigma curriculum reduces aggressive behaviors in the short-term among youth with high MH symptoms. However, in order to sustain these effects longitudinally, a booster intervention may be required at 18-months after first exposure to the intervention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0134

### **Why do young psychiatrists leave Spain?**

C. Gómez Sánchez-Lafuente<sup>1</sup>, R. Reina Gonzalez<sup>2</sup>  
<sup>1</sup> Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain; <sup>2</sup> Hospital Universitario Virgen de la Victoria, General Medicine, Málaga, Spain

\* Corresponding author.

**Introduction.**– Qualified migration of health professionals to developed countries is a long-standing global phenomenon. Due to social and economic situation in Europe, it seems to be a great migratory flow of doctors and other health professionals within the continent.

**Objectives.**– The objective of this study was to explore the factors that motivated migration in this group from Spain to other European countries.

**Methods.**– The population included in the study were psychiatric trainees who were carrying out the last year training in Spain during 2014. The data were obtained through a semi-structured questionnaire of 61 questions designed specifically for the study called Brain Drain, to identify the factors that influence the time to migrate in search of work.

**Results.**– 95 psychiatric trainees participated in the survey, of which 71 (74.7%) had ever considered emigrating to another country in search of work. 21 (29.5%) had already started some practical steps to go abroad. The main reasons were higher wages in other countries (86%) and the opportunity to progress professionally (84%). The degree of satisfaction with the salary received was high or very high in 49% of the sample.

**Conclusions.**– Psychiatric trainees considered migrating outside Spain. Participants perceived that balance between work and life, work according to previous studies and experience, working conditions and work cooperation and team work were major issues to improve in Spain. In the other side, cultural and social environment were the main reasons to stay. The brain drain constitutes a loss of human capital that can deteriorate health care in Spain.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Legislation restrictions of drive licensing as a tool of primary prevention of drug abuse among adolescents**

O. Guseva

Law faculty, Open Law Institute, department of civil law, Moscow, Russia

\* Corresponding author.

**Introduction.**– According to the EMCCDA data, at least 80 new psychoactive substances are appeared annually in the European countries. Nowadays starch, sugar and oils are the sources of new amphetamines and new other drugs. In this situation to protect adolescents is the important task of all health policy makers all over the world.

**Objectives.**– To analyze the preferences among teenagers of 15–17 and according to these results to implement legislation restrictions as the primary prevention tool of drug abuse.

**Methods.**– Comparative analysis of federal statistic data and results of social surveys among teenagers were conducted.

**Results.**– The results of social surveys among adolescents revealed the drive licensing is one the most important attributes of self-assertion. Obligations of describing legislation restrictions for people who use drugs had been provided within the drug tests in schools. At the same time the legislation restrictions of drive licensing had been implemented due to target audience preferences. In 2016 the 41% decrease of new cases of drug use in non-medical purposes among teenagers were fixed in the federal statistics database.

**Conclusion.**– The legislation restrictions cannot influence directly, but it can be used as an efficient tool of primary prevention set of drug abuse among adolescents.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Priorities for funding, research capacity and infrastructures in European mental health research, results from a dedicated Roamer work-package**

J.B. Hazo<sup>1\*</sup>, B. Matthias<sup>1</sup>, G. Coralie<sup>1</sup>, L. Marion<sup>2</sup>, C. Karine<sup>1</sup>, C. Roamer<sup>3</sup>

<sup>1</sup> INSERM, UMR-S 1123, ECEVE, Paris, France;

<sup>2</sup> French National Science Foundation, Fondation FondaMental, Créteil, France; <sup>3</sup> Roamer, Consortium, Paris, France

\* Corresponding author.

The growing epidemiological and economic burdens of mental disorders have to be matched by European mental health research funding, capacities and infrastructures. Europe is in a competitive position in terms of health research resources but, on the mental health field, there is room for improvement in term of coordination and development of such resources. Consequently, an inventory of existing research capacities has been realized as well as a estimation of mental health research funding at both EU and national levels. These works were presented to experts in focus groups allowing the identification of eight overarching goals and consensual emergence of seventeen corresponding recommendations. They are all aiming at research capacities building – adapted to the diversity of national situations – in order to give mental health research the human, structural and financial means needed to face the existing and coming challenges in the field.

**Funding.**– The research leading to these results has received funding from the European Commission's Seventh Framework Programme (FP7,2007–13) under grant agreement number 282586, and from the National R&D Internationalisation Programme of the Spanish Ministry of Science and Technology under Reference ACI-PRO-2011-1080

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Meta-cognitive and mindfulness predictors of hallucination proneness in healthy population**

S.R. Hosseini<sup>1\*</sup>, T. Saeid Par var<sup>2</sup>, A. zahmatkesh<sup>2</sup>

<sup>1</sup> University of social welfare and rehabilitation sciences, substance abuse and dependence research center, Tehran, Iran; <sup>2</sup> Islamic Azad university, Tehran medical branch, clinical psychology, Tehran, Iran

\* Corresponding author.

**Introduction.**– Maladaptive metacognitive and mindfulness processing appears to be an important baseline for some individuals with a diagnosis of psychosis.

**Objectives.**– The aim of this study was to evaluate the Meta-cognitive and mindfulness predictors of hallucination proneness in healthy population.

**Methods.**– A total of 168 healthy volunteers completed revised Launay- Slade Hallucination Scale (LSH), Metacognitive Questionnaire (MCQ) and Mindfulness Questionnaire(MQ).

**Results.**– Regression analysis indicated that MCQ factors encompassing (1) negative beliefs about uncontrollability and danger of thoughts and (2) cognitive non-confidence; and MQ factors include of (1) observation, (2) description, (3) action with consciousness and (4) un reaction were the strongest predictors of hallucination proneness in healthy population.

**Conclusions.**– The results showed that the hallucinatory-like experiences are much more prevalent among general population than their extreme clinical manifestations. Moreover, psychological factors are strong predictors for these experiences and these factors should be considered in early preventions.

**Keywords:** Hallucination proneness; Meta-cognitive; Mindfulness

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Differences in perceived stigma towards mental and physical illnesses amongst healthcare professionals and general public**

N. Chaudhry<sup>1</sup>, M. Husain<sup>1</sup>, A. Khoso<sup>1\*</sup>, S. Zehra<sup>1</sup>, S. Sultan<sup>2</sup>,

S. Farooq<sup>1</sup>, Z. Batool<sup>1</sup>, N. Husain<sup>3</sup>

<sup>1</sup> Pakistan institute of living & learning, research, Karachi, Pakistan;

<sup>2</sup> Bahauddin Zakariya university, research, Multan, Pakistan;

<sup>3</sup> University of Manchester, division of psychology and mental health, Manchester, United Kingdom

\* Corresponding author.

**Introduction.**– Over the past decade, the importance of stigma towards mental illness has been increasingly recognised by organisations such as the World Health Organization (WHO) and the World Psychiatric Association. Along with the burden of the illness itself both physical and mental illnesses are often stigmatised by the general public. In low income countries such as Pakistan mental health stigma has been identified as one of the biggest barriers leading to delays in treatment and poor engagement. There is limited information about the extent to which stigma is exhibited by healthcare professionals in comparison to the general population.

**Objectives.**– To compare the differences in perceived stigma towards mental and physical illness amongst healthcare professionals and the general population in a low income country.

**Methods.**– A sample of 1470 individuals aged 18 and above were recruited from three different groups; healthcare professionals ( $n = 726$ ), nursing students ( $n = 500$ ) and the general public ( $n = 244$ ) in Karachi, Pakistan. Bogardus Social Distance Scale was used to measure the stigma.

**Results.**– All three groups reported higher levels of stigma towards mental illness than physical illness. The general public reported higher stigma towards both physical and mental illnesses as compared to the healthcare professionals and the nursing and medical students.

**Conclusion.**– Stigma towards mental and physical ill health is prevalent amongst the general public and also amongst healthcare professionals. This highlights the importance of anti-stigma campaigns to continue to raise awareness and tackle stigma.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Preliminary study on the efficacy of the MIND programme for cancer patients

I.A. Trindade, C. Ferreira, J. Marta-Simões\*, A.L. Mendes, J. Pinto-Gouveia

CINEICC, cognitive and behavioural center for research and intervention university of Coimbra, clinical psychology, Coimbra, Portugal

\* Corresponding author.

Several meta-analyses have suggested that more studies should test mindfulness-based interventions in cancer patients due to the small effect sizes usually found in mental and physical health outcomes. The MIND Programme (which includes 8 weekly group sessions) is an acceptance, mindfulness and compassion-based intervention, and the first programme for cancer patients to explicitly include these three components together.

Participants were recruited at the Radiotherapy Service of the Coimbra University Hospital. Participants were randomly assigned to the experimental group (TAU+MIND;  $n = 15$ ; no dropout) or the control group (TAU;  $n = 17$ ).

It is apparent from the subjective evaluations of the programme that it seemed useful and relevant for the majority of the patients, helping them to deal better with cancer-related issues and difficult thoughts and emotions. Results revealed that the experimental group presented a significant increase (from the pre-intervention to the post-treatment assessment) in psychological health in comparison with the control group ( $t_{(30)} = -2.24$ ;  $P < 0.05$ ), with a large effect size (Cohen's  $d = -0.79$ ). The experimental group also presented increases in physical health ( $d = -0.16$ ) and social relationships ( $d = -0.42$ ), and decreases in depression ( $d = 0.42$ ), anxiety ( $d = 0.08$ ), and stress ( $d = 0.32$ ).

Although the majority of the mean differences were not statistically significant, probably due to the small sample size, their effect sizes were generally superior to those found in meta-analyses regarding psychological interventions for cancer. These findings suggest that the MIND programme may improve cancer patients' mental health, social functioning and adjustment to the disease, and might be a relevant contribution. Further implications and conclusions will be discussed.

### Elements of self-compassion and self-judgment in body appreciation

J. Marta-Simões, C. Ferreira

CINEICC, cognitive and behavioural center for research and intervention university of Coimbra, clinical psychology, Coimbra, Portugal

\* Corresponding author.

Body appreciation, an aspect of positive body image, defines as an attitude of acceptance, respect and affection toward one's unique body characteristics. Although one of the roots of positive body image refers to Buddhism (e.g., self-compassion), the relationship between self-compassion and body appreciation remains scarcely studied.

The aim of the study was to explore the contribution of the main components of self-compassion (mindfulness versus over-identification, common humanity versus isolation and self-kindness versus self-judgment) for the explanation of the construct of body appreciation.

The study's sample was composed of 848 women, aged between 18 and 35. Participants completed demographic and self-report questionnaires (accessing self-compassion and body appreciation). Descriptive and correlation analysis explored sample's characteristics and relationships among variables. A path analysis explored the effects of self-compassion's component on body appreciation (while controlling the effect of BMI).

The overall model explained 25% of body appreciation's variance and showed that common humanity and self-kindness contribute positively to body appreciation, while self-judgment contributes negatively to body appreciation. Mindfulness, overidentification and isolation did not reveal significant direct effects on body appreciation.

This study seems to suggest that encompassing kindness to oneself, instead of self-criticism and judgment, and regarding one's experiences as part of a broader human experience, should be considered in the equation when explaining women's body appreciation. These results appear to be particularly important to guide the design of programs to prevent body image and eating-related disturbances (via the promotion of body appreciation), in which the cultivation of self-compassion has proved its efficacy.

### Do lithium and arsenic in drinking water influence suicide risk?

M. Pompili

Sapienza University of Rome, department of neurosciences, mental health and sensory organs, Rome, Italy

\* Corresponding author.

The research tested the hypothesis that both natural-cause and suicide death rates would be higher with greater trace concentrations of arsenic, on the contrary that suicide rates would be lower in sites with higher concentration of lithium in drinking water. Arsenic and lithium concentrations in drinking-water samples from 145 sites were assayed by mass spectrometry, and correlated with local rates of mortality due to suicide and natural causes between 1980 and 2011, using weighted, least-squares univariate and multivariate regression modeling. Arsenic levels were negatively associated with corresponding suicide rates, consistently among both men and women in all three study-decades, whereas mortality from natural causes increased with arsenic levels. Contrary to an hypothesized greater risk of suicide with higher concentrations of arsenic, we found a negative association, suggesting a possible protective effect, whereas mortality from natural causes was increased, in accord with known toxic effects of arsenic. A proposed association between trace lithium concentrations in drinking water and risk of suicide was only partially supported, and mechanisms for potential clinical effects of trace levels of lithium are unknown.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### Identification of children with suspect of neurodevelopmental disorders and activation of the early intervention route Monteria - Colombia

I. Ramos Vidal<sup>1</sup>\*, A.M. Romero Otalvaro<sup>2</sup>, M. Muñoz Argel<sup>2</sup>, I. Villamil<sup>2</sup>, M. Brunal Morelos<sup>2</sup>, V. Vilorio<sup>2</sup>

<sup>1</sup> Faculty of psychology, department of social psychology, Sevilla, Spain; <sup>2</sup> Universidad Pontificia Bolivariana, psychology, Monteria, Colombia

\* Corresponding author.

Neurodevelopmental disorders are childhood conditions that alter or delay the psychomotor development of an individual, most of the affected children live in low-resource countries, where the limited resources of trained personnel in primary health and community care make it difficult the intervention (Patel, 2013), for this reason caregivers are primordial in the implementation of stimulation guidelines as a measure against the deprivation of early intervention therapies. The Colombian health system does not intervene immediately, creating a gap that negatively impacts the prognosis of neurodevelopment. Therefore, identifying the patterns of stimulation performed by parents and caregivers, would allow establishing contingency plans in which parents are actively empowered and exploit the advantages of neuroplasticity, while awaiting specialized care. Objective: To detect neurodevelopmental problems early and to identify the route and time of activation for early intervention.

*Method.*– Descriptive, cross-sectional, mixed-qualitative design. The instruments applied in this research were the AGES AND STAGES QUESTIONNAIRE-3 for screening of neurodevelopment in 213 children aged 2–6 years, children’s development centers: El Dorado and La Palma (Monteria, Colombia). SEMISTRUCTURED INTERVIEW to primary caregivers.

*Results* Were detected 56 children with suspected developmental deficit, despite attending daily ICDs, identified that the route for health care for diagnosis and early intervention presents a delay of more than 4.2 months, which impacts negatively in the use of the Neuroplasticity and the best prognosis of the development.

*Conclusions.*– Our study puts into value the importance of developing early diagnoses of neurodevelopmental problems. It is important to implement these instruments of early detection in contexts of care for young children.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0143

### **Anti-stigma effect of a Consumer-Initiated Program with contact in mental illness**

M. Seo

Gyeongsang national university, department of social welfare, Jinju, Republic of Korea

\* Corresponding author.

*Introduction.*– Based on Allport’s contact hypothesis, we propose that contact among members of different groups can reduce uncertainty and anxiety against the other group and conversely increase positive attitude toward each other. Contact is considered as the most effective strategy for anti-stigma. Contact with mental illness is generally utilized in the consumer-initiated program.

*Objectives.*– This study aims to analyze the anti-stigma effect of consumer-initiated program (“contact group”) in comparison with provider-led program (“education group”) and control group. 117 adult subjects were divided to these three groups. Two-way ANOVA was used to compare the pre- and post-prejudice scores (sub factors: dangerousness, incompetence, inability to recover) to persons with mental illness among three groups.

*Results.*– We observed a significant interaction effect between groups and times in all three sub-factors of prejudice (dangerousness:  $F=4.125$ , partial  $\eta^2=.035$ ,  $P=.017$ , inability to recover:  $F=3.463$ , partial  $\eta^2=.029$ ,  $P=.033$ , incompetence:  $F=5.463$ , partial  $\eta^2=.046$ ,  $P=.005$ ). “Contact group” showed a significantly decreased all three sub-factors of prejudice than two other groups (“education and control group”). “Education group” also revealed a relative decrease in prejudices compared with control group although it was not great than the contact group.

*Conclusion.*– In this study, we showed the anti-stigma effect of consumer-initiated program in contact with mental illness. This program is also expected to be very effective to overcome the self-stigma of the persons with mental illness. In this context, we propose that this program can be used for the elimination of social stigma and self-stigma in our society.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Social capital and ethical climate in hospitals: A scale development to evaluate the supportive work environment for hospital nurses**

M. Tominaga<sup>1</sup>, M. Nakanishi<sup>2</sup><sup>1</sup> Kyoto Tachibana university, faculty of nursing, Kyoto, Japan;<sup>2</sup> Tokyo Metropolitan Institute of medical science, mental health and nursing research Team, Tokyo, Japan

\* Corresponding author.

*Introduction.*– The number of cases of workers’ accident compensation owing to mental illness has been increasing in Japan. Medical and welfare ranked first in all industries for number of cases. ‘Trouble with a supervisor’ and ‘harsh harassment, bullying, and violence’ were ranked first and second, respectively, in types of events; and ‘nurse’ ranked seventh among occupations.

*Objectives.*– To foster a supportive work environment for hospital nurses, we aimed to develop a scale to assess social capital and ethical climate in hospitals and to examine its reliability and validity.

*Methods.*– Approval for this study was obtained from the institutional ethics committee. A three-round panel survey using the Delphi technique was conducted with nursing department directors ( $n=74-78$ ) to reach consensus about original question items. After careful selection of the items through panel survey, we conducted another survey on staff nurses using factor analysis and examined the reliability and validity of the items. To examine criterion-related validity and construct validity, we calculated correlation coefficients using the Practice Environment Scale of the Nursing Work Index and a scale for psychological distress (K6) as external criteria.

*Results.*– The response rate was 83% ( $n=779$ ). Factor analysis revealed three factors showing 67.96% of the cumulative contribution ratio. Three factors—‘social capital in the workplace’, ‘ethical leadership’, and ‘exclusive workplace climate’—showed high Cronbach’s alphas (0.87–0.95) and moderate correlation coefficients with the external criteria.

*Conclusions.*– The reliability and validity of the new scale to assess the supportive work environment of hospitals were confirmed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Do older adults with HIV know how to protect or improve their cognition?**

D. Vance\*, P. Fazeli

University of Alabama at Birmingham, school of nursing, Birmingham, USA

\* Corresponding author.

*Introduction.*– HIV-Associated Neurocognitive Disorder (HAND) occurs in 52–59% of adults with HIV; the prevalence and severity of HAND will increase with age. Such adults may be able to protect/improve their cognition through lifestyle behaviors (e.g., physical activity, nutrition).

**Objective.**– To develop a lifestyle intervention to address HAND, it is necessary to determine what older adults with HIV know about their own brain health and how it impacts cognition.

**Aim.**– This focus group study examined what 30 older (50+) African American and Caucasian men and women know about protecting/improving brain health and cognition. This study was approved by IRB.

**Methods.**– Four focus groups were asked open-ended questions about their knowledge between cognitive health and physical activity, nutrition, intellectual activity, mood, sleep hygiene, social activity, drug/alcohol use, and cognitive rehabilitation.

**Results.**– Most older adults reported cognitive problems in the ability to remember and slower processing speed that interfered with driving and medication adherence. Although the detrimental relationship between drug/alcohol use and cognition was clearly articulated, these older adults were less certain about how lifestyle factors could affect cognition. Furthermore, when presented a template of an individualized cognitive-behavioral intervention, most indicated they would like to participate in such a rehabilitation program designed to protect/improve cognition via physical exercise, nutrition, et cetera.

**Conclusion.**– Older adults with HIV are receptive to a formal cognitive rehabilitation program that may protect/improve their cognition. The psychoeducational components of such a program that focuses on physical exercise, social engagement, and so forth are amenable to delivery individually or in group settings.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Impact of mental health stigma and problem recognition on parental help-seeking for adolescents**

A. Villatoro<sup>1\*</sup>, M. DuPont-Reyes<sup>1</sup>, J. Phelan<sup>2</sup>, K. Painter<sup>3</sup>, B. Link<sup>4</sup>

<sup>1</sup> University of Texas at Austin, Latino Research Initiative, Austin, USA; <sup>2</sup> Columbia University Mailman school of public health, sociomedical sciences, New York, USA; <sup>3</sup> Substance abuse and mental health services administration, Washington D.C., USA; <sup>4</sup> University of California, Riverside, public policy and sociology, Riverside, USA

\* Corresponding author.

**Introduction.**– Parents frequently act as gatekeepers to mental health (MH) services for adolescents. The initiation of help-seeking oftentimes requires parents to positively identify MH problems in adolescents. However, stigma may disrupt this identification and prevent help-seeking from occurring altogether.

**Objectives.**– To examine the roles of stigma and recognition of adolescent MH problems on parental help-seeking behaviors

**Methods.**– Parents of adolescents from a school-based anti-stigma intervention study were analyzed. Logistic regressions examined the effect of stigma on parental recognition of adolescent MH problems. Additional models assessed the joint impact of stigma and problem recognition on parental help-seeking behaviors.

**Results.**– The more socially distant parents desired their children to be from individuals with mental illness, the less likely they were to believe their child had a MH problem, controlling for parent-reported MH symptoms and other factors. This was particularly prominent among parents of highly symptomatic adolescents. Social distance and other stigma measures were not significant barriers to help-seeking. In contrast, the strongest impact on help-seeking was problem recognition, over and above stigma, symptom reports, and other factors. No significant interactions were found between stigma and problem recognition on help-seeking.

**Conclusions.**– Stigma may present itself as an early barrier to problem recognition because labeling may impose a significant personal

cost on the adolescent and by affiliation the parent and family. In turn, the positive identification of MH problems is critical to parental help-seeking and suggests the value of developing and implementing interventions that target and inform parents how to recognize mental illness in adolescents.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The use of leverage to influence adherence to psychiatric treatment in Hong Kong**

W.C. Chan<sup>1</sup>, C.S. Wong<sup>1\*</sup>, C.S. Lai<sup>1</sup>, T. Burns<sup>2</sup>

<sup>1</sup> The University of Hong Kong, Department of Psychiatry, Hong Kong, Hong Kong S.A.R.; <sup>2</sup> University of Oxford, Department of Psychiatry, Oxford, United Kingdom

\* Corresponding author.

**Introduction and objectives.**– Leverage refers to an informal practice whereby practitioners attempt to influence patients' treatment adherence. We would like to report on the interim results of the first study in Hong Kong examining the prevalence and correlates of leverage in the local mental healthcare.

**Methods.**– This is an ongoing study in which patients attending psychiatric services were recruited. The use of leverage in areas including finance, housing, child custody and criminal justice were assessed using structure interviews. Participants' clinical data comprising age of onset, age of first contact with mental health services, number of hospitalisations, frequency of visits to outpatient clinics, suicide history and forensic record were retrieved from their electronic medical records.

**Findings.**– To date, 114 participants were recruited from three psychiatric centres (59 from personalised care programmes, 28 from community psychiatric services, and 27 from substance abuse clinics). The mean age of the participants was 46.8 years, and around two-thirds were men. Their primary diagnoses were schizophrenia-spectrum disorders (45.6%), substance use disorders (22.8%) and depression (20.2%). Nearly 30% of the patients reported experiencing leverage. Financial leverage was the most commonly reported (22.8%), followed by housing leverage (11.4%). Patients who reported experiencing leverage were younger when they first contacted with mental health service ( $P < 0.001$ ) and first admitted to psychiatric hospital ( $P < 0.01$ ), and their interval period between outpatient follow-up were longer ( $P < 0.05$ ).

**Conclusions.**– The use of leverage is as common in Hong Kong as reported in other countries. Whether it improves adherence to psychiatric treatment warrants further investigation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Free-T3 as a biological marker for a subgroup of children with ADHD**

H. Caci<sup>1\*</sup>, P. Panaïa-Ferrari<sup>2</sup>, I. Henri<sup>1</sup>

<sup>1</sup> Hôpitaux pédiatriques, CHU Lenval de Nice, pediatrics, Nice, France;

<sup>2</sup> Centre hospitalier universitaire de Nice, biochemistry, Nice, France

\* Corresponding author.

**Introduction.**– Thyroid function of children with ADHD has been studied with an equivocal way. Some authors noticed similarities

between ADHD symptoms and the Thyroid Hormone Resistance while others concluded that the thyroid function was normal based either on total-T3, free-T3, total-T4, free-T4 or TSH (Thyroid Stimulating Hormone). However, environmental factors may affect the thyroid function resulting in ADHD-like symptoms.

**Objectives.**– Our hypothesis was that a subgroup of children with ADHD would have higher levels of free-T3 (that is, the active hormone) and nevertheless has normal free-T4 and TSH levels.

**Methods.**– Retrospective analyses of systematic biological assays performed before prescribing any psycho-stimulant treatment to a child formally diagnosed with ADHD in our department since 2001.

**Results.**– No hypothyroid or hyperthyroid case in our sample of 498 children (including 90 girls). No effect of age and sex on free-T3, free-T4 and log(TSH) whatever the technique used (IECL/Centaur, EIA/Beckman, CMIA/Architect et ECLIA/Roche). 128 children (25.7%) had free-T3 levels beyond the reference interval provided by the laboratories on result sheets. Considering the two most frequent techniques, binomial law showed that 62 children out of 401 (15.5%) had free-T3 levels beyond the percentile 97.5 calculated on very large samples of children. Among them, the odds-ratio for a comorbid Oppositional Defiant Disorder (ODD) was 2.01 ( $P < .05$ ).

**Conclusions.**– Analyses should be replicated in a multicentre, prospective and controlled study. The role of an isolated high free-T3 in ODD should be investigated. Finally, environmental factors should be investigated to understand the underlying mechanisms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Pressure sensitivity as an indicator of impaired proprioception in ASD

M.T. Sindelar<sup>1</sup>, S. Suman<sup>2</sup>, A.P. Tarayre<sup>3</sup>, N. Furland<sup>4</sup>\*

<sup>1</sup> Universidad del Sudoeste, Sede Bahía Blanca, Bahía Blanca,

Argentina; <sup>2</sup> Emily Fenichel Foundation, Investigation, Como, Italy;

<sup>3</sup> Emily Fenichel Foundation, Investigation, Bahía Blanca, Argentina;

<sup>4</sup> CONICET-UNS, Inibibb, Bahía Blanca, Argentina

\* Corresponding author.

**Introduction.**– Autism spectrum disorders (ASD) are neurodevelopmental disorders characterized by deficits in social interaction, communication, and restricted activities and interests. It is well known that autistic children present severe difficulties in sensory processing, including proprioceptive and vestibular systems. The poor proprioceptive processing among ASD children impairs basic functions such as postural control, organization of space, modulation of muscle force and effort and suitable motor patterns involved in imitation, all essential for daily tasks. A general concern among parents and educators is the frequent insensitivity to pain and lack of modulation of physical force of autistic children, which often leads to unintentional situations of aggression to peers or self-injurious behaviors.

**Objectives.**– The aim of this research is to evaluate the pressure sensitivity of neurotypical children compared to children with autism. We hypothesize that the record of pressure sensitivity is a potential clinical parameter indicative of a child's sensitivity threshold when pressure is exerted on its arms and legs. This perception of pressure correlates with proprioceptive modulation that is frequently impaired in children with autism.

**Results.**– A sample of 70 children with ASD and 70 typically developing control children between 3–13 years old were recruited for this study. In the autism group, pressure sensitivity in both arms and legs was significantly altered in comparison with control group.

**Conclusions.**– The present data open up new possibilities to restructuring rehabilitation programs for autistic children that will allow

the development of proprioceptive techniques to improve their body perception and subsequently improve their social interactions and performance in daily tasks.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Psychosomatic symptoms in early adolescents and association with sociodemographic risk factors

J. Hamidovic<sup>1</sup>\*, L. Dostovic Hamidovic<sup>2</sup>, Z. Selimbasic<sup>1</sup>, M. Hasanovic<sup>1</sup>

<sup>1</sup> University clinical center Tuzla, department of psychiatry, Tuzla, Bosnia, Herzegovina; <sup>2</sup> University clinical center Tuzla, department of pediatrics, Tuzla, Bosnia, Herzegovina

\* Corresponding author.

**Aim.**– The aim is to analyze the psychosomatic symptoms in early adolescents and association with sociodemographic risk factors.

**Subject and methods.**– We analyzed a group of 240 early adolescents (11–15 years) from the area of Tuzla Canton, Bosnia and Herzegovina, in the general population. The sample was selected because it is early adolescence vulnerable period in the growing up of children and emotional and psychological development. For the assessment of children's psychosomatic symptoms, the Psychosomatic symptoms questionnaire (PS) is used. For the assessment association between sociodemographic risk factors and psychosomatic symptoms in early adolescents we used Pearson correlation test.

**Results.**– According PS questionnaire, the obtained results showed that gastrointestinal, pseudoneurological and painful symptoms are most commonly present in early adolescents. The results of correlation sociodemographic risk factors and psychosomatic symptoms, showed that low family economic status, leads to a higher incidence of painful symptoms (headaches) and cardiovascular symptoms in early adolescents ( $P < 0.05$ ). Living in a rural environment is associated with a higher incidence of respiratory symptoms, cardiovascular symptoms (excessive sweating) and gastrointestinal symptoms (feeding problems) ( $P < 0.05$ ). Children of unemployed mothers more often show a lack of energy ( $P < 0.05$ ). Disturbed family relationships are significantly associated with febrility ( $P < 0.05$ ).

**Conclusion.**– The obtained results of this study indicate that early adolescents showed significant level of different psychosomatic symptoms. There is a significant correlation between sociodemographic risk factors (employed mothers, place of living, the economic status of the family, disturbed family relationships) and psychosomatic symptoms in early adolescents.

**Keywords:** Psychosomatic symptoms; Early adolescents

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Psychological distress and health-related quality of life in parents of children referred to an outpatient service for children with developmental difficulties

A. Karaivazoglou<sup>1</sup>\*, K. Assimakopoulou<sup>2</sup>, E. Papadaki<sup>1</sup>, G. Iconomou<sup>2</sup>, G. Toulitatos<sup>1</sup>, S. Kotsopoulos<sup>1</sup>

<sup>1</sup> EPSYPEA, day centre for children with developmental disorders, Mesolonghi, Greece; <sup>2</sup> University of Patras, department of psychiatry, Rion, Patras, Greece

\* Corresponding author.

**Introduction.**– Parents of developmentally impaired children frequently suffer from somatic and psychological complaints and report low levels of health-related quality of life (HRQOL).

**Objectives.**– The aim of the current study was to measure anxiety and depressive symptoms and health-related quality of life in parents of children referred for developmental evaluation and determine their demographic correlates.

**Methods.**– The Hospital Anxiety and Depression Scale (HADS) and the Short Form-36 Health Survey (SF-36) were used to assess anxiety, depression and HRQOL, respectively.

**Results.**– 126 parents participated to the study, 91 with a child referred for psychiatric and developmental evaluation and 35 with mentally and physically healthy children. Parents of developmentally impaired children reported increased levels of anxiety ( $P=0.004$ ) and depression ( $P=0.000$ ) and lower scores in social functioning ( $P=0.002$ ) and mental health ( $P=0.017$ ) compared to parents of healthy children. Among parents of children with developmental deficits, mothers reported increased anxiety symptoms ( $P=0.018$ ) and lower levels of vitality ( $P=0.009$ ), social functioning ( $P=0.007$ ) and mental health ( $P=0.009$ ). In addition, the number of children in the family was correlated with higher anxiety scores ( $r=0.287, P=0.010$ ), while older child's age was significantly associated with anxiety symptomatology ( $r=0.351, P=0.001$ ), more role limitations due to emotional problems ( $r=-0.325, P=0.003$ ) and worse mental health ( $r=-0.311, P=0.004$ ). No other significant correlations emerged between psychosocial measures and demographic variables.

**Conclusions.**– Parenting children with developmental difficulties is associated with significant psychological distress and disturbed HRQOL. Mothers, parents in large families and parents of older children appear more prone to display psychosocial dysfunction.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Online and offline deviant behavior in Russian adolescents: Results of population study of parent–child pairs

A. Yarmina<sup>1</sup>, G. Soldatova<sup>1</sup>, S. Khrushchev<sup>2\*</sup>, E. Rasskazova<sup>3</sup>, A. Tkhostov<sup>4</sup>

<sup>1</sup> Lomonosov Moscow State university, department of psychology, Moscow, Russia; <sup>2</sup> National research center for hematology, laboratory studying mental and neurological disorders in hematology, Moscow, Russia; <sup>3</sup> Lomonosov Moscow State university / mental health research center, associate professor, senior researcher, Moscow, Russia; <sup>4</sup> Lomonosov Moscow State university, the head of the clinical psychology department, Moscow, Russia

\* Corresponding author.

**Introduction.**– In adolescence deviant behavior manifests both online (e.g., cyberbullying, sexting, excessive Internet use) and offline making important to study their relationships.

**Objectives.**– The aim was to study online and offline child- and parent-reported deviant behavior in Russian adolescents.

**Methods.**– Study was based on EU Kids Online methodology (Livingstone, Haddon, 2009) and included 1025 parent–child (9–16 years old) pairs (Soldatova et al., 2014) from 11 regions of Russian Federation. Cronbach's alphas for composite scores on deviant behavior were .61–.62).

**Results.**– 13.2% adolescents reported being extremely drunk last year, 6.9% – having sexual contacts, 4.6% – problems with police. Child-reported deviant behavior was related to excessive Internet use ( $r=.21$ ) and meeting online risks concealed from parents ( $t=-3.32; -2.51, \eta^2=0.01-0.07$ ). 6.5% parents reported substance abuse in their children, 5.9% worried about their sexual behavior

and 8.0% – about problems with police but correlation between children's and parental reports was low ( $r=.21$ ). 13% of parents reported deviant behavior of their children online related to offline ones ( $r=.38$ ). Child- and parent-reported deviant behavior negatively correlated with use of programs for parental control but was unrelated to parental restrictions and active mediation of their children's online activity.

**Conclusions.**– There is a relationship between online and offline deviant behavior on adolescents that seems to increase their online risks and almost independent on parental mediation strategies. Low correlation between parental and adolescents reports indicate both poor parental awareness and concealment in adolescents.

**Disclosure of interest.**– Research is supported by the Russian Foundation for Basic Research, project No. 17-06-00762.

### Evaluation of learning through play (LTP) training program for traditional birth attendants (TBAs) in Pakistan: A quasi experimental design

N. Chaudhry<sup>1</sup>, M. Alvi<sup>1</sup>, T. Kiran<sup>2\*</sup>, S. Shah<sup>3</sup>, R. Memon<sup>1</sup>, A. Zehra<sup>1</sup>, N. Husain<sup>3</sup>

<sup>1</sup> Pakistan institute of living and learning, research, Karachi, Pakistan; <sup>2</sup> Pakistan institute of learning and living, research, Karachi, Pakistan; <sup>3</sup> University of Manchester, division of psychology and mental health, Manchester, United Kingdom

\* Corresponding author.

**Background.**– Around 250 million children (43%) younger than 5 years in Lower, Middle, Income Countries (LMICs) do not develop their full potential, probably due to the absence of application of emerging scientific knowledge in nurturing care to enhance child development. The lack of early child development programs in health systems in resource poor settings has been identified as one of the major challenges.

**Aims.**– Considering the major role which Traditional Birth Attendants (TBAs) play in Pakistan, the current project was initiated to train the TBAs in order to enable them to support and encourage parental involvement in early child development, promote parent and child attachment and child's learning about self and the surrounding world.

**Method.**– A total of 322 TBAs from Karachi participated in the training. The 'Learning through Play' program has been designed to improve early child development. Knowledge, Attitude and Practices (KAP) questionnaire was used to measure the change post-training.

**Results.**– Paired sample *T*-test was used for statistical analysis, and results  $t=-29.366$  ( $P<0.05$ ) indicate a significant difference between knowledge and attitude about child development before and after the training of TBAs in low income regions of Karachi.

**Conclusion.**– Training TBAs in LTP program and integrating it into existing health care system can be an effective strategy to improve the knowledge, attitude and practices of parents to promote development of children. This may contribute in reducing the huge development gaps in low resource settings.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The physical development of adolescents with the mental deprivation

T. Mozgova<sup>1</sup>\*, S. Fedorchenko<sup>2</sup><sup>1</sup> Kharkiv national medical university, psychiatry, narcology, medical psychology, Kharkiv, Ukraine;<sup>2</sup> Kharkiv medical academy of postgraduate education, neuropathology and neurosurgery, Kharkiv, Ukraine

\* Corresponding author.

Physical development is an integral indicator and refers to the most important criteria for a comprehensive assessment of the adolescent health status.

Studying the features of the physical development in adolescents with the mental deprivation.

128 adolescent males aged 11–15 years who were brought up in an orphanage with the social disadaptation were examined. The method of assessing physical development included anthropometry. The evaluation of the data obtained was carried out with the help of the centile tables according to sex and age.

The results of the study showed that harmonic physical development was noted in less than a third of adolescents –  $27.34 \pm 3.86\%$ . The most of adolescents had disharmonious physical development. Disharmoniousness was characterized by a combination of adolescent lagging behind growth and low body mass indexes –  $14.06 \pm 3.01\%$ , which in some cases reached pathologically low values –  $17.19 \pm 2.96\%$  of cases. The level of physical development mostly determines the social adaptation of the child, especially in adolescence. The statistical analysis made it possible to identify the main diagnostic features that play an important role in the formation of social disadaptation in adolescents. The list of high-value factors included: physical development with a decrease in growth – with an indicator of 99.7% significance and a pathological decline in physical development – with 99.0% significance.

Thus, disharmonious physical development, especially a low and pathologically low its level are prognostically unfavorable factors in the formation of social maladjustment in adolescents and can be manifested by aggressive behavior. Such adolescents need corrective psychological and pedagogical measures.

### Screens and ADHD: Study on high school Tunisian students

A. Mhalla<sup>\*</sup>, A. Dkhil, M. Gharmoul, W. Souii, A. Guedria, N. Gaddour, L. Gaha

Faculty of medicine of Monastir, university of Monastir, department of psychiatry, Monastir, Tunisia

\* Corresponding author.

*Introduction.*– Attention-deficit/hyperactivity disorder (ADHD) is a multifactorial disease.

The aim of this study was to explore the relationship between screen use and ADHD in a population of high school students in Monastir (Tunisia).

*Methods.*– It was a cross-sectional study concerning a representative sample of 447 third year high school students of the governorate of Monastir during November 2015; we had proceeded to a cluster sampling. The diagnosis of ADHD was made by the Adult ADHD Self-Report Scale (ASRS-v1.1) validated in Arabic language. The sociodemographic and clinical characteristics were evaluated by a pre-established questionnaire. The threshold of 5 hours daily

was selected for the excessive consumption of TV, Internet and video games.

*Results.*– The mean age of our population was  $17.15 \pm 0.7$  years old. The sex ratio was 0.5. The study of the use of screens showed that 93.5% of the students have used the internet daily with an average of 4 hours; 89.7% have watched television each day with an average of 2.8 hours, and 44.7% have played video games with an average of one hour; 25.1% have consumed excessively the Internet, 7.6% have had an excessive television consumption and 5.4% have used excessively video games.

The diagnosis of ADHD was associated to excessive television use ( $P < 0.001$ ), excessive video games use ( $P = 0.02$ ) and excessive internet use ( $P < 0.001$ ). The logistic regression analysis showed an association between the diagnosis of ADHD and excessive internet use ( $P = 0.014$ ).

*Conclusion.*– The screen misuse has an impact on adolescents with ADHD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0156

### Attention deficit / hyperactivity disorder and substance use behaviors in Tunisian adolescents

A. Mhalla<sup>\*</sup>, N. Smari, W. Sbouii, A. Dkhil, A. Guedria, N. Gaddour, L. Gaha

Faculty of medicine of Monastir, university of Monastir, department of psychiatry, Monastir, Tunisia

\* Corresponding author.

*Introduction.*– Attention deficit / hyper activity disorder (ADHD) is reported to be associated with addictive behaviors (smoking, alcohol abuse, gambling, internet addiction. . .) in adolescence.

The aims of the study were to determine the prevalence of ADHD and substance use behaviors in a population of high school students in Monastir (Tunisia) and to explore the relationship between substance use and ADHD in this population.

*Methods.*– This is a cross-sectional study including 447 students from high-schools of the region of Monastir (Tunisia). For the diagnosis of ADHD, we used the Adult ADHD Self-Report Scale (ASRS-v1.1) validated in Arabic language; and for the addictive behaviors (smoking, alcohol abuse, substance abuse), we used yes/no questions.

We used SPSS-20 to analyze data and Chi<sup>2</sup> test for associations.

*Results.*– The mean age was  $17.15 \pm 0.7$  years old. The sex ratio was 0.5. The prevalence of ADHD in the study population was 18.1%; this prevalence was nearly the same for the males (20.93%) and the females (18.12%) ( $P = 1$ ).

We found that 27.3% of the adolescents had a regular substance use: 10.3% have been smokers; 9.4% have used alcohol; 5.6% have used cannabis and 2% have been glue sniffers.

There were significant associations between ADHD and smoking ( $P = 0.002$ ), alcohol use ( $P = 0.002$ ) and cannabis use ( $P = 0.029$ ).

*Conclusion.*– The prevalence of ADHD symptoms in this adolescent sample was extremely elevated and its association with addictive behaviors was undeniable. There is an extreme urge to investigate further the subject.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0157

### Social interactions, traumatic life events and ADHD in high school students: A Tunisian study

A. Mhalla<sup>1</sup>, S. Boubaker, W. Sboui, A. Guedria, N. Gaddour, L. Gaha  
Faculty of medicine of Monastir, university of Monastir, department of psychiatry, Monastir, Tunisia

\* Corresponding author.

**Introduction.**– Attention-deficit/hyperactivity disorder (ADHD) is considered as a neurodevelopmental disorder.

The aims of this study were to determine the prevalence of ADHD in a population of high school students in Monastir and to study the association between ADHD and relationship with parents and with peers.

**Methods.**– It is a cross-sectional study concerning a representative sample of 447 third year high school students. The diagnosis of ADHD was made by the Adult ADHD Self-Report Scale (ASRS-v1.1) validated in Arabic language. The sociodemographic and clinical characteristics were evaluated by a pre established questionnaire.

**Results.**– The mean age of the participants was  $17.15 \pm 0.7$  year-old. The sex ratio was 0.5. The prevalence of ADHD was 18.1%. The study of the family status showed that the majority (93.5%) lived in two-parent families. The relationship between the adolescent and his parents was described as very good in 47.7%, and disturbed in 23.7% of the cases. A history of maltreatment was reported by 18.8% of the participants. 91% of the students reported having friends; the relationship with the friends was described as very good for 42.3% and moderately disturbed for 13.2%. The diagnosis of ADHD was associated to the single parent family status ( $P < 0.001$ ), it was also associated to bad relationships with parents ( $P < 0.001$ ) and with peers ( $P = 0.04$ ). The multivariate regression analysis showed an association between the diagnosis of ADHD and the bad relationships with parents ( $P < 0.001$ ) and antecedents of maltreatment ( $P = 0.009$ ).

**Conclusion.**– The ADHD was associated to several sociodemographic characteristics and traumatic life event.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0158

### Mental health and executive functions (EF) in school children from low income families: Association with mental health of their mothers in Northeastern Brazil

C. Miranda<sup>1\*</sup>, A.L. Exel<sup>2</sup>, J. Coelho<sup>1</sup>, M.M. Rocha<sup>3</sup>, L.R. Carreiro<sup>3</sup>  
<sup>1</sup> Federal University of Alagoas, school of medicine, Maceio, Alagoas, Brazil; <sup>2</sup> Federal University of Alagoas, institute of biological and health sciences, Maceio, Alagoas, Brazil; <sup>3</sup> Mackenzie Presbyterian University, graduate program in developmental disorders, Sao Paulo, Brazil

\* Corresponding author.

**Introduction.**– In low income populations, maternal mental health problems will probably be associated with children's mental health impairment and their poor performance in EF, which might impair their schooling process.

**Objective.**– To evaluate the association between maternal mental health and their children's mental health and EF.

**Methods.**– Cross-sectional study involving mother-child dyads. Children aged 6 to 9 years attending the first year of public schools. To evaluate mental health of mothers and their children it was used the Self-Report Questionnaire (SRQ - 20) and Strengths and Difficulties Questionnaire (SDQ), respectively. Working Memory Index,

an EF important component, was assessed through the Wechsler Intelligence Scale for Children (WISC-IV).

**Results.**– It was evaluated a sample of 69 mother-child dyads. Mental health problems were found in 71,8% of the children and 53,1% of the mothers. In addition, 87% of the children presented below-average performance on the WISC-IV Working Memory Index. The association between maternal mental health and their children's mental health was statistically significant: OR = 3.09 – 95% CI 1.15–8.27.

**Conclusions.**– Maternal mental health is associated with their children's mental health in low-income families. The high percentage of children with below-average performance on the WISC-IV Working Memory Index made it difficult to evaluate their association with mental health of both children and their mothers.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### First episode psychosis in CAMHS: Are we being NICE enough?

A. Theodorou, E. Harrap, T. Ngo\*

West London mental health trust, child and adolescent mental health, London, United Kingdom

\* Corresponding author.

**Introduction.**– Despite accepting referrals from GP's, schools and secondary care for children with First Episode Psychosis (FEP), some West London Child and Adolescent Mental Health Services (CAMHS) do not have access to designated Early Intervention Teams. Early intervention Teams provide early detection, assessment and treatment of symptoms, a wide range of psycho-social interventions and support for families/carers. People can recover fully from psychosis: the most important thing is to get help early.

**Objectives.**– Audit care of FEP cases in Hammersmith and Fulham CAMHS against Standards derived from NICE Guideline CG155 (Psychosis and Schizophrenia in Children and young People: Recognition and Management).

**Methods.**– Clinicians contacted via e-mail

Admission records reviewed against NICE guidance CG155:

- offer oral antipsychotic;
- collaborative choice of medication;
- record side effects young person is most/least likely to tolerate;
- baseline investigations;
- monitoring physical health;
- family intervention;
- CBT.

**Inclusion criteria:**

- 0–18 years old;
- primary diagnosis of psychosis.

**Results.**– 5 cases were identified. While standards such as offering oral antipsychotics were 100% met, there was a clear failure in standards of physical health monitoring and side-effect monitoring. Psychological interventions such as CBT for Psychosis and Family Intervention showed a failing in the majority of standards.

**Conclusion.**– Hammersmith and Fulham CAMHS showed an inconsistent adherence to NICE Guideline CG155. Recommendations for future development of service include liaison with local adult EIP teams to stimulate shared-care options, develop a resource bank to promote accurate documentation and to designate FEP champions within the team to monitor adherence to NICE guidance with particular emphasis on monitoring and psychological therapies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Working memory and attention deficit hyperactivity disorder among children in Kenitra city (North-West of Morocco)

F.Z. Rouim<sup>1</sup>, F.Z. Azzaoui<sup>2</sup>, A.O.T. Ahami<sup>1</sup>, S. Boulbaroud<sup>3</sup>, H. Hami<sup>4</sup>

<sup>1</sup> University IbnTtofail, unit of neuroscience and applied nutrition, biology, Kenitra, Morocco; <sup>2</sup> Faculty of science Ben M'Sik, laboratory of biology and health, Casablanca, Morocco; <sup>3</sup> Polidisciplinary faculty, biology, Beni Mellal, Morocco; <sup>4</sup> University IbnTtofail, laboratory of genetics and biometry, biology, Kenitra, Morocco

\* Corresponding author.

**Background and aims.**– Working memory (WM) is an executive functioning, and it's the ability to retain short-term information, to perform cognitive operations such as listing a digit's series.

Several studies suggested that a deficit of WM could be linked to Attention Deficit Hyperactivity Disorder (ADHD). Therefore the aim of this study is to find out whether there is a relationship between WM and ADHD.

**Methods.**– The study was realized among 239 children studying in an urban school in Kenitra city, aged between 6 and 16 years. To evaluate the relationship between WM and ADHD, four tests were used: The short form of Conners' Teacher and Parents Rating Scale, DSM IV and digit span test (forward and backward).

**Results.**– The results showed that there is a significant correlation, between hyperactivity/impulsivity and normal WM ( $r=0.156$ ,  $P<0.05$ ) and ( $r=0.154$ ,  $P<0.05$ ) according to the short form of the Conners' Teacher Rating Scale and the DSM IV, respectively.

However, a significant correlation was found between learning and behavioral problems, and WM deficiency ( $r=-0.223$ ,  $P<0.01$ ) and ( $r=-0.140$ ,  $P<0.05$ ), according to the short form of the Conners' Parent Rating Scale and the forward digit span test, respectively.

Moreover, a significant correlation was found between Inattention and a deficiency in WM, according to DSM IV and the forward digit span test ( $r=-0.196$ ,  $P<0.01$ ).

**Conclusion.**– The results suggest that children with ADHD have normal WM, but suffer from some learning, attention and behavioral impairment; but deeper investigations are needed to study whether there are any possible factors that could be related to ADHD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Valence and consistency of descriptions of self and others as factors of well-being and coping in adolescents with depressive and conduct disorders

L.S. Pechnikova, E.I. Rasskazova, A. Ryzhov\*, E.T. Sokolova, A.S. Tkhostov

Lomonosov MSU, faculty of psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Negative self-descriptions are related to depression while inconsistency in descriptions of others to personality disorders in adults. Self-focused attention further increases negative thoughts in depression. In adolescence a specific vulnerability due to ongoing identity formation is present.

**Objectives.**– The aim was to study the role of valence and consistency of self-descriptions in well-being and coping in adolescents with mental disorders.

**Methods.**– Adolescents (13–17 years) diagnosed with depressive disorders ( $n=29$ ), conduct disorders ( $n=29$ ) and 26 matched controls were asked to rate self and others using opposite adjectives (Rasskazova et al., 2015) before and after task on self-focused attention, filled Satisfaction with Life Scale (Diener et al., 1985), Cognitive Emotion Regulation Questionnaire (Garnefski et al., 2002).

**Results.**– Depressive adolescents tend to describe themselves more negatively while adolescents with conduct disorder tend to describe others in a more inconsistent manner ( $P<.08$ ). Self-focusing didn't change descriptions. In depression but not in controls positive and consistent self-descriptions correlated with rare self-blaming, acceptance and ruminations ( $r=-.44$ ;  $-.39$  vs  $r=-.14$ ;  $.09$ ,  $Z=-1.65$ ;  $-1.92$ ,  $P<.09$ ). In conduct disorders positive self-descriptions correlated with lower negative emotions ( $r=-.62$  vs  $r=-.14$ ,  $Z=-2.16$ ,  $P<.05$ ) while inconsistent descriptions of others were related to higher satisfaction with life ( $r=.32$  vs  $r=-.18$ ,  $Z=2.07$ ,  $P<.05$ ).

**Conclusions.**– Positive self-descriptions are a protective factor in depressive adolescents while inconsistency in descriptions of others may serve as a defense mechanism supporting life satisfaction in adolescents with conduct disorders.

**Disclosure of interest.**– Study supported by Russian Foundation for Basic Research, project 17-06-00849 "Motivational and cognitive-affective factors of identity formation".

### The association of some socioeconomic indicators with emotional and behavioral problems in 4–5-year-old Kosovar children rated by parents with the child behavior checklist (CBCL 1.5-5)

M. Shala\*, M. Shahini

University of Mitrovica 'Isa Boletini', faculty of education, Mitrovica, Kosovo

\* Corresponding author.

**Background.**– Childhood emotional and behavior problems represent an important topic in developmental psychopathology and the preschool children have long been a neglected population in the study of psychopathology.

**Objective.**– To describe the extent to which parents reported child emotional and behavioral problems vary by different indicators of socioeconomic status.

**Methods.**– The sample consisted of 607 children of 4–5 years old ( $M=4.40$  years,  $SD=.49$ ). Parent completed the Child Behavior Checklist (1.5–5), and reported the socioeconomic indicators of income, education, and employment. Logistic regression models were used to predict internalizing, externalizing and total scores, as reported by parents, and considered all putative socioeconomic status (SES) predictor variables simultaneously.

**Results.**– The prevalence of parent-reported scores was 1.6% for 4-year-olds and 3.8% for 5-year-olds. Sex differences were observed, with boys showing higher scores in externalizing and total scores. The proportions of children scoring in the clinical range varied according to SES indicator. All the SES indicators independently predicted parent-reported child emotional and behavioral problems, although odds ratios were generally small to moderate (1.3 to 2.6), and not all reached statistical significance. Low income and unemployment showed larger associations than parent education. **Conclusions.**– A significant need for early identification of emotional/behavioral problems in young children is highlighted by associations with unemployment and family income that may further contribute to risk for persistent problems.

**Keywords:** Children; Parent report; Psychopathology; Risk factors; Socioeconomic status

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Pressure sensitivity as an indicator of impaired proprioception in ASD

M.T. Sindelar<sup>1\*</sup>, S. Suman<sup>2</sup>, A.P. Tarayre<sup>3</sup>, P. Barrientos<sup>4</sup>, N.E. Furland<sup>5</sup>

<sup>1</sup> Provincial Southwestern University, Bahía Blanca, Bahía Blanca, Argentina; <sup>2</sup> Emily Fenichel Foundation, Como, Como, Italy; <sup>3</sup> Emily Fenichel Foundation, Bahía Blanca, Bahía Blanca, Argentina; <sup>4</sup> Emily Fenichel Foundation, Bahía Blanca, Bahía Blanca, Argentina; <sup>5</sup> CONICET-UNS, Inibibb, Bahía Blanca, Argentina

\* Corresponding author.

**Background.**– Autism spectrum disorders (ASD) are characterized by impairment in social interactions, communication deficits, and restricted interests and behaviors. It is well documented that autistic children present severe difficulties in sensory processing, including proprioceptive and vestibular systems. The poor proprioceptive processing among ASD children impairs basic functions such as gross motor skills, postural control, organization of space, modulation of muscle force and effort and suitable motor patterns involved in imitation. A general concern among parents and educators is the frequent insensitivity to pain and lack of modulation of physical force of autistic children, which often leads to unintentional situations of aggression to peers or self-injurious behaviors. **Objective.**– The aim of this work is to assess if perception of pressure sensitivity is impaired in ASD children compared to neurotypical children. We hypothesized that the record of pressure sensitivity could be a potential indicator of the child's proprioceptive modulation and processing.

**Results.**– To assess this hypothesis we recruited 40 3–12 years old children with ASD and 40 age-matched neurotypical children from Patagonia (Argentina). Pressure sensitivity was measured using a conventional manual sphygmomanometer. In the autism group, pressure sensitivity in both arms and legs was significantly diminished in comparison with control group. This decrement correlated with difficulties in gross motor skills and some insensitivity to pain, both reported by parents and educators.

**Conclusion.**– These results reinforce our hypothesis and highlight the importance of including proprioceptive techniques in intervention programs for ASD children in order to improve their body perception and subsequently social interaction

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Maladaptive behaviors among adolescents with ADHD in the United States

R. Sultan<sup>1\*</sup>, J. Mohatt<sup>2</sup>, M. Olfson<sup>1</sup>

<sup>1</sup> Columbia university, psychiatry, New York, USA; <sup>2</sup> Weill Cornell Medical, psychiatry, New York, USA

\* Corresponding author.

**Objective.**– To assess and compare the risk of maladaptive behaviors for adolescents with and without Attention Deficit/Hyperactive Disorder (ADHD).

**Methods.**– Data were analyzed from the National Comorbidity Survey Adolescent Supplement (NCS-A), a US nationally representative survey of 10,123 adolescents (14–17) DSM-IV mental, emotional,

and behavioral disorders. The strength of association between lifetime ADHD and Non-AHHD was examined/ Total percentages, unadjusted and demographically adjusted odds ratios were calculated for several domains: suicide, aggression, behavior regulation, recent life events, education, and substance use.

**Results.**– ADHD was associated with a significantly elevated risk for a range of maladaptive behaviors. ADHD adolescents had suicide attempts at a rate of 7.4% vs. 3.4% controls (aOR 2.9, 95% CI = 1.3–6.6). 57.0% of ADHD youth had a history of physical aggression to others as compared with 37.5% of controls (aOR 2.1, 95% CI = 1.6–2.6). Adolescents with ADHD were more likely to have been expelled from school or fired from job (8.9% vs. 2.4%), (aOR 3.3, 95% CI = 1.7–6.5). 11.6% of ADHD adolescents, as compared with 6.0% of controls reported lifetime history of problems from drinking (aOR 1.9, 95% CI = 1.2–2.9).

**Conclusions.**– Adolescents with ADHD are at elevated risk for maladaptive behaviors in many diverse domains which have the potential to significantly alter the long-term development of their lives.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### RECOGNeyes: Novel interactive eye tracking game for training attention in ADHD

T. D'Amelio<sup>1</sup>, P. Collins<sup>2</sup>, E. Liddle<sup>2</sup>, H. Super<sup>3\*</sup>

<sup>1</sup> Braingaze, research, Mataro, Spain; <sup>2</sup> University of Nottingham, faculty of medicine & health sciences, Nottingham, United Kingdom;

<sup>3</sup> Braingaze, R&D, Mataro, Spain

\* Corresponding author.

Existing treatments for Attention deficit hyperactivity disorder (ADHD) focus on pharmaceutical medication and cognitive behavioral treatment. The usage of serious games has received considerable interest but has not yet proven to be effective. RECOGNeyes is a computer game that you play using your eyes as the game controller. The game is designed to train people to have better control over their attention. As you advance in the game, you learn to control different aspects of your visual attention system. The game is played on a laptop with a small eye-tracker attached below the screen. Players receive continuous immediate feedback while playing the game. The game employs tracking algorithms that change the game difficulty based on performance.

**Objectives.**– The rationale behind the training game is that individuals with ADHD have an underdeveloped attention control system. This attention control system is underdeveloped not because they lack capacity but because this ability has not been sufficiently developed. RECOGNeyes isolates the underdeveloped attention control system and provides an opportunity to train this system. Results: ADHD children will play RECOGNeyes for several weeks (3 times/week) at home. A control group will play the game using the mouse for responding. Before, during and after the study ADHD severity and symptoms will be assessed with BGaze attention marker, ADHD rating scales, BRIEF-2 questionnaires, and WISC-V Coding and Digit Span subtests.

**Conclusions.**– RECOGNeyes is a child friendly interactive serious game. Here we assess whether this game has potential therapeutic benefits for people with neurodevelopmental disorders, in particular ADHD.

**Disclosure of interest.**– HS is co-founder of Braingaze.

### DSM-5 conduct disorder with limited prosocial emotions: Predictive utility for children referred for conduct problems

J. Toupin<sup>1\*</sup>, M. Déry<sup>2</sup>, V. Bégin<sup>2</sup>, Y. Le Corff<sup>3</sup>

<sup>1</sup> Université de Sherbrooke, Psychoéducation, Longueuil, Canada;

<sup>2</sup> Université de Sherbrooke, psychoéducation, Sherbrooke, Canada;

<sup>3</sup> Université de Sherbrooke, Orientation, Sherbrooke, Canada

\* Corresponding author.

**Introduction.**– The inclusion of a prosocial emotions specifier to conduct disorder (CD) in DSM-5 is based on evidence that less prosocial emotions (LPE) identifies a distinctive group of children with a poorer prognosis. Objective. To determine if the LPE subtype identifies children with a more severe and stable profile of CD problems.

**Methods.**– Participants are 273 6–9 years old children with at least one CD symptom referred to special education services. Based on parent and teacher reports four subgroups were created: CD + LPE ( $n = 54$ ), CD ( $n = 58$ ), LCD (less than 3 symptoms of CD) + LPE ( $n = 67$ ), and LCD ( $n = 94$ ). The children were evaluated annually over four years using  $t$  scores of DSM-oriented scale for conduct problems. Results. Latent growth curve analysis indicated a moderate decline in CD problems overall. When examining subgroups and controlling for the severity of CD at study inception, no differences were found in the slopes. The fit was satisfactory ( $\chi^2(22) = 32.4, P = .07, RMSEA = .04, CFI = .98$ ). Although some groups had higher CD problems at the start, all groups displayed a problem level close to the clinical level ( $t$ -score of 70).

**Conclusion.**– The limited prosocial emotions specifier does not refine prognosis in young children referred for conduct problems. In other words, the prognosis on average is not good for all groups of children, regardless of LPE. Even children with lower CD symptoms at referral tend to exhibit stable patterns of CD problems close to the clinical level over four years.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Efficacy of a third wave cognitive behavioral therapy for attention deficit hyperactivity disorder

C. Villadoro\*, J. Lopez Castroman, L. Crouzet, A. Gramond  
CHU Caremeau, psychiatry, Nimes, France

\* Corresponding author.

**Introduction.**– Attention Deficit Hyperactivity Disorder (ADHD) represents most of the consultations in Childhood Psychiatry settings. Medical treatment is helpful for severe cases, but more effective psychosocial therapies are needed.

**Aims.**– We examined the efficacy of a mindfulness-based cognitive behavioral therapy (mCBT) for children diagnosed with ADHD and their parents, compared to those receiving usual treatment.

**Method.**– An open trial with two parallel arms was conducted at the child psychiatry department of Nimes University Hospital from October 2016 to June 2017. ADHD children were allocated to the intervention group or treatment as usual. mCBT consisted on 16 weekly sessions which were conducted separately for children and their parents. Children in the waiting list received no specific inter-

vention. Changes in ADHD rating scale scores from inclusion to the last visit (3 months later) were the primary outcome. Secondary outcomes included anxiety and depression scales.

**Results.**– ADHD symptoms decreased in the group following the mCBT compared to the waiting list (average score decreases:  $5.9 \pm 7.1$  vs.  $2.6 \pm 9.7$ , respectively). Sex ratios (73% males in both groups) and time lapses between assessments (average time in months: 4 and 3.4, respectively) were similar in both groups, but patients in the waiting lists were slightly younger and received psychopharmacological treatment less often.

**Conclusion.**– We will present the preliminary but promising results of an innovative third-wave CBT for ADHD children. Compared to classical parental guidance intervention, this therapy is enhanced with mindfulness techniques and simultaneously followed by the children and their parents.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Negative emotional memories and depressive symptoms in adolescence: Can self-reassurance play a protective role?

M. Cunha<sup>1,2</sup>, A. Xavier<sup>2\*</sup>, J. Pinto-Gouveia<sup>2</sup>

<sup>1</sup> Instituto Superior Miguel Torga, Coimbra, psychology department, Coimbra, Portugal; <sup>2</sup> CINEICC, cognitive and behavioural centre for research and intervention, faculty of psychology and education sciences of university of Coimbra, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Consistent research have shown that early adverse experiences have a negative impact on mental health from childhood to adulthood. Indeed, early interactions with caregivers characterized by threat, devaluation and subordination are linked to several psychological difficulties such as depression.

**Objectives.**– This study aims to test whether the impact of early negative memories (characterized by threat, subordination and devaluation) on depressive symptoms is moderated by self-reassuring abilities.

**Methods.**– The sample consists of 851 adolescents with ages between 12 and 18 years old ( $M = 14.90, SD = 1.79$ ) from middle and secondary schools in central region of Portugal. Participants answered the following self-report questionnaires: Early Life Experiences Scale; Forms of Self-criticizing and Self-reassuring Scale; Depression Anxiety and Stress Scales.

**Results.**– Results from Moderation Analysis showed that the model accounted for 31% of the depressive symptoms variance. Results indicated that for the same levels of early negative emotional memories, those adolescents who have higher levels of self-reassuring abilities presented lower risk for depressive symptoms.

**Conclusions.**– These findings suggest that the impact of negative emotional memories on depressive symptoms is diminished in adolescents who have the ability to be kind and compassionate towards themselves. Thus, preventive and intervention actions should promote the development of positive and soothing abilities to the self in order to ameliorate the adolescents' emotional states.

### The feasibility and perceived impact of psychosocial my way – Rehabilitation programme targeted at young adults with Asperger's syndrome and/or ADHD/ADD

K. Appelqvist-Schmidlechner<sup>1\*</sup>, R. Lämsä<sup>1</sup>, A. Tuulio-Henriksson<sup>2</sup>  
<sup>1</sup> National institute for health and welfare, mental health unit, Helsinki, Finland; <sup>2</sup> Social insurance institution, research department, Helsinki, Finland

\* Corresponding author.

Young people with Asperger's syndrome and/or ADHD face major challenges in their lives affecting their everyday functioning and general well-being.

The aim of this study is to investigate the feasibility and perceived impact of "My Way" psychosocial rehabilitation programme targeted at young adults with neuropsychiatric disorders. The programme is developed and facilitated by the Finnish Social Insurance Institution. The sample consisted of 188 young adults with diagnosis of Asperger's syndrome and/or ADHD/ADD. The 18-month rehabilitation programme included one-to-one and group sessions and aimed at improving social, study and working skills and life control among programme participants.

The study aimed at investigating the feasibility and perceived impact of the programme and to study changes in functional capacity, health and well-being among participants during the follow-up. The data are collected by using questionnaires at three different point of time (baseline, after 12 months and after 18 months) and focus group interviews. The questionnaires included measures on positive mental health (SWEMWBS), provisions of social relationships (SPS), social competence (MASC) and questions about functional capacity. The data will be completed in January 2018. The findings are presented and discussed in the presentation at the congress.

The My Way psychosocial rehabilitation programme represents a unique model that can be used in preventing the marginalization of young people with neuropsychiatric disorders. The results provide information on feasibility of the programme and novel understanding of aspects that should be taken into account in developing supportive programmes targeted at young adults with Asperger's Syndrome and/or ADHD/ADD.

### Off-label prescriptions of levomepromazine for sleep disturbances in elderly patients

M. Arts<sup>1\*</sup>, S. Petrykiv<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>  
<sup>1</sup> Mental Health Western Northern Brabant, geriatric psychiatry and neuropsychiatry, Halsteren, The Netherlands; <sup>2</sup> University of Groningen, university medical center Groningen, department of clinical pharmacy and pharmacology, Groningen, The Netherlands; <sup>3</sup> Mental health care –Friesland GGZ-Friesland, department of geriatric psychiatry, Leeuwarden, The Netherlands; <sup>4</sup> Leonardo scientific research institute, department of geriatric psychiatry and neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

*Introduction.*– Levomepromazine (Nozinan®) is an antipsychotic, antiemetic, anxiolytic and sedative drug that is mainly used clinically for the treatment of moderate to severe pain and for palliative and end-of-life care. However, it is also used off-label for the treatment of sleep disturbances or insomnia.

*Objectives and aims.*– To report and discuss the level of evidence for "off-label" use of levomepromazine for the treatment of sleep disturbances.

*Methods.*– An English-language literature search was conducted using Pubmed, EMBASE and Cochrane library (1958–2017) using the search terms levomepromazine, nozinan, insomnia, sleep disorders, sleep disturbances, and sleeplessness.

*Results.*– Since the late 1950s, levomepromazine has been prescribed for the approved indications, including severe pain and palliative sedation, with a usual therapeutic dose range of 300 to 500 mg/day p.o. and 0.5 to 8 mg/h SC or IV in combination with midazolam for continuous sedation (halve the dose after 3 days due to prevent accumulation). However, off-label use of levomepromazine for the treatment of insomnia was most evident for the 25 mg/day p.o. Inappropriate antipsychotic use may lead to serious health problems, including metabolic effects, significant increased sudden cardiac death, and age-related side effects with increased risk for orthostatic hypotension, fractures, pneumonia, cognitive impairment, and stroke.

*Conclusion.*– There is growing concern regarding the potential harm from off-label prescription of antipsychotics, particularly levomepromazine. There is little evidence supporting the enormous off-label uses of levomepromazine. In addition, prescribing levomepromazine for indications that are not evidence-based has ethical, financial, and safety implications, especially in the older (frail) population.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Comparison between donepezil 10 mg and 23 mg in patients with moderate–severe Alzheimer's disease: Single blinded randomized controlled trial in tertiary care center

P. Jadhav<sup>1\*</sup>, P.T. Sivakumar<sup>2</sup>, P. Sinha<sup>2</sup>, A. Dahale<sup>2</sup>  
<sup>1</sup> District Hospital, Navanagar, Bagalkot, Karnataka, India, Psychiatry, Bagalkot, India; <sup>2</sup> National institute of mental health and neurosciences, Bengaluru, psychiatry, Bengaluru, India

\* Corresponding author.

*Introduction.*– Moderate to severe stage Alzheimer's disease (AD) patients are having more cognitive deficits and behavioural and psychological symptoms of dementia (BPSD). Occurrence of BPSD is associated with more cognitive deficits, significant impairment in activities of daily living (ADL), lower the QOL of patient and caregiver, psychotropic prescription.

*Objectives.*– To compare the effectiveness of Donepezil 10 mg and 23 mg in behavioural and psychological symptoms in patients with moderate to severe AD(primary) and effect on the caregiver burden, quality of life, functionality, cognitive deficits and adverse side effects(secondary).

*Methods.*– Patients (n = 19) were randomly assigned to receive high-dose donepezil (23 mg once daily) or standard-dose donepezil (10 mg once daily) for total 12 weeks into two follow ups i.e. at 6th week and 12th week with the researcher as blind. BPSD was assessed by Neuropsychiatric inventory (NPI) and Behavioral pathology in Alzheimer's disease 84 (BEHAVE-AD).

**Results.**– At the 1st follow up there were statistically significant results noted only in functionality ( $P=0.042$ ) and behavioral symptoms assessed (0.028). during 1st & 2nd follow ups we found a similar pattern of clinical improvement in from the baseline in both 10mg & 23mg groups i.e. behavioral symptoms > severity > ADL > side effects scores > cognitive deficits and also scores of caregiver burden and quality of life.

**Conclusions.**– Though there were high attrition rates, patients on 10mg Donepezil were efficacious, better tolerable and found a pattern of higher clinical improvement in behavioral symptoms followed by quality of life, caregiver burden, functionality, severity of AD compared to 23mg group.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The effectiveness of the comprehensive cognitive rehabilitation program in elderly persons with mild cognitive impairment: Preliminary evaluation**

M. Kurmyshev<sup>1\*</sup>, D. Efremova<sup>1</sup>, V. Savilov<sup>1</sup>, M. Pak<sup>2</sup>, G. Kostyuk<sup>2</sup>

<sup>1</sup> Psychiatric hospital no. 1 named after N.A. Alekseev, Memory Clinic, Moscow, Russia;

<sup>2</sup> Psychiatric Hospital no. 1 named after N.A. Alekseev, Administration, Moscow, Russia

\* Corresponding author.

**Introduction.**– Persons with memory impairment who were not demented were characterized as having mild cognitive impairment (MCI). These subjects were at increased risk for developing dementia or Alzheimer's disease when compared with similarly aged individuals in the general population. At the moment, a few studies have examined the efficacy of non-pharmacological treatment in MCI.

**Objectives.**– Approbation carried out regarding the effectiveness of a comprehensive cognitive rehabilitation program in MCI group of elderly individuals. Our objective was to analyze the peculiarities of cognitive sphere dynamics during the rehabilitation process.

**Methods.**– Clinical data on 178 patients, 61 years of age or older, with MCI were analyzed. For efficacy analysis, patients were categorized by baseline Modified Hachinski Ischemic Score (MHIS), and examined by clinical psychological testing including Mini Mental State Examination (MMSE), Analytical Diagnostic (ANDI), and Clock Drawing test (CDT).

**Results.**– Data support the evidence that cognitive status of patients with MCI is malleable and responsive to rehabilitation cues. Our results demonstrate that a systematic rehabilitation, that provides comprehensive cognitive program training, produces an improvement in cognitive status of patients with MCI.

**Conclusions.**– There were sufficient data to recommend the comprehensive cognitive training along with clinical monitoring of persons with MCI due to their risk for developing dementia. Increasing attention should be paid to provide a platform from which to design effective cognitive rehabilitation programs to enhance cognition and also to alter the rate of progression to dementia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The association of hyperlipidemia with decreased cognitive function and instrumental activities of daily living in Alzheimer's disease**

C.T. Lee<sup>\*</sup>, S.Y. Lee, H.K. Lee, K.U. Lee, Y.S. Kweon  
Uijeongbu St. Mary's Hospital, department of psychiatry, Uijeongbu, Republic of Korea

\* Corresponding author.

**Introduction.**– In addition to vascular dementia, hyperlipidemia may also play a role in Alzheimer's disease (AD). Amyloid beta synthesis is closely related to cholesterol metabolism and the most established genetic risk factor for AD is apolipoprotein E4 allele. However, mixed results were found whether hyperlipidemia actually increases the risk of AD. The current study focuses on the role of hyperlipidemia on the functioning level of patients newly diagnosed with AD.

**Objectives.**– To investigate the relationship between hyperlipidemia and cognitive functioning in Alzheimer's disease.

**Methods.**– The medical records of the newly diagnosed early stage AD patients in the psychogeriatric clinic of the Uijeongbu St. Mary's hospital were reviewed from May of 2015 to January of 2017. We divided the 65 newly diagnosed early AD patients according to hyperlipidemia status and group comparisons on mini mental status examination (MMSE) and activities of daily living (ADL) were performed using Mann-Whitney test or Chi<sup>2</sup>/Fisher's exact test with a two-sided  $P$ -value of 0.05.

**Results.**– The two groups did not demonstrate a significant difference in demographic findings. AD patients with hyperlipidemia ( $n=16$ ) demonstrated significantly lower performance in the MMSE score (median: 15.6 vs. 17.2,  $P=0.027$ ) compared to those without hyperlipidemia ( $n=50$ ). The instrumental ADL was also significantly worse in the group with hyperlipidemia (median: 18.0 vs. 12.8,  $P=0.032$ ).

**Conclusions.**– Although there are contradicting literatures on the role of hyperlipidemia in the pathogenesis of AD, our results illustrate that hyperlipidemia is associated with decreased cognitive functioning and complex ADL in patients an established diagnosis of AD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Background.**– Most epidemiological studies focus on only one measure of social adjustment in older age, precluding the comparison of structural, functional aspects and subjectivity.

**Aims.**– To validate the Social Dysfunction Rating Scale (SDRS), its factorial structure and its relationship with cognitive function, global severity psychopathology and social deprivation in the elderly community of the GreatAGE Study.

**Methods.**– The SDRS was administered to 484 Italian community-dwelling elderly sub grouped in psychiatric and non-affected subjects, according to Semi-structured Clinical Diagnostic Interview for DSM-IV-TR Axis I Disorders. ROC curves were used to detect the cut-off scores for discrimination between diagnostic categories of social dysfunction. Social deprivation was assessed with Deprivation in Primary Care Questionnaire.

**Results.**– A five factors structure was carried out with Vari-max rotation. The optimal cut-off of 26 maximized both sensitivity (SE: 0.73, 95% CI:0.6259–0.8359) and specificity (SP: 0.57, 95% CI:0.4961–0.6419) of SDRS.SDRS scores were greater in psychiatric disorders in course vs. long life ( $P=.02$ ) and vs. non-affected subjects ( $P<.001$ ). The levels of education and global cognitive functions (Mini Mental State Examination and Frontal Assessment Battery) were inversely correlated to SDRS, while a direct correlation with global psychopathology, depression and apathy was found.

**Conclusions.**– The SDRS could be a valid instrument to capture both size and quality of elderly social adjustment, although the absence of correlation with material deprivation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Smurf Feet

E. Mancha<sup>1</sup>, Y. D' Hiver Cantalejo<sup>2</sup>, M.J. Leñero Navarrete<sup>3</sup>, H. Saiz García<sup>4</sup>

<sup>1</sup> Servicio Navarro de Salud, CSM Ansoain, Pamplona, Spain;

<sup>2</sup> Sescam, Hospital Universitario de Guadalajara, Guadalajara, Spain;

<sup>3</sup> Sacyl, Hospital Universitario Río Hortega, Valladolid, Spain;

<sup>4</sup> Servicio Navarro de Salud, Complejo Hospitalario de Navarra, Pamplona, Spain

\* Corresponding author.

**Objectives.**– To analyze the high prevalence of paranoid delusions in the elderly. The explanation is found in the different associated risk factors: cognitive impairment, focused on specific areas that determine the formation of ideas as well as social isolation, low educational level, somatic comorbidity or depressive symptoms.

**Background and aims.**– In predisposed personalities, we see with relative frequency how, as they grow old, their physical ailments are attributed to “enemies”, neighbors or relatives, who claim to produce harm or suffering in the patient.

**Materials and methods.**– We present the case of a 65-year-old woman with no affiliated psychiatric history but with somatic: cataracts in both eyes, intervened for the left eye. The patient comes to the emergency department, saying that they have replaced their feet when sleeping for someone else's: “they are like a Smurf.”

**Results.**– The patient entered Internal Medicine to be affiliated with the clinical picture and was diagnosed on discharge from Charles-Bonnet syndrome in the context of an incipient cognitive impairment. This entity is a visual hallucinosis secondary to vision disorders that originates a delirious paranoid structure of characters that visit the patient, especially at night time, with the idea of causing some type of damage.

**Conclusions.**– We can see how a somatic illness, a pain or a body dysfunction, can trigger a delusional ideation of paranoid type in premorbid personalities in the schizoid line, nevertheless it is

worth noting that even in these cases there must exist a substrate cognitive, psychological and Social development that favors its appearance.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Long-term evaluation of an intervention program for stigma-suffering female caregivers of persons with mental illness

A. Moustafa

Alexandria University, Mental Health, Alexandria, Egypt

\* Corresponding author.

**Introduction.**– Stigma is a crucial barrier to seeking and receiving mental illness (MI) treatment in the Middle Eastern collectivist communities. Stigma also affects the stigmatized person's community integration, and the resulting social isolation is equated to death. After all, effective interventions to reduce MI-related stigma, particularly in caregivers are largely under-researched in the Middle East.

**Objectives.**– Assessing the long term efficacy of an intervention program for female caregivers of persons with MI.

**Methods.**– An RCT for 205 stigma-suffering female caregivers of persons with MI identified using Devaluation & Discrimination Questionnaire. Knowledge, attitude and behavior concerning MI were assessed using: Mental Health Knowledge Schedule (MAKS), Attitudes to Mental Illness Questionnaire (AMIQ), and Reported and Intended behavior scale (RIBS), respectively. Two groups were assigned to either an anti-stigma intervention program (IP) ( $n=99$ ), or discussion-group attention placebo control (APC) ( $n=106$ ). The IP was a series of three sessions with assessments performed upon conclusion using same questionnaires; immediately, 6 months, and 1 year later.

**Results.**– 1 year follow-up data were provided by 82. MAKS: improvement was significant in both the IP ( $t/z: -9.5$ , 95% CI:  $-3.8$  to  $-2.1$ ,  $P \leq 0.002$ ) and the APC groups ( $t/z: -7.1$ , 95% CI:  $-3.5$  to  $-2.1$ ,  $P \leq 0.001$ ). AMIQ: significant improvement in the IP ( $t/z: -6.3$ , 95% CI  $-2.2$  to  $-0.8$ ,  $p \leq 0.007$ ) vs. APC ( $t/z: -2.6$ , 95% CI:  $-0.9$  to  $0.1$ ,  $P=0.3$ ). RIBS: significant improvement in the IP ( $t/z: -4.7$ , 95% CI:  $-0.9$  to  $-0.3$ ,  $P \leq 0.0001$ ) compared to APC ( $t/z: -2$ , 95% CI:  $-0.6$  to  $0.1$ ,  $P=0.2$ )

**Conclusions.**– Significant reductions of stigma confirm the efficacy of the intervention through changing mental health knowledge, attitudes and behavior.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### The influence of depressive symptoms on sleep disturbance in elderly people

B. Nam

Konkuk university, psychiatry, chungju, Republic of Korea

\* Corresponding author.

**Objectives.**– This study was conducted to collect basic data for the elderly mental health by identifying the influence of depressive symptoms and physical illness on sleep disturbance.

**Methods.**– Among 1535 Medicaid people at least 60 years of age residing in Chungju, 1262 people were examined from 25 April 2011 until 31 July 2011. We investigated the general characteristics of the patients and the history of physical illness. Also we did screening test for depression and sleep quality. Data analysis

was done by t-test, Pearson's correlation, step by step regression analysis with SPSS. SPSS/PC WIN 19 version.

**Results.**– Among the 1262 survey personnel, 520 (41%) people had depressive symptoms and 718 (57%) people had sleep disturbance. Also, 140 (11%) people had been diagnosed as stroke, 712 (56%) people had hypertension, and 279 (22%) people had diabetes mellitus. Among the variables, depressive symptoms and hypertension showed positive correlation with sleep quality.

**Conclusion.**– The study demonstrated that depressive symptoms have a significant effect on sleep quality in elderly over 60 years old. So we suggest that elderly people with sleep disturbance need care for depression and hypertension.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Priorities in psychosocial interventions for multiple sclerosis: From onset to relapse and remission of the disease**

E. Nikolaev<sup>1\*</sup>, N. Vasil'eva<sup>2</sup>, E. Chekhlyat<sup>3</sup>, T. Karavaeva<sup>3</sup>

<sup>1</sup> Chuvash State university, department of social and clinical psychology, Cheboksary, Russia; <sup>2</sup> Chuvash Republic clinical hospital, neurology unit, Cheboksary, Russia; <sup>3</sup> Bekhterev National center for psychiatry and neurology, department of neuroses and psychotherapy Saint-Petersburg, Saint-Petersburg, Russia

\* Corresponding author.

**Introduction.**– The content of clinical interventions for multiple sclerosis (MS) is determined by the severity of the illness and its clinical stage. What is the dependence of psychosocial interventions in MS on its different clinical stages?

**Objectives.**– The study is aimed to present the priority goals of psychosocial interventions for MS patients in different clinical stages of the disease – its onset, relapse and remission.

**Methods.**– This was a psychological analysis in the frame of phenomenological interpretation of the results of clinical and psychological interviews and observation of 104 patients with MS.

**Results.**– It was found out that at the initial stage of MS progression the priority goals of psychosocial interventions were: psychological diagnosis, identifying risk factors for mental disorders, reducing the patient's emotional tension, helping the patient in acceptance of the disease, providing the patient's compliance with the treatment. At the stage of relapse, the following goals were relevant: the patient's adaptation to the symptoms of MS, reduction of individual perception of stress factors, promoting motivation for treatment, reinforcement of anti-suicide barrier, work involving the patient's life experience, providing emotional and social support. During the stage of remission, it was important to work on strengthening the extant cognitive functions, maintaining adherence to treatment, reinforcement of coping skills, deepening social integration, resolving acute psychological problems.

**Conclusions.**– The findings of this study can be used by mental health professionals in planning personalized programs of psychosocial interventions for MS patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0179

### **Validation of the Italian version of the computerised interactive remediation of cognition program (CIRCuiTS)**

P. Davide<sup>\*</sup>, G. Piegari, D. Pietrafesa, N. Annarumma, L. Giuliani, C. Aiello, A. Mucci, S. Galderisi

University of Campania "Luigi Vanvitelli", department of psychiatry, Naples, Italy

\* Corresponding author.

**Introduction.**– The Computerised Interactive Remediation of Cognition (CIRCuiTS) is a cognitive remediation program aimed at improving different cognitive domains in patients with schizophrenia or schizoaffective disorder. Through the use of non-emotional material, it teaches basic thinking skills (i.e. neurocognitive and metacognitive skills) that could facilitate more complex social behaviors and life skills. Although several studies have investigated the feasibility and applicability of the programme, only a few studies, mostly case reports, investigated its effects.

**Objectives.**– The purpose of this study is to provide a first validation of the Italian version of CIRCuiTS by investigating its effect on several indices in a group of patients with schizophrenia.

**Methods.**– The experimental sample included 80 patients with a DSM-IV diagnosis of schizophrenia. Participants received up to 40 therapy sessions three times a week, for about an hour for approximately three months. Changes in neurocognition, psychopathology, self-esteem and functional outcome with respect to the baseline were assessed at the end of the program.

**Results.**– After the end of CIRCuiTS program, an improvement was observed in several domains of neurocognition, disorganization, self-esteem, functional capacity and real-life functioning in the areas "self-care", "interpersonal relationships" and "working abilities".

**Conclusion.**– According to our findings, CIRCuiTS lead to some benefits on cognition, disorganization and self-esteem and this results in an improvement in functional capacity and real-life functioning. The study yielded encouraging data suggesting the effectiveness of the CIRCuiTS programme in an Italian sample of subjects with schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Prevention of cruel treatment of elderly people**

L. Pishchikova

Charitable Fund "Gerontological protection", Ministry of Health, Moscow, Russia

\* Corresponding author.

The ageing of the world's population is accompanied by an increase in cases of age discrimination, abuse and violence. In Russia there is no monitoring of cases of abuse of elderly people. There has been an increase in crimes against the elderly people related to fraud with their property, physical violence by children. We observe a growing number of property transactions committed under the influence of fraud, deceit. There is an increasing number of elderly people, deprived of legal capacity.

In order to identify the determinants and forms of ill-treatment we examined 235 patients of late age who underwent forensic psychiatric examination in criminal and civil cases.

The results revealed forms of abuse and violence: physical—bodily injury; psychological—involuntary placement in a psychiatric hospital and examination by a psychiatrist, psychiatric hold in a hospital, unlawful deprivation of legal capacity; financial—fraud

with housing for older people, manipulation in the process of conclusion of civil-legal acts.

Risk of abuse is increased by biological determinants—sensory and motor deprivation, multimorbidity pathology, specific disorders later in life, dementia; socio-psychological—the termination of labor activity, loneliness, conflicts in relationships with children, alcohol; legal—conclusion and contestation of civil legal acts, legal illiteracy, legal controversy, lack of legal protection.

To prevent abuse of elderly people a complex of legislative measures is required aimed at protection of their rights, monitoring of cases of abuse, legal, psychological, educational, medical education and assistance programs, enhancing spiritual culture of people.

### Falls and recurrent depression in older adults

W. Rachel<sup>1\*</sup>, S. Krupnik<sup>2</sup>, W. Datka<sup>1</sup>, D. Dudek<sup>1</sup>, M. Zak<sup>3</sup>

<sup>1</sup> Jagiellonian university, department of psychiatry, Krakow, Poland;

<sup>2</sup> University of physical education, physiotherapy, Krakow, Poland;

<sup>3</sup> The Jan Kochanowski university, faculty of medicine and health sciences, institute of physiotherapy, Kielce, Poland

\* Corresponding author.

*Introduction.*— Major Depressive Disorder (MDD) in the older adults is correlated with a significant decline in daily physical activity, consequently resulting in increased exposure to falls-risk.

*Objectives.*— Establishing whether falls in patients with MDD modified results of muscle strength assessed by 30s Chair Stand (30sChS), balance as Single Limb Stance with open and closed eyes (SLS OP and CL), dual motor tasks (TUG<sub>MAN</sub>) and cognitive test constraints (TUG<sub>COG</sub>) and comparison to normative values of the tests.

*Methods.*— The study was conducted in the outpatient clinic, University Hospital, Krakow, on 43 patients over 60 years of age presenting recurrent MDD. The assessment consisted of GDS, MMSE, TUG, TUG<sub>MAN</sub>, TUG<sub>COG</sub>, 30sChS, SLS. Number of falls within past 12 months was collected. Wilcoxon test was applied to determine the differences between the variable. Odds ratios were counted for variables with distinction the groups.

*Results.*— In the last 12 months, 44.2% of the respondents have fallen. Patients who had fallen were taking more medications ( $P < 0.02$ ), longer TUGT ( $P < 0.01$ ), worse TUG<sub>MAN</sub> ( $P < 0.05$ ) and TUG<sub>COG</sub> ( $P < 0.01$ ), lower 30sChS ( $P < 0.01$ ), compared to those who did not fall. The odds ratios, comparing two groups and normative data for the tests, were significant for TUG (OR 11.05, CL95% 2.05–59,  $P < 0.01$ ) and 30sChS (OR 7.8, 1.93–31, 2,  $P < 0.01$ ).

*Conclusion.*—

1. The fall negatively affects a single-task and two-way functional efficiency.
2. Persons treated for depression who have a history of collapse have a significantly higher risk of reduced mobility and lower limb muscular strength.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

### Are we prescribing memantine in Alzheimer's disease efficiently?

C. Rasanayagam\*, J. Schwartz-Mesa

Juniper centre, old age psychiatry, Birmingham, United Kingdom

\* Corresponding author.

*Introduction.*— Memantine is a non-competitive NMDA receptor antagonist which is approved for the management of moderate to severe Alzheimer's disease. It has shown benefits in function, cognition, behavioural and global measures of the disease. NICE has implemented evidence-based recommendations for the use of Memantine as a second line drug after acetylcholinesterase inhibitors (ACEi's). NICE also states that treatment should only be continued if it is considered to be having a valuable effect on all global symptoms.

Furthermore, It is advised to avoid Memantine in service users with an eGFR  $< 5$  mL/minute/1.73 m<sup>2</sup>.

*Objectives.*— To review the appropriate use of Memantine in clinical practice and to assess adherence to NICE guidelines (for the use of Memantine in patients with Alzheimer's).

*Methods.*— A retrospective audit using systemic sampling to include all service users referred to MHSOP in 2016 with a diagnosis of Dementia on Memantine. Case notes and IT systems obtained further information about each prescription.

*Results.*— 40 service users were identified whom 23/40 had tried ACEi's prior to Memantine. Out of those whom did not have a trial of ACEi's, 6/20 had contraindications.

8/40 service users' Memantine was stopped as it was not considered to be having a worthwhile effect on the individual. Only 2 service users had renal function recorded before treatment was started.

*Conclusions.*— We are adhering to the NICE guidance for the prescription of Memantine, however documentation warrants improvement especially for renal function prior to treatment. Furthermore a higher percentage of service users need to be started on ACEi's unless contraindicated.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

### Telling us how it is: The patient's experience of psychological assessment

N. Semenova<sup>1\*</sup>, G. Kostyuk<sup>2</sup>, G. Rupchev<sup>3</sup>, N. Chernov<sup>4</sup>

<sup>1</sup> Moscow research institute of psychiatry MoH RF, outpatient

psychiatry, Moscow, Russia; <sup>2</sup> Psychiatric hospital no. 1 named after N.A. Alekseev, administration, Moscow, Russia; <sup>3</sup> Lomonosov Moscow State university, psychology department, Moscow, Russia;

<sup>4</sup> Psychiatric Hospital no. 1 named after N.A. Alekseev, pathopsychology laboratory, Moscow, Russia

\* Corresponding author.

*Introduction.*— This paper will present the findings of a study that investigated the experience of psychological assessment from the patient's perspective.

*Objectives.*— The study sought to gain an understanding of how the patient viewed the purpose of assessment and experienced the assessment process. It explored the impact of the assessment on the patient's sense of self and elicited patients' views about what was particularly helpful about the assessment process.

*Methods.*— A within-group qualitative design was employed to investigate the experiences of nine ( $n = 9$ ) men and women who presented for psychological assessment in the context of an outpatient assessment clinic or as part of an evaluation for rehabilitation programme. Verbatim transcripts of semi-structured interviews were analysed by means of Interpretive Phenomenological Analysis (Smith and Osborn, 2003).

*Results.*— Six master themes were identified: expectations of assessment, context of referral, experience of process, impact on self, components of a good assessment and experience of illness. The findings indicated that patients are poorly prepared for assessment but come with positive expectations for information that will help

them understand and cope with their impairments. Their relationship with the clinician is central in determining the quality of their experience and in facilitating improved self-esteem, coping and better awareness of strengths and deficits.

**Conclusions.**– It is concluded that psychological assessment can have an educative and therapeutic function that should be further exploited in a rehabilitation context. The implications of the research findings for psychosocial service provision are discussed and consideration given to future research opportunities.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Clinical factorial distribution of Anosognosia Questionnaire for Dementia (AQ-D)**

M.F.B. Sousa<sup>1\*</sup>, R.L. Santos<sup>1</sup>, M.C.N. Dourado<sup>1</sup>, J.L. Conde-Sala<sup>2</sup>

<sup>1</sup> Universidade Federal do Rio de Janeiro, Centro para Doença de Alzheimer, Instituto de Psiquiatria, Rio de Janeiro, Brazil;

<sup>2</sup> Universitat de Barcelona, Facultat de Psicologia, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Anosognosia is a common symptom in patients with Alzheimer's disease (AD), patients with anosognosia have been presented more dangerous behaviours.

**Objectives.**– This study investigated the factorial structure of the Anosognosia Questionnaire–Dementia (AQ-D) from a clinical perspective and to verify the association between the AQ-D clinical factors and patients and caregivers' variables.

**Methods.**– This is a cross-sectional study composed by 221 outpatients with AD and their caregivers. Patients were assessed with the AQ-D, Mini Mental State Examination, Functional Activities Questionnaire, Disability Assessment for Dementia, Neuropsychiatric Inventory and Clinical Dementia Rating Scale. Caregivers answered the AQ-D, Zarit Burden Interview, SF-12 Health Survey, and Sociodemographic Questionnaire. Our data was analyzed using factorial analysis and linear regressions.

**Results.**– Cronbach's alpha was high ( $\alpha = 0.91$ ), indicating excellent internal consistency. Three factors were grouped: Cognition, Functionality, and Behaviour/Personality. In the multivariate analysis, to patients, the factor Functionality was the most relevant in the association between high levels of anosognosia and deficits in activities of daily living (ADLs), less depressive symptoms, more neuropsychiatric symptoms, and older patients. To caregivers, the factor Personality was the most important in the relationship between high levels of anosognosia and caregiver burden and female gender.

**Conclusions.**– In a clinical perspective, anosognosia is a multidimensional phenomenon. Besides, deficits in ADLs, more neuropsychiatric symptoms, less depression, and older age had negative effect on the patients' AQ-D clinical ratings, whereas caregivers' AQ-D ratings were affected by burden and female gender.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Burden in caregivers of patients with Alzheimer's disease in Brazil and Spain**

M.F.B. Sousa<sup>1\*</sup>, R.L. Santos<sup>1</sup>, M.C.N. Dourado<sup>1</sup>, J.L. Conde-Sala<sup>2</sup>

<sup>1</sup> Universidade Federal do Rio de Janeiro, Centro para Doença de Alzheimer, Instituto de Psiquiatria, Rio de Janeiro, Brazil;

<sup>2</sup> Universitat de Barcelona, Facultat de Psicologia, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Transcultural studies regarding the comparison of levels of burden in caregivers of patients with Alzheimer's disease (AD) from Europe and Latin America are rare.

**Objectives.**– This study investigated the differentiating factors associated with burden in Brazilian and Spanish caregivers of patients with AD.

**Methods.**– This is a cross-sectional study composed by samples of outpatients with AD and their caregivers from Brazil ( $n = 128$ ) and Spain ( $n = 146$ ). Caregivers answered the Zarit Burden Interview and a Sociodemographic Questionnaire. Patients were assessed with the Mini Mental State Examination, Functional Activities Questionnaire, Disability Assessment for Dementia, Neuropsychiatric Inventory and Clinical Dementia Rating Scale.

**Results.**– In the multivariate regression analysis, high burden levels were reported in Brazil, when caregivers were female ( $P = 0.025$ ) and when patients did not attend Day Care Center ( $P = 0.025$ ). In Spain, high burden levels were associated with living with the patient ( $P = 0.014$ ), younger caregivers ( $P = 0.003$ ) and participation of patients at Day Care Center ( $P = 0.046$ ). Also, different neuropsychiatric symptoms explained high burden levels: in Brazil, depression ( $P < 0.001$ ) and anxiety ( $P = 0.024$ ) and, in Spain, apathy/indifference ( $P < 0.001$ ), agitation/aggression ( $P = 0.019$ ) and irritability/lability ( $P = 0.027$ ).

**Conclusions.**– Caregivers' gender, patients who attended Day Care Center and neuropsychiatric symptoms were differentiating factors in the burden of Brazilian and Spanish caregivers.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0186

### **The role of the psychiatric clinical pharmacist in pharmacotherapy management in elderly patients with mental health problems**

M. Stuhec<sup>1\*</sup>, N. Bratovič<sup>2</sup>

<sup>1</sup> Faculty of pharmacy, biopharmacy and pharmacokinetics,

Ljubljana, Slovenia; <sup>2</sup> University of pharmacy Ljubljana, biopharmacy and pharmacokinetics, Ljubljana, Slovenia

\* Corresponding author.

**Introduction.**– Collaborative care approach is one of the possible approach to cope with mental health problems (MHP).

**Objectives.**– In most European countries there are no data where clinical pharmacist (CP) interventions can have an impact on pharmacotherapy of elderly with MHP. The main aim of this research was to present impact of CP in optimization of pharmacotherapy of elderly with MHP.

**Methods.**– A prospective study was carried between december 2016 and may 2017 in one Slovenian nursing home. General practitioner (GP) chose patients to participate in the study. CP prepared pharmacotherapy review (PR) and it was immediately sent to GP. CP recorded which interventions have been accepted by GP after 2 months and identified drug-related problems (DRP). Potentially drug-drug interactions (DDIs) were identified by Lexicomp<sup>®</sup> 4.0.1 and 4.0.2 version. We included interaction type X and D. Priscus lists were used to determine potentially inappropriated medication (PIM).

**Results.**– 24 patients (age = 80.6, SD = 6.8) were included (87.5% women). The mean of the total number of medications before PR was 12.2 (SD = 3.1) per patients and it was decreased to 10.3 (SD = 3.0) medicines per patients after GP's review ( $p < 0.05$ ). The total number of PIM and DDIs were reduced after GP's review ( $p < 0.05$ ). The most identified DRP were related to the treatment of MHP (28.2%) followed by treatment of cardiovascular diseases

(22.8%) and pain (12.4%). GP accepted only 29.2% interventions for optimization treatment of MHP.

**Conclusions.**– A collaborative care approach including CP has important impact on decrease of DRP, DDIs and PIM.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0187

### Algorithm for evaluation of the quality of life in caregivers of patients diagnosed with Alzheimer neurocognitive disorder

D. Vasile<sup>1</sup>\*, O. Vasiliu<sup>2</sup>, A.F. Fainarea<sup>2</sup>, M.C. Patrascu<sup>2</sup>, E.A. Morariu<sup>2</sup>, R. Manolache<sup>2</sup>, I. Alexandru<sup>2</sup>

<sup>1</sup> University of medicine and pharmacy “Dr. Carol Davila”, clinical psychopharmacology, Bucharest, Romania; <sup>2</sup> Central university and emergency military hospital “Dr. Carol Davila”, psychiatry, Bucharest, Romania

\* Corresponding author.

Caregivers of the patients diagnosed with neurocognitive disorders are facing a large number of challenges in their daily life, which are associated with various degrees of discomfort, lower quality of life, and even with an increased vulnerability to the onset of stress-related reactions. An algorithm for the monitoring of caregivers' quality of life could help in the early detection of the population at risk for developing stress related reactions, depression, adjustment or anxiety disorders, and recommendations for psychological counselling or even more symptom-focused approaches could be made based on the results of such an algorithm. A structured evaluation should include 3 directions: quality of life, overall functionality, and the severity of the perceived burden related to the caregiver status. EuroQol (EQ-5D) is a very user-friendly instrument, which requires a minimal time for administration, and its results can be interpreted very easy. Zarit Burden Interview (ZBI) is the golden standard for the evaluation of caregivers' burden in neurocognitive disorders. Global Assessment of Functioning (GAF) is a very useful scale and largely-validated for practically any psychiatric disorder in terms of symptoms severity and ability for daily functioning. We consider that a periodic administration of these instruments in caregivers of Alzheimer neurocognitive disorder diagnosed patients could have important social and economic consequences. In conclusion, implementing an algorithm for the evaluation of the quality of life in Alzheimer neurocognitive disorder patients' caregivers at the primary care level could be helpful by detecting population at risk for development of new psychiatric, stress-related, disorders.

### The young-old and the oldest-old: Correlates of adjustment to aging

S. von Humboldt, I. Leal

ISPA-Instituto Universitário, William James center for research, Lisbon, Portugal

\* Corresponding author.

**Objectives.**– This study aims to compare the correlates of adjustment to aging (AtA) reported by young-old and oldest-old adults and to build two structural models to explore the correlates of AtA for these two age groups.

**Methods.**– A crossnational study encompassing a community-dwelling sample of 823 older adults aged 65 years and older was undertaken. Several measures were employed to assess AtA, subjective well-being, and sense of coherence. A questionnaire to determine socio-demographic (sex, age, professional and marital status, education, household, adult children, family's annual income, living setting, and self-reported spirituality), lifestyle and health-related characteristics (perceived health, recent disease, medication, and leisure) was also used. Structural equation modeling was employed to investigate a structural model of AtA, comprising socio-demographic, lifestyle, and health-related variables, as well as SWB and SOC for both groups.

**Results.**– Leisure was the most significant correlate of AtA for the young-old ( $\beta = .422$ ;  $P < .001$ ) while selfreported spirituality was the most significant correlate of AtA for the oldest old ( $\beta = .711$ ;  $P < .001$ ). Significant correlates explain 67.8% and 73.1% of the variability of AtA, respectively.

**Conclusions.**– The results presented in this study highlighted different perspectives of AtA, outlined in two structural models, for the groups, and the need of addressing the differences between these, when implementing health care interventions, in particular the relevance of leisure and self-reported spirituality.

### Analyzing sexual unwellness in old age in a sample of older adults

S. von Humboldt\*, S. Silva, I. Leal

ISPA-Instituto Universitário, William James center for research, Lisbon, Portugal

\* Corresponding author.

**Objectives.**– To analyze the contributors to Sexual Unwellness (SU) and to explore the latent constructs that can work as major determinants in SU for a cross-national older community-dwelling population.

**Methods.**– Study design: Complete data were available for 109 English and Portuguese older adults, aged between 65 and 87 years old ( $M = 70.1$ ,  $SD = 5.99$ ). Data was subjected to content analysis. Representation of the associations and latent constructs were analyzed by a Multiple Correspondence Analysis. A socio-demographic and health questionnaires were completed, assessing participants' background information. Interviews were completed, focused on the contributors to SU.

**Results.**– The most frequent response of these participants was “lack of intimacy and affection” (25.1%) whereas “poor sexual health” was the least referred indicator of SU (11.2%). A two-dimension model formed by “poor affection, intimacy and sexual health”, and “poor general health and financial instability” was presented as a best-fit solution for English older adults. SU for Portuguese older adults were explained by a two-factor model: “daily hassles and health issues”, “poor intimacy and financial instability”.

**Conclusions.**– These outcomes uncovered the perspective of older adults concerning SU and the need of including these factors when considering the sexual well-being of older cross-national samples.

**Keywords:** Community-dwelling older adults; Content analysis; Multiple correspondence analysis; Qualitative study; Sexual unwellness

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Validation of the Positive and Negative Affect Scale (PANAS) for use with cross-national older adults

S. von Humboldt<sup>1</sup>, A. Monteiro<sup>2</sup>, I. Leal<sup>2</sup>

<sup>1</sup> ISPA, Instituto Universitário, William James center for research, Lisbon, Portugal; <sup>2</sup> ISPA, Instituto Universitário, William James center for research, Lisbon, Portugal

\* Corresponding author.

**Objectives.**– Positive and negative affect is a relevant facet of well-being for community-dwelling older adults. This article reports the validation of the Positive And Negative Affect Scale (PANAS), by means of confirmatory analysis.

**Methods.**– A community-dwelling cross-national sample of 1291 older adults aged 75 years-old and older voluntarily completed the PANAS. The relations between variables in the model were evaluated using structural equation based on maximum likelihood estimation. The distributional properties, cross-sample stability, internal reliability, and convergent, external and criterion-related validities of the PANAS were analyzed and found to be psychometrically acceptable.

**Results.**– Our results outcomes support for the hypothesis that the PANAS is valid and reliable in the two 10-item mood scales, hence fit for use with older adults, within a culturally diverse view of well-being.

**Conclusions.**– The psychometric properties of the PANAS are satisfactory in this older sample, and according to those of its early version. Taken together, these results substantiate the validity of this measure when applied to an older community cross-national population.

**Keywords:** Older adults; Psychometric properties; Positive and negative affect; Positive And Negative Affect Scale

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Posttraumatic Stress Disorder / Research Methodology

### Synthesis and characterization of a novel highly affine and selective, fluorescence-labeled 5-HT<sub>2A</sub> receptor agonist

S. Aatz<sup>1</sup>, T. Sorkalla<sup>1</sup>, S. Franken<sup>1</sup>, C. Kolb<sup>2</sup>, H. Abdel-Aziz<sup>2</sup>, H. Häberlein<sup>1</sup>

<sup>1</sup> Institute of biochemistry and molecular biology, molecular drug research, Bonn, Germany; <sup>2</sup> Phytomedicines supply and development center, Bayer Consumer Health Division, Steigerwald Arzneimittelwerk GmbH, Darmstadt, Germany

\* Corresponding author.

**Introduction.**– Malfunctions in noradrenergic and/or serotonergic neurotransmitter systems are often responsible for depressive disorders. Deeper insights into the mode of action of antidepressants interacting with those neurotransmitter systems are crucial to bet-

ter understand their pharmacological effects and side effects as well and to use antidepressants therapeutically differentiated. Fluorescently labeled ligands are useful for molecular drug research with single molecule detection and allow the observation of receptor-ligand interactions in living cells.

**Objectives.**– Synthesis and characterization of the first selective and highly affine fluorescence-labeled 5-HT<sub>2A</sub>-agonist is reported within this work.

**Methods.**– SAH268-Atto532 was synthesized by direct alkylation of TCB-2, acid catalyzed cleavage of a Boc-protected amine and finally the coupling to succinimidylester-activated Atto532. Identity of SAH268-Atto532 was confirmed by mass spectrometry. 5-HT<sub>2A</sub>-receptor binding studies in SH-SY5Y cells were performed using fluorescence correlation spectroscopy (FCS). For calcium measurements HEK293 cell lines stably expressing B-GECO-1 alone or together with hu5HT<sub>2A</sub> receptors were generated.

**Results.**– FCS binding experiments in SH-SY5Y cells using SAH268-Atto532 revealed two receptor-ligand-complexes, with distinct lateral mobilities. Saturation experiments revealed a B<sub>max</sub>-value of 23.95 ± 5.91 nM and a K<sub>D</sub>-value of 81.03 ± 24.99 nM. Selective 5-HT<sub>2A</sub>-receptor binding was confirmed by displacement using TCB-2 and ligands for 5-HT<sub>1A</sub>, 5-HT<sub>2C</sub> and 5-HT<sub>7</sub> in excess. Calcium release experiments verified the agonistic profile of SAH268-Atto532.

**Conclusion.**– SAH268-Atto532 allows for the first time the observation of 5-HT<sub>2A</sub>-receptor-agonist complexes on cell surfaces. Influences of antidepressants on the 5-HT<sub>2A</sub>-receptor binding of agonists and subsequently regulatory processes can now be observed in real-time in living cells.

**Disclosure of interest.**– The research project was financially supported by Bayer Consumer Health Division, Steigerwald Arzneimittelwerk GmbH, Darmstadt, Germany.

### Recognition of facial emotions among Tunisian military soldiers with PTSD

M.W. Krir<sup>1</sup>, S. Aloui<sup>2</sup>, H. El Kefi<sup>1</sup>, A. Baatout<sup>1</sup>, I. Bouzouita<sup>1</sup>, S. Edhi<sup>2</sup>, A. Oumaya<sup>2</sup>

<sup>1</sup> Military hospital, psychiatry, Tunis, Tunisia; <sup>2</sup> Military hospital of Tunis, psychiatry, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Post-traumatic stress disorder (PTSD) is associated with interpersonal dysfunction including impairments in emotional experience. Research has largely focused on fear processing. However, experimental investigations examining the impact of trauma exposure on the perception of other emotions are sparse.

**Objective.**– The current study investigated facial emotion recognition. We hypothesized that individuals with PTSD have deficits in emotion recognition that may explain their difficulties in social interactions.

**Methods.**– Forty trauma exposed military officers and 18 healthy controls were screened for trauma history and demographic information. All participants completed the following scales:

- the Life Events Checklist for DSM-5 (LECS);
- the PTSD Checklist for DSM-5 (PCL-5);
- the Beck depression inventory (BDI).

To evaluate the recognition of emotional facial expressions, we used 6 pictures of a face expressing the six universal emotions (EKMAN test). We identified 3 groups of participants: PTSD group ( $n = 22$ ), trauma exposed healthy control (TEHC) group ( $n = 18$ ) and the no trauma healthy control (NTHC) group ( $n = 18$ ).

**Results.**– The PTSD group had significantly higher symptom levels across the PCL-5 total and cluster scores compared to the TEHC group ( $P < 0.001$ ).

In the PTSD group, 63.6% of participants didn't identify the emotion sadness and 54.5% the emotion fear. Most accurate recognition performance was observed for the emotion happiness. The analysis showed a significant difference between the 3 groups in the accuracy of recognizing fear ( $P=0.001$ ) and sadness ( $P<0.001$ ).

**Conclusion.**– Patients suffering from PTSD have a selective deficit in the recognition of emotions. This selective impairment might be helpful in trying to understand this form of psychopathology and should be targeted during treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0193

### **Nicotine dependence and PTSD symptoms in Tunisian military soldiers**

S. Aloui<sup>\*</sup>, M.W. Krir, H. El Kefi, R. Lansari, C. Bechikh, I. Bouzouita, S. Edhif, A. Oumaya

Military hospital, psychiatry, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Post-traumatic Stress Disorder (PTSD) has been linked with increased use of cigarettes. An association between PTSD and smoking may reflect the use of nicotine to attempt to alleviate PTSD symptoms.

**Objective.**– The aim of this study was to investigate the association between nicotine dependence and PTSD symptoms and to examine whether this relationship is specific, or instead a reflection of their joint association with a third variable such as depression.

**Methods.**– Thirty trauma exposed military soldiers were screened for trauma history, tobacco use history and demographic information. All participants completed the following four self-administered scales:

- the Life Events Checklist for DSM-5 (LEC5) designed to screen 17 potentially traumatic events in a respondent's lifetime;
- the PTSD Checklist for DSM-5 (PCL-5) to assess the 20 DSM-5 symptoms for PTSD;
- the Beck depression inventory (BDI) to measure the presence and the intensity of depression;
- the Fagerström Test for Nicotine Dependence (FTND) consisting of six items assessing smoking rate and characteristics.

**Results.**– PCL-5 total score was not significantly associated with nicotine dependence. Emotional numbing and avoidance were positively associated to nicotine dependence ( $P=0.472$  and  $P=0.238$ ). Depression was not associated to PCL-5 total score but to avoidance symptoms. Variation in depression severity mediated the relation between PCL-C total score and negative nicotine dependence ( $\beta=0.79$ ;  $P=0.063$ ).

**Conclusion.**– The association between PTSD and nicotine dependence is more likely mediated by depression symptoms. Additional consideration of other variables would also be valuable. Results of such studies could have important implications for understanding comorbidity of PTSD and substance use disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0194

### **Dissociative vs. non-dissociative posttraumatic stress disorder among asylum seekers: Functional neurological symptoms as a component of the subtype**

U. Altunoz<sup>1\*</sup>, V. Sar<sup>2</sup>, T. Agar<sup>1</sup>, S. Castro-Nunez<sup>1</sup>, R. Ozbas-Durak<sup>1</sup>, I.T. Graef-Calliess<sup>1</sup>

<sup>1</sup> Klinikum Wahrendorff psychiatry hospital, transcultural psychiatry, Hannover, Germany; <sup>2</sup> Koc university school of medicine, department of psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Diagnostic and statistical manual of mental disorders-5 (DSM-5) includes a dissociative subtype of posttraumatic stress disorder (D-PTSD) marked by prominent depersonalization and derealization symptoms. The diagnostic criteria of D-PTSD are rather restricted and more research is needed to deepen our understanding of this subtype.

**Objectives.**– We aimed to compare D-PTSD with non-dissociative PTSD (ND-PTSD) with regard to clinical-sociodemographic characteristics in a sample of asylum seekers (AS).

**Methods.**– The files of a consecutive sample of ( $n=152$ ; F/M=66/86) AS who admitted to a centre of transcultural psychiatry in Germany between 01.01.2014–01.03.2017 were evaluated retrospectively regarding DSM-5-diagnostic criteria for PTSD and other clinical-sociodemographic characteristics.

**Results.**– PTSD was diagnosed in 112 (M/F=57/55, age =  $34.6 \pm 10.2$ ) of the AS (D-PTSD/ND-PTSD=58/54). D-PTSD was significantly more common in females, associated with higher trauma load, more bodily injuries and higher suicidal ideation when compared to ND-PTSD ( $P<0.05$  for all). From DSM-5 diagnostic criteria: B3, B4, B5, C1, D1, D2, D3, D6, E1, E2, E3 were significantly more common in D-PTSD than in ND-PTSD ( $P<0.05$  for all). Psychogenic non-epileptic seizures (PNES) were solely encountered in D-PTSD group (25.9%). Functional neurological symptoms other than PNES were also significantly more common in D-PTSD (D-PTSD/ND-PTSD = 39.7%/7.4%;  $P<0.001$ ).

**Conclusions.**– This study showed that AS with D-PTSD differed regarding many clinical characteristics from AS with ND-PTSD, which supports and strengthens the subtype model in this specific population. Functional neurological symptoms, especially PNES were common and seem to be specific to D-PTSD, which may be considered as a candidate diagnostic criterion for D-PTSD in DSM-6.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Post-traumatic stress disorder and violence in prison**

M. Antonioli<sup>1\*</sup>, A. Nivoli<sup>1</sup>, D. Vazzana<sup>1</sup>, A. Zeppa<sup>1</sup>, P. Milia<sup>1</sup>, C. Depalmas<sup>1</sup>, M. Clerici<sup>2</sup>

<sup>1</sup> Institute of psychiatry, psychiatry, Sassari, Italy; <sup>2</sup> Institute of psychiatry, psychiatry, Milano, Italy

\* Corresponding author.

**Introduction.**– Prior research indicates an association between trauma and perpetration of crime (1). Incarceration has been significantly associated with lifetime post-traumatic stress disorder (PTSD) (2). Research examining the relationship between PTSD and specific aspect of violence and aggression in forensic samples is lacking.

**Methods.**– A sample of prisoners restricted in a jail in Sardinia were assessed using the MINI International Neuropsychiatric Interview, the Aggression Questionnaire and the Barratt Impulsiveness

Scale (BISS-11). Student's *t*-tests, ANOVA, Pearson Chi-square and Fisher's exact test were performed.

**Results.**– PTSD was present in 14.9% of prisoners. The majority of prisoners with PTSD (60%) showed a severe violent behavior (homicide, attempted homicide, physical and sexual assaults), while no statistical significant differences were detected comparing prisoners with and without PTSD depending on severity of committed crime. All inmates with PTSD have been restricted more than once at the time of interview. A significant difference was showed in current psychiatric treatment: 100% of PTSD prisoners were on treatment versus 66.7% of prisoners without PTSD diagnosis. Higher rates of psychiatric service consultation were found in PTSD inmates compared with non-PTSD subjects (70% versus 38.6%). Higher scores at BISS-11 Cognitive impulsivity were showed in PTSD prisoners. None of variables has retained statistical significance at logistic regression.

**Conclusions.**– PTSD in a forensic population is associated with chronicity of violence, incarceration and with more severe psychopathology, in terms of current and past treatment needs. This may have adverse consequences both for prisoners and for the effective functioning of the criminal justice system and psychiatric assessment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Child psychiatric care in the emergency situation following the terrorist attack on July 14th, 2016 in Nice, France**

F. Askenazy<sup>1</sup>, M. Battista<sup>1</sup>, M. Gindt<sup>1</sup>, F. Guenolé<sup>2</sup>, O. Nachon<sup>1</sup>, S. Thümmel<sup>1</sup>

<sup>1</sup> *Hôpitaux pédiatriques, CHU Lenval de Nice, university department of child and adolescent psychiatry, Nice, France;* <sup>2</sup> *CHU de Caen, department of child and adolescent psychiatry, Caen, France*

\* Corresponding author.

**Introduction.**– The terrorist attack during the evening of July 14th, 2016 on the 'Promenade des Anglais' in Nice implicated a high number of families. Therefore, there was immediate need of the implementation of a medico-psychological emergency unit (CUMP) especially dedicated to the high number of children, adolescents and their families exposed to this traumatic event.

**Objectives.**– We describe the organization of early intervention dedicated to children and families and the population received during the first two weeks.

**Results.**– Immediately after the attack, faced to the need of continuous psychological care, a specialized unit for the pediatric population has been created inside the Children's Hospitals of Nice CHU-Lenval. This pediatric CUMP mobilized 126 caregivers over the first 2-weeks period with 57.6% of consultations conducted by a pair-working team.

Overall, 708 individuals have been registered between July, 14th and 28th, 2016, with 576 (81.4%) being present on the 'Promenade des Anglais' during the attack. Consultations included 382 children (53.9%) aged 3 months to 17.7 years and 135 family members (19.1%).

**Conclusions.**– The creation of a pediatric CUMP in the context of a terrorist attack against children and families was a unique experience in France. We describe how this type of specialized early intervention has been organized in order to manage the specificities of the affected public, but also how it could be improved. Our experience underlines the importance of an emergency unit specialized in psycho-traumatism of children, adolescents and their

families, as well as a specialized training of caregivers in order to face similar situations.

### **Prevalence and risk factors of post traumatic stress disorder in a North Cyprus Household Adult Survey**

A. Babayiğit\*, M. Çakıcı

*Near East university, psychology, Nicosia, Cyprus*

\* Corresponding author.

**Introduction.**– Post Traumatic Stress Disorder (PTSD), in other words impairment after post-traumatic difficulty, is one of the most important topics investigated by mental health professionals all over the world.

**Objectives.**– In this article, the results of the 2016 national household survey of PTSD in North Cyprus (NC) are presented. The aim of the study is to determine the prevalence and risk factors of depression in NC households. The study was conducted between April and June 2016, the sample consisting of Turkish-speaking individuals between 18–88 years of age living permanently in NC. A multi-stage stratified (randomized) quota was used in the survey, and 978 people were selected according to the 2011 census. Demographic Information Form, Traumatic Events List and Traumatic Stress Symptom Scale were used.

**Results.**– PTSD prevalence was stated as 19% for NC. Being women, widow, unemployed, housewife, having a physical illness, having a psychiatric illness, being treated by a physical illness, living in a Greek property, living single or with a relative, defined as risk factors of PTSD in the present study.

**Conclusion.**– When we consider the world prevalence, NC has higher PTSD prevalence similar with other post conflict regions in the world. NC has environmental and socio-cultural characteristics such as a history of war, migration and colonization, high unemployment rates, socioeconomic problems, similar to other high prevalence PTSD countries and regions, which give a strong indication of the importance of socio-cultural factors on PTSD.

### **The impact of terrorist attack on medical students intervened at the morgue: Results from psychological evaluations conducted after July 14th in the Nice University Hospital**

C. Bernardi<sup>1</sup>, R. Orio<sup>2</sup>, V. Alunni<sup>1</sup>, G. Quatrehomme<sup>1</sup>

<sup>1</sup> *Faculté de médecine, institut universitaire d'anthropologie médico-légale, forensic pathology and forensic anthropology department, Nice, France;* <sup>2</sup> *Centre hospitalier d'Antibes Juan-les-Pins, service de psychiatrie, Antibes, France*

\* Corresponding author.

**Introduction.**– Following the terrorist attack on July, 14th 2016 in Nice, the Department of Forensic Medicine at the Nice University Hospital was involved for the identification of the victims and the establishment of the causes of death.

100 medical students of the Nice University Hospital were integrated into the process, on a voluntary basis, with specific tasks

to be accomplished, including the transport of human remains between the refrigerated trucks and the mortuary room, and the on-line transcription of the autopsy reports.

*Objective.*– To examine the psychological impact after this intervention on the medical students.

*Methods.*– 1-hour semi-directed interviews were conducted 6 months after the attack, associated with a specific questionnaire assessing psychological trauma, changing the career path, emotional life and vision of world.

*Results.*– Preliminary results from 12 students suggest that the good organization of the intervention led to limited traumatic impact on medical students.

*Conclusion.*– Future doctors had the feeling of learning their profession and being useful to society. In the current context of terrorist threat, such process may be reused and medical students can reasonably play an important role without significant psychological repercussions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Influence of adjuvant mindfulness-based cognitive therapy (MBCT) on Symptoms of post-traumatic stress disorder (PTSD) in Veterans – Results from a randomized control study**

J. Mirzaee<sup>1</sup>, M. Jasbi<sup>1</sup>, D. Sadeghi Bahmani<sup>2</sup>, E. Holsboer-Trachsler<sup>2</sup>, S. Brand<sup>3\*</sup>

<sup>1</sup> Tehran university of medical sciences, department of clinical psychology, Tehran, Iran; <sup>2</sup> University of Basel, psychiatric clinics, Basel, Switzerland; <sup>3</sup> Psychiatric university hospital, center of affective-stress and sleep disorders, Basel, Switzerland

\* Corresponding author.

*Background.*– Even thirty or more years after the end of a war, veterans can suffer from post-traumatic stress-disorder (PTSD). There are various options for the treatment of PTSD. In the present study, we explored the influence on symptoms of PTSD among Iranian veterans of the Iran-Iraq war of mindfulness-based cognitive therapy (MBCT) as add-on to a standard treatment with citalopram.

*Method.*– Forty-eight male veterans with PTSD (mean age: 50.26 years) took part in this eight-week intervention study. Standard treatment for all patients consisted of citalopram (30–50 mg/day at therapeutic dosages). Patients were randomly assigned either to the treatment or to the control condition. Treatment involved MBCT delivered in group sessions once a week. Patients in the control condition met at the hospital with the same frequency and duration for socio-therapeutic events. At baseline and at study completion patients completed questionnaires covering symptoms of PTSD, depression, anxiety, and stress.

*Results.*– At study completion after eight weeks, scores for PTSD (re-experiencing events, avoidance, negative mood and cognition, hyperarousal), depression, anxiety and stress were lower, but more so in the intervention than the control group.

*Conclusions.*– Data suggest that, as adjuvant to standard SSRI medication, MBCT is an effective intervention to significantly reduce symptoms of PTSD, depression, anxiety and stress among veterans.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Emotional content in narrative of trauma in battered women**

M. Crespo<sup>\*</sup>, V. Fernández-Lansac, A. Funcia, C. Soberón, M.M. Gómez-Gutiérrez

Universidad Complutense de Madrid, clinical psychology, Madrid, Spain

\* Corresponding author.

*Introduction.*– Narrative studies have associated the use of emotional expressions and the psychological adaptation after trauma. However, few studies have analysed the relationship between the emotional narrative content and the adjustment after trauma in battered women.

*Objective.*– To analyse emotional content in narrative of violence episodes in battered women and its association with psychological symptoms.

*Method.*– The current study explored the use of emotional expressions in trauma narratives from 50 battered women, by comparing them with stressful narratives from 50 non-traumatized women. Emotional narrative content was assessed using the Coding and Assessment System for Narratives of Trauma (CASNOT) and the Language Inquiry and Word Count (LIWC).

*Results.*– Narratives from battered women contained significantly more words related to a range of negative emotions. Unexpectedly, for the trauma group humiliation/shame and guilt were associated neither with intimate partner violence characteristics nor with psychological symptoms. However, posttraumatic symptoms were associated to the use of more affective words and negative emotions. Discussion: Altogether, the analysis of emotional content in narratives from victims of intimate partner violence could help us to identify specific emotional responses linked to a poor trauma adaptation, and therefore to further develop psychological interventions focused on the management of such emotions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0201

### **Making sense and meaning of trauma in battered women**

M. Crespo<sup>\*</sup>, C. Soberón, A. Gabaldón, V. Fernández-Lansac, M.M. Gómez-Gutiérrez

Universidad Complutense de Madrid, clinical psychology, Madrid, Spain

\* Corresponding author.

*Introduction.*– Making sense appears to be an important cognitive aspect for the individual adaptation to stressful life events. However, evidence is inconclusive. In addition, few studies have explored this aspect in women victims of intimate partner violence, and all of them have used American samples.

*Objective.*– To analyse making sense and meaning of violence episode in battered women and their association with psychological symptoms.

*Method.*– This study analyses trauma narratives by 50 Spanish battered women (trauma group) in comparison with stressful narratives by 50 non-traumatized women (controls). The use of words and language expressions related to making sense were coded using the Coding and Assessment System for Narratives of Trauma (CASNOT) and the Language Inquiry and Word Count (LIWC).

*Results.*– Trauma narratives from battered women contained significantly more words and language expressions related to helplessness, insight, control, uncertainty and causation. However, no significant associations were found between making sense expressions and psychological symptoms. Discussion: Overall, this study

provides further evidence about the role of making sense in the trauma adaptation, specifically for women victims of intimate partner violence. Clinical implications and future research directions will be discussed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0202

### **Autobiographical memory specificity in battered women**

M. Crespo\*, V. Fernández-Lansac, M. Cabezas, C. Soberón, M.M. Gómez-Gutiérrez

*Universidad Complutense de Madrid, clinical psychology, Madrid, Spain*

\* Corresponding author.

*Introduction.*– A number of studies has shown a reduced ability to retrieve specific memories in trauma survivors. Hence, overgeneral memory retrieval has been linked to the development of post-traumatic and depressive symptoms. However, few studies have explored specificity vs. overgenerality in memory retrieval among victims of chronic or repetitive traumas.

*Objective.*– To analyse overgenerality in the memory of trauma in battered women.

*Method.*– The present study assessed overgenerality in trauma narratives from 50 battered women and in stressful narratives from 50 control women using the Coding and Assessment System for Narratives of Trauma (CASNOT).

*Results.*– Battered women reported more specific memories as compared with those from control women. Contrary to expectations, women with PTSD diagnosis and depressive symptoms did not differ significantly in specificity. However, battered women with higher levels of trauma centrality, intrusion symptoms and nightmares reported significantly greater overgeneralization in their trauma memories. Discussion: All in all, a better understanding of autobiographical memory in trauma could lead to the development of innovative strategies focused on the event elaboration for the prevention, detection and treatment of trauma-related symptoms.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0203

### **Panic-related posttraumatic stress disorder**

M. Dolgin<sup>1</sup>, T. Shasha<sup>1</sup>, E. Somer<sup>2</sup>

<sup>1</sup> Ariel university, department of psychology, Ariel, Israel; <sup>2</sup> University of Haifa, school of social work, Haifa, Israel

\* Corresponding author.

Studies have demonstrated significant comorbidity between post-traumatic stress disorder (PTSD) and panic attacks/panic disorder (PA/PD), such that persons diagnosed with PTSD resulting from a traumatic experience are at increased risk for PA/PD. Approaching this association from another direction, and given that PA/PD are often experienced as events that involve threatened death, loss of control or a threat to one's physical integrity, and that the person's response typically involves intense fear and helplessness (i.e., DSM-V Criterion A), the current study assessed the incidence and associated features of panic-related PTSD. One hundred seventy eight participants meeting diagnostic criteria for PA/PD on the Panic Disorder Self Report (PDSR) were assessed for posttraumatic stress in relation to their PA/PD using the Posttraumatic Stress Disorder Checklist-Civilian Version (PCL-C-5). Results indicated that 63 (35.4%) of the participants scored above the cutoff

(PCL-C-5 total scores > 38) for PTSD in relation to the worst PA they had experienced. Adjusted means for the PCL-C-5's four symptom clusters (Re-experiencing, Avoidance, Negative alterations in cognitions and mood, Hyperarousal) indicate that that Panic-related PTSD symptoms are, on average, experienced as "moderately" to "quite a bit." The likelihood of Panic-related PTSD was best predicted by subjective levels of distress, fear of losing control or going crazy, chest pain, agoraphobia, fear of recurrent PAs, and total number of PAs experienced ( $R^2 = 0.33$ ). These findings are discussed in terms of the diagnostic, prognostic, and treatment implications for a subset of individuals presenting with PA/PD who may also be suffering from Panic-related PTSD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Do real-time peritraumatic dissociation experiences during conflict predict posttraumatic stress symptoms? An experience sampling methodology study**

T. Greene\*, M. Gelkopf

*University of Haifa, community mental health, Haifa, Israel*

\* Corresponding author.

*Introduction.*– Dissociation experiences are frequently reported during and after trauma exposure (peritraumatic dissociation). Innovative intensive longitudinal assessment methods, such as experience sampling methodology (ESM), use multiple real-time assessments, thus minimizing recall and ecological biases.

*Objectives.*– This study used ESM in Israeli civilians to assess peritraumatic dissociation (periTD) experiences during the 2014 Israel-Gaza conflict, investigating whether periTD levels, acute dissociative reactivity to rocket warning sirens, and periTD over time, predict subsequent posttraumatic stress symptoms (PTSS).

*Methods.*– 96 Israeli civilians reported siren exposure and dissociation experiences during conflict twice-daily for 30 days via mobile phone. PTSS were measured two months later. Mixed effects models assessed periTD levels, dissociative reactivity to sirens, and the effect of time on periTD. Individual intercepts and slopes were extracted from the model and used as predictors of PTSS in hierarchical regression analyses.

*Results.*– PeriTD levels, but not dissociative reactivity to sirens, predicted PTSS at two months, with higher periTD associated with higher PTSS. When the time slope was added to the model it became the only significant predictor; the less periTD experiences reduced over time during the conflict, the higher the levels of PTSS at two months. The course of periTD during conflict is therefore a stronger predictor of PTSS, than periTD levels and dissociative reactivity to sirens.

*Conclusions.*– These findings show that intense stressful experiences, such as experiencing a rocket siren, can elicit acute dissociation reactions. PeriTD experiences generally reduced over time, indicating habituation. People with more persistent dissociation experiences are more vulnerable to developing PTSS.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0205

### Center of Epidemiologic Studies – Depression Scale (CES-D): A global measurement of depression or four separate dimensions?

R. Jahn<sup>1\*</sup>, R.W. Alexandrowicz<sup>2</sup>, J. Wancata<sup>1</sup><sup>1</sup> Medical university of Vienna, clinical division of social psychiatry, department of psychiatry and psychotherapy, Vienna, Austria;<sup>2</sup> Alps-Adria university Klagenfurt, institute for psychology, Klagenfurt, Austria

\* Corresponding author.

**Introduction.**– The CES-D (Radloff, 1977) is a widely used screening instrument for depression. Despite the 4-factor structure originally suggested the sum score is commonly used and interpreted as proposed by Radloff (1977) herself. However, from a psychometric point of view this is only permitted if all items measure the same latent construct (one-dimensionality assumption).

**Objectives.**– We addressed the issue of dimensionality of the CES-D using Rasch-models. In addition, we investigated the influence of background variables (age and gender) on the response behavior.

**Methods.**– We analyzed data of 518 respondents deriving from a population-based study representative of the general population in Austria. A one-dimensional and a four-dimensional Rasch-model with and without background variables were applied. Infit-measures on item level as well as a DIF analysis for gender and depression were conducted.

**Results.**– The direct model comparison via the LRT (Likelihood-ratio test) identified the four-dimensional model to fit the data significantly better than the one-dimensional one ( $\chi^2 = 398.77$ ;  $df = 9$ ;  $P < 1 \cdot 10^{-10}$ ). Nevertheless, the EAP reliability index of the latent scale of the one-dimensional-model was 0.795. Gender showed a small effect as a background variable and a weak general effect in the DIF-analysis.

**Conclusions.**– The one-dimensional model showed sufficient overall model fit, therefore the use of the CES-D's sum score can be justified from a statistical point of view. However, if one total score is required, we would recommend to compute a sum score only from subscale II (Negative Affect) and subscale III (Somatic Symptoms).

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Sociodemographic and clinical characteristics of patients who had new onset psychiatric symptoms following April 2015 earthquake in Nepal

K. Kafle\*, S. Adhikary, C.P. Sedain

Chitwan medical college, psychiatry, Chitwan, Nepal

\* Corresponding author.

**Introductions.**– Having firsthand experience of a traumatic event can have immediate and long term psychological consequences.

**Objectives.**– We studied socio-demographic and clinical profile of the patients who had new onset symptoms following April 2015 earthquake.

**Methods.**– Previously asymptomatic patients who had developed psychiatric symptoms within 24 hours of April earthquake or its aftershocks and having such symptoms for less than 1 month at the time of first visit were included in the study. Patients were assessed with study-specific socio-demographic profile sheet and Trauma Symptom Checklist-40. Descriptive statistics were used for analysis of result.

**Results.**– Female constituted majority of the symptomatic patients. They were mainly from urban locality. More than 50% patients had predominant physical complains so they first visited other specialties from where they were referred to psychiatric services. More than half of the patients had onset of symptoms after subsequent aftershocks. Among all, 22% fulfilled diagnosis of co-morbid alcohol use disorders and 11% had history of mental illness in first degree relatives. Most common presentations were Anxiety and Dissociative symptoms. Dizziness, Anxiety attacks and Restless sleep were the individual symptoms which most patients reported.

**Conclusion.**– Female are more prone to develop psychiatric symptoms following exposure to traumatic events. Aftershocks, though are of lesser magnitude, can have more pronounced psychological consequences than the initial major quake can do. Physical complains can divert patients from seeking mental health service to other specialties and if not properly evaluated they can be misdiagnosed. Follow up studies are needed to know how these symptoms evolve over time.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0207

### Secondary traumatization, dyadic adjustment and differentiation of the self among wives' of ex-prisoners of war

R. Lev-ari<sup>1\*</sup>, D. Horesh<sup>1</sup>, Z. Solomon<sup>2</sup><sup>1</sup> Bar Ilan university, psychology, Ramat Gan, Israel; <sup>2</sup> Tel Aviv university, social work, Tel Aviv, Israel

\* Corresponding author.

**Background and objectives.**– Prisoners of war (POWs) endure a severe trauma. People close to trauma victims, such as spouses, may also develop psychological and emotional difficulties. This phenomenon is called “secondary traumatization”. Several theories suggest dysregulated inter-personal distance as a general mechanism, which may explain vulnerability to others' distress. The present study aims to examine the role of differentiation of self (i.e., fusion vs. individuality) in secondary traumatization, as well as its complex inter-relationships with marital adjustment, among wives of Israeli ex-POWs.

**Methods.**– This study is part of a longitudinal study assessing ex-POWs and their spouses. Wives of 161 veterans who have fought in the Yom-Kippur War (106 wives of ex-POWs and 55 controls), completed self-report questionnaires regarding secondary PTSD, differentiation and dyadic adjustment.

**Results.**– Wives of ex-POWs reported more secondary PTSD symptoms, more fusion and less dyadic adjustment compared to controls. Significant associations were found between secondary PTSD symptoms, dyadic adjustment and fusion. Interactions were found between fusion and dyadic adjustment in relation to PTSD levels. Among women who showed high levels of fusion, dyadic adjustment was associated with PTSD levels, whereas there was no association found under low levels of fusion.

**Conclusions.**– Our results can be interpreted in light of the original theories of secondary traumatization, which emphasize the importance of a non-enmeshed style of caregiving. Mental health professionals may benefit from a deeper understanding of specific factors that are associated with secondary traumatization. In particular, couples' differentiation patterns may be targeted during therapy, as a way to reduce trauma symptoms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0208

### **System approach to stress research: How convergence of genetics, neurobiology and connectomics can facilitate the search for novel biomarkers**

A. Pashkov

South Ural State university, biomedical school, Chelyabinsk, Russia

\* Corresponding author.

*Introduction.*– Stress is considered as a subject of study in both psychological and medical-biological disciplines. However, an interdisciplinary study of stress requires the development of unified framework that would allow to integrate the data obtained from separate scientific disciplines.

*Objectives.*– Our aim was twofold: (1) to figure out and systematize the main directions and findings in stress research field; (2) to describe the main theoretical provisions of interdisciplinary research from the viewpoint of a system approach bridging the gap between micro-scale (genetics and molecular neurobiology of stress) and macro-scale (stress-induced alterations in structural, functional and effective connectomes);

*Methods.*– A systematic review of the scientific literature on the subject of current state of affairs in the field of genetic, molecular, network, electrophysiological biomarkers of stress was conducted for the period from January 2007 to December 2016, using Google Scholar, Science Direct and PubMed databases.

*Results.*– One hundred thirty four studies met the inclusion criteria. We found that the patterns of organism's response to stressors cannot be fully determined without taking into account the system grounds for the formation of such a response, relying solely on correlative approaches in modern neuroscience.

*Conclusions.*– The application of the system approach for studying the problem of stress allows us to postulate the feasibility and utility of integration the approaches of dynamic system theory and computational neuroscience with the data accumulated by now in the mainstream of psychology, physiology, medicine to deepen our understanding of stress biomarkers.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Emergency organization of child psychological care during the first 48 hours following the terrorist attack on July 14th, 2016, in Nice, France**

S. Thümmeler<sup>1</sup>, M. Gindt<sup>1</sup>, L. Chauvelin<sup>1</sup>, B. Olliac<sup>2</sup>, P. Robert<sup>3</sup>, F. Askenazy<sup>1</sup>

<sup>1</sup> Hôpitaux pédiatriques, CHU Lenval de Nice, university department of child and adolescent psychiatry, Nice, France; <sup>2</sup> Esquirol hospital, department of child and adolescent psychiatry, Limoges, France;

<sup>3</sup> University Côte d'Azur, CoBTek, Nice, France

\* Corresponding author.

*Introduction.*– On July 14th, 2016, in Nice, France, a terrorist attack occurred along the 'Promenade des Anglais'. Around 30,000 people were present including many babies, children and their parents. Therefore, it seems particularly important to testify our experience of the emergency psychological care setup for the pediatric population.

*Objectives.*– We describe (1) the organization of the early intervention dedicated to children and families, and (2) the population received during the first 48 hours.

*Results.*– The psychological care setup was organized within the hour following the attack within the Children's Hospitals of Nice, including 6 child and adolescent psychiatrists caregivers the first night. In the following, three teams turned over each day, receiving at least 163 individuals (99 children and 64 adults) during the first 48 hours.

We observed anxiety, depressive and acute stress reactions; dissociative responses with derealisation, depersonalization and amnesia; as well as somatic symptoms. The main objective of the immediate therapeutic intervention was to provide a secure framework, to give information, to contain the distress of individuals, and to arrange early preventive interventions for post-traumatic reactions.

*Conclusion.*– In the actual context, it seems necessary to describe and pool different experiences of psychological emergency care for the pediatric population after terrorist attacks. Our experience leads us to conclude that it seems necessary to adapt the logistics and training of health care workers to psychotrauma and its paediatric specificities in order to be able to cope with an unexpected emergency situation of mass psychotrauma as experienced in Nice.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **A survey on methodological characteristics described in health qualitative studies published in pubmed database in a recent period of six months**

R.A. Bastos, V.L.P. Alves, R.M.C. Sena, L. Rodrigues, J.V. Freitas-de-Jesus, F.G.C. Surita, E.R. Turato  
UNICAMP, Universidade Estadual de Campinas, medical psychology and psychiatry, laboratory of clinical-qualitative research, Campinas, Brazil

\* Corresponding author.

*Introduction.*– Describing health studies with qualitative approaches regarding technical and methodological features, we can favour the understanding of its validity and employment as a scientific method. This academic approach focuses on exploring the life experienced subjectivity of certain phenomena within the field and health sciences.

*Objective:* The purpose of the study was to know and to discuss the characteristics of qualitative studies published in biomedical and health journals from a reputed international database.

*Method.*– We performed bibliographic search of qualitative studies published in periodicals indexed in PubMed in a six-month period of 2016, through keywords. We analysed the articles according to: published periodical, number of authors, reference to the expression "Qualitative Study" in the title, verb of the general objective, method used, type of study participants, sample size, data collection technique, analysis technique data, software use, and research topic.

*Results.*– We found 1870 articles. The journals that publish articles on general health topics focus on the top of the 579 different periodicals covered. Most authors focus on the United States of America and the United Kingdom (54.2%). The most searched objective of qualitative health research is "Explore" (35.7%), the individual interview is the most frequent data collection technique (71.9%) and the thematic analysis of content (29.6%), the most used analysis technique. Analysis software was used in only 4.7% of qualitative health research.

*Conclusion.*– Scientific production using qualitative methods is much diversified and many not yet published by journals whose themes are more specific to health.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Post-traumatic stress disorder and depression among adults survivors of the 7.8 magnitude earthquake in Ecuador**

V. Valdez<sup>1\*</sup>, C. Santana<sup>2</sup>, M. Cajas<sup>1</sup>, D. Reyes<sup>1</sup>, E. Avila<sup>1</sup>, V. Naranjo<sup>1</sup>, V. Cevallos<sup>1</sup>, D. Orellana<sup>1</sup>, M. Borja<sup>1</sup>

<sup>1</sup>Universidad Catolica Santiago de Guayaquil, psychiatry, Guayaquil, Ecuador; <sup>2</sup> Universidad Catolica Santiago de Guayaquil, investigation, Guayaquil, Ecuador

\* Corresponding author.

*Introduction.*– In April, 2016, a 7.8 magnitude earthquake affected the Ecuadorian coast, leaving 673 deaths, and 28.775 people living in shelters. The economy and health conditions were severely affected, situation that persists.

*Objective.*– To determine the prevalence of post-traumatic stress disorder (PTSD) and Depression among adults survivors, after 10 months of the earthquake. The sample was collected in Pedernales, Manabi, the earthquake's epicenter, a rural area of Ecuador.

*Methods.*– A cross-sectional prevalence study was performed in a random sample of 93 adults (37 men, 56 women). They lived in Pedernales during the earthquake. We randomly chose 42 participants who lived in shelters and 52 in the surrounding areas nearby the shelters. The scales used were: the Davidson Trauma Scale (DTS), the PCL 5 and the Beck depression inventory (BDI). Premedical students collected the sample; they were trained to offer scales information.

*Results.*– The median age of the sample was 29 [22–44.5], 38 (41%) single, 73 (79%) at least 1 child, 84 (94%) primary level education, 14 (15%) reported alcohol abuse. According to DTS, 61 participants (66%) were positive for PTSD. PCL 5 reported 30% of PTSD. BDI showed 20% minimal depression, 10%, mild depression, 4% moderate and 3% severe depression.

*Conclusions.*– After 10 months of the earthquake, PTSD was positive at 66%. People with higher educational level were more likely to be affected on PTSD and depression ( $P \leq 0.05$ ). The educational factor was a challenge; the residents could not manage the self-rating scales. The Province of Manabi-Ecuador, has an urgent need to be fulfilled.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Men raped in war captivity – Consequences even 20 years later**

A. Vlastic<sup>1\*</sup>, F. Kovac<sup>2</sup>, M. Arambasic Odak<sup>3</sup>, D. Ivanisevic<sup>4</sup>

<sup>1</sup> Faculty of humanistic sciences, university Hercegovina, psychology, Livno, Bosnia, Herzegovina; <sup>2</sup> Institute for medical assessment of health status, medical expert of second instance proceedings, Sarajevo, Bosnia, Herzegovina; <sup>3</sup> Institute for medical assessment of health status, head of division for first instance procedure, Mostar, Bosnia, Herzegovina; <sup>4</sup> Faculty of education, university Dzemal Bijedic, psychology, Mostar, Bosnia, Herzegovina

\* Corresponding author.

*Introduction.*– The war in Bosnia and Herzegovina ended over 20 years ago, but the consequences are still visible. Probably the greatest taboo of war are hundreds of men raped in war captivity. Women stood up long ago, but men kept quiet for a long time. Their stories have different dimension then those of raped women. Their

voices need to be heard. There are no known researches examining extensive consequences of male rape in war.

*Objectives.*– We hypothesised higher risk of different mental health problems and personality changes among men who experienced rape in war captivity than those who didn't experience rape in war captivity and control group.

*Methods.*– 80 men who were raped in war captivity are compared to 80 men not raped in war captivity and 80 men of the same age, who lived in Bosnia and Herzegovina during war, but had no war-traumas (control group).

*Results.*– Men who were raped in war captivity showed higher prevalence of suicide attempts, psychosomatic symptoms, self-destructive behaviour, sleeping difficulties, marital and sexual dissatisfaction compared to two other groups ( $P < .05$ ) even two decades later. The most valuable findings are personality differences between men who were raped and men who were solely kept in captivity and control group.

*Conclusions.*– The war rape among men has expected intensive long-term effects on mental health but also personality changes that were not found in other populations. Better psychological support is needed as well as research on transgenerational effects of trauma.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **A microgenetic approach to the relationship between creativity and aggression in mental disorders**

H. Yaniv<sup>1\*</sup>, J. Glicksohn<sup>2</sup>

<sup>1</sup> Bar Ilan university, criminology, Jerusalem, Israel; <sup>2</sup> Bar Ilan university, criminology, Ramat Gan, Israel

\* Corresponding author.

The lecture will present a research investigates the connection between creativity and aggression in different mental disorders, and examining their mutual influence on each other, in reference to Eysenck's three dimensions of personality, as well as to other personality's traits. The study examines five different groups: (1 and 2) individuals dealing with mental disorders – with or without a background of aggression; (3) creative-individuals; (4) aggressive-individuals; (5) and a control group. The main comparison focuses on examining cognitive psychopathology which leads the positive aspect to creativity on the one hand, and the negative aspect to aggression on the other hand.

These topics are investigated by using various questionnaires as well as by the microgenetic-method, which uses visual stimulation, in this study artworks. By using this method it is possible to investigate the influence of visual perception of stimuli and the way individual projects his or her inner world and personality is tested by examining the projection content toward the stimulus.

The expectation is to find relationship between creativity and aggression, especially in psychopathology groups. This relationship connects broadly to the psychoticism dimension of Eysenck's three personality dimensions, which is also expected to be high among the pathologies groups. These pathology populations were deliberately chosen because they are on the extreme expression of various personality traits and dimensions, particularly the aspects related to measures of creativity and aggression. Consequently, psycho-therapy for those populations can be suited specifically to the individual's profile, using different creative therapy methods. First results will presents.

### Bipolar disorder and schizophrenia with postpartum onset: Clinical cases study

F. Amdouni\*, R. Damak, H. Maatallah, I. Berrahal, W. Cherif, S. Ellini, M. Cheour

Razi hospital, psychiatry E, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Postpartum psychosis can be isolated or inaugurate either schizophrenia or bipolar disorder. The clinical course of this entity is still unspecific and few studies focused on acute and follow up characteristics predicting outcome of this first episode.

**Aims.**– The aim of our study is to describe clinical course of first postpartum episode psychosis in schizophrenia and bipolar disorder.

**Methods.**– It is a retrospective study. We collected the cases of female patients hospitalized between 2011 and 2017, in department “E” of psychiatry in Razi hospital, for first psychotic episode. We studied the clinical characteristics of acute episode, quality of follow up (treatment adherence and relapses frequency) and diagnostic stability.

**Results.**– 9 patients were included in the study. 5 have bipolar disorder and 4 are schizophrenic. Both groups had mood disorders in first postpartum episode psychosis. Patients who presented mania in postpartum psychosis seem to evaluate to bipolar disorder. Patients with depressive disorder showed diagnosis instability. No difference in adherence treatment or relapses frequency was observed between the groups.

**Conclusion.**– The outcome of postpartum psychosis is still unclear. Depressive mood disorder is still a confusing element between schizophrenia and bipolar disorder, which causes delayed diagnosis. Future studies should focus on first episode psychosis in postpartum period in order to enhance therapeutic care.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Dynamics of formation of psychopathological disturbances in premenstrual syndrome

M. Belokrylova<sup>1</sup>, N. Garganeeva<sup>2</sup>, Y. Zinkevich<sup>3</sup>

<sup>1</sup> Mental health research institute, Tomsk national research medical center, Russia, borderline states department, Tomsk, Russia;

<sup>2</sup> Siberian state medical university, general medical practice and polyclinic therapy department, Tomsk, Russia; <sup>3</sup> Women's health center, gynecology department, Tomsk, Russia

\* Corresponding author.

Cyclical alterations in the females of reproductive age are frequently accompanied by psychopathological disturbances manifested as transient alterations in emotional, cognitive and behavioral spheres.

**Objective.**– To study dynamics of formation of psychopathological disturbances in premenstrual syndrome.

**Material and methods.**– 75 women with neuropsychiatric form of premenstrual syndrome aged 18–41 years were examined. Methods used: clinical, anamnestic, clinical-psychopathological, clinical-dynamic, statistical. Mental status and dynamics of disorders were evaluated according to ICD-10; Zung Depression Scale,

Zung Self Rating Anxiety Scale, and Hamilton Anxiety Rating Scale were used.

**Results.**– Two variants of neuropsychiatric form of premenstrual syndrome (PMS) were revealed. Their difference was characterized by presence of anxiety-depressive disorders only in the first (luteal) or in both phases of the menstrual cycle. Variant 1 was characterized by anxiety-depressive disorders' presence in the follicular phase that became more substantial in the luteal phase of the menstrual cycle; high level of comorbidity with neurotic, stress-related disorders was revealed (65%). Variant 2 was represented by neuropsychiatric form of PMS with cyclically emerging anxiety-depressive disorders in the luteal phase of the menstrual cycle. The association between this variant and demonstrative type of accentuation of the personality (45%) was shown. Anxiety and anxiety-depressive syndrome determined mental status.

**Conclusions.**– Presence of neurotic, stress-related disorders in anamnesis of women of reproductive age was associated with longer duration of psychopathological disturbances during the cycle and major degree of severity of the premenstrual syndrome. Short-term manifestations of anxiety-depressive disorders in the luteal phase of cycle were more frequently associated with personality deviations.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Psychiatric comorbidity, self-esteem and intimate partner violence in women with infertility

S. Bondade<sup>1</sup>\*, R. Iyengar<sup>2</sup>

<sup>1</sup> The Oxford medical college hospital and research center, psychiatry, Bangalore, India; <sup>2</sup> The Oxford Medical college hospital and research center, obstetrics and gynaecology, Bangalore, India

\* Corresponding author.

**Introduction.**– Child bearing in Asian countries is a social obligation. Experience of infertility profoundly affects the personal well-being of women. Women with infertility are at a higher risk of anxiety, depression, and Intimate partner violence (IPV) poor quality of life compared to fertile women.

**Objective.**– To assess the psychiatric comorbidity, self-esteem and intimate partner violence in women with infertility.

**Methodology.**– Hundred women with primary infertility in the age group of 18 years to 45 years were included. Socio demographic details were collected. Psychiatric diagnosis was made according to DSM-V. Following scales were applied:

- the WHO violence against women instrument;
- Hamilton Anxiety Rating scale (HAM-A);
- Hamilton Depression Rating Scale (HAM-D);
- Rosenberg self-esteem scale (RSES).

**Results.**– The mean age of the 100 women was 26.73 ± 4.23 years, duration of marriage was 7.11 ± 4.177 years and duration of infertility treatment in years was 5.56 ± 3.89. The prevalence of IPV among patients was 50% and psychiatric comorbidity was 46%.

When we compared the women who experienced IPV and who did not, the prevalence of anxiety disorder and depressive disorder was high among IPV group. Anxiety, depressive scores in HAM A, HAM D were higher and self-esteem was low in IPV group compared to the other group and was statistically significant (Table 1).

**Conclusion.**– A significant number of women who had infertility reported IPV. This emphasize the importance of screening of IPV in these women. It is observed that women with IPV had higher psychiatric comorbidity and low self-esteem and may require psychotherapeutic intervention.

Table 1 Comparison of women with IPV and No IPV in infertile patients.

Variables		IPV absent N=50	IPV present N=50	Statistical analysis
Psychiatric diagnosis	W	40	14	$\chi^2=27.28$ $p<0.001$
	Depression	5	20	
	Anxiety disorder	5	16	
HAND		9.4±6.16	13.16±7.58	t=6.336 $p<0.001$
HANA		11.1±4	15.4±2.86	t=6.179 $p<0.001$
ISES		19.74±3.22	13.72±3.896	t=8.416 $p<0.001$

### Psychopathological side-effects of hormonal contraception: A meta-analysis of randomized placebo-controlled trials

N. Brondino<sup>1</sup>, E. Codrons<sup>2</sup>, E. Martini<sup>3</sup>, R. Nappi<sup>3</sup>

<sup>1</sup> University of Pavia, department of brain and behavioral sciences, Pavia, Italy; <sup>2</sup> University of Pavia, department of public health, experimental and forensic medicine, section of hygiene, Pavia, Italy;

<sup>3</sup> University of Pavia, research center for reproductive medicine, gynecological endocrinology and menopause, IRCCS S. Matteo Foundation, department of clinical, surgical, diagnostic and pediatric sciences, Pavia, Italy

\* Corresponding author.

*Introduction.*– Despite a long debate, there is no consistent evidence of the presence and extent of psychopathological side-effect of hormonal contraception. However, these side-effects are often reported as the main motive of hormonal contraception discontinuation and poor compliance.

*Objectives.*– The aim of the present meta-analysis is to evaluate the psychopathological effect of hormonal contraception in healthy women.

*Methods.*– We searched Web of Science and Embase (from database start date to August 2017) for articles with the keywords (“contraception”, “anxiety”, “depression”, “randomized”) and related MESH terms combined with Boolean operators. We selected all randomized placebo-controlled trials yielding data on the effect of hormonal contraception on psychological symptoms in healthy women. Statistical analysis was conducted using Comprehensive Meta-Analysis 2.0 and RevMan 5.3.

*Results.*– The literature search identified 440 publications. After title/abstract screening, 39 publications were obtained for detailed evaluation, of whom 11 were deemed useful for meta-analytical purposes.

*Conclusions.*– There is still need for well-designed larger randomized trials in order to better elucidate this issue.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The effect of perinatal depression on breastfeeding habits and child growth in a low-income setting

C.E. Holm-Larsen<sup>1</sup>, F. Kjerulff Madsen<sup>1</sup>, G.N. Sigalla<sup>2</sup>, M. Declare<sup>2</sup>, D.W. Meyrowitsch<sup>3</sup>, R. Manongi<sup>2</sup>, J. Rogathi<sup>2</sup>, T. Gammeltoft<sup>4</sup>, V. Rasch<sup>1</sup>

<sup>1</sup> University of southern Denmark, research division of gynecology and obstetrics, department of clinical research, Odense C, Denmark;

<sup>2</sup> Kilimanjaro Christian medical university college, department of public health, Moshi, Tanzania; <sup>3</sup> University of Copenhagen, department of public health, Copenhagen, Denmark; <sup>4</sup> University of Copenhagen, department of anthropology, Copenhagen, Denmark

\* Corresponding author.

*Introduction.*– The incidence of perinatal depression in low-income countries is between 12 and 35%. Perinatal depression is likely to have an adverse effect on child growth, through a negative impact on the stress responsive system of the unborn child, the breastfeeding habits, and the mothers self- and childcare abilities. An increased focus on mental health and its risk factors could have a positive impact on both maternal health and child mortality.

*Objectives.*– The aim of the study was to assess the effect of perinatal depression on breastfeeding practices and child growth.

*Methods.*– A prospective cohort study was performed among pregnant women attending antenatal care in Moshi, Tanzania. Participants, women and their children, were followed until 6–8 weeks postpartum, and again at 2–3 years postpartum using a questionnaire and recordings of anthropometric measurements. Breastfeeding practices were recorded on a dichotomous scale as exclusive breastfeeding for 6 months or less. Child growth outcomes were measured as continuous variables via Z-scores.

*Results.*– Of the 1233 mother–child pairs that were eligible for this follow-up, 1196 were included in the study (follow-up rate of 97%). Further analyses are currently underway.

*Conclusions.*– The results of the study will help close the data gap concerning maternal mental health and its risk factors in low-income settings.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Mental health and self-esteem during pregnancy: A follow of study

Ö. Kısaoğlu<sup>1</sup>, P.D.H. Tel<sup>2</sup>

<sup>1</sup> Cumhuriyet university health science institute, psychiatric nursing master programme, Sivas, Turkey; <sup>2</sup> Cumhuriyet university health science faculty, Cumhuriyet university health science faculty, Sivas, Turkey

\* Corresponding author.

Recently, in terms of mental disorders, pregnancy being a preventive or “feeling good” period has not been an accepted thought anymore. Pregnancy is a natural life crisis for females. An increase in level of anxiety in pregnant women, emotional swings, crying tends to be more sensitive and vulnerable to mental changes such as and depression, anxiety disorder, obsessive-compulsive disorder, may be observed According to the trimesters, woman’s feelings and response to the woman during pregnancy is different. Pregnant women, during pregnancy important psychological, physiological and emotional changes live. These changes also affect body perceptions and subsequent self-esteem. While these differ-

ences influence of women mental health, they also make them more inclined to psychiatric illnesses.

This study is to evaluate the mental health and self-esteem during pregnancy. For this reason, at first trimester, at second trimester and at third trimester 107 pregnant women were included in the study. All women were three times evaluated with Brief Symptom Inventory and Rosenberg Self-esteem Scale. The first pregnancy of 57% of pregnancies, the planned pregnancy of 72%. There is a statistically significant negative correlation between the self-esteem score and the short symptom inventory scores. Depression, anxiety, somatization, hostility scores and self-esteem scores were decreased in the second trimester, and increased in the third trimester. There was a statistically significant difference between variables such as educational status, working status, income status, family type, number of pregnancies and short symptom inventory scores ( $P < 0.05$ ).

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Intimate partner violence during pregnancy: Child growth and breastfeeding outcomes**

F. Kjerulff Madsen<sup>1</sup>, C.E. Holm-Larsen<sup>2</sup>, J. Rogathi<sup>3</sup>, R. Manongi<sup>3</sup>, D. Mushi<sup>3</sup>, D. Meyrowitsch<sup>4</sup>, T. Gammeltoft<sup>5</sup>, G. Sigalla<sup>3</sup>, V. Rasch<sup>1</sup>

<sup>1</sup> University of Southern Denmark, research division of gynecology and obstetrics, department of clinical research, Odense, Denmark;

<sup>2</sup> Research division of gynecology and obstetrics, department of clinical research, university of Southern Denmark, Odense C, Denmark; <sup>3</sup> Kilimanjaro Christian medical center, department of public health, Moshi, Tanzania; <sup>4</sup> University of Copenhagen, department of public health, Copenhagen, Denmark; <sup>5</sup> University of Copenhagen, department of anthropology, Copenhagen, Denmark

\* Corresponding author.

*Background.*– Intimate partner violence (IPV) is a global problem that affects 1/3 of women worldwide.

Research suggests that IPV has a negative impact on breastfeeding and child growth, but the data gap is still substantial. Specifically, pregnancy related studies are needed.

*Objective.*– The objectives of this study are to assess the effect of IPV during pregnancy on breastfeeding and child growth.

*Method.*– The study consists of a cohort of women from Moshi, Tanzania. The women were enrolled during pregnancy in 2014–2015 and followed up with interviews during pregnancy, after birth and 2–3 years postpartum. Anthropometric measures were registered for the children.

Breastfeeding practices were registered on a dichotomous scale as either exclusive or not exclusive breastfeeding until at least 6 months of age and will be analyzed with a logistic regression model. Child growth outcomes are measured as continuous variables via Z-scores for height-for-age, weight-for-height and weight-for-age and will be analyzed with a linear regression model.

IPV was assessed during pregnancy and physical, sexual and psychological violence will be analyzed separately and combined.

*Results.*– Out of 1233 women eligible for the study, 1195 women completed all relevant interviews, resulting in a follow-up rate of 96.9% after 3 years.

Analyses are currently being carried out. Further results will be presented.

*Conclusion.*– The results of this study will help uncover the relationship between pregnancy related violence and child health in Tanzania.

### **Lithuanian suicide rate and allostatic load – Putting the pieces together**

A. Lengvenytė<sup>1</sup>, R. Strumila<sup>2</sup>

<sup>1</sup> Vilnius university, faculty of medicine, clinic of psychiatry, Vilnius, Lithuania; <sup>2</sup> Clinic of psychiatry, Vilnius, Lithuania

\* Corresponding author.

*Introduction.*– Lithuania has one of the highest suicide rates, which peaked in 1995, four years after the independency from Soviet Union. Constant challenges in a new country may have caused suicides not only directly, but also by inducing a plethora of metabolic changes that may be explained by allostatic load paradigm. Allostasis describes mechanisms that change the variable by predicting future demand and overriding local feedback to meet it. While it is vital for adaptation, excess challenges lead to inefficient response by adaptive systems. This phenomenon is called allostatic load.

*Objectives.*– To find out whether allostatic load is a plausible explanation of the high Lithuanian suicide rate.

*Methods.*– Literature search in PubMed was carried out.

*Results.*– It is proven that stress causes a wide-waisted phenotype. Lithuanians waist to hip ratio has increased significantly during independency. A possible mechanism for that is through allostatic load, caused by various stressors, that leads to hyperinsulinemia and insulin resistance. LiVicordia study from year 1992, where Lithuanian men showed an attenuated cortisol response to the laboratory stress test, compared to Swedes, supports this hypothesis [1]. Allostatic load has been linked to anxiety, depression and addiction – states that are highly correlated with suicide.

*Conclusions.*– Too big allostatic load, caused by constant multiple stresses linked to transition in country economic, political and institutional system, without time to adjust, may be behind the country's high suicide rate.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Trajectories of maternal prenatal stress, depression, and anxiety, and their association with prematurity and neonatal outcomes**

H.A. Lim<sup>1</sup>, T.E. Chua<sup>2</sup>, R. Malhotra<sup>3</sup>, J.C. Allen- Jr<sup>4</sup>, I. Teo<sup>3</sup>, K.H. Tan<sup>5</sup>, H. Chen<sup>2</sup>

<sup>1</sup> Duke-NUS medical school, office of education, Singapore, Singapore;

<sup>2</sup> KK women's and children's hospital, psychological medicine, Singapore, Singapore; <sup>3</sup> Duke-NUS medical school, health services and systems research, Singapore, Singapore; <sup>4</sup> Duke-NUS medical school, centre for quantitative medicine, Singapore; <sup>5</sup> KK women's and children's hospital, maternal fetal medicine, Singapore

\* Corresponding author.

*Introduction.*– Maternal prenatal distress has controversially been associated with poor foetal outcomes; past work has often used only one assessment to represent the entire pregnancy without adjusting for prematurity. This prospective cohort study sought to (1) identify trajectories of prenatal distress (stress, depression, and anxiety) throughout pregnancy, and (2) determine the influence of the delineated prenatal distress trajectories on neonatal outcomes (prematurity and neonatal anthropometry).

*Methods.*– 926 healthy women with singleton pregnancies from a tertiary hospital in Singapore self-reported symptoms of stress

(PSS), depression (EPDS), and anxiety (STAI) during their first, second, and third trimesters, and before birth. Neonatal body weight (kg), length (cm), head circumference (cm) and gestational age (weeks) were recorded at birth. Prenatal distress trajectories were estimated via latent growth mixture models; their association with gestational age and neonatal anthropometry were determined via regressions.

**Results.**– Analyses suggested that women fell into either: (1) High-Stable (HS; scoring consistently above recommended instrument cut-offs); (2) Subclinical/Subthreshold (hovering consistently at or just above/below recommended instrument cut-offs); or (3) Low-Stable (scoring consistently below recommended instrument cut-offs) trajectories through the pregnancy. Only the HS depression trajectory was associated with shorter gestations ( $\beta = -.068$ ,  $P < .05$ ). After adjusting for gestational age, only the HS stress trajectory was associated with lower birth weights ( $\beta = -.058$ ,  $P < .05$ ) and smaller head circumferences ( $\beta = -.071$ ,  $P < .05$ ).

**Conclusions.**– Women maintain relatively stable distress symptoms throughout the pregnancy, which highlights the potential for early identification of women at-risk for HS trajectories. When coupled with early and appropriate interventions, these may also improve neonatal outcomes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Stockholm syndrome, a rare psychological disease: Results of the development, validation and real life application of the Stockholm Syndrome Scale**

S. Obeid<sup>1\*</sup>, S. Hallit<sup>2</sup>

<sup>1</sup> Psychiatric hospital of the Cross, psychology, Beirut, Lebanon;

<sup>2</sup> Psychiatric hospital of the Cross, research, Jal-Eddib, Lebanon

\* Corresponding author.

**Objective.**– To validate the Stockholm Syndrome Scale (SSS) and assess the role of this syndrome at the level of activation of early maladaptive schemas in women that are victims of marital violence.

**Methods.**– This case-control study, performed between April and August 2016 in 3 specialized centers for women abuse, included 30 women (14 cases and 16 controls).

**Results.**– The SSS items converged over a solution of two factors, explaining a total of 85.33% of the variance. The internal consistency of the scale was high, with a high Cronbach's alpha found for the full scale (0.936). Having a severe level of fusion, a moderate level of dependence on the partner and being beaten in a frequency of multiple times per month would significantly increase the SSS score (Beta = 48.37; Beta = 58.03 and Beta = 12.587) respectively. Having a moderate level of fusion, a moderate and severe level of sacrifice would decrease the SSS score (Beta = -56.30; Beta = -56.53 and Beta = -55.83) respectively.

**Conclusion.**– This study highlighted the correlation between dysfunctional cognitive schemas, developed during childhood and adolescence, and the development of the Stockholm syndrome in women victims of domestic violence.

**Keywords:** Stockholm syndrome; Fusion; Dependence; Beating

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Violence of a couple affected by men in a heterosexual relationship: Sociodemographic and emotional aspects**

I. Ramos Vidal<sup>1\*</sup>, M. Muñoz Argel<sup>2</sup>, A.M. Romero Otalvaro<sup>2</sup>, A. Uribe<sup>2</sup>, I. Villamil<sup>2</sup>

<sup>1</sup> Faculty of psychology, department of social psychology, Sevilla, Spain; <sup>2</sup> Universidad Pontificia Bolivariana, department of social psychology, Monteria, Colombia

\* Corresponding author.

**Introduction.**– Gender violence has become a public health issue because of the problems it produces at the individual, family and societal level (WHO, 2016). In 2016, 731 women were killed in Colombia by their partners.

**Objectives.**– The research aimed to assess emotional processing, emotional and/ affective regulation and impulse control by and to establishing a comparison between the variables evaluated, in a sample of men who effected violence in a heterosexual couple and conduct a hearing in the “judicial Court” of the city Monteria (Colombia).

**Methods.**– To collect the information, a structured interview was carried. A questionnaire was applied to evaluate out and three domains of emotion recognition scales were applied. Sixty men were selected by random sampling based on cases of violence hearing in “judicial Court”, and previous consent to participate in the study. Participants signed an informed consent and were informed of the purpose of the investigation.

**Results.**– This research highlights the show the important role of relevant sociodemographic characteristics in the detonation of violent behaviors against the couple. In particular, the most important factors are: (a), the antecedents history of violence in the family context, (b) the patterns of parenting based on physical punishment and (c) low educational level.

**Conclusions.**– These results demonstrate the need to implement prevention programs focused on education in values and the development of parenting models based on dialogue. The educational contexts are privileged environments to implement this type of programs since the violence of couple occurs at earlier ages.

**Keywords:** Violence in the couple; Emotional regulation; Emotional dependence

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Intimate dating violence in Iranian university students: A cross-sectional study**

Z. Shahhosseini<sup>\*</sup>, Z. Hamzehgardeshi, K. Abedian-Kasgary  
Mazandaran university of medical sciences, department of reproductive health and midwifery, Sari, Iran

\* Corresponding author.

**Introduction.**– Although intimate dating violence has been researched for many years, this issue only in recent years has been considered as one of the health concerns around the world.

**Objectives.**– This study was conducted to assess intimate dating violence in Iranian university students.

**Methods.**– A cross-sectional survey by data collection from 430 female and male university students from three higher educations in northern Iran was established in 2015. They were enrolled through by the stratified cluster random sampling method and were requested to fill out the demographic data form and to answer

the questions about abusive behaviors through Persian version of youth risk behavior survey questionnaire. Descriptive and inferential statistics were used for data analysis via the SPSS v.16 software. *Results.*– The mean age of the participants was  $21.9 \pm 8.26$  years (ranged from 18 to 35 years) and 43.5 percent of them were female. In this study 9.1 percent of the university students reported being hit, slap, or physically hurt by a boyfriend or girlfriend during the last 12 months. In addition, 6.7 percent of them reported being physically forced into sexual relationship. No statistically significant difference was reported in dating violence between the male and female university students ( $P > 0.05$ ).

*Conclusion.*– Evidence supports that male university students expose to dating violence as well as female ones, so the screening programs must be implemented to both genders.

*Keywords:* Intimate dating violence; Dating violence; Young people

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Spectrum of medical and social problems in the female opium addicts**

F. Shigakova

*Tashkent institute of postgraduate medical education, department of psychiatry and psychotherapy, Tashkent, Uzbekistan*

\* Corresponding author.

*Aim.*– The work was initiated to study peculiarities of medical and social c problems of the female opium addiction.

*Materials and methods.*– We examined 56 female opiate addicts aged from 18 to 56. To be included into the study the patients were to be diagnosed with ICD 10 code F 11.2

*Results and discussion.*– 70 women were employed, only three of them were working in their specialization, 39 patients were either unemployed or engaged in the unskilled labor, that is, the one being out of tune with their education level. Eight examinees served penal servitudes, eleven women (19.6%) being detained without imprisonment. The findings reflect disorders in social adaptation of the most examinees. It should be noted that a drug using sex partner shapes not only drug exposure of the women but her drug addiction itself. Almost half of our 56 examinees had drug using husband, cohabitant or sex partner. Basic addiction syndromes tend to form more rapidly in these women to be explained by introduction of a woman into ready drug addiction way of life. As in all drug addicts, changes in personality manifesting in falsity, egotism, volatility and instability of intentions, parasitic tendencies and volitional defect can be observed in the female drug users. These persons rapidly lose working capacity and interest to study. Drug using mothers are completely indifferent to their children's upbringing, leaving it to some relatives.

*Conclusions.*– The study revealed a number of peculiarities in medical and social consequences of the female drug addiction.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

<sup>1</sup> Faculty of social science and health care, Constantine the Philosopher university in Nitra, Slovak Republic, department of psychology sciences, Nitra, Slovak Republic; <sup>2</sup> Constantine the Philosopher university in Nitra, Slovak Republic, faculty of medicine and dentistry, Olomouc, department of psychology sciences, department of psychiatry, Nitra, Slovak Republic; <sup>3</sup> Faculty of medicine, Pavol Josef Safarik university in Košice, Slovak Republic, 1st department of internal medicine, Košice, Slovak Republic; <sup>4</sup> MUDr Ivan Majercak, Mudronova 29, Košice, internal medicine and cardiology private practice, Kosice, Slovak Republic; <sup>5</sup> Jessenius faculty of medicine in Martin, Comenius University in Bratislava, Martin, Slovak Republic, department of physiology, biomedical center Martin, Martin, Slovak Republic

\* Corresponding author.

*Background.*– The epidemiological data displayed that the psychosocial problems are considerably associated with the development of cardiovascular diseases. Emotional distress stimulates sympathetic activity creating the variations in cardiovascular system – an increase in blood pressure, heart rate, and relocation of blood flow. It is a question whether some personality traits associated with a higher level of distress are related to dysregulation of the autonomic nervous system.

*Method.*– Cross sectional study collected data for the evaluation the relationship between personality traits, and psychophysiological measurements as early risk indicators of CVD. Seventy four healthy persons with no medication in the age higher than 21 years were measured under standard conditions. Participants fill out Temperament and Character Inventory (TCI-R), Dissociative Experience Scale (DES), and Demographic questionnaire. Power spectra were computed by a fast Fourier transformation for three spectrum ranges: (a) Very low frequency (VLF: 0.0033–0.04 Hz), (b) Low-frequency (LF: 0.04–0.15 Hz) and (c) High frequency (HF: 0.15–0.40 Hz) powers.

*Results.*– In basal conditions: Dissociation measured by DES negative correlated with heart rate in basal conditions. Three domains, Novelty-Seeking, Harm-Avoidance, and Persistence have no correlation with any psychophysiological measures in basal condition. Reward-Dependence negative correlate with SCL, and with respiratory thorac-abdomen difference. Self-directedness correlated negatively with SDRR. Cooperativeness negatively correlated with SDRR, HF, SCL, and respiration thorac-abdomen difference.

*Conclusion.*– Results suggest that particular personality traits may be connected with specific characteristics of the autonomic nervous system activity.

*Disclosure of interest.*– This paper was supported by the research grant Slovak Research and Development Agency APVV-15-0502.

\* Corresponding author.

Psychological distress is often considered a component of a cardiovascular risk. Emotional distress stimulates sympathetic activity producing fluctuations in the cardiovascular system – tachycardia, hypertension, and relocation of the blood flow.

**Objective.**– The study aim is to determine which psychological, psychophysiological, and anthropometric factors are connected with life events, depressivity, and quality of life in the persons in risk for the cardiovascular disease and healthy controls.

**Method.**– The patients treated with arterial hypertension were compared with healthy controls. The measurements included a physical examination, an administration of questionnaires, anthropological assessments, parameters of the cardiovascular system, and measurements of psychophysiological functions in a cross-sectional study.

**Results.**– There were 45 patients with cardiovascular problems with age  $46.33 \pm 12.39$  years, and 54 healthy participants with age  $35.59 \pm 13.39$ . In healthy subjects, total score the life events was not correlated with any cardiovascular or anthropometric factor. A score of depression significantly correlated with the Waist-to-height ratio, Augmentation Index, Body fat percentage, and Fat control. The quality of life - visual scale correlated with the body temperature, blood pressure, and Percentage of body fat. In the group of the patients with the cardiovascular disorders, the score of life events did not correlate with any measured cardiovascular or anthropometric factor. The level of depression correlated with Augmentation index. The quality of life - visual scale significantly correlated with body temperature, Waist-to-height ratio, and Fat control.

**Conclusion.**– Results suggest some possible mechanisms by which stress may exert adversarial effects on cardiovascular morbidity in healthy persons

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Stress profile in panic disorder patients in comparison with matched healthy controls

M. Slepecky<sup>1\*</sup>, A. Kotianova<sup>1</sup>, J. Prasko<sup>1</sup>, M. Kotian<sup>1</sup>, M. Chupacova<sup>1</sup>, M. Zatkova<sup>1</sup>, I. Tonhajzerova<sup>2</sup>

<sup>1</sup> Faculty of social science and health care, Constantine the Philosopher university in Nitra, Slovak Republic, department of psychology sciences, Nitra, Slovak Republic; <sup>2</sup> Jessenius faculty of medicine, Mala Hora 10701, 03 601 Martin, department of physiology, biomedical center Martin, Martin, Slovak Republic

\* Corresponding author.

Alarming somatic symptoms are the characteristic features of panic attacks. Increased cardiac mortality and morbidity have been proposed in these patients. Power spectral analysis of electrocardiogram R-R intervals is known to be a particularly successful tool in the detection of autonomic instabilities in various clinical disorders. The aim of our study is to measure the differences between autonomic nervous system and cardiac parameters in healthy volunteers and patients with panic disorder.

**Methods.**– We assessed psychophysiological variables in 30 patients with panic disorder (10 men, 23 women, and 30 age and gender matched healthy controls. Patient were treatment naïve. Pulse, blood pressure, muscle tension, and heart rate variability in basal conditions and after the psychological task was assessed. Power spectrums were computed for total power, very low frequency, low-frequency and high frequency bands using fast Fourier transformation.

**Results.**– There were statistically significant differences between healthy controls and patients with panic disorder in pulse, totalpower spectrum, SDRR, and surface EMG in baseline. During the mental arithmetic task, we found higher LF / HF ratio in patients with PD (panic disorders  $2.1 + 2.1$  versus controls  $1.3 + 0.9$ ;  $P < 0.05$ ).

**Conclusion.**– These findings demonstrate a higher sympathetic activity, a lower parasympathetic activity, a higher ratio between sympathetic and parasympathetic activity, in panic disorder patients in comparison with healthy controls. During the mental task the ratio between sympathetic and parasympathetic activity was increased.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Acknowledgement.**– This paper was supported by the research grant Slovak Research and Development Agency APVV -15- 0502.

### Adjustment disorders in mothers and wives of heroin addicts and their needs for psychotherapy

A. Vasileva<sup>1\*</sup>, N. Neznanov<sup>2</sup>, V. Bocharov<sup>3</sup>, A. Shishkova<sup>3</sup>

<sup>1</sup> Bekhterev psychoneurological institute, medical faculty of St. Petersburg Univer, neurosis and psychotherapy, Saint-Petersburg, Russia; <sup>2</sup> Bekhterev psychoneurological institute, medical faculty of St. Petersburg Univer, director, Saint-Petersburg, Russia; <sup>3</sup> Bekhterev psychoneurological institute, medical faculty of St. Petersburg Univer, clinical psychology, Saint-Petersburg, Russia

\* Corresponding author.

The addiction of the affected close one can be considered as a serious psychotraumatic factor for their family members especially mothers and wives. 104 mothers and 50 wives, 48 fathers and 36 siblings of heroin addicts were included in the study with clinical and psychological methods. The test battery consisted of ISTA personality test and Family environment scale. The test results revealed that mothers and wives carry the main emotional burden in the

family and involved more than the others in the addicts problems. the main psychotherapeutic targets for these most vulnerable family members could be personal anxiousness, feeling of guilt, lack of assertivity and self-confidence, sexual relationship issues and moderation of family conflicts.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Psychological interventions in early onset psychosis: A systematic review

N. Anagnostopoulou<sup>1\*</sup>, M. Kyriakopoulos<sup>2</sup>, A. Alba<sup>3</sup>

<sup>1</sup> South London & Maudsley NHS Trust, Bethlem adolescent unit,

London, United Kingdom; <sup>2</sup> King's college London, institute of psychiatry, psychology & neuroscience, London, United Kingdom;

<sup>3</sup> South London & Maudsley NHS Trust, Acorn Lodge children's unit, London, United Kingdom

\* Corresponding author.

*Background.*– Early onset psychosis (EOP), with onset before the age 18, is a more severe form of psychosis associated with worse prognosis. While medication is the treatment of choice, psychological interventions are also considered to have an important role in the management of symptoms and disability associated with this condition. The present review aimed to explore the effectiveness of such interventions.

*Method.*– An electronic search was conducted on the Embase, Medline and PsychInfo databases for papers of randomized controlled trials (RCTs) referring to psychological interventions in EOP. References of identified papers were hand searched for additional studies. Identified studies were quality assessed.

*Results.*– Eight studies were included in the present review evaluating cognitive remediation therapy (CRT), cognitive behavioural therapy (CBT), a family intervention and psychoeducation. CRT was associated with improvement in cognitive function and CBT and CRT seem to also have a positive effect in psychosocial functioning. Symptom reduction appears to not be significantly affected by the proposed treatments.

*Conclusions.*– There is some evidence supporting the effectiveness of psychological interventions in EOP. However, most research on adolescents is focused on CRT and its effects on cognitive deficits. More studies on the effects of psychological interventions in EOP are urgently needed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Developmental adjustment among individuals at different risk of psychosis

S. Andric Petrovic<sup>1\*</sup>, M. Mihaljevic<sup>1</sup>, T. Mirjanic<sup>2</sup>, G. Knezevic<sup>3</sup>, N. Maric<sup>1</sup>

<sup>1</sup> Clinic for psychiatry clinical center of Serbia, department for research and early interventions in psychiatry, Belgrade, Serbia;

<sup>2</sup> Special hospital for psychiatric disorders "Kovin", department for psychotic disorders, Kovin, Serbia; <sup>3</sup> University of Belgrade, faculty of philosophy, department for psychology, Belgrade, Serbia

\* Corresponding author.

*Introduction.*– Family studies of schizophrenia have established its strong familial aggregation with a relative risk of about 11 compared with matched comparison groups. Multiple reports indicate the presence of subtle premorbid neuromotor, cognitive and behavioral alterations in children who later develop schizophrenia. However, it remains largely unknown whether individuals at heightened genetic risk of psychosis, but without the adverse outcome – overt psychosis (i.e. probands' healthy siblings), also manifest certain compromise of developmental adaptive capacities.

*Methods.*– The sample comprised 52 patients with schizophrenia-spectrum disorders, 55 of their healthy siblings and 51 controls. The Premorbid Adjustment Scale was used to evaluate participants' psycho-social adaptation during childhood and early adolescence. Between-group differences were assessed using ANOVA (with post-hoc Scheffe's test) and Chi<sup>2</sup>, while intra-individual differences in psycho-social adjustment between childhood and adolescence were tested with Wilcoxon signed-rank test.

*Results.*– Groups did not differ in age and sex. Patients had significantly poorer psycho-social adaptation during childhood and adolescence in comparison to other examined groups. Although the siblings exhibited somewhat poorer achievement of developmental goals than controls, the differences were not significant. However, both patients and their siblings showed significantly poorer adaptation in adolescence in comparison to their childhood, which was not observed in the control group.

*Conclusions.*– Present results suggest that shared liability to psychosis impacts the psycho-social adaptation in adolescence. However, the different outcome scenarios in adulthood reflect the existence of resilience enhancing mechanisms in probands' healthy siblings. Elucidation of these neural processes will improve our abilities to intervene early in at risk populations.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

*Introduction.*– Neurocognitive deficits in schizophrenia are present from the beginning of the illness, with the majority of authors reporting domain specific differences (e.g. verbal fluency) in neurocognitive deficits. However, it is unclear whether neurocognitive impairment is progressive/ variable over time, or relatively stable from the first episode psychosis.

*Objectives.*– To analyze the neurocognitive profile in patients with first episode psychosis and schizophrenia.

*Methods.*– We conducted a cross-sectional study including patients with first episode psychosis (n = 100) and schizophrenia (n = 100) recruited from three Croatian hospitals during their hospital treat-

ment due to acute psychosis. Assessment included battery of various neurocognitive tests representing five domains of neurocognition.

**Results.**– Our results showed that three structurally equivalent neurocognitive profiles fitted the data the best for both patient groups. Profiles differed in the successfulness in domain specific tests, with Profile 1 being “The best”, Profile 2 “Medium” and Profile 3 “The worst”. “The best” profile was more prevalent in the first episode patients’ group (40.2%), who also had better performance in all neurocognitive tasks.

**Conclusions.**– Neurocognitive profiles present specific traits of schizophrenia, that are present from the first episode of psychosis and do not change in its nature, but rather deteriorate linearly with the progression of illness.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Differences in cognitive profiles between optimal and sub-optimal educational attainment in students with schizophrenia

A. Chattopadhyay<sup>1\*</sup>, C. Naveen Kumar<sup>2</sup>, T. Sivakumar<sup>2</sup>, U. Mehta<sup>2</sup>, J. Thirthalli<sup>2</sup>

<sup>1</sup> Pravara institute of medical sciences, psychiatry, Mumbai, India;

<sup>2</sup> NIMHANS, psychiatry, Bengaluru, India

\* Corresponding author.

**Introduction.**– Schizophrenia is a severe mental illness with significant dysfunction in various life areas. Cognition has become the key talking point with cognitive impairments noted not only in patients with chronic schizophrenia but also pre-dating the psychotic changes as noted in several studies.

**Objectives.**– To observe differences, if any, in various cognitive domains between students affected with schizophrenia with optimal educational outcomes and sub-optimal educational outcomes

**Methods.**– Convenient sampling was done was done to identify patients between 16–30 years of age, who were students diagnosed to have schizophrenia and were in remission, were recruited from inpatient population in NIMHANS psychiatry department.

22 patients were included for the interview. Of these, 2 were not included in the final sample for analysis due to change in diagnosis Cognitive Assessment was done using the MATRICS-CCB equivalent scale.

The domains assessed were working memory, speed of processing, verbal memory, visual memory, attention and vigilance as well as executive function.

The results were analyzed using appropriate statistical methods.

**Results.**– With respect to the neuropsychological parameters, the sub-optimal group scored significantly better with respect to AVLT

and Verbal N Back 1 scores. Other differences were not reaching significance.

The results are displayed in Table 1.

**Conclusion.**– Though the sample size would need to be increased to generate a hypothesis, an interesting finding of the study was that cognition (that too isolated variables measuring a limited aspect of it) alone is not sufficient to account for educational outcome.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Are there gender differences in the impact of symptoms on health-related quality of life in schizophrenia?

C. Domenech<sup>1\*</sup>, V. Moneta<sup>2</sup>, C. Bernasconi<sup>3</sup>, A.L. Nordstroem<sup>3</sup>, J.M. Haro<sup>2</sup>

<sup>1</sup> Parc Sanitari Sant Joan de Deu, Universitat de Barcelona, Barcelona, Spain; <sup>2</sup> Parc Sanitari Sant Joan de Deu, Cibersam, Barcelona, Spain;

<sup>3</sup> F. Hoffmann-La Roche Ltd, Basel, Basel, Switzerland

\* Corresponding author.

**Introduction.**– Health related quality of life (HRQoL) is the patient self-perception of health.

**Objectives.**– To analyze gender differences in the relationship between the symptoms and HRQoL.

**Methods.**– Data is part of the Pattern study, an international, multi-centric, observational study. Adult outpatients with schizophrenia who did not have an acute psychotic exacerbation in the three months prior to baseline were evaluated with the PANSS, the Schizophrenia Quality of Life Scale (SQLS), the Short Form-36 (SF-36), and the EuroQol-5 Dimension (EQ-5D) questionnaires. Lindenmayer et al.’s five factors were used. Separate regression models were fitted for women and men using each HRQoL measure as dependent variable. All models included country, age and variables significantly associated to the outcome as covariates.

**Results.**– The sample included 391 females and 954 males. PANSS total score was 80.6 (SD 23.6) for females and 77.9 (SD 22.1) for males. Men reported a higher HRQoL in all scales. In females, higher PANSS negative and affective symptoms were associated with lower SQLS score. In males, higher PANSS positive and affective symptoms were associated with lower SQLS score. The same pattern appeared with EQ-VAS and EQ-tariff. In females, the SF-36 mental component score was lower with increasing age and increasing severity of the PANSS affective score. In males, the SF-36 mental component score was lower with increasing severity of the PANSS affective, positive and cognitive scores.

**Conclusions.**– HRQoL may be influenced by different types of symptoms in women and in men. This should be considered when determining treatment targets.

**Disclosure of interest.**– The Pattern Study was funded by Roche, who freely provided the database to the authors. The statistical analysis and manuscript content were directed, conducted and approved by the authors. Corrado Bernasconi and Anna-Lena Nordstroem are Roche employees. Josep Maria Haro received honoraria for participating in the PATTERN study advisory board. Cristina Domenech and Victoria Moneta have no conflict of interest.

### Retrospective one-year follow-up study of one-monthly paliperidone palmitate in in-patient unit

E. Segura<sup>\*</sup>, C. Rodríguez, L. Asensio, L. Nuevo, L. Cabanillas, I. Gomez, L. Beato

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– Mental illness are characterized by non-adherence treatment, frequently relapse and bad prognosis. To prevent and to improve these aspects in the last years we have long-acting antipsychotics. The use of long-acting antipsychotics are extended in the treatment of schizophrenia and in severe mental disorder.

**Objets.**– Retrospective one-year follow-up analysis of patients admitted in an inpatient unit that were discharge with one-monthly paliperidone palmitate.

**Method.**– We analyze patients admitted during a year in an In-patient Unit and discharged with one-monthly paliperidone palmitate. We review the previous 6 months and next 6 months to control pre-/re-admissions.

**Results.**– Of total admissions, 76 patients were discharge with one-monthly paliperidone palmitate, with a significantly lower average stay than the global one. The mean age was 31.8, 37% were women and 63% men. 56.5% had substance abuse. 72% of patients were admitted in the previous 6 months. Abandonment of treatment is the cause of admission in the 50%. In re-admissions in the next 6 months, only 26 patients were admitted and the first cause was abandonment of treatment. The more frequent doses were: 150 mg (57%), 100 mg (34%). 42% were discharge in antipsychotic monotherapy. The most frequent diagnosis were paranoid schizophrenia (35%), Schizoaffective disorder (22%) [1].

**Conclusions.**– Due to clinical experience, we can conclude that paliperidone palmitate is associated with reduction in hospital re-admissions and days in hospital in patients with severe mental disorder, improves adherence and therapeutic compliance.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Treatment retention and tolerability of high doses of second-generation long-acting antipsychotics in the treatment of patients with severe resistant schizophrenia. A 24-month follow-up

J.J. Fernandez-Miranda<sup>1\*</sup>, S. Díaz-Fernández<sup>2</sup>, D.F. Frías-Ortiz<sup>3</sup>

<sup>1</sup> AGCS Mental-V-SESP Asturias mental health service, Centro Tratamiento Integral, Gijón, Spain; <sup>2</sup> AGC-S MENTAL-V-SESPA Asturian mental health service, Centro tratamiento Integral, Gijón, Spain; <sup>3</sup> AGC-S MENTAL-V-SESPA-Asturian mental health service, Centro Tratamiento Integral, Gijón, Spain

\* Corresponding author.

**Introduction.**– Adherence to treatment of people with schizophrenia is important to reach clinical and rehabilitation goals, and effective and tolerable doses of antipsychotics are needed.

**Objectives.**– To evaluate treatment retention, effectiveness and tolerability of high doses of second-generation long-acting antipsychotics in patients with severe (CGI-S  $\geq$  5) resistant schizophrenia.

**Methods.**– 24-month prospective, observational study of patients treated with  $\geq$  75 mg risperidone long-acting injectable (RLAI)

( $n=60$ ),  $\geq$  175 mg paliperidone palmitate (1MPP) ( $n=30$ ) and  $\geq$  600 mg aripiprazole once-monthly (AM) ( $n=10$ ). Assessment included CGI-S, WHO-DAS and Camberwell (CAN) at the beginning and after 3–12–24 months; and also laboratory tests, weight, adverse effects, reasons for discharge and hospital admissions in the previous two years and during the follow-up.

**Results.**– Average doses were: RLAI=111.2 (9.1)mg/14 days; 1MPP=228.7 (11.9)mg-eq/28 days; and AM=720 (110)mg/28 days.

For all LAIs tolerability was good, decreasing side effects and biological parameters alterations. There were no discharges due to side effects with AM, one with PP and three with RLAI; and three with RLAI and one with PP due to lack of effectiveness. Weight and prolactin levels decrease. CGI-S ( $P<0.01$ ), CAN ( $P<0.01$ ) and WHO-DAS ( $P<0.01$ ) decreased with all injectables. There were less hospital admissions ( $P<0.001$ ) for all injectables. Retention in treatment after 24 months was 90% with RLAI, 93,3% with 1MPP and 100% with AM.

**Conclusions.**– Tolerability of high doses of second generation long acting antipsychotics (RLAI, PP and AM) was very good, being useful in improving treatment adherence in patients with severe resistant schizophrenia, and helping this way to get clinical stabilization and better functioning.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Suicide among people with severe schizophrenia preventive strategies. Role of second-generation long-acting-injectable antipsychotics

J.J. Fernandez-Miranda<sup>\*</sup>, S. Díaz-Fernández, D.F. Frías-Ortiz  
AGC-S MENTAL-V-SESPA Asturian mental health service, Centro Tratamiento Integral, Gijón, Spain

\* Corresponding author.

**Introduction.**– Adherence to treatment of people with severe schizophrenia is important to reach clinical and rehabilitation goals and to prevent suicidal behaviour.

**Objectives.**– To know the retention in treatment of people with severe schizophrenia, suicide rates among them, and treatment characteristics related (oral vs long-acting-injectable antipsychotics).

**Methods.**– 8-year prospective, observational, study of patients with severe schizophrenia (CGI-S  $\geq$  5) undergoing community based comprehensive treatment in Spain ( $n=200$ ). Assessment included the CGI-S, the WHO-Disability Assessment Schedule (DAS), medications prescribed, laboratory tests, weight and adverse effects reported, at the beginning and after 3, 12, 24, 36 and 96 months. Hospital admissions and reasons for treatment discharge, including deaths by suicide, were recorded.

**Results.**– CGI-S at baseline was 5.9 (0.7). After eight years 42% of patients continued under treatment (CGI-S=4.1 (0.9);  $P<0.01$ ) and 37% were medical discharged (CGI=3.4 (1.5);  $P<0.001$ ); WHO-DAS decreased in the four areas ( $P<0.0$ ) in both groups; 10% were voluntary discharges. Twelve patients died during the follow up, four of them by suicide (2%; suicide rates among people with schizophrenia in standard treatment in Spain between 5–10%). 65% of all patients were treated with second-generation long-acting-injectable antipsychotics, with high tolerability. Among them, there was higher retention (4 vs 16 patients voluntary discharges;  $P<0.01$ ) and less suicides than patients with oral antipsychotics (1 vs 3 patients).

**Conclusions.**– Retention in treatment of patients with severe schizophrenia in a community based comprehensive programme

and treated with second generation long-acting antipsychotics was really high and seemed to be more useful to prevent suicidal behaviour than oral medications.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The Massachusetts general hospital schizophrenia program patient registry: A population-based tool for patient-centered and reverse integrated care for patients with serious mental illness**

O. Freudenreich\*, S. MacLaurin, K. Irwin, H. Brown, A. Donovan, C. Cather, J. Roffman, B. Brent, K. Cieslak, J. Puckett, E. Evins, L. Namey, D. Holt

*Massachusetts general hospital, schizophrenia clinical and research program, Boston, USA*

\* Corresponding author.

*Introduction.*– Providing safe and patient-centered care to patients with serious mental illness is challenging in a fragmented care system. In the United States, siloed psychiatric and medical care complicates access to care and, for those with schizophrenia, contributes to high medical morbidity. A patient registry can serve as a population-based tool to promote care integration, implement guidelines, and identify patients who need more intensive management.

*Objectives.*– Introduce the concept of a patient registry for a schizophrenia program to increase integration between their physical and mental health care; describe our program's experience with the process of implementing such a registry; and provide baseline assessment data.

*Methods.*– Our program developed a registry to systematically collect psychiatric and physical data (metabolic risk assessment) for all our patients. Routinely collected information, including general- and disorder-specific rating scales, becomes part of the registry.

*Results.*– We established the registry first for our clozapine program. With the help of the registry, we implemented a metabolic monitoring program; added a diabetes self-management group; increased efforts supporting smoking cessation; improved the process of referral to community services; and improved access to cancer care. Expanding the registry to other patients groups (first-episode clinic) has been challenging due to different electronic medical records, complex work-flows, and a high administrative burden (data entry).

*Conclusions.*– Creating a disorder-specific registry can serve as a platform to better organize care for patients with schizophrenia. However, maintaining a registry requires a sustained effort and substantial resources, including information technology support.

### **Gut microbiome and magnetic resonance spectroscopy study of subjects at ultra-high risk for schizophrenia support the membrane hypothesis**

Y. He

*University of California, San Diego, department of psychiatry, San Diego, USA*

\* Corresponding author.

*Background.*– The microbiota-gut-brain axis and membrane dysfunction in the brain has attracted increasing attention in the field of psychiatric research. However, the possible interactive role of gut microbiota and brain function in the prodromal stage of schizophrenia has not been studied yet.

*Methods.*– To explore this, we analyzed differences in fecal microbiota and choline concentrations in the anterior cingulate cortex (ACC) of 81 high risk (HR) subjects, 19 ultra-high risk (UHR) subjects and 69 health controls (HC).

*Results.*– Presences of the orders Clostridiales, Lactobacillales and Bacteroidales were observed at increase levels in fecal samples of UHR subjects compared to the other two groups. This finding indicates the increase of Short Chain Fatty Acids (SCFAs) and further activation of microglia. This is confirmed by an increase in choline levels, an imaging marker of microglia activation, which is also significantly elevated in UHR subjects compared to the HR and HC groups.

*Conclusion.*– Both gut microbiome and imaging studies of UHR subjects suggest the activation of microglia in the brain and hence support the membrane hypothesis of schizophrenia.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Neurocognitive predictors of psychological excitation in psychotic patients**

S.R. Hosseini<sup>1</sup>\*, E. Amere<sup>2</sup>, K. Naserbakht<sup>2</sup>

<sup>1</sup> *University of social welfare and rehabilitation sciences, substance abuse and dependence research center, university of social welfare and rehabilitation sciences, Tehran, Iran;* <sup>2</sup> *University of social welfare and rehabilitation sciences, Razi psychiatric hospital, Tehran, Iran*

\* Corresponding author.

*Introduction.*– Psychological excitation is an important clinical status that engage clinical health services and prognosis of individuals with psychotic disorders.

*Objectives.*– The aim of this study was to evaluate the neurocognitive predictors of psychological excitation in psychotic patients.

*Methods.*– A total of 52 psychotic (schizophrenia, bipolar, substance induced psychosis) patients were evaluated by means of positive and negative syndrome scale and also neuropsychological tools (Wisconsin card sorting test, Stroop test, n-back test).

*Results.*– One-way ANOVA revealed no significant differences of psychological excitation between three groups. Regression analysis indicated that cognitive inhibition and mental flexibility were the strongest predictors of psychological excitation in psychotic patients.

*Conclusions.*– The results showed that the cognitive functions are the baseline for the psychological excitation that experienced by the psychotic patients. so, cognitive rehabilitation can improve the psychological status of these patients and these factors should be considered in clinical interventions.

**Keywords:** Cognitive inhibition; Mental flexibility; Psychosis; Psychological excitation; Working memory

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The efficacy of vitamin D supplementation in the treatment of schizophrenia**

H. Jamilian<sup>1\*</sup>, B. Sadeghi Sedeh<sup>2</sup>, H. Ahmadloo<sup>1</sup>

<sup>1</sup> School of medicine, Arak university of medical sciences, psychiatry, Arak, Iran; <sup>2</sup> School of medicine, Arak university of medical sciences, social medicine, Arak, Iran

\* Corresponding author.

**Introduction.**– Vitamin D as a neuroactive compound, a pro-hormone, is highly active in regulating cell differentiation, proliferation, and peroxidation in a variety of structures, including the brain. The central nervous system is increasingly recognized as a target organ for vitamin D via its wide-ranging hormonal effects, including the induction of proteins such as nerve growth factor.

**Objectives.**– To evaluate the efficacy of vitamin D in the treatment of schizophrenia

**Methods.**– In this randomized clinical trial 70 patients with schizophrenia according to DSM-5 criteria were divided randomly in two equal groups. Intervention group received 20–25 mg olanzapine per day for 3 months and 300,000 IU vitamin D as intramuscular injection once at the beginning of the study. The other group received 20–25 mg olanzapine per day for 3 months plus placebo. Positive and negative syndrome scale (PANSS) was done at the beginning of the treatment and repeated 1, 2, and 3 months after the beginning of the treatment. Creatinine, fasting blood sugar, parathyroid hormone, calcium, and phosphor were assessed in both groups before and at the end of the study.

**Results.**– Intervention group (olanzapine + vitamin D) showed a significantly greater improvement on PANSS than the placebo group (olanzapine + placebo) at month 2 and endpoint ( $P < 0.001$ ). There was not any significant difference between two groups regarding to Creatinine, fasting blood sugar, parathyroid hormone, calcium, and phosphor.

**Conclusion.**– Vitamin D is effective in the treatment of schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **“The Doubt” as treatment in psychosis**

L. Asensio Aguerri<sup>\*</sup>, V. Muñoz Martínez, B. Mata Saenz, E. Segura Escobar, L. Nuevo Fernández, C. Rodríguez, L. Beato Fernández

Hospital general de Ciudad Real, psychiatry, Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– The paranoid thoughts and irrational beliefs can be the result of a negative assessment of situations, relationships with others, and interpretations of these. There are a new therapy, investigated by a group from Hamburg, denominated Metacognitive training (CMT), which is based on the cognitive errors that the patient perceives, give rise to the interpretation of thoughts and are associated with delusional beliefs causing the distortion of reality.

**Objectives.**– The objective is to provide a bibliographic review of the “Metacognitive training” and their possibilities of use in the treatment of psychosis.

**Methods.**– A systematic review from the literature has been carried out by PubMed/ Medline (keywords: Metacognitive training, psychosis, delusional beliefs).

**Results.**– This therapy is composed of eight modules, which focus on cognitive errors and cognitive bases. These are the ones that can become delusions. It is done in group format, making a weekly session, two maximum of 45 to 60 minutes. The main therapeutic objective of the CMT is to be able to modulate the cognitive infrastructure of the delirious ideation. It is intended to increase the patient’s awareness of these biases and to teach them to think critically about them. With the work in these techniques it is tried to avoid relapses in new psychotic episodes, trying that the patient is able to realize critic of his own thoughts.

**Conclusions.**– CMT is an effective therapy in the treatment of psychotic symptoms. The combination of treatment with psychotropic drugs and psychological therapies aimed at improving cognition, are more effective than pharmacological treatment alone.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Background and aim.**– An important endophenotype in the genetic research of schizophrenia (SCH) and bipolar disorder (BD) are cognitive functions. Impairments in working memory, declarative memory and attention are core symptoms for SCH and BD and they fulfill the criteria of an endophenotype. *FKBP5* gene is a gene, which has previously been shown to be associated with cognition. The aims of our research were to determine the degree of cognitive impairment in patients suffering from SCH and BD and to explore the connection between genotype of *FKBP5* variant rs3800373 with the cognitive endophenotypes.

**Methods.**– Patients and healthy controls recruited over a period of two years from the Psychiatric Clinic, Clinical Center University of Sarajevo. Genotyping and neuropsychological assessments were performed for 263 subjects (129 SCH, 53 BD, 81 HC). Neurocognition was assessed with Trail Making Test-A&B (TMT-A&B)

and Digit-span forward & backwards. Rs3800373 in FKBP5 was genotyped using Infinium PsychArray Bead Chips.

**Results.**– SCH and BD performed lower than HC in the TMT-A&B and in the Digit-span backwards, while no differences were observed between SCH and BD. Additionally SCZ performed lower in Digit-span forwards, while there were no differences between BD and HC and BD and SCZ. Rs3800373 was not associated with performance in TMT-A& TMT-B, or Digit-span forwards and backwards.

**Conclusions.**– Rs3800373 in FKBP5 gene was not associated with performance in the neuropsychological tests. Furthermore, as the analysis was limited to one SNP in this gene, the results cannot be generalized to other genetic variants in FKBP5.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Improvement in outcomes after switching to one-month long-acting injection paliperidone palmitate**

J.E. Muñoz Negro<sup>1</sup>, V. Martí Garnica<sup>2</sup>, M.D. Ortega Garcia<sup>3\*</sup>, R. Gómez Pasaalacqua<sup>4</sup>, S. Marin Garcia<sup>5</sup>

<sup>1</sup> UGC Salud Mental Granada. Hospital Campus de la Salud. Servicio Andaluz de Salud., Psychiatry, Granada, Spain; <sup>2</sup> CSM Caravaca, Psychiatry, Caravaca, Spain; <sup>3</sup> CSM Cartagena, Child and Adolescent Mental Health Centre, Cartagena, Spain; <sup>4</sup> Psychiatrist trainee. Hospital de Agudos Parmenio T. Piñero, Psychiatry, Ciudad Autónoma de Buenos Aires, Argentina; <sup>5</sup> CSM Lorca. Servicio Murciano de Salud., Psychiatry, Lorca, Spain

\* Corresponding author.

**Introduction.**– Long acting antipsychotics can provide a higher clinical stability and an improvement in patients' global functionality leading to decrease in hospital admissions, better therapeutic compliance and less relapse rate and side effects.

**Objective.**– Describe changes of global functioning in patients after switching to one-month long-acting paliperidone palmitate.

**Methods.**– One-year prospective, observational study of 50 outpatients with psychotic disorders, belonging to the Spanish National Health System, who switched to one-monthly paliperidone palmitate in order to get clinical stability. Assessment functionality included the Global Assessment Functionality (GAF) at the baseline and at endpoint after 12-months of switching treatment. Family satisfaction was measured by a 5 items questionnaire based on Solution-Focused Brief Therapy at the endpoint. Sociodemographic data were described. Changes in GAF scoring between baseline and endpoint were evaluated using One-Way ANOVA and a linear regression model.

**Results.**– The improvement in GAF at the endpoint experienced by outpatients after switching to one-monthly paliperidone palmitate was statistically significant ( $F=14.123$ ;  $P<.001$ ). Baseline GAF  $M=60$ ;  $SD=12.7$ ;  $CI(56.3-63.7)$  and endpoint GAF  $M=76.3$   $SD=9.6$ ;  $CI(73.5-79)$ . A linear regression model was built including age, sex, previous antipsychotic treatment, family medical records and diagnose as co-variables and an effect size was estimated ( $F=658,979$ ;  $P\leq 0.0001$ , Partial Eta Square: 0.981).

**Conclusions.**– A statistical significant improvement, in global functionality after switching the previous antipsychotic to one-monthly paliperidone palmitate was achieved, most of improvement was due to the paliperidone palmitate regardless of previous antipsychotic.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A systematic review comparing the neural correlates of empathy associated with the onset and progression of schizophrenia**

M. Ponnampalam

The University of Birmingham,

College of Medical and Dental Sciences, Birmingham, United Kingdom

\* Corresponding author.

**Introduction.**– Empathic deficits present in nearly all Schizophrenia patients (SCZ). These result from impairments in various social cognitive tasks, often leading to social isolation and withdrawal. There is evidence that empathy deficits occur before illness-onset in those at 'ultra-high risk of psychosis' (UHR) and those with a 'first-episode of psychosis' (FEP). Empathy defects are associated with neurological abnormalities, which have been studied separately in UHR, FEP and SCZ populations.

**Objectives.**– This review aims to gain further insight into neurological changes associated with illness progression, by comparing brain changes associated with empathy across UHR, FEP and SCZ populations. Studies considering functional activity, connectivity and structural changes in UHR, FEP and SCZ populations were systematically reviewed.

**Methods.**– Data from 26 studies was used. All three subgroups showed abnormal patterns of activation and connectivity across a range of regions, particularly in the frontal, limbic and temporal areas.

**Results.**– Structural abnormalities appeared as widespread grey matter loss, largely in the temporal lobe, across all three participant groups. Notably, impaired empathic behavioural responses were found in FEP and SCZ subjects only, despite neurological abnormalities being evident in all three groups.

**Conclusion.**– Our findings suggest that abnormal connectivity, structure and activation of the frontal, limbic and temporal areas contribute significantly to empathy deficits, and worsen prior to and during illness progression. However, the multifaceted nature of empathy means that behavioural impairments likely result from a combination of disruptions of the frontal, limbic and temporal areas alongside many other neural networks involved in social information processing.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

"Carmona". U.G.C. Salud Mental área hospitalaria Virgen Macarena, department of psychiatry, Seville, Spain;

<sup>2</sup> Nuestra Señora de Valme hospital, department of psychiatry, Seville, Spain; <sup>3</sup> De la Merced hospital, department of psychiatry, Osuna, Spain

\* Corresponding author.

**Introduction.**– Paliperidone Palmitate 3-month formulation (PP3M) is a new formulation of the Palmitate salt ester of Paliperidone which provides an extended sustained release of Paliperidone.

**Objectives.**– The aim of this study was to assess the effectiveness, safety and tolerability of the PP3M in patients with non-acute schizophrenia on an outpatient basis.

**Methods.**– 35 outpatients with diagnosis of schizophrenia (DSM 5) that started treatment with PP3M were recruited.

On a bimonthly basis, the following evaluations were performed during a follow-up period of 10 months: Positive and Negative Syndrome Scale (PANSS), Personal and Social Performance Scale (PSP), UKU Side Effect Scale and Patient Satisfaction with Medication Questionnaire (PSMQ). Treatment adherence, concomitant medication and hospital admissions.

Efficacy values: Percentage of patients who remained relapse free at the end of the 10 months (as defined by Csernansky).

**Results.**– Percentage of patients who remained relapse free at the end of the 10 months was 100%.

Mean variations from baseline scores at 10 months were: ( $-2.7 \pm 3.6$ ) on the PANSS and ( $-2.98 \pm 2.35$ ) on the PSP scale.

A not significant increase was found in the number of patients reporting to be “extremely satisfied” or “very satisfied” with their medication (PSQM) (80% at baseline vs. 85.71% at 10 months)

The rate of adherence to treatment with PP3M after 10 months was 94.28%. Tolerance to PP3M was high and none of the patients discontinued their treatment due to adverse effects.

**Conclusions.**– According to the published works to date, we also found of Paliperidone Palmitate 3-month formulation is effective, safe and well tolerated in clinical practice conditions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0248

### **The Importance of long-term effectiveness in clinical practice: A 54-month follow-up study of paliperidone palmitate one-month formulation**

S.L. Romero Guillena<sup>1\*</sup>, B.O. Plasencia Garcia de Diego<sup>2</sup>, F. Gotor Sanchez-Luengo<sup>3</sup>, O. Santamaria<sup>3</sup>, R. Navarro<sup>3</sup>

<sup>1</sup> U.S.M.C Carmona. U.G.C. Salud Mental área hospitalaria Virgen Macarena, department of psychiatry, Seville, Spain; <sup>2</sup> De la Merced Hospital, department of psychiatry, Osuna, Spain; <sup>3</sup> Nuestra Señora de Valme hospital, department of psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– Paliperidone Palmitate one-month formulation (PP1M) has been proven to be an effective treatment for schizophrenia. Long-term follow-up studies are required to assess the effectiveness to preventing relapse.

**Objective.**– To assess the long-term efficacy of PP1M in preventing relapse in schizophrenia

**Methods.**– 28 patients with schizophrenia (ICD-10) that started treatment with PP1M.

During a follow-up period of 54 months were performed:

- Positive and Negative Syndrome Scale (PANSS);
- UKU Side Effect Scale;
- Patient Satisfaction with Medication Questionnaire (PSMQ);
- Personal Social Performance Scale (PSP);
- Screen for Cognitive Impairment in Psychiatry (SCIP);
- Percentage of patients who remained relapse free at the end of the study. Relapse was defined as  $\geq 1$  of the following [4]: Psychiatric hospitalization, an increase of 25% from base line in the PANSS total score, or an increase of 10 points if the base-line score was 40 or less and an increase in PANSS item scores (P1, P2, P3, P6, P7, or G8) for 2 consecutive assessments.

**Results.**– Percentage of patients who remained relapse free at the end of the 54 months was 64.26%.

We observed a decrease in the PANSS total score ( $\Delta = 21.142 \pm 3.17$ ;  $P < 0.01$ ).

We found a decrease in the PSP total score ( $\Delta = 14.562 \pm 2.73$ ;  $P < 0.01$ ).

A decrease was observed in the number of patients with moderate and severe cognitive impairment (42.84% at baseline vs. 21.42% at 54 months;  $P < 0.05$ ).

Tolerance to PP1M was high and only one of the patients discontinued their treatment due to adverse effects.

The rate of adherence to treatment was 85.68%.

**Conclusions.**– Long-term treatment with PP1M is effective in the prevention of relapse. An improvement in the functionality was achieved as well.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cognitive alterations in schizophrenia. paliperidone palmitate one-month formulation versus traditional depot antipsychotics**

S.L. Romero Guillena<sup>1\*</sup>, B.O. Plasencia Garcia de Diego<sup>2</sup>,

J.A. Alcalá Partera<sup>3</sup>, L. Gutierrez Rojas<sup>4</sup>

<sup>1</sup> U.S.M.C Carmona. U.G.C. Salud Mental área hospitalaria Virgen Macarena, Department of psychiatry, Seville, Spain; <sup>2</sup> De la Merced Hospital, Department of psychiatry, Osuna, Spain; <sup>3</sup> U.S.M.C Palma del Río. Reina Sofia Hospital, Department of psychiatry, Córdoba, Spain; <sup>4</sup> San Cecilio Hospital, Department of psychiatry, Granada, Spain

\* Corresponding author.

**Introduction.**– Several studies reveal that atypical antipsychotics improve the cognitive function of patients significantly, as compared to traditional neuroleptics. Limited data is available on long-acting injectable antipsychotics.

**Objective.**– To assess differences in cognitive impairment in a group of patients with schizophrenia receiving Paliperidone Palmitate one-month formulation (PP1M) vs. a group of patients with schizophrenia receiving traditional long-acting antipsychotics (Depots)

**Methods.**– This is a descriptive, cross-sectional, multi-center study. Study sample: 36 patients.

Inclusion criteria were: Clinically stable patients with a diagnosis of schizophrenia (according to DSM-5 criteria).

Simple stratified sampling was performed to collect data from patients with schizophrenia receiving PP1M ( $n = 18$ ) versus patients with schizophrenia receiving Depots ( $n = 18$ ). Groups were matched by age, gender, years of evolution of the disease, and years on formal education.

Functionality in the different cognitive domains was evaluated based on the Brief Assessment of cognition in Schizophrenia (BACS). BACS evaluates the following cognitive domains: Verbal memory, workingmemory, Motor speed, Verbal fluency, Attention and Executive function.

The data obtained were analyzed using the SPSS 22.0 statistical package.

**Results.**– In the group receiving PP1M, the most severely impaired cognitive domain was attention, whereas motor speed was barely affected. In contrast, verbal memory was most impaired, whereas motor speed was the least impaired cognitive domain in the group receiving depots.

Patients with schizophrenia taking PP1M showed a better cognitive function in all domains (except for motor speed and attention) than patients receiving depots ( $P < 0.05$ ).

**Conclusion.**– In our study, Patients with schizophrenia receiving Paliperidone Palmitate one-month formulation have a better cognitive function than patients receiving traditional long-acting antipsychotics.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### PP3M treatment satisfaction and caregiver burden: 6 months follow up

E. Ros-Cucurull<sup>1</sup>, R.F. Palma-Álvarez<sup>1</sup>, L. Grau-López<sup>1</sup>, A.C. Abad<sup>1</sup>, M. Robles-Martínez<sup>1</sup>, A. Esojo<sup>1</sup>, R. Martínez-Arias<sup>2</sup>, E. Castrillo<sup>1</sup>, M. Pelaez<sup>1</sup>, M.Á. Cantillo<sup>1</sup>, R. Llopiz<sup>1</sup>, E. Franch<sup>3</sup>, J.A. Ramos-Quiroga<sup>1</sup>, C. Roncero<sup>1</sup>

<sup>1</sup> Addiction and dual diagnosis unit, Vall Hebron university hospita, Cibersam, autonomous university of Barcelona, psychiatry service, Barcelona, Spain; <sup>2</sup> adult psychiatry outpatient unit, psychiatry service, Gerona, Spain; <sup>3</sup> International institute for neuroscience, psychiatry service, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Schizophrenia is a complex and disabling affection which causes functional impairment in individuals, and usually patients have lack of treatment adherence, and hence worse outcomes (not only affects patients but also, causes caregivers burden). Studies have shown that monthly paliperidone palmitate (PP1M) is superior to oral medications in improving adherence and avoiding decompensations. In 2016 3-Month Paliperidone Palmitate (PP3M) was approved in Spain for the maintenance treatment of patients affected by Schizophrenia.

**Objectives.**– To describe a sample of patients under PP3M treatment, objectifying their level of acceptance and satisfaction with treatment and the level of overload of the main caregiver.

**Methods.**– A multicenter, prospective, 6 months follow-up study carried out in three psychiatric units of Barcelona and Gerona. The following scales have been administered: Treatment Satisfaction Questionnaire for Medication and Zarit Test to patients and caregivers, respectively.

**Results.**– 58 patients from 17 to 68 years old were evaluated. Most of them suffered from both psychotic disorder (mainly Schizophrenia) and substance use disorder. Clinical stability has been maintained and, in the majority of cases, monotherapy was used and substance abstinence allowed. Results from TSQM and Zarit Test showed a great satisfaction level with this formulation and low levels of burden in caregivers.

**Conclusions.**– PP3M has contributed to maintain symptomatic stability avoiding new relapses and maintaining an adequate tolerability profile. This new formulation has been accepted willingly by the majority of patients and by their relatives, allowing reducing burden of the caregiver in its struggle to assure the pharmacological adherence.

**Disclosure of interest.**– Dr. Ros-Cucurull, Dr. Grau-López, Dr. Ramos-Quiroga and Dr. Roncero have received fees as speakers for Janssen-Cilag. Dr. Ros-Cucurull, Dr. Ramos-Quiroga and Dr. Roncero have received financial compensation for their participation as board members of Janssen-Cilag. Dr. Ramos-Quiroga has received research funding from Janssen-Cilag.

### Disease and health-related beliefs in psychiatric disorders with dermatologic symptoms: Delusional infestation and hypochondriacal disorder

A. Malyutina<sup>1</sup>, M. Vinogradova<sup>1</sup>, G. Rupchev<sup>2\*</sup>, A. Tkhostov<sup>1</sup>

<sup>1</sup> Lomosov Moscow state university, faculty of psychology, Moscow, Russia; <sup>2</sup> Federal State Budgetary scientific institution “Mental Health Research Center”, laboratory of psychopharmacology, Moscow, Russia

\* Corresponding author.

**Introduction.**– In psychodermatology delusional infestation and hypochondriacal disorder are psychiatric disorders with delusional beliefs and overvalued ideas, respectively, pathological bodily sensations, self-mutilation and secondary dermatologic symptoms. Despite the intense discussion of their therapeutic challenge there have been few studies evaluating patients' beliefs about disease and health.

**Objectives.**– To reveal specifics of disease and health-related beliefs in delusional infestation and hypochondriacal disorder.

**Methods.**– 33 patients with delusional infestation and 16 patients with hypochondriacal disorder with complaints of pathological skin sensations participated in the study. The psychosemantic method “Classification of sensations” was used: patients were asked to select disease and health-related sensations from 80 descriptors from 6 classes of bodily sensations: skin (for example, “itch”), inner body (“sickness”), receptor (“sticky”), emotional (“anxiety”), dynamics (“exhaustion”) and attitudinal (“badly”) descriptors. Fisher's exact test was applied.

**Results.**– Associated with disease unhealthy skin sensations (“burning”, “itch”), negative attitudinal (“unbearable”) and emotional (“melancholy”) descriptors were frequently ( $P \leq 0.05$ ) chosen in delusional infestation which showed more intense patients' desperation in comparison to patients with hypochondriacal disorder. Analysis of healthy sensations choices revealed a selection ( $P \leq 0.05$ ) of positive emotional descriptors (“peace”, “joy”, “bliss”) in delusional infestation. By contrast, more frequent ( $P \leq 0.05$ ) usage of unpleasant skin (“numbness”, “hard”, “heat”), attitudinal (“nasty”), dynamics (“frequent”) sensations was in hypochondriacal disorder which demonstrated more intense attention to bodily sensations and a readiness to experience unpleasant bodily sensations.

**Conclusions.**– Altered beliefs about disease and health should be concerned as a factor in adherence reduction in psychiatric and dermatological treatment in delusional infestation and hypochondriacal disorder

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The association between the duration of untreated psychosis and help seeking behaviors in Tunisia

A. Tounsi<sup>1</sup>, M. Karoui, S. Ben Fadhel, M. Daoud, F. Ellouze, F. Mrad Razi Hospital, Psychiatry ward G, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– The duration of untreated psychosis (DUP) is defined as the period between the onset of psychotic symptoms and the establishment of an effective medical treatment. Caregivers play a key role in deciding whether to seek help from traditional healers or psychiatrists.

**Objectives.**– We aimed to determine the association between the DUP and caregivers' explanatory models of psychosis and their help seeking behaviors.

**Methods.**– We conducted a descriptive study. A total of 52 patients treated for first psychotic episode and their caregivers were recruited. A semi-structured interview assessed caregivers' beliefs and perspectives about the episode.

**Results.**– The mean age was 23.07 years ( $\pm 4$  years). The average DUP was 49.8 weeks. In 46.15% of cases, supernatural causes were invoked mainly possessions by a jinn and bewitchment. One third of caregivers had psychiatric explanations for the episode essentially post-traumatic stress and depression. 40.3% of patients visited a traditional healer before treatment. A prolonged DUP correlated with traditional healing ( $P=0.001$ ). Supernatural explanations correlated with traditional healing ( $P=0.03$ ). Delay in treatment was mostly explained by the stigma of psychiatric patients (77%) and lack of knowledge of psychosis by the general population (82.7%).

**Conclusion.**– Supernatural explanatory models of mental illness are frequent in Tunisia's cultural context. Psychiatrists need to raise awareness about mental disorders in order to de-stigmatize patients and offer a more rapid and effective treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Domains of stigmatization and reported causal factors for discrimination in schizophrenia – A survey of patients and their caregivers**

O. Vasiliu

“Dr. Carol Davila” Central Military Hospital, Psychiatry, Bucharest, Romania

\* Corresponding author.

**Introduction.**– Stigmatization in schizophrenia is an important social and mediatic phenomenon, patients diagnosed with this disorder being often targets of misconceptions and discrimination. Mass media illustrates cases of schizophrenia-diagnosed patients which have been involved in hetero-aggressive or self-aggressive acts, which creates a biased image of this pathology.

**Objective.**– Evaluation of patients and their caregivers' considerations about stigmatization related to health status.

**Methods.**– A survey applied on 20 pairs of patients with schizophrenia diagnosed for at least 5 years and their caregivers, included 12 items focused on stigmatization related to the psychiatric symptoms, diagnosis, social and professional functioning and treatment.

**Results.**– According to the results of the survey, 75% of the patients and 65% of their caregivers reported discrimination in the domains of employment opportunities and acceptance in the professional milieu; 60% of the respondents presented arguments for stigmatization related to the diagnosis in the domain of interpersonal relationships (rejection from friends, relatives, or other significant ones); 80% of the respondents considered treatment and its adverse events are the main reasons for which patients are discriminated against, while 70% considered psychotic symptoms are the main reason; 65% of the respondents invoked mass media as the main cause of stigmatization, 60% considered the lack of social policies is the main source of stigmatization, and 50% blamed traditional misconceptions about psychiatric disorders, in general.

**Conclusions.**– A large majority of the patients and their caregivers reported discrimination related to their disorder in important domains of daily living, like social interactions and professional activity.

**Disclosure of interest.**– The author was speaker for Servier, Eli Lilly and Bristol-Myers, and participated in clinical trials funded

by Janssen Cilag, Astra Zeneca, Otsuka Pharmaceuticals, Sanofi-Aventis, Sunovion Pharmaceuticals.

### **Opioid addiction treatment outcome and employment**

M. Delic<sup>1</sup>, K. Kajdiz<sup>1</sup>, P. Pregelj<sup>2</sup>

<sup>1</sup> University psychiatric hospital Ljubljana, center for treatment of drug addiction, Ljubljana, Slovenia; <sup>2</sup> University psychiatric hospital Ljubljana, university of Ljubljana, faculty of medicine, Ljubljana, department of psychiatry, Ljubljana, Slovenia

\* Corresponding author.

**Background.**– Persons who use drugs are significantly less likely to be in employment than other adults of working age.

**Objectives.**– This study aims to examine association of employment and opioid addiction treatment outcome.

**Methods.**– A cohort of 197 patients consecutively admitted to the detoxification unit was investigated. The research interview was administered during the first week of admission to the detoxification unit, the Treatment Outcomes Profile (TOP) and urine tests (UT) were administered on the day of admission and after twelve months.

**Results.**– Employment rate in individuals entering inpatient treatment was 25.4%. Unemployment rate was higher among those with higher doses of opioid substitution therapy ( $U=2694.5$ ;  $P=0.005$ ). There were no differences in employment rate among those with co-occurring mental illness and those without ( $\chi^2=0.007$ ;  $P=0.935$ ), also there were no differences between male and female regarding employment ( $\chi^2=0.42$ ;  $P=0.517$ ) and between those with and without hepatitis C infection ( $\chi^2=2.545$ ;  $P=0.111$ ). Employment rate was not associated with abstinence after twelve months ( $\chi^2=0.448$ ;  $P=0.503$ ). There were no differences in employment rate after 12 months among those who abstain and those who do not abstain ( $\chi^2=2.52$ ,  $P=0.113$ ).

**Conclusions.**– It seems that higher doses of prescribed substitution therapy were associated with lower employability. However, patients with higher doses of prescribed substitution therapy could be more severely addicted. Having job before inpatient treatment was not related to abstinence after twelve months. Also, abstinence after twelve months is not directly associated with higher employability.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0255

### **Relationship of attention deficit hyperactivity disorder with severity of craving in a sample of male patients with opioid use disorder**

C. Evren<sup>1</sup>, I. Alniak<sup>1</sup>, V. Karabulut<sup>1</sup>, T. Cetin<sup>1</sup>, G. Umut<sup>1</sup>, R. Agachanli<sup>1</sup>, B. Evren<sup>2</sup>

<sup>1</sup> Bakirkoy training and research hospital for psychiatry, neurology and neurosurger, research treatment and training center for alcohol substance dependence, Istanbul, Turkey; <sup>2</sup> Baltalimani state hospital for musculoskeletal disorders, department of psychiatry, Istanbul, Turkey

\* Corresponding author.

**Objective.**– The aim of the present study was to evaluate relationship of attention deficit hyperactivity disorder (ADHD) severity of craving, withdrawal and psychopathology in a sample of patients with opioid use disorder.

**Method.**– Participants included 248 male patients with opioid use disorder. Participants were evaluated with the Symptom Checklist-90-R (SCL-90-R), the Clinical Opiate Withdrawal Scale (COWS), the Substance Craving Scale (SCS) and the Adult ADHD Self-Report Scale (ASRS-v1.1).

**Results.**– Age, marital, educational and employment status did not differed between those with the high ADHD risk ( $n = 55$ , 22.2%) and those without ( $n = 193$ , 78.8%). While the severity of withdrawal did not differed between the groups, severity of craving (except SCS-Item 3) ( $t = -3.221$ ,  $P = 0.001$ ) and psychopathology ( $t = -5.580$ ,  $P < 0.001$ ) were higher among those with the high ADHD risk. In logistic regression analyses, severity of craving, particularly SCS-Item 2 (During the past week, how strong was your craving, at the most intense point?) predicted high ADHD risk. In a linear regression models although inattention dimension (but not hyperactivity/impulsivity) of ADHD predicted severity of craving in the first model, after including the severity of psychopathology and withdrawal in the new model as independent variables, inattention was no longer a predictor, while severity of somatization and withdrawal predicted the severity of craving.

**Conclusion.**– These findings suggest that the high ADHD risk, particularly severity of inattention dimension, may be related with the severity of craving, severity of somatization and withdrawal may have mediator effect on this relationship among patients with opioid use disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Are there coping strategies differences in cocaine, cannabis and methamphetamine addicted persons in Bulgaria?**

V. Giannouli<sup>1</sup>\*, D. Ivanova<sup>2</sup>

<sup>1</sup> Aristotle university of Thessaloniki, school of medicine, Drama, Greece; <sup>2</sup> South-West university “Neofit Rilski”, department of psychology, Blagoevgrad, Bulgaria

\* Corresponding author.

**Introduction.**– Although, it is widely claimed that people are starting to use drugs to cope with stress on a daily basis, because they can not find other options, the strategies that individuals use to cope with stress while addicted is not examined so far in detail.

**Objective.**– The aim of this study is to compare the coping strategies of cocaine, cannabis and methamphetamine addicted persons with exactly the same demographic characteristics in Bulgaria.

**Method.**– Thirty-nine cocaine, thirty-nine methamphetamine and thirty-nine cannabis addicted persons, were examined with the Bulgarian version of the COPE Inventory (Carver, Scheier, & Weintraub, 1989). All groups were equated in regard to gender (31 men), age ( $M_{age} = 29.07$ ,  $SD_{age} = 4.44$ ), years of education ( $M_{education} = 8.79$ ,  $SD_{education} = 1.39$ ), and years of addiction ( $M_{years\ of\ addiction} = 6.97$ ,  $SD_{years\ of\ addiction} = 1.70$ ).

**Results.**– One-way analysis of variance (one-way ANOVA) revealed that there were no statistically significant differences between the three groups for all the following self-reported strategies ( $P > .05$ ): active coping, planning, suppression of competing activities, restraint coping seeking social support for instrumental reasons, seeking social support for emotional reasons, positive reinterpretation and growth, denial, acceptance, turning to religion,

focusing on and venting of emotions, behavioral disengagement, mental disengagement, and alcohol-drug disengagement.

**Conclusions.**– According to the results of stress coping of cocaine, cannabis and methamphetamine addicted young individuals, the substance seems not to play a differential role in the preference and use of specific coping strategies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Coping strategies in methamphetamine addicted persons in Bulgaria**

V. Giannouli<sup>1</sup>\*, D. Ivanova<sup>2</sup>

<sup>1</sup> Aristotle university of Thessaloniki, school of medicine, Drama, Greece; <sup>2</sup> South-West University “Neofit Rilski”, department of psychology, Blagoevgrad, Bulgaria

\* Corresponding author.

**Introduction.**– The assessment of how people respond to stress and the relevant coping strategies that they use, is a topic of interest in the general population as well as in individuals with different forms of substance addiction.

**Objective.**– The aim of this study is to examine the possible influence of demographic factors on the coping strategies of methamphetamine addicted persons.

**Method.**– One hundred forty-two methamphetamine addicted persons (103 men, 39 women;  $M_{age} = 28.17$ ,  $SD_{age} = 4.44$ , 23–37 range of age,  $M_{education} = 9.29$ ,  $SD_{education} = 1.46$ , 7–11 range of education years,  $M_{years\ of\ addiction} = 7.16$ ,  $SD_{years\ of\ addiction} = 1.63$ , 5–10 range of years with addiction) were examined with the Bulgarian version of the COPE Inventory.

**Results.**– Results indicated that age, education, years of addiction, and gender do not predict in a statistically significant way none of the following self-reported strategies: active coping, planning, suppression of competing activities, restraint coping seeking social support for instrumental reasons, seeking social support for emotional reasons, positive reinterpretation and growth, denial, acceptance, turning to religion, focusing on and venting of emotions, behavioral disengagement, mental disengagement, and alcohol-drug disengagement.

**Conclusions.**– The above findings suggest that further research should examine other demographic or psychological variables that may play a significant role in the prediction of the coping strategies used by the individuals who suffer from this specific form of addiction.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0258

### **Exploring coping strategies in cannabis addicted users in Bulgaria**

V. Giannouli<sup>1</sup>\*, D. Ivanova<sup>2</sup>

<sup>1</sup> Aristotle university of Thessaloniki, school of medicine, Drama, Greece; <sup>2</sup> South-West university “Neofit Rilski”, department of psychology, Blagoevgrad, Bulgaria

\* Corresponding author.

**Introduction.**– Although coping strategies play an important role in recovery from addictions, people with cannabis addiction are still little investigated in regard to the ways that they react to stress.

**Objective:** The aim of this study is to examine the role that demographic factors play on the prediction of coping strategies in cannabis addicted individuals in Bulgaria.

**Method.**– Two hundred nineteen Bulgarian cannabis-addicted persons (175 men, 44 women;  $M_{age} = 28.70$ ,  $SD_{age} = 4.32$ , 23–36 range of age,  $M_{education} = 9.10$ ,  $SD_{education} = 1.47$ , 7–11 range of education years,  $M_{years\ of\ addiction} = 7.05$ ,  $SD_{years\ of\ addiction} = 1.79$ , 5–10 range of years with addiction) were examined with the Bulgarian version of the COPE Inventory.

**Results.**– Results indicated that age, education, years of addiction, and gender do not predict in a statistically significant way none of the following self-reported strategies: active coping, planning, suppression of competing activities, restraint coping seeking social support for instrumental reasons, seeking social support for emotional reasons, positive reinterpretation and growth, denial, acceptance, turning to religion, focusing on and venting of emotions, behavioral disengagement, mental disengagement, and alcohol-drug disengagement.

**Conclusions.**– This research suggests that demographic factors are not good predictors for the identification of specific coping strategies in use by cannabis addicts. Future research should further investigate the contribution of other social and psychological factors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Expert consensus on best practices for opioid prescription for chronic pain. Risk management and benefits**

A. Lligoña<sup>1\*</sup>, P. Bruguera<sup>1</sup>, A. Henche<sup>2</sup>, A.I. López<sup>1</sup>, L. Ortega<sup>1</sup>

<sup>1</sup> Addictions unit, hospital clínic de Barcelona, Barcelona, Spain;

<sup>2</sup> Addictions unit, Complejo Hospitalario de Toledo, Toledo, Spain

\* Corresponding author.

**Introduction.**– Opioid prescription (OP) is a widespread practice, which raises concerns for the risks involved. In the last decade, its expanding use has led to an important increase of adverse events, such as OP abuse and dependence, and opioid-related deaths. It is important to remark that chronic pain often involves psychiatric symptoms which at the same time can increase the perception of pain. For all this, patients with chronic pain and psychiatric disorders tend to receive higher doses for longer periods.

**Objectives.**– We aimed at developing a clinical guideline based on scientific literature to improve clinical approach to chronic pain and avoid adverse events related to its use, by helping clinicians to identify and treat OP abuse and dependence.

**Methods.**– An interdisciplinary expert consensus (general practitioners, anesthesiologists, oncologists, psychiatrists, psychologists and nursery) performed a review of the literature regarding prescription opioids for chronic pain with the support of scientific societies such as SEMFyC (Spanish Society of General Practitioners) and SOCIDROGALCOHOL (Spanish Society on Substance Use).

**Results.**– We present our best practice recommendations for OP in the “Consensus guideline for an appropriate use of analgesic opioids. Risks management and benefits.”

We describe general indications for health authorities, health professional and for patients.

**Conclusions.**– A rigorous consensus method led to key recommendations for OP. This is an important step toward reducing practice variation, closing the evidence-practice gap, and reducing adverse events related to OP.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Leptin and ghrelin levels in alcohol dependent patients and their relationship with withdrawal and craving**

S. Mehta<sup>1\*</sup>, A. Baruah<sup>2</sup>, S. Das<sup>2</sup>, S. Khattri<sup>1</sup>

<sup>1</sup> SMI, psychiatry, Dehradun, India; <sup>2</sup> LGBRIMH, psychiatry, Tezpur, India

\* Corresponding author.

**Introduction.**– Association between leptin and ghrelin plasma levels and alcohol craving have been found in few studies but they have failed to differentiate this correlation with alcohol withdrawal state.

**Objectives.**– To study levels of leptin and ghrelin in relation with alcohol craving and to study this correlation with respect to hyperexcitable state of alcohol withdrawal.

**Methods.**– 25 indoor patients fulfilling the alcohol dependence criteria were assessed for alcohol withdrawal symptoms and craving. Leptin and ghrelin levels were measured on 1st day, @ the end of 1st week, @ the end of 3rd week of stopping alcohol. Withdrawal was assessed using CIWA-A at day 1 and day 7, craving was assessed using PENN's scale of craving at the end of week 1 and week 3. Control group consisted of 15 first degree relatives not taking alcohol. **Results.**– It was found that leptin [ $t(38) = 2.95$ ,  $P = 0.005$ ] and ghrelin [ $t(38) = 2.56$ ,  $P = 0.015$ ] were significantly higher in alcohol dependent patients. Levels of hormones had no significant correlation with alcohol withdrawal scores but had positive correlation with craving scores after abstinence.

**Conclusions.**– Leptin and ghrelin, known for balancing the energy homeostasis of body, also seem to play a role in pathways of drug dependence and craving. This relation is independent of stress hormone axis as leptin and ghrelin levels are not correlated with withdrawal scores, which is an indicator of stress hormone axis activation during alcohol withdrawal.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Depression disorder with peripartum onset – Approach and treatment in primary care**

L. Monteiro<sup>1\*</sup>, J. Ferreira<sup>2</sup>, B. Almeida<sup>3</sup>, C. Fragoeiro<sup>3</sup>, C. Machado<sup>1</sup>

<sup>1</sup> Magalhães Lemos hospital, Ward C, Porto, Portugal; <sup>2</sup> Low Vouga centre hospital, department of psychiatric and mental health, Aveiro, Portugal; <sup>3</sup> Magalhães Lemos hospital, Ward B, Porto, Portugal

\* Corresponding author.

**Introduction.**– Peripartum depression is a public health problem. Pregnancy and postpartum is socially and culturally seen as a period of joy and fulfilment, however, 10% of pregnant women develop feelings of sadness, despair and demotivation. This problem is commonly underdiagnosed and not treated, with severe consequences for the mother and child bonding and the cognitive and socioemotional development of the later.

**Objectives.**– Our purpose is to draw attention to the methods of diagnosis and treatment of peripartum depression best suited to the field of primary care.

**Methods.**– Pubmed search with the query “peripartum depression primary care”, during the last 5 years, national health guidelines and the latest The Maudsley Prescribing Guidelines.

**Results.**– We found some preventive measures to perinatal depression: the father should be present in health appointments; the physician should recognize pregnant' emotions and identify psychosocial risk factors. Psychoeducation is very important and

can be offered by the program “What were we thinking” – 6 h group psychoeducation. Diagnosis should be made applying Edinburgh Postnatal Depression Scale. Treatment starts with supportive therapy. Difficult cases should be referenced to psychiatrists and interpersonal psychotherapy or cognitive-behavioural therapy should be given. The safest antidepressants are sertraline and fluoxetine. During breastfeeding paroxetine and sertraline are recommended.

**Conclusions.**– Peripartum depression is frequently unrecognized. General practitioners are the front line physicians and can truly prevent, diagnose and treat this disease, with no major financial burden, and no major time consumption, leading to great benefits to women, children and families.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0262

### **Correlates of benzodiazepine dependence in patients with depression**

B. Oueslati<sup>1</sup>\*, L. Menif<sup>2</sup>, O. Meziou<sup>3</sup>, W. Melki<sup>2</sup>, H. Zalila<sup>3</sup>  
<sup>1</sup> Razi hospital, psychiatry, Mannouba, Tunisia; <sup>2</sup> Razi hospital, psychiatry D, Mannouba, Tunisia; <sup>3</sup> Razi hospital, psychiatric outpatient unit, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Benzodiazepines may be prescribed to manage anxiety and insomnia in patients with depression. However, as noticed during our daily practice, a considerable proportion of patients treated for depression and receiving benzodiazepines developed a dependence to these molecules.

**Objectives.**– To estimate the proportion of patients with depression who develop a benzodiazepine dependence and to identify its related predicting factors.

**Methods.**– We conducted a comparative study in Razi Hospital's outpatient psychiatry unit (Tunisia). We included patients aged 18 to 65 who were diagnosed with depression during 2014's first three quarters. Included patients were prescribed benzodiazepines. Follow-up period was of two years. A multivariate analysis was performed in order to identify dependence predicting factors.

**Results.**– We included 54 patients. 52% developed a benzodiazepine dependence during the follow-up period. Two predicting factors were identified: a daily mean benzodiazepine dose of more than 9.5 milligrams of diazepam equivalents prior to taper off ( $P=0.001$ ) and a benzodiazepine taper off initiated after the fifth week of benzodiazepine intake onset ( $P=0.007$ ).

**Conclusions.**– The proportion of patients who developed a benzodiazepine dependence was high. Low doses and time-limited benzodiazepine prescription should be taken into consideration when managing patients with depression in order to prevent dependence.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0263

### **Does physical health monitoring reduce mortality in people with psychotic disorders?**

A. Ilyas<sup>1</sup>, E. Chesney<sup>2</sup>, R. Patel<sup>2</sup>  
<sup>1</sup> Institute of psychiatry, psychology and neuroscience, department of psychology, London, United Kingdom; <sup>2</sup> Institute of psychiatry, psychology and neuroscience, department of psychosis studies, Box PO63, London, United Kingdom

\* Corresponding author.

**Introduction.**– Psychotic disorders are associated with a significant reduction in life expectancy due, in part, to increased cardiovascular risk factors such as smoking, obesity and metabolic syndrome. Physical health monitoring programmes have been implemented by UK mental health services in an attempt to improve life expectancy in people with psychotic disorders but little is known about their effectiveness.

**Objectives.**– To determine whether physical health monitoring strategies are effective in reducing mortality in people with psychotic disorders.

**Methods.**– Literature review of studies investigating the implementation and effectiveness of physical health monitoring.

**Results.**– A number of studies found that physical health monitoring programmes are poorly implemented with variable uptake ranging from 25 to 70%. There were no RCTs or systematic reviews investigating the effectiveness of physical health monitoring in psychotic disorders. Studies investigating physical health monitoring in the general population found that although such programmes may help to reduce cardiovascular risk factors in a selected population, there is no evidence that they reduce mortality.

**Conclusions.**– There is little evidence to support the use of physical health monitoring in people with psychotic disorders. Instead, more emphasis should be placed on the role of primary prevention strategies such as assertive smoking cessation, dietary and exercise interventions and avoiding unnecessary long-term use of antipsychotics which may contribute to increased cardiovascular risk. Greater investment in primary prevention would substantially improve life expectancy in people with psychotic disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Single and multiple substance opioid exposures in acute care hospitals and emergency departments reported to U.S. poison centers, 2011–2016**

S. Rege<sup>1</sup>\*, H. Borek<sup>1</sup>, J. Rizer<sup>1</sup>, N. Ait-Daoud Tiouririne<sup>2</sup>, C. Holstege<sup>1</sup>

<sup>1</sup> University of Virginia, emergency medicine, Charlottesville, USA;

<sup>2</sup> University of Virginia, psychiatry and neurobehavioral sciences, Charlottesville, USA

\* Corresponding author.

**Background.**– Opioid overdoses have increased dramatically over the last decade in the U.S. This study aims to examine the characteristics of single substance (SSE) and multiple substance (MSE) opioid exposures reported to U.S. poison centers (PCs).

**Methods.**– The National Poison Data System (NPDS) was queried for opioid exposures evaluated at hospital based emergency departments (EDs) from 2011 to 2016, further segmenting these into SSE and MSE. Patient characteristics were analyzed descriptively and trends were evaluated using Poisson regression.

**Results.**– During the study period, there were 145,322 reports of opioid exposures, with SSE accounting for 38.9% calls. SSE demonstrated a higher increase (28.1%,  $P < 0.001$ ) compared to MSE (16.7%,  $P < 0.001$ ). The proportion of males was higher in the SSE (53.1% vs 46.3%). SSE were more frequently treated and released (44.8% vs 24.7%), and were less frequently admitted to the critical care unit (CCU) (24.2% vs 41.2%). Major (10.8% vs 13.6%) clinical effects were less common in SSE. Intentional opioid abuse (28.5% vs 18.4%) was more frequent in SSE. Conversely, suspected suicides were more common in MSE (27.4% vs 57.9%). Tramadol (29.1% and 11.7%) and oxycodone (29.8% and 20.8%) were the most frequent exposure agents in SSE and MSE, respectively. Intubation was reported more commonly for MSE (4.9% SSE vs 13.4% MSE), while naloxone was

the more frequently reported therapy for SSE (36.4% SSE vs 32.9% MSE).

**Conclusions.**– Among the opioid calls received by the PCs, a higher proportion reported MSE which demonstrate a greater severity of effects and higher resource utilization.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0265

### **Serum BDNF levels in patients with opioid dependence during the early withdrawal period: A case control study**

S. Sarkar\*, R. Jain, R. Gupta, S. Mohan, M. Kumar  
All India Institute of Medical Sciences, New Delhi, department of psychiatry and NDDTC, New Delhi, India

\* Corresponding author.

**Introduction.**– The neurobiology of opioid dependence has been explored on various fronts, but still remains elusive. The levels of brain-derived neurotrophic factor (BDNF), a neuropeptide important for neural growth and differentiation, have been explored as a marker for opioid use, though evidence has been limited and contradictory. The present study aimed to explore the serum BDNF levels in opioid dependent patients.

**Methods.**– Thirty patients with opioid dependence syndrome according to ICD-10, and 42 age and gender matched healthy controls were included. After inclusion, Socio-demographic details of all patients were recorded. At day 1 and after 10 days of inpatient detoxification, patients were administered the Fagerstrom's Test for Nicotine Dependence (FTND) and the Alcohol Smoking and Substance Involvement Screening Test (ASSIST) and serum BDNF levels were measured by ELISA technique.

**Results.**– In the present study the mean BDNF serum level among cases at Day 1 was 12.05 ng/ml, while that of controls was 12.20 ng/ml, the difference being non-significant ( $t=0.239$ ,  $P=0.812$ ). Also, there was no significant difference observed in the BDNF levels in patients at day 1 and 10 of inpatient detoxification. BDNF levels at day 1 and 10 correlated with each other ( $r=0.718$ ,  $P<0.001$ ).

**Conclusion.**– These results suggest that BDNF may play a critical role in the course of opiate addiction and withdrawal. (Supported by All India Institute of Medical Sciences New Delhi India).

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Integrated nanotherapeutic strategies for narcoassociated pain syndrome correction**

I. Sosin\*, Y. Chuiev, O. Goncharova  
Kharkiv medical academy of postgraduate education, department of narcology, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**– Innovation nanotechnology approaches within precision medicine (Van der Stel J., 2015) searched to correct pain syndrome (PS) in clinical addictology are recognized as prospective, that is confirmed by European Psychiatric Association policy, recommendations and prognoses.

**Objectives.**– Instrumental detoxification integrated therapeutic set: membrane plasmapheresis (MPP), laser therapy (LT), and rational pharmacotherapy used for PS complex treatment in opioid dependence (OD).

**Methods.**– “Visual analogue scale” clinical psychopathological, quantification monitoring of PS treatment efficiency.

**Results.**– 60 OD patients with prevailing PS in their abstinence syndrome structure were examined. Main group (MG) included 35 patients treated with the proposed method (Patent of Ukraine 53586), observation group (OG) included 25 patients received medication therapy.

Integrated technique included MPP – 1 session per 3 days, 1.0 ml non-narcotic analgesic Ketorolac intramuscular injection, once every day for 3 days. In addition, 0.63  $\mu$ m wavelength intravascular LT, 2 mW radiation intensity, 30–40 min exposure, once a day for 3 days was prescribed.

After day 1 treatment, OG patients' pain parameter decreased to  $5.6 \pm 0.8$  points, meanwhile in MG patients this parameter values went on increasing to  $8.3 \pm 0.9$ . Post-treatment pain level decreased reliably in OG to  $1.60 \pm 0.05$  points ( $P<0.01$ ), and in MG to  $2.90 \pm 0.08$  points ( $P<0.01$ ). Difference between the post-treatment OG and MG values was valid ( $P<0.01$ ). MPP, LT, Ketorolac use allowed to relieve pain syndrome in OD patients for 3 days.

**Conclusions.**– The developed integrated method gives pathogenically targeted adjuvant medical effects, that allows to recommend it to use in analgesic programs for OD treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0267

### **Integrated synergistic combination of pharmacological complex therapeutic effects for management of pain disorders of narcotic origin**

I. Sosin\*, Y. Chuiev, O. Goncharova  
Kharkiv medical academy of postgraduate education, department of narcology, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**– Pain syndrome is pathognomonic, pathophysiological and pathopsychological obverse component of narcotic dependence (ND) acute and chronic signs, therefore, searching new approaches to its management remains extremely topical. Neuro-pathic and nociceptive pain causes suffering, dysphoria, aggressive behavior, emotional exhaustion, depressions, suicidal tendencies, decreased life quality, risk of relapses.

**Objective.**– To study analgesic effects of multimodality pharmacological triad synergistic combination in complex treatment for narcotic dependence at abstinence syndrome.

**Methods.**– This pain syndrome (PS) management technique in ND patients (Patent of Ukraine 68975) includes combined synergistic therapeutic effects of 3 medicines: Diazepamum tranquiliser (a.m., p.m., and at night 0.5% solution 2.0–4.0 mL intramuscular), Paracetamol non-narcotic analgesic (a.m. and p.m. 0.2–0.4 g oral) and Caffeine psychomotor stimulant (10% solution 1.0–2.0 mL subcutaneous).

The technique efficiency monitoring was performed by PS verification: Visual analogue scale; Verbal assessment scale; The McGill pain questionnaire; The Roland-Morris pain questionnaire.

**Results.**– 37 narcotic addicts were observed with opioid abstinence syndrome within marked PS period. They were divided into 2 groups: 20 patients were referred to main group (MG) treated by the proposed method; 17 patients were included into observation group (OG) received common conventional treatment.

At the first 4 days, PS manifestations intensity conventional parameter value in MG was equal to 43%, and in OG patients it was 30% ( $P<0.05$ ), that is considered to be effective in opioid dependence clinical course.

*Conclusions.*– Mechanisms of effect and recommendations are given concerning prospective introduction of PS pharmacological correction in ND clinical course.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0268

### **Differentiated use of precision analgesic mechanisms of transcerebral electrophoresis for treatment programs in addictology**

I. Sosin\*, Y. Chuiev, O. Goncharova

*Kharkiv medical academy of postgraduate education, department of narcology, Kharkiv, Ukraine*

\* Corresponding author.

*Introduction.*– Progress of analgesic therapy in addictology is connected with integrated precision approaches (Van der Stel J., 2015) combining therapeutic effects of transcerebral electrophoresis (TCE) with bilaterally applied electrodes and implementation of bipolar ions of analgesic and sedative pharmaceuticals from different orbits.

*Objectives.*– To study special features of dynamics of analgesic spectrum effects in narcotic addicts (NA) under basic integrated TCE therapy.

*Methods.*– Pain syndrome (PS) treatment in NA was performed by TCE (“Potok” unit), herewith, Diphenhydramine active cathode was fixed at superciliary frontal skin, Metamizole sodium active anode was applied on the back in the seventh vertebra area (Bourguignon’s orbital-occipital electrophoresis) with 1.5–5.0 mA amperage, exposure 25–30 minutes, 1–2 times daily. Treatment duration was determined by evidence of pain sensitivity threshold monitoring, and at its 2–3-fold increased level the treatment was ceased (Patent Ukraine 70867).

*Results.*– 32 NA with marked PS were examined. 19 patients were referred to main group (MG) treated with the proposed method. 13 patients were included to observation group (OG) treated conforming to addictology conventional therapeutic standards.

Efficiency of the proposed medical method was determined by the monitored pain sensitivity threshold. In MG pretreatment pain sensitivity threshold was  $0.84 \pm 0.72$ , in OG –  $0.96 \pm 0.69$ , difference was not valid ( $P > 0.05$ ). Intra-treatment monitoring demonstrated pain sensitivity threshold increase in MG up to  $3.57 \pm 0.61$ , in OG up to  $2.14 \pm 0.84$ . MG and OG posttreatment values difference was valid ( $P < 0.01$ ).

*Conclusions.*– Complex electrophoretic and pharmacotherapeutic actions of the technique provide reliable relieving analgesic effect at narcotic dependence.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0269

### **Alcoholic origin of positional compression syndrome – Identification of emergency addictology problem**

I. Sosin\*, O. Goncharova, Y. Chuev

*Kharkiv medical academy of postgraduate education, department of narcology, Kharkiv, Ukraine*

\* Corresponding author.

*Introduction.*– Within recent decade in Ukraine, alcohol dependence syndrome demonstrated considerable clinical, pathomorphological, pathokinetic changes of its forms, emerging the subject

of intensive studies for Ukrainian scientific addictology. Alcohol dependence, being associated with atypical forms of drunkenness, acute intoxications, consumption of energetic beverages, beer, megacompulsive alcohol craving, lost capacity of quantitative and situational control, alcohol toxic dosages consumption, represents risk factor for severe psychic, somato-neurological disorders, incapitation.

Continuous massive alcoholization exposes patients unconscious, dormant intoxicated, soporose, comatose states, resulting in positional compression syndrome (PCS) due to nervous impulse ischemia and cutoff of muscles, peripheral vessels, local nerves, mechanically compressed by own body mass. It is real threat of PCS transforming into severe emergency. But, PCS problem hasn’t been identified in addictology, integrated approaches to therapy haven’t been developed.

*Objectives.*– To perform PCS targeted research within scientific addictology and didactics.

*Methods.*– Targeted special PCS monitoring test (questionnaire) for in-patients examination was developed.

*Results.*– 37 addicted in-patients were examined by massive non-sampling method and target questionnaire scanning for PCS evidence in history and feasible residual signs at the moment. Among 32 alcohol-dependent patients, medium severe forms of intoxication were revealed to be one of principal causes of continuous (over 1 hour) unnatural positions followed by acute PCS clinical picture. Clinically, PCS severity degree varied from mild (subclinical, masked, latent) to medium and severe with relative surgical consequences.

*Conclusions.*– PCS diagnosis and therapeutic principles were grounded, didactic approaches to implementation of new subdivision in clinical addictology are proposed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Current stage of the biological therapies for cocaine dependence – A narrative review**

D. Vasile<sup>1,2\*</sup>, O. Vasiliu<sup>1</sup>

<sup>1</sup> *Central university and emergency military hospital “Dr. Carol Davila”, psychiatry, Bucharest, Romania;* <sup>2</sup> *University of medicine and pharmacy “Dr. Carol Davila”, clinical psychopharmacology, Bucharest, Romania*

\* Corresponding author.

Immunological therapies for addictive disorders are subject of intensive research, but clear results that could support their clinical use on large scale haven’t been offered yet. Cocaine dependence and nicotine dependence are the most extensively studied addictions in the field of biological therapies, but pre-clinical data regarding anti-methamphetamine and anti-opioid vaccines are also available. While the expectations for this therapy are quite high, problems related to its efficacy, especially on long term, hindered the clinical use of anti-drug vaccines. A narrative review was considered necessary in order to establish the current stage of the development in the field of cocaine dependence, as no specific treatment for this disorder have yet been validated. The first step was conducting a literature review focused on clinical trials detected between 2000 and 2017 which had as the main objective detection of anti-cocaine vaccines efficacy and tolerability. A number of 6 trials were identified, and they presented a moderate rate of efficacy, with a fair tolerability. The second step was the detection of difficulties in the current research regarding anti-drug vaccines. Based on the available pre-clinical informations and clinical trials results, the design of the haptens used in anticocaine vaccines is a major challenge. Cocaine

is a small molecule and it must be conjugated with an immunogenic particle, like cholera toxin B, in order to provoke significant immune response from the organism. In conclusion, more effort is needed for finding haptens which can induce long-lasting immune response, which correlates with the vaccine's efficacy.

*Disclosure of interest.*– The first author was speaker for Astra Zeneca, Bristol Myers Squibb, CSC Pharmaceuticals, Eli Lilly, Janssen Cilag, Lundbeck, Organon, Pfizer, Servier, Sanofi Aventis, and participated in clinical research funded by Janssen Cilag, Astra Zeneca, Eli Lilly, Sanofi Aventis, Schering Plough, Organon, Bioline Rx, Forenap, Wyeth, Otsuka Pharmaceuticals, Dainippon Sumitomo, Servier, Sunovion Pharmaceuticals.

### **Opioid antagonists efficacy and tolerability in young patients diagnosed with gambling disorder – A case series**

O. Vasiliu

*“Dr. Carol Davila” central military hospital, psychiatry, Bucharest, Romania*

\* Corresponding author.

*Background.*– Based on the effect of the opioid antagonists to inhibit dopamine neurotransmission in the motivational circuits, these agents seem to be good therapeutic choices in both drug and behavioral addictions.

*Objective.*– To evaluate the efficacy and tolerability of two opioid antagonists, naltrexone and nalmefene, in the treatment of gambling disorder in young adults.

*Methods.*– Four cases of gambling disorder, diagnosed according to the DSM 5 criteria, three male and one female, mean age 22.4, medium duration of the disorder 16.9 months, without prior pharmacological treatment with opioid antagonists, were evaluated monthly during 6 months of treatment with naltrexone 50 mg prn ( $n=2$ ) or nalmefene 18 mg prn ( $n=2$ ). Patients were instructed to take their medication whenever they felt the craving for gambling. Yale-Brown Obsessive Compulsive Scale adapted for Pathological Gambling (Y-BOCS-PG), Global Assessment of Functioning (GAF) and Clinical Global Impression-Severity (CGI-S) were applied monthly.

*Results.*– After 6-month of treatment 3 patients recorded significant changes of the Y-BOCS-PG (–65.5%), GAF (+25.5%), and CGI-S (–21.5%) scores, and one patient registered sub-optimal changes of the main outcome, Y-BOCS-PG (–34.5%), with modest improvements on GAF (+12.5%), and no change on CGI-S. Mean duration of naltrexone administration was 89.5 days, and for nalmefene 88.5 days. No differences in the Y-BOCS-PG scores were detected between patients treated with naltrexone and those treated with nalmefene. Both agents were very well tolerated.

*Conclusions.*– Opioid antagonists could be a useful therapeutic option in young patients diagnosed with gambling disorder, with a favorable efficacy/tolerability rapport.

*Disclosure of interest.*– The author was speaker for Servier, Eli Lilly and Bristol-Myers, and participated in clinical trials funded by Janssen Cilag, Astra Zeneca, Otsuka Pharmaceuticals, Sanofi-Aventis, Sunovion Pharmaceuticals.

### **Pharmacodynamic and pharmacokinetic genetic polymorphisms affect adverse drug reactions of haloperidol in patients with alcohol-related psychosis**

M. Zastrozhin

*Russian medical academy of postgraduate education of the ministry of health of the Russian Federation, addictology, Moscow, Russia*

\* Corresponding author.

Haloperidol is used for treatment of alcohol use disorders in patients with signs of alcohol-related psychosis. Haloperidol therapy poses a high risk of adverse drug reactions (ADR).

The primary objective of this study was to evaluate the correlation between DRD2, SLC6A3 (DAT) and COMT genetic polymorphisms and to investigate their effect on the development of adverse drug reactions in patients with alcohol use disorder who received haloperidol. Also we have tried to investigate the effects of CYP2D6 and CYP3A5 genetic polymorphisms on haloperidol equilibrium concentration.

The study included 71 male patients with alcohol use disorder. Genotyping was performed using the allele-specific real-time PCR. CYP2D6 and CYP3A were phenotyped with high-performance liquid chromatography-mass spectrometry using concentration of endogenous substrate of the enzyme and its urinary metabolites (6-hydroxy-1,2,3,4-tetrahydro-beta-carboline (6-HO-THBC) to pinoline ratio for CYP2D6 and 6-beta-hydroxycortisol to cortisol ratio for CYP3A).

Results of this study detected a statistically significant difference in the adverse drug reactions intensity in patients receiving haloperidol with genotypes 9/10 and 10/10 of polymorphic marker SLC6A3 rs28363170. In patients receiving haloperidol in tablets the increases in the UKU score of  $9.96 \pm 2.24$  (10/10) vs  $13 \pm 2.37$  (9/10) ( $P < 0.001$ ) and in the SAS score of  $5.04 \pm 1.59$  (10/10) vs  $6.41 \pm 1.33$  (9/10) ( $P = 0.006$ ) were revealed. The equilibrium concentration levels depend on CYP2D6 genetic polymorphism (0.26 ng/ml [0.09; 0.48] vs 0.54 ng/ml [0.44; 0.74],  $P = 0.037$ ). Thus, the study demonstrates that CYP2D6 and SLC6A3 genetic polymorphism can affect haloperidol concentration levels in patients with alcohol use disorder.

hospital, behavioral medicine, Muscat, Oman

\* Corresponding author.

*Aim.*– The aim of this study was to estimate the prevalence and predictors of depression among Oman adult population attending primary healthcare clinics (PHCs) in Muscat Governorate in 2011.

**Methodology.**– A cross-sectional study was conducted on 2005 participants attending 27 different PHCs in Muscat Governorate during 2011. A Patient Health Questionnaire (PHQ-9), together with a socio-demographic and relevant clinical data questionnaire was administered.

**Results.**– Of the 2005 participants, 61.8% were women and 42.1% were of 25–50 age group. Of the total, 44.4% were employed of whom 51% were government employees. The prevalence of depression among them was 8.1%. The adjusted odds ratios generated by logistic regression models indicated that depression was significantly associated with age greater than 50 years old (OR=2.23; 95% CI 1.07, 4.22;  $P=0.04$ ), female (OR=1.34; 95% CI 1.12, 3.82;  $P=0.03$ ), married (OR=1.91; 95% CI 1.11, 3.30;  $P=0.02$ ), graduated or attended higher education (OR=1.40; 95% CI 1.03, 2.66;  $P=0.04$ ), working in the private sector if employed (OR=1.72; 95% CI 1.08, 2.75;  $P=0.02$ ), and having chronic illness such as diabetes mellitus, hypertension, asthma, heart, thyroid, and renal diseases (OR=1.82; 95% CI 1.03, 3.51;  $P=0.01$ ).

**Conclusion.**– The rate of depression appears to be in the lower range compared to rate reported from elsewhere. Some socio-cultural factors that may contribute to the present findings are discussed.

### Subjective sleep quality is associated with neurocognitive impairment in patients with depression

E. Berdzenishvili, S. Tabagua

*Ltd. Acad. O. Gudushauri national medical centre, department of psychiatry, Tbilisi, Georgia*

\* Corresponding author.

**Introduction.**– Sleep is essential for cognitive performance. Frontal brain areas are vulnerable to sleep disorders. Sleep disturbances are common among patients with Major Depressive Disorder (MDD). Persons with depression show impaired performance on measures of frontotemporally mediated cognitive function.

**Objective.**– To investigate association of subjective sleep quality and objective measures of neurocognitive dysfunction in patients with MDD.

**Methods.**– Two groups of patients, who met DSM V diagnostic criteria of MDD, were selected and matched. One group (15 patients, mean age 44.2, SD=4.8) had MDD and poor sleep quality and second group (13 patients, mean age 46.2, SD=4.3) consisted of patients having MDD and good sleep quality.

To measure the sleep quality participants completed The Pittsburgh Sleep Quality Index (PSQI).

To measure frontotemporally mediated cognitive functioning Wisconsin Card Sorting Test and Continuous Performance Test were administered.

**Results.**– Participants with MDD and poor sleep quality performed worse than patients with MDD and good sleep quality. Sleep duration scores on the PSQI were correlated with the CPT Hit Reaction Time ( $r=.965$ ;  $P=0.01$ ). In degraded CPT performance measure of sustained attention were related to scores of sleep disturbance ( $r=-.874$ ;  $P=0.01$ ), such that less sleep disturbances were associated to better performances. Shorter sleep latency were associated to higher scores on correct answers in WCST ( $r=-.879$ ;  $P=0.01$ ).

**Conclusion.**– Sleep quality, specifically sleep latency, disturbances and duration, is related to specific impairments in neurocognitive

functioning in patients with MDD. Sleep quality should ideally be assessed before treatment, as they may influence MDD treatment response.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Risk factors for mortality in unipolar depression: Findings from an ethnically diverse cohort followed for eight years

J. Das-Munshi<sup>1\*</sup>, C.K. Chang<sup>2</sup>, P. Schofield<sup>3</sup>, S. Robert<sup>4</sup>, M. Prince<sup>5</sup>

<sup>1</sup> King's College London institute of psychiatry, psychology & neuroscience, health services & population research, London, United Kingdom; <sup>2</sup> University of Taipei, department of health and welfare, Taipei, Taiwan R.O.C.; <sup>3</sup> KCL, primary care and public health sciences, London, United Kingdom; <sup>4</sup> KCL, department of psychological medicine, London, United Kingdom; <sup>5</sup> KCL, health services & population research, London, United Kingdom

\* Corresponding author.

**Background.**– Depression is associated with increased mortality, however little is known about its variation by ethnicity.

**Methods.**– We conducted a cohort study of individuals with ICD-10 unipolar depression from secondary mental healthcare, from an ethnically diverse location in southeast London, followed for eight years (2007–2014) linked to death certificates. Age- and sex-standardised mortality ratios (SMRs), standardised to the population of England and Wales, were derived. Hazard Ratios for mortality were derived through multivariable regression procedures.

**Results.**– Data from 20,320 individuals contributing 91,635 person years at risk with 2366 deaths were used for analyses. SMR for all-cause mortality was 2.55 (95% CI: 2.45–2.65) overall. Adjusted Hazard Ratios (aHRs) for all-cause mortality, in ethnic minority groups relative to the White British group were 0.62 (95% CI: 0.53–0.74;  $P<0.0001$ ) (Black Caribbean), 0.53 (95% CI: 0.39–0.72);  $P<0.0001$  (Black African) and 0.69 (95% CI: 0.52–0.90);  $P=0.007$  (South Asian). Male sex and alcohol/substance misuse were associated with an increased all-cause mortality risk (aHR:1.94 (95% CI: 1.68–2.24);  $P<0.0001$  and aHR:1.18 (95% CI: 1.01–1.37);  $P=0.035$  respectively), whereas comorbid anxiety was associated with a decreased risk (aHR: 0.72 (95% CI: 0.58–0.89);  $P=0.003$ ). Similar associations were noted for natural-cause mortality. Alcohol/substance misuse and male sex were associated with a near-doubling in unnatural-cause mortality risk, whereas Black Caribbean individuals had a much reduced unnatural-cause mortality risk (aHR: 0.30 (95% CI: 0.14–0.66);  $P=0.002$ ), relative to White British people.

**Conclusions.**– Although individuals with depression experience an increased mortality risk, marked heterogeneity exists by ethnicity. Research and clinical practice should focus on addressing tractable causes underlying increased mortality in depression.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0276

### Structural abnormalities predictive of pejorative outcome in depression: A voxel based morphometry study

J.M. Batail<sup>1,2,3\*</sup>, J. Coloiner<sup>3</sup>, M. Soulas<sup>1</sup>, C. Barillot<sup>3</sup>, D. Drapier<sup>1,2</sup>

<sup>1</sup> Centre hospitalier Guillaume-Régnier, adult psychiatric department, Rennes, France; <sup>2</sup> Rennes 1 university, behavior and basal ganglia research team, Rennes, France; <sup>3</sup> INRIA, VISAGES research team, Rennes, France

\* Corresponding author.

**Objective.**– Major Depressive Disorder (MDD) is a common mental disorder with low remission rate and few reliable biomarker of outcome. In this study, we propose to compare whole brain volume differences between two groups of depressed patients followed during six months. In accordance with literature, the aim is to replicate previous results using a naturalistic prospective study in real life. We hypothesize that patients who do not achieve remission will have baseline abnormal brain structures affecting key regions involved in emotional and cognitive processes.

**Method.**– We compared baseline clinical and morphologic data (Gray Matter volumes) between 2 groups based on CGI-I scores at 6 months of follow-up: 22 MDD patients in the responders group (R) (CGI-I  $\leq 2$ ) and 28 in the non-responder group (NR) (CGI-I  $> 2$ ) using optimized voxel based-morphometry (VBM).

**Results.**– NR patients had higher HAMA scores ( $P=0.039$ ) and showed significant GM volume decreases (after correction for multiple comparisons) in the bilateral thalami (left:  $t$ -value=4.16; right:  $t$ -value=3.54), right frontal lobe and right limbic lobe. Thus, we found significant GM volume increase in the bilateral cerebellum ( $t$ -value=4.39); all results were controlled for age, gender, medication status and total intracranial volume.

**Conclusion.**– Our results suggest an underlying implication of thalamus and cerebellum in the prognosis of the depressive disorder through its involvement in emotion regulation. The present findings provide steps towards the development of neurobiological prognostic markers for depression.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0277

### Antidepressant augmentation and co-initiation treatment in acute major depressive disorder: A systematic review, meta-analysis and meta-regression analysis

B. Gallig<sup>1,2,3\*</sup>, C.U. Correll<sup>1,2,3</sup>

<sup>1</sup> Charité Universitätsmedizin, child and adolescent psychiatry, Berlin, Germany; <sup>2</sup> Hofstra Northwell school of medicine, department of psychiatry and molecular medicine, Hempstead, USA; <sup>3</sup> The Zucker Hillside hospital, psychiatry research, Glen Oaks, USA

\* Corresponding author.

**Introduction.**– Although antidepressant (AD) monotherapy is recommended first-line for major depressive disorder (MDD), AD+AD co-treatment is common, despite insufficient evidence.

**Objectives.**– To evaluate the efficacy and/or safety of AD monotherapy compared to AD augmentation or AD co-initiation in adults with MDD.

**Methods.**– Systematic literature search (PubMed/ MEDLINE/PsycInfo/Embase/CJN/WangFan/CBM) until 01/26/2016. Random effects meta-analysis of randomized controlled trials. Co-primary outcomes were overall symptom reduction and study-defined response. Secondary outcomes included all-cause and specific-cause discontinuation, partial response,

remission, and adverse effects (AEs). Sensitivity analysis of “high-quality” (double-blind, intent-to-treat) studies and meta-regression analysis, separately for augmentation and co-initiation studies.

**Results.**– Meta-analyzing 45 studies ( $n=4238$ , duration =  $6.7 \pm 1.9$  weeks), AD augmentation (studies/comparisons = 8,  $n=1216$ , duration =  $5.9 \pm 2.9$  weeks) and monotherapy were similar regarding overall symptom reduction (SMD =  $-0.23$ , 95% CI =  $-0.60$ – $0.14$ ,  $P=0.224$ ) and response (RR = 1.08, 95% CI =  $0.87$ – $1.33$ ,  $P=0.499$ ). Conversely, AD co-initiation (studies = 37, comparisons = 50,  $n=3022$ , duration =  $6.9 \pm 1.6$  weeks) was superior for symptom reduction (SMD =  $-0.93$ , 95% CI =  $-1.20$ ;  $-0.66$ ,  $P<0.001$ ) and response (RR = 1.29, 95% CI =  $1.22$ – $1.37$ ,  $P<0.001$ ). However, the large effect size for symptom reduction in all studies together became small in “high-quality” studies (SMD =  $-0.30$ , 95% CI =  $-0.57$ ;  $-0.04$ ,  $P=0.023$ ) like for treatment response (RR = 1.22, 95% CI =  $1.09$ – $1.38$ ,  $P=0.001$ ). No between-group differences emerged regarding all-cause, inefficacy-related or AE-related discontinuation in augmentation or co-initiation studies. AE burden was higher in 3/9 outcomes reported in  $\geq 2$  augmentation studies ( $\geq 1$  AE:  $P<0.001$ ; dry mouth:  $P=0.006$ , weight gain  $\geq 7\%$ :  $P=0.010$ ), and 1/21 outcomes reported in  $\geq 2$  co-initiation studies (hypersomnia:  $P=0.041$ ).

**Conclusions.**– AD augmentation after partial/full non-response to AD monotherapy lacks evidence for superior efficacy, whereas AD+AD co-initiation seems to potentially increase or speed up depressive symptom reduction and response.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Do living home space dimensions influence depression in elders? Preliminary data

V. Giannouli

Aristotle university of Thessaloniki, school of medicine, Drama, Greece

\* Corresponding author.

**Introduction.**– Although it is widely claimed that living space influences mood, we still know little about the influence that this factor has on perceived depression in elders.

**Objective:** The aim of this study is to examine if living home space or other factors such as demographic characteristics and emotion regulation strategies predict depression levels.

**Method.**– Fifty volunteers from Greece (aged 60–70 years old, 30 women) participated in the study. The participants completed a demographic questionnaire regarding their age, gender, marital status, number of family members, economic status (average income during the last year), and then they were tested with the Emotion Regulation Questionnaire (ERQ) in order to explore the use of emotion regulatory strategies (cognitive reappraisal and/or expressive suppression), and the Geriatric Depression Scale (GDS) which was used as a depression test.

**Results.**– Regression analysis included demographic factors, emotion regulation strategies, and home dimensions (measured in square feet as reported by participants) as independent predictors, and the total score of GDS as the dependent variable. GDS was not predicted by home dimensions and emotion regulation strategies, but only by the current socio-economic status. No positive correlation was found between expressive suppression and high GDS scores, but married elders were found to use a specific coping style (expressive suppression) less than never married elders.

**Conclusions.**– This research suggests that living home space does not to predict current depression levels, maybe because the current economic status of the participants reflects more accurately the problems that individuals face in their everyday life.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Does brief talking on a mobile phone influence short-term memory and reported depression levels in elders?**

V. Giannouli

*Aristotle university of Thessaloniki, school of medicine, Drama, Greece*

\* Corresponding author.

*Introduction.*– Although it is widely claimed that mobile phone use can cause short-and-long-term changes in cognition, we still know little about the influence that this activity has on depression levels. *Objective:* The aim of this study is to compare if exposure to ten minutes of talking on the mobile phone influences immediate verbal memory and depression.

*Method.*– Forty-five older adult volunteers from Northern Greece (aged 60–70 years old, 15 men and 30 women) participated in the study. The participants were tested with the Word List Learning Immediate Condition of the Verbal Memory Test, and the Geriatric Depression Scale (GDS) which was used as a depression test. Fifteen of the participants were tested before and after a 10-minute talking session on their mobile phone, while another group of fifteen completed the same tests without talking on the phone, but after a 10-minute conversation with a person in the room, and the rest were tested after a 10-minute silence interval (control group).

*Results.*– One-way analyses of variance (one-way ANOVAs) revealed that there were no statistically significant differences between the three groups in their GDS total score ( $P > .05$ ), as well as the immediate verbal memory of words ( $P > .05$ ).

*Conclusions.*– According to the above results, it seems that talking on the cell phone does not play a differential role in short-term verbal memory and self-reported depression levels, while speaking to others in the room or staying in silence seem not to play a role in short-term memory and mood as well.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Imbalance of cytokines in patients with major depressive disorder**

H. Jamilian<sup>1</sup>, G. Mosayebi<sup>1</sup>, A. Ghaznavi-Rad<sup>1</sup>, E. Ghaznavi-Rad<sup>2</sup>

<sup>1</sup> *School of medicine, Arak university of medical sciences, Psychiatry, Arak, Iran;* <sup>2</sup> *School of medicine, Arak university of medical sciences, microbiology and immunology, Arak, Iran*

\* Corresponding author.

*Introduction.*– Major depressive disorder (MDD) as a common and recurrent disorder is a correlated with a considerable rate of morbidity and excess mortality each year. Evidence indicates that there is an emerging tendency towards autoimmunity occurring in MDD. *Objectives.*– The aim of our study is to investigate the mechanism of autoimmune process in MDD from a novel insight of cytokines which have been identified as the significant activators of autoimmunity.

*Methods.*– In this case-control study, the serum of 40 patients who were confirmed clinically as MDD patients (according to DSM-5 criteria), and 40 healthy people as the control group were evaluated regarding the TGF- $\beta$ , IL-17 and TNF- $\alpha$  values with the ELISA method.

*Results.*– The serum concentration of TGF- $\beta$ , IL-17 and TNF- $\alpha$  in the patient group were 286.44 p/ml, 199.33 p/ml, and 678.84 p/ml, respectively, and in the healthy control group were 227.02 p/ml, 475.31 p/ml, and 165.52 p/ml, respectively ( $P$ -value  $< 0.05$ ). The result of the study revealed that the patient group was frequently positive for the TGF- $\beta$  and TNF- $\alpha$ , and negative for IL-17 than the control group, significantly.

*Conclusion.*– There is an imbalance of the cytokines in the MDD which may play a role in the pathogenesis and contribute to the existing evidence of autoimmune inclination in MDD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The impact of depression on verbal memory**

K. Masiulevičienė<sup>1</sup>, K. Petraškaitė<sup>2</sup>, E. Długauskas<sup>1</sup>, N. Grigutytė<sup>2</sup>

<sup>1</sup> *Vilnius university, faculty of medicine, clinic of psychiatry, Vilnius, Lithuania;* <sup>2</sup> *Vilnius university, department of clinical and organizational psychology, Vilnius, Lithuania*

\* Corresponding author.

*Introduction.*– Studies have reported an association between depression and memory impairments, however, the relationship is not clear. Some studies have found that patients with depression are impaired in verbal delayed memory and verbal percent retention but not in immediate verbal memory.

*Objectives.*– To evaluate if verbal memory is different in depression group compared to control group.

*Methods.*– Data from 30 patients (10 males, 20 females) who were diagnosed depression and were treated in Vilnius University hospital Santaros Klinikos Psychiatry department and 30 healthy controls (11 males, 19 females) with the age of forty five years and older were included in this study. Verbal memory (immediate recall, delayed free recall, percent retained) was evaluated by using Hopkins Verbal Learning Test.

*Results.*– Mean age in depression group was  $60.53 \pm 10.94$ , control group –  $57.03 \pm 7.43$ . Immediate recall results of the first trial was  $6.13 \pm 1.43$  words in depression group compared to  $7.3 \pm 2.04$  words ( $P = 0.013$ ) in control group; results of the second trial in depression group was  $7.9 \pm 1.83$  words compared to control group –  $9.0 \pm 1.74$  ( $P = 0.020$ ); results of the third trial in depression group –  $9.07 \pm 1.64$ , control group –  $9.87 \pm 1.48$  words ( $P = 0.052$ ). Total recall in depression group was  $23.1 \pm 4.29$  compared to control group  $26.17 \pm 4.81$  words ( $P = 0.012$ ). Delayed free recall in depression group was  $7.3 \pm 2.38$ , control group –  $8.83 \pm 2.12$  words ( $P = 0.011$ ). Percent retained in depression group was  $79.14 \pm 16.76$ , control group –  $88.76 \pm 12.15$  ( $P = 0.014$ ).

*Conclusions.*– The first and the second immediate recall trials, total recall, delayed free recall and percent retained were statistically significantly worse in the depression group compared to control group.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

**Compare the effectiveness of acceptance and commitment therapy (ACT), pharmacotherapy and combination of these methods in treatment of middle-aged patients suffering from major depressive disorder**

A. Mirghiasi<sup>1\*</sup>, S. Samandari<sup>2</sup>, K. Namdari<sup>3</sup>, N. Mortazi<sup>1</sup><sup>1</sup> Isfahan university of medical sciences, Modares hospital, psychiatry department, Isfahan, Iran; <sup>2</sup> Isfahan university of medical sciences, Modares hospital, geriatric psychiatry department, Isfahan, Iran;<sup>3</sup> University of Isfahan, faculty of educational science and psychology, department of psychology, Isfahan, Iran

\* Corresponding author.

**Introduction.**– The large number of people are afflicted with major depressive disorder with the high human and social costs in societies, while the treatment still remains one of the most challenging and controversial issue in mental health.

**Method.**– This study adopted a quasi-experimental method using a pretest-post test design with a control group. a sample of 60 subjects was selected randomly from the middle-aged patients suffering from major depressive disorder (based on DSM V criteria). The subjects were divided into four groups; 1. acceptance and commitment therapy (ACT). 2. Pharmacotherapy 3. blend of the two aforementioned methods during 2 months. And, the control group did not receive any of the aforementioned treatments. the Beck Depression Inventory (BDI-II) was administered to the patients before and after the treatment. The data were analyzed using SPSS-20 software in the analysis of co-variance method, and the results were presented in the two forms of descriptive and inferential statistics.

**Results.**– The mean scores of depressions in the pretest and post test are 41.67 and 44.60 in the control group; 44.33 and 17.66 in the Pharmacotherapy group; 40.86 and 26.53 in the ACT group; and 42.73 and 15.13 in the pretest and post-test for the combination group, respectively. There is a significant difference in terms of depression between the three treatment groups ( $P < 0.05$ ).

**Discussion.**– Pharmacotherapy and ACT demonstrated significance decrease in the depression symptoms in the post test and follow-up but the combinations are the most effective treatment for major depressive disorder in middle-aged Iranian patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Impact of agomelatine on sexual function in patients with mood disorders**

B.O. Plasencia García de Diego<sup>1\*</sup>, S.L. Romero Guillena<sup>2</sup>, R. Navarro Pablo<sup>3</sup>, O. Santamaría Gómez<sup>3</sup>, F. Gotor Sánchez-Luengo<sup>3</sup><sup>1</sup> De la Merced Hospital, Osuna, department of psychiatry, Seville, Spain; <sup>2</sup> U.S.M.C “Carmona” U.G.C. Salud Mental, Virgen Macarena hospital, department of psychiatry, Seville, Spain; <sup>3</sup> Nuestra Señora de Valme hospital, department of psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– Sexual side effects are considered unacceptable by 38,3% of patients and are related to lack of adherence of treatment [1].

**Objective.**– Evaluate the efficacy and safety of agomelatine in patients diagnosed with major depressive disorder and previous

suboptimal response to antidepressant treatment and with treatment discontinuation due to sexual dysfunction.

**Method.**– 22 outpatients with major depressive episode and previous suboptimal response to antidepressant treatment (one of the following: Fluoxetine, Sertraline, Citalopram, Escitalopram, Paroxetine, or Venlafaxine) and with treatment discontinuation due to sexual dysfunction were recruited. Patients received treatment with agomelatine as monotherapy (25–50 mg/24 h)

Evaluations at baseline, and every two weeks until endpoint (eight week): Montgomery-Asberg Depression Rating Scale (MADRS) and Psychotropic-Related Sexual Dysfunction Questionnaire. (PRSexDQ-SALSEX) Optimal response was defined as a reduction of 50% MADRS scores and remission was defined with  $\leq 8$  score in the MADRS, both measured at endpoint.

**Results.**– A reduction of 14.12 points (median) in the total score of MADRS from baseline was observed, being more effective in the main symptoms of the depressive disorder such a sadness, anhedonia and pessimistic thoughts. At endpoint, we observed remission rates of 36.36%. Moderate or severe sexual dysfunction was never reported

**Conclusion.**– Agomelatine has found to be effective and safe in the treatment of patients diagnosed with major depressive disorder, and demonstrates favorable sexual acceptability

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Antidepressant for major depressive disorder. Comparison with vortioxetine, agomelatine, desvenlafaxine and bupropion XR**

B.O. Plasencia García de Diego<sup>1\*</sup>, S.L. Romero Guillena<sup>2</sup>, R. Navarro Pablo<sup>3</sup>, F. Gotor Sánchez-Luengo<sup>3</sup>, O. Santamaría Gómez<sup>3</sup><sup>1</sup> De la Merced Hospital-Osuna, department of psychiatry, Seville, Spain; <sup>2</sup> U.S.M.C “Carmona” U.G.C. Salud Mental Virgen Macarena hospital, department of psychiatry, Seville, Spain; <sup>3</sup> Nuestra Señora de Valme hospital, department of psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– Major depressive disorder (MDD) is a frequent and disabling disorder. Given the considerable societal burden, achieve clinical remission, with minimal adverse effects, is considered a public priority. Comparisons of antidepressants efficacy and tolerability is needed.

**Objective.**– Compare the effects of Vortioxetine, agomelatine, desvenlafaxine, and Bupropion XR in outpatients with MDD.

**Methods.**– Data from 80 MDD were recruited. Inclusion criteria: baseline score  $\geq 20$  on Montgomery-Åsberg Depression Rating Scale (MADRS). Patients were assigned to: Vortioxetine (5–20 mg/d;  $n = 20$ ), agomelatine (25–50 mg/d;  $n = 20$ ), desvenlafaxine (50–100 mg/d,  $n = 20$ ), or Bupropion XR (150–300 mg/d;  $n = 20$ ). Informed consent was obtained.

**Assessments.**– Baseline, and every two weeks until endpoint (eight weeks): MADRS, Snaith Hamilton Rating Scale (SHAPS) and Sheehan Disability Scale (SDS). Safety and tolerability were monitored. The primary efficacy endpoint was a mean change in the MADRS total score; additional measures included the SHAPS and SDS scores.

Statistically significant differences were analyzed using an analysis of covariance model with the SPSS 22.0.

**Results.**– All groups showed significant reductions in MADRS, SHAPS, and SDS, with no significant differences between group observed in relation to MADRS, SDS Social and Family scores in 8 weeks.

Agomelatine-group showed greater reduction on SAHPS scores ( $P < 0.05$ ), with a mean change of 4.1 points.

Vortioxetine-group showed greater reduction on SDS-Work scores ( $P < 0.05$ ), with a mean change of 5.6.

**Conclusions.**– In patients with MDD, after 8 weeks, vortioxetine, desvenlafaxine, agomelatine and bupropion-XR show a similar antidepressant efficacy according on MADRS. The agomelatine-treated group, improved anhedonia, and vortioxetine-treated group improved work functioning more than the other antidepressants.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Living environment and its relationship to depressive mood: A systematic review**

N. Rautio<sup>1,2,3\*</sup>, S. Filatova<sup>1,2</sup>, H. Lehtiniemi<sup>1,2</sup>, J. Miettunen<sup>1,2</sup>

<sup>1</sup> University of Oulu, center for life course health research, Oulu, Finland; <sup>2</sup> Oulu university hospital and university of Oulu, medical research center Oulu, Oulu, Finland; <sup>3</sup> Oulu university hospital, unit of primary health care, Oulu, Finland

\* Corresponding author.

**Introduction.**– Individual level characteristics, such as female gender, medical illnesses, early trauma and adverse life-events are known risk factors for depression, but it is also important to study environmental risk factors for this major public health concern.

**Objectives.**– To examine whether living environment is associated with depressive mood.

**Methods.**– We searched databases of Pubmed, Scopus and Web of Science for population-based English written original studies until October 2016. We included studies, which measured depressive symptoms or depression and had also objective or subjective measures of urbanization, population density, aesthetics of living environment, house/build environment, green areas, walkability or accessibility of a living environment, noise, pollution or services.

**Results.**– Out of 1578 articles found, 44 studies met our inclusion criteria. Manual searches of the references yielded 13 articles resulting 57 articles included in the systematic review. Most of the studies showed statistically significant associations at least one of the characteristics of living environment and depressive mood. Adverse house/build environment, lack of green areas, noise and pollution were more clearly associated with depressive mood even after adjustment for different individual characteristics. Instead, results concerning population density, aesthetics and walkability or accessibility of living environment and availability of services and depressive mood were more inconsistent.

**Conclusions.**– Adverse house/built environment, lack of green spaces, noise and pollution are associated with depressive mood and should be taken into account in planning of living environment in order to prevent depressive mood.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Efficacy of vortioxetine in the treatment of cognitive symptoms of major depressive disorder**

S.L. Romero Guillena<sup>1\*</sup>, B.O. Plasencia Garcia de Diego<sup>2</sup>, O. Santamaria<sup>3</sup>, F. Gotor Sanchez-Luengo<sup>3</sup>, R. Navarro<sup>3</sup>

<sup>1</sup> U.S.M.C Carmona. U.G.C. Salud Mental área hospitalaria Virgen Macarena, department of psychiatry, Seville, Spain; <sup>2</sup> De la Merced hospital, department of psychiatry, Osuna, Spain; <sup>3</sup> Nuestra Señora de Valme hospital, department of psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– Therapeutic options for major depressive disorder (MDD) do not improve residual cognitive symptoms. A representative number of clinical studies using vortioxetine shows significant improvement of the cognitive performance and symptoms of depression in patients with MDD.

**Objectives.**– The main goal of this study was to assess the efficacy of vortioxetine in the treatment of cognitive symptoms in MDD. Secondary objectives included evaluating the efficacy of vortioxetine in improving depressive symptoms and functionality in patients with MDD.

**Methods.**– Prospective observational 8-week follow-up study in a real setting.

**Population of study:** patients  $\geq 18$  years of age with a diagnosis of major depressive disorder (according to DSM5 diagnostic criteria) who initiated adjusted-dose Vortioxetine treatment (5–20 mg/24 h) in monotherapy and provided informed consent. Clinical evaluations were performed at baseline, four and eight weeks.

**Outcome variables.**–

1- Variation in cognitive evaluation methods using:

– Digit Symbol Substitution Test (DSST);  
– Perceived Deficits Questionnaire (PDQ-D);

2- Variation in depression symptoms, measured using the Montgomery-Asberg Depression Rating Scale (MADRS).  
3- Variation in functionality, measured using the Sheehan Disability scale (SDS).

Student's *t*-test and Chi<sup>2</sup> test were used to assess differences between baseline evaluation and subsequent visits.

**Results.**– A total of 24 patients were recruited.

Patient with Vortioxetine showed significant increase in the scores on the DSST ( $\Delta = 9.78 \pm 1.26$ ;  $P < 0.01$ ) after 8 weeks of treatment. In addition significant decrease on PDQ-D ( $\Delta = 14.88 \pm 9.56$ ;  $P < 0.01$ ), MADRS ( $\Delta = 8.567 \pm 2.56$ ;  $P < 0.01$ ), SDS-work ( $\Delta = 4.8 \pm 1.8$ ;  $P < 0.01$ ), SDS-social ( $\Delta = 4.3 \pm 2.3$ ;  $P < 0.05$ ) and SDS-family ( $\Delta = 3.9 \pm 1.8$ ;  $P < 0.05$ ) were demonstrated after vortioxetine treatment.

**Conclusions.**– Vortioxetine is effective in reducing cognitive impairment symptoms significantly and improving depression symptoms and functionality in adults with major depressive disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Depression is associated with reduced suppression of negative emotional interference in working memory

B. Velichkovsky<sup>1</sup>, G. Rupchev<sup>2</sup>, A. Kachina<sup>3</sup>, F. Sultanova<sup>1</sup>, A. Alekseev<sup>2</sup>, V. Kaleda<sup>2</sup>, D. Tikhonov<sup>2</sup>

<sup>1</sup> Lomonosov Moscow state university, faculty of psychology, Moscow, Russia; <sup>2</sup> Federal State Budgetary scientific institution "mental health research center", laboratory of psychopharmacology, Moscow, Russia; <sup>3</sup> Lomonosov Moscow State university, psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Depression is a common psychiatric disorder which makes important the study of its psychological mechanisms. A possible factor in the development of depression may be decreased efficiency of processing of negative working memory representations.

**Objectives.**– To compare the efficiency of emotional working memory representations processing in patients with depression and healthy controls.

**Methods.**– Patients with depressive spectrum disorders ( $n=29$ , 20 females, mean age 49 years) and healthy controls (21 females, mean age 32 years) were studied. The subjects performed a self-paced working memory counting task with face stimuli. The task was either neutral (counting male/female faces) or emotional (counting happy/angry faces). Response times indicative of working memory counters' updating efficiency were recorded with E-Prime 2.0 software and analyzed via a repeated-measures ANOVA and Student's  $t$ -criterion.

**Results.**– There was a tendency for less efficient processing of angry faces in depression ( $P<0.05$ ). This slowing of negative stimuli processing in depression was observed in the emotional task condition only ( $P<0.05$ ). This slowing was specifically driven by a slowing in the processing of angry faces following a now irrelevant angry face ( $t=2.01$ ,  $P<0.5$ ). That is, in depression the presentation of an angry stimulus in a previous probe negatively affects the processing of angry stimulus in the next probe. In controls the repetition of stimulus' valence leads to a speeded processing of the second stimulus ( $t=2.54$ ,  $P<0.01$ ).

**Conclusions.**– Depression is associated with less efficient processing of negatively valenced representations in working memory and, specifically, with less efficient suppression of irrelevant negative working memory representations.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### A descriptive study about depressive symptoms among Iranian College students

Z. Shahhosseini\*, Z. Hamzehgardeshi, K. Abedian-Kasgary  
Mazandaran university of medical sciences,  
department of reproductive health and midwifery, Sari, Iran

\* Corresponding author.

**Introduction.**– Depression is serious and, if left untreated, can worsen to the point of becoming life-threatening.

**Objectives.**– The aim of the study is to evaluate the depressive symptoms among Iranian college students.

**Methods.**– The study population consisted of 430 female and male university students in three higher education institutions located in the northern part of Iran. They were completed the intentional injuries questions related to depression adopted from Persian version of youth risk behavior survey questionnaire about

**Results.**– It showed that 39.1 percent of the university students were feeling despair and sadness during the last 12 months. Although 9.8 and 10.7 percent of participants having suicidal thoughts and having a serious plan for suicide during the last 12 months respectively. However merely 1.9 percent of them trying suicide during the last 12 months. No statistically significant difference was reported in depressive symptoms between the male and female university students  $P>0.05$ .

**Conclusion.**– The findings emphasize on need to prevention programs for improving university students' mental health.

**Keywords:** Depression; Intentional high risk behavior; Young people

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Neuroticism as a predictor of inflammatory response in depressive disorders

M. Talarowska, P. Gałeczki\*, A. Orzechowska, M. Kowalczyk,  
J. Mossakowska-Wójcik, K. Bliźniewska  
Medical university of Lodz, department of adult psychiatry, Lodz,  
Poland

\* Corresponding author.

**Introduction.**– Human personality is a mental construct determined by the functioning of branched networks of nerve endings. It involves typical interpersonal behaviours, subjective reactions, feelings, and the objectives we are striving after.

**Objectives.**– The aim of the research was to verify whether neurotic personality traits (the so-called neurotic triad – hypochondria, depression, hysteria) are linked with changes in the peripheral expression of genes for selected proinflammatory and anti-inflammatory cytokines.

**Methods.**– Fifty patients, who met the diagnostic criteria for recurrent depressive disorders based on the ICD-10 guidelines, were qualified to take part in the experiment. The Minnesota Multiphasic Personality Inventory (MMPI-2) test by S. Hathaway and J. McKinley was applied in the assessment of the personality structure of the examined individuals. Expression of three proinflammatory interleukins (IL-1, IL-6, and IL-12) as well as IL-10 (anti-inflammatory interleukin) and TNF- $\alpha$ , at the protein and mRNA level, was evaluated.

**Results.**– The authors observed a significant positive relationship between expression for IL-1, IL-10, and IL-12 at the protein level and at the mRNA level and the depression scale, as well as for IL-10 and the hysteria scale for the MMPI-2 test. Gradual intensification of neuroticism features was observed in each subsequent episode of depressive disorders.

**Conclusions.**– As a personality trait, neuroticism may be a significant marker of inflammation during a depression episode.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0290

### Indicators to facilitate the early identification of patients with major depressive disorder in need of highly specialized care: A concept mapping study

F. van Krugten<sup>1\*</sup>, M. Goorden<sup>1</sup>, A. van Balkom<sup>2</sup>, J. Spijker<sup>3</sup>, W. Brouwer<sup>1</sup>, L. Hakkaart-van Roijen<sup>1</sup>

<sup>1</sup> Erasmus university Rotterdam, Erasmus school of health policy and management, Rotterdam, The Netherlands; <sup>2</sup> VU university medical center, department of psychiatry, Amsterdam, The Netherlands;

<sup>3</sup> Radboud university medical center, behavioural science institute, Nijmegen, The Netherlands

\* Corresponding author.

**Introduction.**– Early identification of the subgroup of patients with major depressive disorder (MDD) in need of highly specialized care could enhance personalized intervention. This, in turn, may reduce the number of treatment steps needed to achieve and sustain an adequate treatment response.

**Objectives.**– To identify patient-related indicators that could facilitate the early identification of the subgroup of patients with MDD in need of highly specialized care.

**Methods.**– Initial patient indicators were derived from a systematic review. Subsequently, a structured conceptualization methodology known as concept mapping was employed to complement the initial list of indicators by clinical expertise and develop a consensus-based conceptual framework. Subject-matter experts were invited to participate in the subsequent steps (brainstorming, sorting and rating) of the concept mapping process. A final concept map solution was generated using non-metric multidimensional scaling and agglomerative hierarchical cluster analyses.

**Results.**– In total, 67 subject-matter experts participated in the concept mapping process. The final concept map revealed ten major clusters of indicators: (1) depression severity, (2) onset and (treatment) course, (3) comorbid personality disorder, (4) comorbid substance use disorder, (5) other psychiatric comorbidity, (6) somatic comorbidity, (7) maladaptive coping, (8) childhood trauma, (9) social factors, and (10) psychosocial dysfunction.

**Conclusions.**– The study findings highlight the need for a comprehensive assessment of patient indicators in determining the need for highly specialized care, and suggest that the treatment allocation of patients with MDD to highly specialized mental healthcare settings should be guided by the assessment of clinical and non-clinical patient factors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The Association of olfaction on everyday outcomes in older African, American and Caucasian men with HIV: A pilot study

D. Vance<sup>\*</sup>, P. Fazeli

University of Alabama at Birmingham, school of nursing, Birmingham, USA

\* Corresponding author.

**Background.**– Deficits in olfaction are observed with advanced age and in certain diseases such as HIV. As people age with HIV, they may become more vulnerable to developing olfactory deficits that may compromise their eating habits, safety, cognition, and quality of life. In addition, African Americans are predisposed to such olfactory declines.

**Objective.**– This IRB-approved study examined whether racial differences were observed in olfactory measures in older African American and Caucasian men with HIV. In addition, the association between olfaction and everyday functioning (e.g., quality of life, eating habits) was examined.

**Methods.**– In this cross-sectional study, 33 African American ( $M_{age} = 52.99$  years) and 18 Caucasian ( $M_{age} = 56.16$  years) men with HIV were administered measures on quality of life, eating habits, in addition to two age-normed measures of olfaction (i.e., The Smell Threshold Test, The University of Pennsylvania Smell Identification Test).

**Results.**– With both olfactory tests, adults with HIV significantly performed below the adjusted HIV-negative age-norms; however, African Americans with HIV tended to display poorer olfaction sensitivity compared to their Caucasian counterparts. Furthermore, in African Americans, a greater sense of change in the way foods taste experienced poorer quality of life ( $r = .36$ ;  $P = .04$ ) and more depressive symptomatology ( $r = 4.0$ ;  $P = .018$ ). In Caucasians, better quality of life was associated with less change in the way foods taste ( $r = -.50$ ;  $P = .03$ ). Olfaction was not related to t-cell count or viral load.

**Conclusions.**– In HIV, neurological and structural damage to the nasal epithelium and olfactory bulb may compromise olfaction resulting in poorer health outcomes. Implications for clinical practice and research are provided.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0292

### The association between olfactory functioning in aging African, American and Caucasian men with HIV and cognitive functioning

D. Vance<sup>\*</sup>, P. Fazeli

University of Alabama at Birmingham, school of nursing, Birmingham, USA

\* Corresponding author.

**Introduction.**– Deficits in olfaction are observed with advanced age and in certain diseases, including HIV. Concerns grow that as people age with HIV, the synergy from both will exacerbate such olfactory functioning. Furthermore, some evidence suggests that olfactory deficits may serve as a clinical marker for cognitive decline. This point is particularly germane as 52–59% of adults with HIV have observable cognitive deficits.

**Objectives.**– This study assessed whether olfactory functioning was associated with cognitive functioning in a racially diverse sample of older adults with HIV.

**Methods.**– This IRB-approved cross-sectional study examined olfaction between 33 African American ( $M_{age} = 52.99$  years) and 18 Caucasian ( $M_{age} = 56.16$  years) men with HIV. Age-normed measures of olfaction included the Smell Threshold Test and the University of Pennsylvania Smell Identification Test (UPSIT) as well as self-reported measures of smell and taste.

**Results.**– For African American men with HIV, better ability to identify odors was associated with better verbal recall on the Hopkins Verbal Learning Test ( $r = .44$ ;  $P = .009$ ) and fewer cognitive complaints. For Caucasian men with HIV, better odor threshold performance was associated with better executive functioning on Trails B ( $r = .48$ ;  $P = .42$ ). Better verbal recall on the Hopkins Verbal Learning Test was associated with fewer self-reported changes in the ability to smell ( $r = -.57$ ;  $P = .013$ ).

**Conclusions.**– In general, partial support was found for the association between olfaction and cognition. Although more research is needed, clinically changes/declines in olfaction may possibly

indicate underlying neurological dysfunction in adults with HIV. Implications for practice and research are provided.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### COMT Val158Me polymorphism influences the cerebral blood flow changes related to psychomotor retardation in major depressive disorder

Y. Yin

*Affiliated ZhongDa hospital and institute of neuropsychiatry of Southeast Univer, department of psychosomatics and psychiatry, ZhongDa hospital, school of medicine, Southeast university, Nanjing, China*

\* Corresponding author.

*Objective.*– To investigate the influence of COMT Val158Met Polymorphism on the CBF changes in MDD patients with PMR.

*Methods.*– COMT Val158Met genotypes and ASL-MRI data of 98 Chinese Han subjects (59 MDD, 39 NC) were collected in this study. MDD patients were divided into PMR group and NPMR group. CBF were analyzed based on the ASL-MRI data. Two-way ANCOVA was performed to analyze the main effect of group and genotype, and the interactions between group and genotype on the CBF.

*Results.*– The main effect of group on the CBF unraveled increased CBF of the limbic system (LS) in PMR group compared with NC and NPMR groups, and decreased CBF of the right calcarine in MDD group compared with NC group. The main effect of the genotype significantly impacted the CBF of left precuneus and bilateral thalamus. The CBF of the two brain regions were both significantly increased in A (Met) allele carriers compared with GG group. The interaction between group and genotype primarily influenced the CBF of left lingual gyri (LG) and right caudate. The A (Met) allele led a decreased CBF in NC and NPMR group, but an increased CBF in PMR group. Spearman correlation analyses showed significantly positive correlations between the CBF of left LS and the retardation severity.

*Conclusion.*– The increased CBF in the left LS is associated the PMR in MDD, and it positively correlated with the retardation severity. COMT Val158Met could modulate the CBF changes in the left LG and the right caudate, which are associated with PMR.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Validation of a widely-used depression scale for detecting depression in family caregivers of persons with dementia

J. Ying<sup>1\*</sup>, P. Yap<sup>2</sup>, M. Gandhi<sup>3</sup>, T.M. Liew<sup>4</sup>

<sup>1</sup> Institute of mental health IMH, general psychiatry general psychiatry, Singapore, Singapore; <sup>2</sup> Khoo Teck Puat hospital, department of geriatric medicine, Singapore, Singapore;

<sup>3</sup> Biostatistics, Singapore clinical research institute, Singapore, Singapore; <sup>4</sup> Institute of mental health, department of geriatric psychiatry, Singapore, Singapore

\* Corresponding author.

*Introduction.*– Depression occurs in at least 1 in 3 caregivers of persons with dementia (PWD). Among the case-finding scales for caregiver depression, the Center for Epidemiological Studies

Depression Scale (CES-D) is one of the most widely-used scales in caregivers of PWD.

*Objective.*– We sought to evaluate the validity and reliability of CES-D for detecting caregiver depression in dementia.

*Methods.*– We conducted a cross-sectional study with consecutive sampling in Singapore. Participants completed self-administered questionnaires containing CES-D and other scales of related construct. Factorial validity was assessed by confirmatory factor analysis; construct validity by Pearson's correlation coefficient; known-group validity by comparing CES-D scores at differing severities of caregiver burden; and internal-consistency reliability by Cronbach's  $\alpha$ .

*Results.*– We recruited 394 participants. After analysis, CES-D demonstrated factorial, construct and known-group validity. Internal-consistency reliability was good for CES-D total scale (Cronbach's  $\alpha = 0.92$ ), but lower for Positive Affect and Interpersonal Problems subscales ( $\alpha = 0.70$ – $0.74$ ).

*Conclusions.*– CES-D can be used in clinical care, as a valid and reliable scale, to detect caregiver depression in dementia. However, two subscales of CES-D (Positive Affect and Interpersonal Problems) show more modest reliability, possibly due to the influence of culture, and may need to be interpreted with caution when they are used among non-Caucasian caregivers.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Neural correlates of selective attention to threat during target detection in persecutory delusions

C. Al-Ibrahim\*, J. Yiend, S. Shergill

*Institute of psychiatry, psychology & neuroscience, King's College London, psychosis studies research, London, United Kingdom*

\* Corresponding author.

*Objective.*– Selective attention to threat has been implicated in the development, maintenance and exacerbation of persecutory delusions in schizophrenia. This study is using the attention probe cuing paradigm to examine threat modulation of selective attention and mechanisms of spatial orienting, and investigate whether selective attention to threat is independent of paranoid symptoms severity.

*Methods.*– Using an event-related functional magnetic resonance imaging (fMRI), neural correlates of selective attention to threat were investigated by applying three types of semantic stimuli (i.e. paranoia relevant, physical threat and social threat) paired with neutral words. A sample of high ( $n = 19$ ) and low ( $n = 17$ ) paranoid patients with schizophrenia and healthy controls ( $n = 27$ ) performed the task in which participants were instructed to detect a target appearing after a pair of emotional-neutral words by pressing a corresponding button as quickly and accurately as possible.

*Results.*– Patients showed decreased activation compared to healthy controls within the fronto-parietal brain regions. Differences between the high and low paranoia groups were significant during regions of interest analysis (ROI) within the anterior and posterior intraparietal cortices (IPC) in which the high paranoia group demonstrated increased activation when detecting targets within the same spatial location of social threat stimuli relative to the low paranoia group.

*Conclusion.*– Our findings suggest that the persistence of paranoid symptoms in schizophrenia may reduce responsiveness to threat-

related stimuli in patients compared to healthy controls in the IPC, and that attenuation of fMRI BOLD signal within this area might be influenced by the severity of paranoid symptoms.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Value priorities are related to the fear of illness

M. Iosifyan, G. Arina\*, V. Nikolaeva

Lomonosov Moscow State university, department of neuro- and pathopsychology, Moscow, Russia

\* Corresponding author.

*Introduction.*– Fear of injury (or illness/injury sensitivity) is one of three fundamental fears and plays a key role in anxiety disorders (Reiss, 1991; Taylor, 1993). Value priorities are related to some fears people experience (for example, to the fear of war; Schwartz et al., 2000). However, it is not clear if values are related to fear of illness. *Objectives.*– The study investigates how value priorities are related to the fear of illness.

*Method.*– Participants ( $n = 43$ ,  $M_{age} = 27.45$ , 8 males) ranked 14 illnesses/injuries from most to least frightening. They next selected life values which a person will most probably lose in the case of each of these 14 diseases/injuries (e.g., stimulation, self-development, success).

*Results.*– Regression analysis revealed that values explained 76% of variance of fear of illness ( $F(5,8) = 9.131$ ,  $P = .004$ ). Values of success, self-development and stimulation were positively associated with the fear of illness; values of hedonism, health and conformism were negatively associated with it; and values of self-transcendence were not related to it.

*Conclusions.*– Value priorities, at least partly, explain the fear of illness. More the potential disease affects the loss of openness to change values, more frightening it is, contrary to conservation values (e.g. health value). Probably, among young healthy adults who did not experience any trauma related to health, conservation values are not affectively related to fear of illness, contrary to openness to change values. Health anxiety treatment strategies should take into account the associations between personal values and fear of illness.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Is ultrasound the future of neuroimaging in psychiatry?

T. Desmidt

CHU de Tours, clinique psychiatrique universitaire, Tours, France

\* Corresponding author.

Recent progresses in both probe technology and signal processing have allowed the development of innovative methods of ultrasound neuroimaging for characterizing brain physiology and for the stimulation of neural circuitry.

We want to review here the increasing data showing that, beyond the assessment of cerebrovascular functioning, newly developed techniques can accurately measure biomechanical properties of the brain, such as Brain Tissue Pulsatility (BTP) as the natural micro-movements of the brain parenchyma.

Notably, we and others have found that BTP was changed in cognitive tasks and tends to decrease with ageing. Moreover, our team has found that BTP was impaired in depression [1] (Fig. 1) and was correlated to brain volume and white matter lesions, suggesting

that the progressive accumulation of excessive micro pulsatility in the brain can progressively damage the tissue and lead to cerebral impairments [2].

Our team has also demonstrated the efficacy of ultrasound neurostimulation in an animal model of depression, while trials are currently under inclusion in human resistant depression.

As costless, portable and easy-to-realize methods, Ultrasound neuroimaging could ultimately provide routinely accessible techniques to characterize and to treat psychiatric pathologies such as depression.

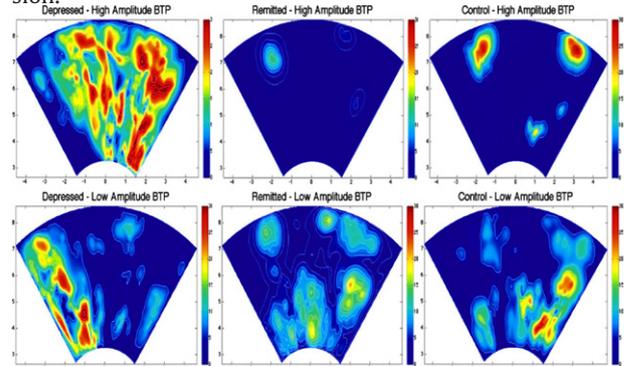

Fig. 1.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Behavioral digit span and spatial span performance and their correlates with brain connectivity: Insights into the cognitive machinery

B. Dvoracek<sup>1,2\*</sup>, I. Stamou<sup>1,2</sup>, E. Bourama<sup>1,2</sup>, K. Sedlakova<sup>1,2</sup>, F. Spaniel<sup>1,2</sup>, I. Fajnerova<sup>1,2</sup>, Z. Yuliya<sup>1,2</sup>

<sup>1</sup> 3rd faculty of medicine, Charles university in Prague, Prague, Czech Republic, department of psychiatry, Prague, Czech Republic;

<sup>2</sup> National institute of mental health, Klecany, Czech Republic, department of psychiatry, Prague, Czech Republic

\* Corresponding author.

*Objectives.*– The application of tests in which different information context is manipulated in a similar way can bring insight into the cognitive machinery. Errors in performance in Digit Span and Spatial Span might be related to the altered brain connectivity. Thus we explored if the errors result on the connectome of the brain.

*Methods.*– We have administered Digit Span and Spatial Span and performed fMRI resting state scans in 70 first episode psychosis patients and healthy controls (patients 40, healthy controls 30). In the Digit Span 60 subjects performed without errors, in 10 subject errors were identified. In the Spatial Span 23 subjects performed with errors whereas in 47 subjects the performance was errorless. The performance was confronted to the resting state fMRI connectivity analysis.

*Results.*– Digit Span performance in error vs non-error group correlated with hypoconnectivity between inferior occipital cortex L and cerebellum L and hyperconnectivity bilaterally within cerebellar regions, temporal cortex, fusiform cortex and nucleus accumbens. Spatial Span performance in error vs non-error group

was associated with hyperconnectivity in R hemisphere between inferior lateral occipital cortex and parietal operculum cortex, supramarginal gyrus, postcentral gyrus and planum temporale  
**Conclusion.**– The analysis of behavioural tests and resting fMRI data revealed that patients who make errors in the tests exhibit disrupted connectivity. Errors in tests were associated with the cortical and subcortical structures that are related to the specific cognitive units, e.i processing of numbers, spatial positioning, error monitoring. The hyperconnectivity is presumably due to necessity for more effortful processing needed during the task performance.  
**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparison of quality of life and psychiatric comorbidities in patients with functional (psychogenic) and organic movement disorders

T. Gendre<sup>1\*</sup>, G. Carle<sup>2</sup>, F. Mesrati<sup>3</sup>, M. Houot<sup>4</sup>, B. Degos<sup>5</sup>, B. Garcin<sup>5</sup>  
<sup>1</sup> Henri Mondor hospital, neurology unit, Créteil, France; <sup>2</sup> Salpêtrière university hospital ICM-A-IHU WP4, behavioral neuropsychiatric unit, Paris, France; <sup>3</sup> Salpêtrière university hospital, neuropsychology unit, Paris, France; <sup>4</sup> Salpêtrière university hospital, institute of memory and Alzheimer's disease IM2A, centre of excellence of neurodegenerative disease CoeN, ICM, Paris, France; <sup>5</sup> Avicenne university hospital, neurology unit, Bobigny, France

\* Corresponding author.

**Introduction.**– Patients with functional movement disorders (FMD) often report disability and have psychiatric comorbidities (PC). However, only few studies have compared their quality of life (QoL) and their PC to patients with organic movement disorders (OMD).  
**Objectives.**– To compare the QoL and PC of FMD and OMD patients.  
**Methods.**– 30 and 21 FMD patients were respectively compared to 30 sex- and age-matched parkinsonian patients and 21 sex- and age-matched dystonic patients. QoL was assessed using the Parkinson's Disease Summary Index (PDSI). PC and traumatic events were screened with the Hospital Anxiety and Depression Scale (HADS) and the Composite International Interview (CIDI), along with a psychiatric examination performed by a trained psychiatrist.  
**Results.**– The QoL in FMD patients was as much impaired as in parkinsonian patients (PDSI=38.3 vs 32.2;  $P=0.61$ ) and more impaired than in dystonic patients (PDSI=42.1 vs 25.1;  $P=0.003$ ). Moreover, FMD patients were more often unemployed because of their health condition than parkinsonian patients (53.3% vs 13.3%;  $P=0.005$ ) and dystonic patients (61.9% vs 14.3%;  $P=0.01$ ). Three groups reported the same prevalence of anxiety ( $P=1.0$  and 0.58) and depression ( $P=0.77$  and 0.77). Notably, the three groups reported the same prevalence of traumatic events ( $P=0.75$  and 0.58). FMD patients reported more often sexual abuse than parkinsonian (23% vs 0%;  $P=0.02$ ) and dystonic patients (28.6% vs 4.8%;  $P=0.13$ ).  
**Conclusions.**– FMD patients presented with an equally to higher impairment in QoL but a similar occurrence of PC compared to OMD patients. In this regard, management of FMD patients requires a collaboration between neurologists and psychiatrists.  
**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Is psychological morbidity associated with gastric sensitivity in patients with functional dyspepsia?

J. Hammer<sup>\*</sup>, M. Führer  
 Medizinische Universität Wien, Gastroenterologie und Hepatologie, Wien, Austria

\* Corresponding author.

The oral capsaicin test (CapsTest) is a novel diagnostic test to determine gastric hypersensitivity in patients with functional dyspepsia (FD). FD is associated with an increased risk of psychological morbidity.

**Aims:** To assess whether psychological illness or several clinical parameters are associated with the results of the CapsTest in patients with FD.

**Methods.**– 69 patients with confirmed FD (52 women; 17 men; mean age  $\pm$  SEM: 39.4  $\pm$  12.9 years) filled out HAD, Eysenck neuroticism scale, and SF12 QoL. The CapsTest evaluates intensity of upper gastrointestinal symptoms (by a graded questionnaire) after ingestion of 0.75 mg capsaicin. A score difference (before vs. after capsaicin) of  $> 9$  was considered as a positive test (gastric hypersensitivity). Data are given as mean  $\pm$  SEM, significance level:  $P < 0.05$ ; NS = not significant.

**Results.**– The CapsTest was positive in 58% ( $n=40$ ; 32 female, 8 male; NS). Patients with gastric hypersensitivity (capsaicin positive) did not differ significantly from capsaicin negative patients in terms of anxiety scores (10.6  $\pm$  0.4 vs. 9.9  $\pm$  0.4), depression (8.5  $\pm$  0.3 vs. 8.7  $\pm$  0.4), neuroticism (5.7  $\pm$  0.6 vs. 6.6  $\pm$  0.7) or QoL (physical nor mental). However, patients with clinical manifest depression (HAD-score above 10) had significantly higher capsaicin scores (17.7  $\pm$  4.4 vs 10.7  $\pm$  7.8;  $P < 0.05$ ) than patients with normal to mild depression levels. Multivariate analyses did not show a significant influence of any of the clinical parameters tested (Age, gender, Helicobacter status, clinical manifestation of FD) on the capsaicin test.

**Conclusion.**– Psychological morbidity is not associated with the results of the CapsTest in patients with functional dyspepsia, although patients with clinical depression score higher in the CapsTest than patients without manifest depression.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Variations in gray matter volume and neuropsychological scale following donepezil treatment in patients with Alzheimer's disease

G.W. Jeong<sup>\*</sup>, G.W. Kim  
 Chonnam national university medical school and hospital, department of medicine, Gwangju, Republic of Korea

\* Corresponding author.

Alzheimer's disease (AD) is characterized by the presence of neurofibrillary tangles and senile plaques, impaired synaptic function, and cell loss. Until now, we have had no picture of how donepezil treatment influences brain morphological and metabolic changes in AD. Although several studies have reported the effect of donepezil treatment on either localized brain metabolism or on regional gray matter (GM) volumetry in patients with AD, a combined study of hippocampal metabolic changes and all-areas volume changes following donepezil treatment has not yet been attempted. The purpose of this study was to evaluate the gray matter (GM) volume changes and its correlation with neuropsychological scales after donepezil treatment in patients with AD using

voxel-based morphometry (VBM), and further to assess cellular metabolic changes in the hippocampus using proton magnetic resonance spectroscopy ( $^1\text{H MRS}$ ) at 3 Tesla. Compared with untreated patients with AD, donepezil-treated patients with AD showed significantly higher GM volumes in the caudate nucleus, putamen, inferior frontal gyrus, and inferior temporal gyrus. The GM volumes of the caudate nucleus, putamen, inferior frontal gyrus, and inferior temporal gyrus in treated patients were positively correlated with K-MMSE scores. In the  $^1\text{H MR}$  spectral analysis for the hippocampus, the treated patients showed a significant increase of  $\text{b} \times \text{g-Glx/Cr}$  ratio compared with untreated patients. It is considered that enhancement of GM volumes and Glx level in specific brain areas are potentially associated with increased K-MMSE scores in AD with donepezil treatment.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Trauma and health symptoms: In the context of gender and daily stress

G. Karakurt<sup>1\*</sup>, K. Silver<sup>2</sup>, D. Concklin<sup>3</sup>, M. Kumari<sup>3</sup>

<sup>1</sup> Case Western Reserve university, psychiatry, Cleveland, USA;

<sup>2</sup> University of Akron, psychology, Akron, USA; <sup>3</sup> CWRU, psychiatry, Cleveland, USA

\* Corresponding author.

As many people are affected by psychological distress and trauma across the lifespan, understanding risk factors, protective factors, and the relationships between types of stressors and medical variables is important for mental and physical health. The current study investigated whether trauma symptoms (anxiety, depression, dissociation, sexual abuse trauma, sleep disturbance, and sexual problems) are predictors of self-reported mental and physical health among adults. Furthermore, we are also curious as to whether daily stress and gender differences play a role in these relationships. Participants ( $n = 103$ ; 50.5% women) completed self-report measures of trauma symptoms (TSC-40), mental health, physical health (SF-36), and daily stress (FDHI), along with demographic information. The Trauma Symptom Checklist-40 (TSC-40; Elliott & Briere, 1992) is a self-report instrument with 40 items designed to measure a range of traumatic stress symptoms. Short-Form Health Survey (SF-36; Ware & Sherbourne, 1992) is composed of 36 self-report quality-of-life items that measure both mental and physical health. The Family Daily Hassles Inventory (FDHI; Rollins, Garrison, & Pierce, 2002) consists of 22 items that characterize how much the daily life of their family is affected by each item's dimension: time and energy, negative influence, and positive influence. Regression results indicated that trauma symptoms predicted 25.2% of the variance in physical health symptoms. Gender significantly added to the variance accounted for, but daily stress was not significant in the model. Trauma symptoms predicted 37.1% of the variance in mental health symptoms. Daily stress added to the model, but gender did not.

### The effect of feedback manipulation in social anxiety

S. Lee<sup>1</sup>, E. Kim<sup>2\*</sup>

<sup>1</sup> Seoul national university child's hospital, psychological assessment center, Seoul, Republic of Korea; <sup>2</sup> Ajou university, psychology,

Yeongtong-gu-Suwon-si, Republic of Korea

\* Corresponding author.

*Introduction.*– Socially anxious individuals are negatively affected by receiving negative feedback. However, they are also negatively affected even if they receive positive feedback. Nevertheless, there are little research on positive feedback in social anxiety.

*Objectives.*– The purpose of this study was to examine whether feedback manipulation on the speaking performance in socially anxious individuals affected the anticipatory anxiety, perceived others' expectations, and social ability.

*Methods.*– 100 participants with high social anxiety and 100 participants with low social anxiety screened by Social Phobia Scale were randomly assigned to four feedback conditions (i.e., two positive conditions and two negative conditions). Participants presented the speaking. After the presentation, they were provided with a feedback and were told to make a second presentation.

*Results.*– Participants high in social anxiety were significantly higher in anticipatory anxiety and significantly lower in perceived others' expectations and social ability than those low in social anxiety. In the two positive feedback conditions, participants experienced reduced anticipatory anxiety, and increased perceived others' expectations and social ability regardless of participants groups. Socially anxious individuals rated higher feedback acceptance in the two negative feedback conditions than in the two positive feedback ones.

*Conclusion.*– This study found that socially anxious individuals adopted negative feedback more than positive feedback, and positive feedback had the effect of reducing anticipatory anxiety. Considering this, the study reaffirmed the importance of interventions focused on modification of negative thoughts. In addition, this study suggests that intervention to expose positive aspects such as positive feedback of others also be important.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Psychological manifestations of maladjustment to educational activities

H. Kozhyna<sup>\*</sup>, D. Marakushyn, K. Zelenska, M. Khaustov, V. Mykhaylov, G. Zelenska

Kharkiv national medical university, psychiatry, narcology and medical psychology, Kharkiv, Ukraine

\* Corresponding author.

*Aim.*– The study of the psychological features of adaptation disorders in students of medical University.

*Material and methods.*– A comprehensive survey of 603 students of Kharkiv national medical University were conducted.

*Results.*– 4.5% of the surveyed students revealed a high level of maladjustment; 13.3% severe level of maladjustment; 36.2% – moderate level of distress; in 20.2% – low level of maladjustment; 25.8% – no signs of maladjustment.

Students who have the high, pronounced and moderate level of maladjustment was the first study group, students with low levels or absence of signs of maladjustment – the second group.

As the results of diagnostic research of students of the first group at 15.8% of the observed clinical symptoms of anxiety, 16.3% – subclinical manifestations, compared with 3.5% and 8.2% of students in group II respectively. The clinical manifestations of depression typical of 5.4% of students of the first group and 2.1% of students in group II; subclinical symptoms of depression for of 20.1% and 9.5%, respectively.

For students of the 1st group had higher average levels of asthenic state on a scale Malkova L.M. and T.G. Chertova ( $54.12 \pm 1.98$ ), neuro-mental stress on a scale of T.A. Nemca ( $48.38 \pm 1.79$ ) and gotm on a scale of Zung ( $50.30 \pm 1.66$ ) compared with students

of group II, which had the lowest results and was respectively  $41.97 \pm 1.73$ , the  $38.24 \pm 1.22$  and  $44.51 \pm 1.96$  scores.

Mental, manifested by deterioration of psychological well-being, growth, asthenia, anxiety and depressive disorders, decrease of activity, violation of interpersonal relations, increased intrapersonal conflicts.

### **Yoga reduces the brain's amplitude of low-frequency fluctuations in patients with early psychosis**

J.J. Lin<sup>1\*</sup>, X. Geng<sup>2</sup>, E.Y.H. Chen<sup>3</sup>

<sup>1</sup> The university of Hong Kong, school of nursing, Hong Kong, Hong Kong S.A.R.; <sup>2</sup> The university of Hong Kong, state key lab of brain & cognitive sciences, Hong Kong, Hong Kong S.A.R.; <sup>3</sup> The university of Hong Kong, Psychiatry, Hong Kong, Hong Kong S.A.R.

\* Corresponding author.

*Background.*– Exercise attracted increasing attention for improving neurocognitive functioning in patients with psychotic disorders. However, there has been limited understanding of the neural mechanism of these effects. This study aimed to investigate the effects of aerobic exercise and yoga on cerebral spontaneous functional fluctuations in patients with early psychosis.

*Methods.*– A total of 140 female patients with early psychosis were recruited and 124 received the allocated intervention in a randomized controlled study of 12 weeks of yoga or aerobic exercise compared with a wait-list group. 91 participants were scanned at baseline, and 72 had completed the scans at 12 weeks. The amplitudes of low-frequency functional (ALFF) fluctuations were compared among three groups, and the correlation between ALFF, cognition and clinical symptoms were examined.

*Results.*– Both yoga and aerobic exercise improved working memory and overall symptoms in patients with psychosis compared to the control group. There was no significant changes of ALFF in aerobic exercise group. The ALFF decreased in the left precuneus for the yoga group compared to the control group, which was correlated to the improvements of negative symptoms in all the participants.

*Conclusions.*– It is the first study to investigate the effects of yoga and aerobic exercise on brain function in patients with early psychosis. The results help to understand the possible neurobiological underpinnings for the cognitive and clinical improvements from yoga and aerobic exercise.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The relationship between burnout and quality of work life in pediatric and neonatal intensive care unit nurses**

M. Marofi<sup>1\*</sup>, F. Mosavi<sup>2</sup>, Z. Hemati<sup>3</sup>

<sup>1</sup> Isfahan university of medical sciences, nursing, Isfahan, Iran;

<sup>2</sup> Isfahan university of medical sciences, pediatric department, Isfahan, Iran; <sup>3</sup> Isfahan university of medical sciences, pediatric, Isfahan, Iran

\* Corresponding author.

*Introduction.*– Pediatrics and Neonatal Intensive Care Unit (NICU) nurses, due to more stressors, may be at a higher risk. Nurse's burnout not only negatively affects patient's care, but also can harm their physical and mental and general health as well as the quality of work life. The aim of this study was to determine the relation-

ship between burnout and quality of work life in pediatric and NICU nurses.

*Methods.*– In this descriptive and correlation study, 76 nurses employed at the pediatrics/NICU wards of Isfahan Medical University hospitals in 2014 were selected. The data was gathered by Maslach Burnout and Quality of work Life, and was completed by the samples. They were analyzed by SPSS20 and Student's independent *t*-test, and Pearson correlation test.

*Results.*– The results showed that the mean score of burnout for frequency and intensity of "personal performance" was respectively  $74.2 \pm 20.3$  and  $59.7 \pm 20.6$ , and in terms of frequency and intensity of "conflict" this was  $47.4 \pm 22.1$  and  $44.8 \pm 20.5$ , with the highest average score of burnout within the first personal performance and conflict ( $P < 0.05$ ).

*Conclusions.*– Due to the high average burnout score, the managers and directors of nursing by creating a good working environment and job protection of complications, should reduce productivity and prevent low quality care.

*Keywords:* Burnout; Nurses; Quality of work life; Pediatric and neonatal intensive care unit

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Anxiety levels predict low bone mineral density in postmenopausal women assessed for osteoporosis**

G. Martino<sup>1\*</sup>, A. Catalano<sup>2</sup>, F. Bellone<sup>2</sup>, V. Langher<sup>3</sup>, R.A. Fabio<sup>4</sup>, S. Cataudella<sup>5</sup>, P. Velotti<sup>6</sup>, C. Lasco<sup>2</sup>, A. Lasco<sup>2</sup>, N. Morabito<sup>2</sup>

<sup>1</sup> University of Messina, department of cognitive sciences, psychology, education and cultural studies, university of Messina, Messina, Italy; <sup>2</sup> University of Messina, department of clinical and experimental medicine, Messina, Italy; <sup>3</sup> University of Rome, department of dynamic and clinical psychology, Rome, Italy;

<sup>4</sup> University of Messina, department of cognitive sciences, psychology, education and cultural studies, Messina, Italy; <sup>5</sup> University of Cagliari, department of pedagogy, psychology, philosophy, Cagliari, Italy;

<sup>6</sup> University of Genoa, department of educational studies, Genoa, Italy

\* Corresponding author.

*Introduction.*– Anxiety may be observed as a consequence of several chronic diseases, but the effects of anxiety levels per se on bone health in postmenopausal women are poorly investigated.

*Objective.*– To investigate the impact of anxiety severity on bone mineral density (BMD) and prevalent vertebral fractures in a set of ambulatory care Caucasian women referred for osteoporosis.

*Methods.*– Hamilton Anxiety Rating Scale (HAMA) for anxiety levels, Beck Depression Inventory for depressive symptoms and the 36-Item Short Form Health Survey (SF-36) for quality of life, in addition to multiple clinical risk factors (CRFs) for fractures and FRAX score, dual-energy X-ray absorptiometry for BMD measurement at lumbar spine and femoral neck, X-ray vertebral morphometry, were evaluated.

*Results.*– Of the 192 recruited women (mean age  $67.5 \pm 9.5$  yr), patients allocated in the tertile of lower HAMA score (HAMA-1) showed lower probability of fracture compared with patients in the highest one (HAMA-3) ( $20.44 \pm 9.3$  vs.  $24.94 \pm 13$  SD;  $P = 0.01$ ). Women in HAMA-3 exhibited lower *T*-score values at lumbar spine in comparison with women in HAMA-1 ( $-2.84 \pm 1.4$  vs.  $-2.06 \pm 1.2$  SD, respectively,  $P < 0.001$ ), and lower *T*-score values at femoral neck ( $-2.21 \pm 0.9$  vs.  $-1.93 \pm 0.6$  SD;  $P < 0.05$ ); lower *T*-score values were observed in HAMA-3 compared with HAMA-2. A higher rate of prevalent vertebral fractures were observed in HAMA-3 vs. HAMA-1. Anxiety levels were significantly related with age, menopausal

age, years since menopause and depressive symptoms, and at a multiple regression analysis were predictive of reduced BMD.

**Conclusions.**– Anxiety levels were associated with BMD at both lumbar spine and femoral neck.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Mobile phone use related anxiety among university students: Prevalence and typical symptoms

E. Nikolaev<sup>1\*</sup>, S. Petunova<sup>1</sup>, A. Zakharova<sup>1</sup>, G. Dulina<sup>1</sup>, M. Kulygina<sup>2</sup>

<sup>1</sup> Chuvash State university, department of social and clinical psychology, Cheboksary, Russia; <sup>2</sup> Moscow State institute of international relations, medical and psychological center, Moscow, Russia

\* Corresponding author.

**Introduction.**– Use of mobile phones all over the world results in an increasing number of previously unrecorded mental and behavioral disorders that do not always fit into the present classifications.

**Objectives.**– The research is aimed to find out the prevalence among university students of a specific anxiety associated with mobile phone use, as well as its characteristic manifestations.

**Methods.**– The research covered 406 university students (mean age 22.6) specializing in different professional spheres. To define the symptoms of the mobile phone use related anxiety, the students were asked to fill in a 35-item questionnaire. The current stress level was measured with the stress inventory (Ivanova, 2008). Basic statistics and correlation analysis were used for the data interpretation.

**Results.**– Two thirds of the respondents showed different degrees of anxiety manifestation. All the anxiety disorders can fit into five groups of clinical and behavioral manifestations: phantom ringing (66.0%) and phantom vibration (61.6%) syndromes; potential phone loss or theft related anxiety (64.8%); continual unmotivated check of missed calls and messages (62.3%); “nomophobia” as an increased nervousness and anxiety over being without access to a working mobile phone (42.1%); high interest to brand-new mobile technologies accompanied by unreasonably frequent purchase of a more upgraded phone (31.0%). Manifestation of these symptoms positively correlates with the stress level ( $P < 0.05$ ), but it does not correlate with the sex and age ( $P < 0.05$ ).

**Conclusions.**– A wider access to modern mobile communication technologies not only promotes communication, but it also brings about new risks to mental health, which should become the subject of new studies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The psychological structure of perfectionism and motivational conflicts in patients with anxiety disorders

E. Pervichko<sup>1\*</sup>, Y. Babaev<sup>1</sup>, I. Emelyanova<sup>2</sup>, V. Krjukov<sup>2</sup>, V. Krasnov<sup>2</sup>, Y. Zinchenko<sup>1</sup>

<sup>1</sup> Lomonosov Moscow state university, faculty of psychology, Moscow, Russia; <sup>2</sup> Moscow research institute of psychiatry, department of affective disorders, Moscow, Russia

\* Corresponding author.

**Introduction.**– Many studies show connections between anxiety disorders (AD), motivation and perfectionism; however, the inner nature of these connections is yet to be discovered.

**Objectives.**– To examine the connections between direction and power of motivation, strength of motivational conflicts and the structure of perfectionism in patients with AD compared to healthy individuals.

**Methods.**– Projective and semi-projective motivation tests (TAT of Heckhausen, Multi-Motive Grid (Sokolowski et al., 2000)), perfectionism questionnaires (Garanyan, Kholmogorova, Yudeeva, 2001; Hewitt, Flett, 2004). The participants were 21 AD patients (mean age 35.6) and 20 healthy individuals (mean age 28.4).

**Results.**–

1. AD patients differ from healthy individuals in total perfectionism (189.48 vs 170.15,  $P < 0.05$ ) and socially prescribed perfectionism (63.62 vs 51.85,  $P < 0.01$ ), polarized thinking (9.33 vs 5.15,  $P < 0.01$ ) and negative filtering (8.10 vs 4.15,  $P < 0.01$ ).

2. AD patients show prevalence of fear of failure over hope for success (–2.90 vs 4.35,  $P < 0.01$ ), lower overall level of achievement motivation (4.81 vs 10.45,  $P < 0.01$ ), increased fear of losing control in social situations (7.62 vs 5.30,  $P < 0.01$ ) and fear of rejection (6.76 vs 4.60,  $P < 0.05$ ).

3. In AD patients, achievement motivation correlates negatively with socially prescribed perfectionism (–0.533,  $P < 0.05$ ), polarized thinking (–0.618,  $P < 0.01$ ) and total perfectionism level (–0.550,  $P < 0.05$ ), whereas in healthy individuals connection is between self-oriented perfectionism and achievement motivation (–0.544,  $P < 0.05$ ). Total perfectionism correlates with fear of losing control (0.592,  $P < 0.01$ ).

**Conclusions.**– The study results help broaden our vision of the psychological causes and correlates of anxiety disorders and open up perspectives for further studies on this topic.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Aberrant ongoing brain activity after premature birth

J. Shang<sup>1,2\*</sup>, J.G. Bäuml<sup>2,3</sup>, N. Koutsouleris<sup>1</sup>, P. Bartmann<sup>4</sup>, D. Wolke<sup>5</sup>, C. Sorg<sup>2,3,6</sup>

<sup>1</sup> Ludwig-Maximilians-university, department of psychiatry and psychotherapy, Munich, Germany; <sup>2</sup> Technische Universität München, TUM-NIC neuroimaging center, Munich, Germany; <sup>3</sup> Technische Universität München, department of neuroradiology, Munich, Germany; <sup>4</sup> University hospital Bonn, Germany, department of neonatology, Bonn, Germany; <sup>5</sup> University of Warwick, department of psychology, Coventry, United Kingdom; <sup>6</sup> Technische Universität München, department of psychiatry, Munich, Germany

\* Corresponding author.

**Introduction.**– Premature birth is characterized by long-term changes in large-scale brain organization. It has been suggested that slowly fluctuating ongoing activity is affected by premature birth. To test this idea, we investigated whether slow fluctuations in ongoing blood oxygenation of resting-state functional MRI (rs-fMRI) represent a robust feature to separate very premature born adults from term born ones.

**Methods.**– To investigate this question, 94 very preterm/very low birth weight (VP/VLBW) and 92 full term (FT) born young adults underwent rs-fMRI with the amplitude of low-frequency fluctuations (ALFF) as main outcome measure. Multivariate pattern classification framework based on support-vector machines (SVM) was used to generate and validate ALFF patterns for group separation. The dependence of birth complications, sociodemographic and IQ variables was evaluated.

**Results.**– ALFF patterns showed 79.1% accuracy to classify VP/VLBW from FT subjects, and clinical variables predicted SVM decision scores of ALFF (80.7% accuracy) by  $\epsilon$ -support vector regression (SVR).

**Conclusions.**– Our results provide evidence for aberrant ongoing brain activity in premature born adults, mainly in lateral temporal and limbic cortices, with stronger alterations in persons with more severe birth complications and/or lower gestational age.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0311

### **Effect of anxiolytics on the plasma malondialdehyde levels in patients with anxiety disorders**

T. Syunyakov<sup>\*</sup>, N. Zolotov, G. Neznamov  
FSBI "Zakusov institute of pharmacology", laboratory of clinical psychopharmacology, Moscow, Russia

\* Corresponding author.

**Background.**– Anxiety disorders associated with disturbed redox processes and excessive lipid peroxidation (LPO). Benzodiazepines and fabomotizole potentially have different mechanisms to reduce LPO: via interaction with peripheral benzodiazepine receptors or effects linked to membrane modulation. It is hypothesized that benzodiazepine and fabomotizole will have different effects on LPO. **Objectives.**– To compare phenazepam and fabomotizole effects on the malondialdehyde (MDA) levels as a measure of LPO in patient with anxiety disorders.

**Methods.**– 66 patients with anxiety disorders participated the study (generalized anxiety disorder, agoraphobia and nosophobia). 36 were treated with phenazepam and 30 with fabomatizole. Treatment duration was 14 days. MDA plasma levels ( $\mu\text{mol/l}$ ) measured before and after 14-day treatment. The control group included 33 healthy volunteers. To analyze MDA levels changes the three-way ANOVA was used with drug and diagnosis as fixed factors. All statistical tests were two-tailed, and  $P$ -values  $< 0.05$  considered significant.

**Results.**– Background MDA levels didn't differ between phenazepam ( $1.23 \pm 0.50$ ) and fabomotizole ( $1.19 \pm 0.21$ ) but were significantly higher than in control ( $0.55 \pm 0.1$ ,  $P < 0.05$ ). ANOVA revealed that MDA levels significantly decreased from the start to the endpoint without significant effect of interactions with drug and diagnosis. Analysis found that MDA levels variability of changes was significantly lower with fabomotizole comparing to phenazepam (standard deviations: 0.207 and 0.50, respectively,  $F = 5.91$ ,  $P < 0.001$ ).

**Conclusion.**– Both fabomotizole and phenazepam associated with MDA plasma levels reduction. Though fabomotizole induced more consistent effect comparing to phenazepam. Different patterns of drug effects on LPO may reflect distinct mechanisms of drug activity.

**Disclosure of interest.**– Syunyakov T. receive money from Pfizer LLC.

### **Exploration of effects of repetitive transcranial magnetic stimulation targeting medial prefrontal cortex after exposure and before re-exposure on response to exposure therapy in claustrophobic patients**

I. Tallarida<sup>\*</sup>, N. Paquin, K. Kammoun, V. Aubin, D. Szekely  
Centre hospitalier princesse Grace Monaco, psychiatry, Monaco

\* Corresponding author.

Phobia can be associated with high functional impairment. First line therapies, cognitive and behavioral therapy possibly associated with pharmacotherapy, are not necessarily available or effective. Virtual Reality Exposure-based Therapy (VRET) has been shown to be a therapeutic tool for specific phobia.

Greater activation of the ventral medial prefrontal cortex (vmPFC) during learning extinction of fear has been associated with better response to exposure protocols, which is thought to be mediated by the inhibition the PFC may exert on amygdala among other neural structures. High frequency, excitatory, transcranial magnetic stimulation (TMS) targeting vmPFC before VRET sessions accelerated therapy response in a sham-controlled protocol in patients with acrophobia.

We aim to explore if combined excitatory frequencies TMS targeting mPFC and exposure based-therapy can be associated with a therapeutic response in claustrophobic patients.

A case series will be conducted. After an initial evaluation (clinical, subjective functional evaluations and in vivo exposition), patients will undergo one week of treatment consisting in one per day session of exposure, using first VR then in vivo exposure, followed immediately by intermittent theta burst stimulation (iTBS) targeting the mPFC (Fz), followed immediately by a re-exposure. Subjective anxiety will be evaluated at all steps, latency time to enter and time spent in the chosen confined places and subjective real life functioning during treatment will be recorded. A re-evaluation will then be conducted and monthly follow-up proposed.

If clinical improvements are observed a randomized control trial will be designed, potentially resulting in extended treatment decision support in claustrophobia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0313

### **Utilization of virtual reality exposure therapy in treatment of the patient with acrophobia – Pilot study**

K.M. Wilczynski<sup>1\*</sup>, K. Krysta<sup>2</sup>, E. Mazgaj<sup>2</sup>, M. Ciułkiewicz<sup>2</sup>, J. Paliga<sup>2</sup>, A. Szczęśna<sup>3</sup>, A. Strzelczyk<sup>3</sup>, M. Wojciechowska<sup>3</sup>, K. Wojciechowski<sup>3</sup>, M. Krzystanek<sup>2</sup>

<sup>1</sup> Medical university of Silesia, department of psychiatry and psychotherapy of developmental age, Katowice, Poland; <sup>2</sup> Medical university of Silesia, department of psychiatric rehabilitation, Katowice, Poland; <sup>3</sup> Polish-Japanese academy of information technology, research and development center, Bytom, Poland

\* Corresponding author.

**Background.**– Virtual reality exposure therapy (VRET) is becoming increasingly popular method of augmentation of treatment for patients suffering from anxiety disorders. One of the VRET methods, which could be utilized in this group of patients, is the MOTEK CAREN system, however, so far no studies have been published on its implementation in psychiatric disorders.

**Methods.**– Presented here is a case of a 32-year-old woman suffering from acrophobia, who underwent a series of four subsequent trainings with the use of the MOTEK CAREN system. Each of the trainings consisted of the control part, during which participant was walking through forest, and the test part, during which patient was crossing a catenary bridge over precipice. Data from the system were collected on the work of muscles, joints, reactions of the ground, etc. Blood pressure, pulse and salivary cortisol level were measured before and after each training.

**Results and conclusions.**– Visible differences in performance of the participant, between each part, suggest that the test part was more stressful than the control. Improvement noticed with each training

may suggest a gradual adaptation of the patient to the stressful situation. Increased cortisol levels before training, in comparison with levels on a usual day, imply that the sole perspective of upcoming exposition was stressful for the participant. Trainings with the MOTEK KAREN system seem to be a promising adjunct method in treatment of patients with anxiety disorders, however further studies on large groups of patients are required.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Bipolar Disorders - Part I

### Cognitive functioning in unaffected first degree relatives of patients with bipolar one disorder and healthy controls: A comparison

Y. Abid<sup>1</sup>\*, S. Ellini<sup>2</sup>, F. Amdouni<sup>2</sup>, A. Feki<sup>2</sup>, H. Maatallah<sup>2</sup>, M. Cheour<sup>2</sup>

<sup>1</sup> Psychiatry, Razi hospital, ENNASR2, Tunisia; <sup>2</sup> Psychiatry, Razi hospital, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– Neurocognitive functions are considered to be reliable endophenotypes for bipolar disorders. They are consistently reported to be impaired in bipolar one disorder including executive functioning, language, and sustained attention. However, it is not clear which domains of cognitive impairment are most often linked to genetic transmission.

*Objectives.*– This study aimed to identify the neurocognitive functioning of unaffected first degree relatives of patients with bipolar one disorder and to compare the same with a group of healthy controls.

*Methods.*– We proceeded to a prospective and analytical study. Our study population was constituted by 30 unaffected first degree relatives of patients with bipolar one disorder and compared to 30 healthy control subjects. Matching was based on age, gender and level of education. Neurocognitive functioning was evaluated using the “Montreal Cognitive Assessment” test which assesses different cognitive domains: attention, executive functions, memory, language, visuoconstructional skills, conceptual thinking, calculations, and orientation.

*Results.*– Compared to healthy controls, unaffected first degree relatives of patients with Bipolar one disorder performed poorly on tests of executive functions, memory, conceptual thinking, and attention (respectively  $P=0.003$ ;  $P=0.025$ ;  $P=0.04$ ;  $P=0.015$ ). There were no significant differences between the two groups for language, visuoconstructional skills, calculations and orientation.

*Conclusions.*– Cognitive markers like executive functions, memory, conceptual thinking, and attention can distinguish unaffected first degree relatives of bipolar one disorder from healthy controls and can serve as an endophenotype for bipolar one disorder.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### A phenomenological study of mania

S. Adhikari\*, D. Joshi

Tranquility hospital and research center, psychiatry, Lalitpur, Nepal

\* Corresponding author.

*Aims and hypothesis.*– This research was conducted to study symptomatology & diagnosis in manic patient and to investigate the possibility that there might be a natural division of manic episodes into clinical sub-types.

*Background.*– Several empirical studies have been done to arrive at phenomenological subtypes of schizophrenia and depression but such studies are scarce in mania. Factor analysis of signs and symptoms of mania have been done using different rating scales in different studies. This study was carried out to study the core features of the manic state.

*Methods.*– We studied 75 individuals with mania. It was descriptive, cross sectional hospital based study. Patients with mixed episodes and those with features suggestive of organic etiology were excluded from the study. All patients were rated on Scale for manic states (SMS) and subsequent factor analysis was done.

*Results.*– Among patients involved in this study, majority were married (52%). With principal component analysis three eigenvalues greater than unity were extracted. The three factors were euphoric activation, dysphoria and psychosis. These factors accounted for 68.16% of the rotated variance.

*Conclusions.*– This study identified at least three sub dimensions specific to mania. These findings support the multidimensional nature of manic symptoms. Use of sub dimensions, in addition to overall mania severity may enhance the ability to detect meaningful biological correlates of bipolar disorder.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Assessment of the compliance level in patients with bipolar disorder I

Y. Ashenbrenner<sup>1,2</sup>\*, E. Chumakov<sup>1,2</sup>, N. Petrova<sup>1</sup>

<sup>1</sup> Saint Petersburg State university, department of psychiatry and addictions, St. Petersburg, Russia; <sup>2</sup> Saint Petersburg psychiatric hospital no. 1 named after P.P. Kaschenko, outpatient department no. 2, St. Petersburg, Russia

\* Corresponding author.

*Introduction.*– Compliance in patients with Bipolar Disorder (BD) has become particularly relevant in recent years due to the emphasis on the prevention of relapse.

*Objective.*– To estimate the compliance level in patients with BD I. *Methods.*– 1900 patient’s medical records were studied. 34 patients had BD I, including 12 men (average age  $33.33 \pm 3.94$ ) and 22 women ( $37.23 \pm 8.48$ ). Age of the onset was  $22.59 \pm 3.21$  years.

*Results.*– It was found that 31 patients with BD I (91.2%) had a history of non-compliance (lower doses or irregular therapy), which was associated with a subjective feeling that “I already became healthy” (70.6%), relapse (32.6%), “lack of good contact with a doctor” (26.5%), side effects (17.7%), lack of medication, financial problems, alcohol abuse (8.8% each). Psychiatrist visits were irregular in the first month in 29.5% of cases. 67.7% of patients were characterized by non-compliance after the last hospitalization: visiting non-compliance (29.4%), therapy non-compliance (11.8%) and mixed non-compliance (26.5%). Residual symptoms were observed in 55.9% of patients in remission. Non-compliance was linked with such residual symptoms as sleep disturbances ( $R=0.57$ ,  $P<0.001$ ), loss of appetite ( $R=0.43$ ,  $P=0.01$ ), transitory affective fluctuations ( $R=0.66$ ,  $P<0.008$ ).

*Conclusions.*– Patients with BD I in remission are characterized by the high level of non-compliance, which can be due to the presence of residual symptoms of the disease. These data indicate the need to develop new approaches to BD I treatment in remission.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

<sup>1</sup> *Fattouma Bourguiba university hospital, psychiatry, Monastir, Tunisia;* <sup>2</sup> *University hospital of Monastir, research laboratory vulnerability to psychosis, faculty of medicine of Monastir, university of Monastir, Tunisia, psychiatry, Monastir, Tunisia*

\* Corresponding author.

**Introduction.**– Bipolar disorder is an illness involving extreme shifts in mood. Age at onset of may be a key indicator for identifying more homogeneous clinical subtypes.

**Objective.**– To test whether bipolar disorder among adolescents represents a specific form in terms of clinical features, individual and familiar antecedents.

**Methodology.**– It was a case-control study involving 208 bipolar patients hospitalized at psychiatric Monastir department until December 2016. We have subdivided patients in two groups, group 1 with a beginning in adolescence < 18 years ( $n=48$ ) and group 2 a control group with first episode at  $\geq 19$  years ( $n=160$ ). In accordance with the case control design, patients were matched to control subjects.

**Results.**– The early onset of Bipolar Disorder was associated with lack of academic and professional qualifications ( $P=0.003$ ). We found a significant difference between groups in marital status. Group 1 was associated with the presence of a psychiatric family history ( $P=0.02$ ) and with the existence of suicidal behavior ( $P=0.01$ ). In addition, they had significantly more substance abuse and significantly more criminal record ( $P=0.02$ ). As regards the characteristics of the mood relapses, the 1st episode was more frequently of the manic type for the two groups without significant difference. However, the dominant polarity of the manic type was significantly associated with the early onset ( $P=0.01$ ). The psychotic symptoms during mood relapses were associated with the early onset of BD

**Conclusion.**– Our study showed bipolar disorders among adolescents differs in historical and clinical expression

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Relationship of suicidal behavior with metacognition in patients with bipolar disorder**

E. Cesur<sup>\*</sup>, Ö. Şahmelikoğlu Onur, E. Erten, N. Karamustafaloğlu Bakirkoy research and training hospital for psychiatry, neurology and neurosurge, psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Metacognitions are beliefs about thinking and strategies used to regulate and control thinking processes. Although metacognitive problems in clinical populations can disrupt daily functioning, metacognition is poorly understood in bipolar disorder and suicidal patients.

**Objectives.**– Differences about metacognitions between bipolar disorder type I (BPDI) patients with or without suicide attempt and healthy individuals and relationship between metacognitive parameters with parameters related to suicidal behavior were aimed to investigate.

**Methods.**– 72 suicidal and 73 non-suicidal BPDI euthymic patients were included in the study, 86 healthy controls were matched statistically with respect to age and gender. Sociodemographic form, Beck Depression Inventory, Young Mania Rating Scale, Metacogni-

tive Questionnaire-30, The Suicidal Behaviors Questionnaire, UKU Side Effect Rating Scale, SCID-I, SCID-II were applied to patients.

**Results.**– When the total score of the Metacognition Questionnaire-30 was examined, the scores of the both of BPDI groups were significantly higher than control group ( $P<0.01$ ). The controls of worries subscale scores of the suicidal BPDI group and in the non-suicidal BPDI group were found to be higher compared to the control group ( $P<0.01$ ). The control of worries scores of BPDI group with suicide attempt were also higher than non-suicidal group ( $P<0.01$ ). In terms of cognitive self-consciousness subscale, the scores of BPDI group without suicide attempt were higher than both BPDI group with suicide attempt and control group ( $P<0.01$ ).

**Conclusions.**– Considering suicidal behavior in BPDI patients, there are differences in control of worries and cognitive self-consciousness subscales. Metacognitions is important in determining BPBI disease progression and the protection of patients from suicide.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A new comprehensive and empirical clinical staging model for bipolar disorder**

M.P. Garcia-Portilla<sup>1</sup>, L. De La Fuente<sup>1\*</sup>, G. Safont<sup>2</sup>, M. Sanchez-Autet<sup>2</sup>, B. Arranz<sup>3</sup>, P. Sierra<sup>4</sup>

<sup>1</sup> *University of Oviedo, psychiatrist, Oviedo, Spain;* <sup>2</sup> *University of Barcelona, psychiatry, Barcelona, Spain;* <sup>3</sup> *Parc Sanitari Sant Joan de Deu, psychiatry, Barcelona, Spain;* <sup>4</sup> *La Fe university and polytechnic hospital, psychiatry, Valencia, Spain*

\* Corresponding author.

**Objective.**– Bipolar disorder (BD) is a progressive condition that would benefit from a clinical staging. Our aim was to develop a comprehensive clinical staging model empirically.

**Method.**– Naturalistic, prospective, 3-year follow-up, multicenter study. We included 224 subjects with BD (DSM-IV-TR) under outpatient treatment from 4 sites in Spain. We obtained information on sociodemography, clinical course, psychopathology, cognition, functioning, vital signs, anthropometry and lab analysis. Statistical analysis: k-means clustering, comparisons of between-group variables, and expert criteria.

**Results.**– We obtained 12 profilers from 5 life domains that classified patients in five clinical stages. The profilers were: Number of hospitalizations and of suicide attempts, comorbid personality disorder, body mass index, metabolic syndrome, the number of comorbid physical illnesses, cognitive functioning, being permanently disabled due to bipolar disorder, global and leisure time functioning, and patients' perception of their functioning and mental health. We obtained preliminary evidence on the construct validity of the model: (1) all the profilers behaved correctly, significantly increasing in severity as the severity of the stages increased, and (2) late stages needed more complex pharmacological treatment.

**Conclusion.**– We propose a new, empirically developed, comprehensive clinical staging model for BD that could easily be used in clinical daily practice and research.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0320

### A study on the personality traits associated with a delayed diagnosis of bipolar disorder

M. Fraigneau<sup>1\*</sup>, P. Courtet<sup>1</sup>, J. Lopez Castroman<sup>2</sup><sup>1</sup> CHU de Montpellier, urgences et post-urgences psychiatriques, Montpellier, France; <sup>2</sup> CHU de Nîmes, unité d'évaluation médico-psychologique, Nîmes, France

\* Corresponding author.

**Introduction.**– Bipolar Disorder (BD) is a frequent disease, with great morbidity and mortality. The later the diagnosis, the greater are the consequences. The average time to diagnosis is 8 to 10 years. Some diagnostic delay factors have already been identified, but to our knowledge no studies have investigated the influence of personality.

**Objectives.**– Our main objective was to look for the association between impulsive-aggressive personality traits in BD and longer diagnostic delay. Other personality traits were also examined, and we tried to determine specific profiles of diagnostic delay according to BD type.

**Methods.**– We used retrospective data from the FACE-BD cohort (French expert centers for BD). A total of 598 bipolar patients recruited from 2007 to 2015 were included in Cox logistic regression analyses according to BD type. Results were adjusted for socio-demographic and clinical factors, as well as several personality traits. Impulsivity and aggressiveness were measured using the BIS-10 and BDHI scales respectively.

**Results.**– The median diagnosis delay was 9 years. There was no association between diagnostic delay and impulsive-aggressive personality traits for any BD type. Factors associated with longer diagnostic delay were a high score on the Childhood Trauma Questionnaire (CTQ), with an OR = 1.016 ( $P = 0.017$ ) for each additional point, for type I BD, and an early disease onset (before 21 years) for type II BD (OR = 1.861,  $P < 0.001$ ).

**Conclusions.**– Our results suggest that a long diagnostic delay in BD can be predicted. Further studies are needed to establish a risk score of late (or difficult) BD diagnosis.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Does gender influence clinical expression of hypomania?

L. Jouini<sup>1\*</sup>, U. Ouali<sup>1</sup>, M. Ghazzai<sup>2</sup>, Y. Zgueb<sup>1</sup>, R. Jomli<sup>1</sup>, F. Nacef<sup>1</sup><sup>1</sup> Razi hospital, "A" adult psychiatry department, Tunis, Tunisia; <sup>2</sup> Razi hospital, child and teenager psychiatry department, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– The clinical features of bipolar disorder differ between men and women. However, few studies have explored the gender influence on hypomanic episodes.

**Objectives.**– The main objective was to determine the gender influence on hypomanic episodes in a sample of Tunisian bipolar patients.

**Methods.**– Fifty-four patients with Bipolar Disorder I (BPDI) or Bipolar Disorder II (BPDII) were evaluated for hypomania using the 32-items- Hypomania Checklist Questionnaire (HCL-32). Socio-demographic and clinical data were recorded.

**Results.**– BPDI was more prevalent among men (66.7%) and BPDII was more prevalent among women (62.1%). Male patients had more hypomanic episodes (5.67% vs 1.59%,  $P = 0.39$ ). HCL-32 differed according to gender. The following items were significantly more prevalent among women: more energetic and more active (100.0% vs 76.2%,  $P = 0.019$ ), more self-confident (100.0% vs 81.0%,

$P = 0.044$ ), more activities and projects (95.5% vs 61.9%,  $P = 0.009$ ), more colorful and more extravagant clothes/make-up (63.6% vs 28.6%,  $P = 0.022$ ), want to meet or actually do meet more people (86.4% vs 52.4%,  $P = 0.017$ ), think faster (95.7% vs 71.4%,  $P = 0.042$ ), more jokes or puns when talking (90.9% vs 52.4%,  $P = 0.006$ ). On the other hand, men smoked significantly more cigarettes during their hypomanic episode (19.0% vs 68.4%,  $P = 0.002$ ).

**Conclusions.**– Our study reflects that Tunisian women experience rather the sunny, positive side of hypomania whereas Tunisian men experience rather the dark, negative side, including increased consumption of coffee, tobacco, alcohol and drugs.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0322

### Sociodemographic variables and clinical correlates of the treatment adherence in bipolar patients

A. Kokurcan

Diskapı Yıldırım Beyazıt research and training hospital, psychiatry, Ankara, Turkey

\* Corresponding author.

**Introduction.**– Bipolar disorder is a mood disorder featuring with both depressive and manic episodes. The primary aim of this study was to assess sociodemographic and clinical correlates of poor treatment adherence among outpatients with bipolar disorder.

**Materials and methods.**– This was a cross-sectional study carried out in a University Hospital in Turkey. All participants were administered a socio-demographic form, the Structured Clinical Interview for DSM Disorders-I (SCID-I), the Morisky 8-item Medication Adherence Questionnaire (MMAS-8), the Hamilton Depression Scale (HAM-D), the Young Mania Rating Scale (YMRS), Turkish version of Schedule for Assessing the three components of insight (SAI), Global Assessment of Functioning Scale (GAF) and Bipolar Disorder Functioning Questionnaire (BDFQ).

**Results.**– Patients with poor treatment adherence were low educated, were more likely to be not married, more frequently showed melancholic or atypic pattern, and had a greater prevalence of anxiety disorder and higher HDRS total scores. Only 8% of patients with good adherence had comorbid anxiety disorder, as compared with 32% of respondents in the poor adherence group. Logistic regression analyses revealed that comorbid anxiety disorder, lower education level, and duration of depression period were the independent predictors of poor adherence.

**Discussion.**– Assuring full adherence in bipolar patients may be an ideal target which can't be succeeded in a short period but increasing the number of adherent patients is possible and substantial for sufficient outcome. Adherence-focused psychoeducational interventions may be handled as a part of the treatment, further research is needed to assess the role of psychoeducational interventions in treatment adherence of patients with bipolar disorder.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### The concentration of the stem cells in long-term treated bipolar disorder patients

J. Kucharska-Mazur<sup>1\*</sup>, A. Regina<sup>1</sup>, M. Jabłoński<sup>1</sup>, M. Tarnowski<sup>2</sup>, B. Dołęgowska<sup>3</sup>, J.K. Rybakowski<sup>4</sup>, M.Z. Ratajczak<sup>5</sup>, J. Samochowiec<sup>1</sup>

<sup>1</sup> Pomeranian medical university, department of psychiatry, Szczecin, Poland; <sup>2</sup> Pomeranian medical university, department of physiology, Szczecin, Poland; <sup>3</sup> Pomeranian medical university, department of microbiology, immunology and laboratory medicine, Szczecin, Poland; <sup>4</sup> University of medical sciences, department of adult psychiatry, Poznań, Poland; <sup>5</sup> University of Louisville, stem cell biology program at the James Graham Brown cancer center, USA

\* Corresponding author.

**Introduction.**– Literature data and our previous experiments proved that the stem cells and factors involved in their trafficking are engaged in etiopathogenesis of psychiatric disorders.

**Aims.**– In the present study we show the mobilisation of stem cells in long-term treated bipolar disorder (BP) patients.

**Methods.**– A group of 30 patients with BP, without the history of lithium treatment, was examined in remission and compared with a group of 30 healthy volunteers. In peripheral blood we have analysed the concentration of hematopoietic stem cells (Lin–/CD45+/CD34+ and Lin–/CD45+/AC133+) and very small embryonic-like stem cells (Lin–/CD45–/CD34+ and Lin–/CD45–/AC133+) and expression of several genes being potential markers of pluripotential or nervous stem cells.

**Results.**– The peripheral blood concentration of investigated stem cells does not distinguish BP patients from controls. In the analysis of the gene expression we found statistically significant correlations between pluripotency markers and nervous stem cells markers.

**Conclusion.**– Our results are indicative to the unclear role of the stem cells in aetiology of BP and suggest necessity of further studies.

**Disclosure of interest.**– This work was supported by grant POIG.01.01.02-00-109/09.

PW0324

### Personality traits as a risk factor for bipolar disorders

R. Mesbah<sup>1\*</sup>, E.J. Giltay<sup>1</sup>, M. de Leeuw<sup>1</sup>, A.M. van Hemert<sup>1</sup>, M.A. Koenders<sup>2</sup>

<sup>1</sup> Leiden university medical center, psychiatry, Leiden, The Netherlands; <sup>2</sup> Leiden university, faculty of social sciences, Leiden, The Netherlands

\* Corresponding author.

**Introduction.**– The bipolar disorder (BD) is characterized by the alternately occurrence of (hypo)manic and depressive episodes. It affects 1-2% of the population and has often serious consequences for the functioning of patients. Little is known about the role of personality factors on the course of the disorder.

**Objective.**– To determine which personality traits independently predict the incidence of BD episodes.

**Methods.**– The Netherlands Study of Depression and Anxiety (NESDA) study ( $n = 239$ ) is a cohort study with measurement points at baseline, 2, 4, 6, and 9 years of follow-up. The three groups were categorized as patients with current ( $n = 1701$ ) or remitted ( $n = 628$ ) anxiety and depressive disorders, and healthy controls ( $n = 652$ ). Based on the Mood Disorder Questionnaire (CIDI) and Mood Disorder Questionnaire (MDQ), the presence of a (hypo)mania was determined at each time point. The NEO Five Factor Inventory

served as the independent variable in Cox and mixed regression analyses.

**Results.**– From all the participants (mean age 41.9 years, 66.4% women), 115(4.8%) have in total developed a BD during follow up. In multivariate analyses, high Neuroticism and low Agreeableness were the independent predictors for a bipolar disorder. Findings were consistent for the CIDI diagnoses (hazard ratios [HR] 1.77; 95% confidence interval [B1] 1.30–2.40;  $P < 0.001$ ; and 0.77; 95% B1: 0.63–0.93;  $P = 0.008$ ; respectively) and for the MDQ (HR 1.44; 95% B1: 0.97–2.13;  $P = 0.07$ ; 0.60; 95% B1: 0.46–0.78;  $P < 0.001$ ).

**Conclusions.**– High Neuroticism and Low Agreeableness are the personality-related risk factors for developing a (hypo)manic episode.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0325

### Gut microbiome, methylation and the molecular clock in bipolar disorder

S. Mörk<sup>1\*</sup>, S. Bengesser, A. Rieger, F. Fellendorf, M. Platzer, E. Reininghaus

Medical university of Graz, psychiatry and psychotherapeutic medicine, Graz, Austria

\* Corresponding author.

**Objectives.**– The gut microbiome harbors even more genetic material than our body cells and has an impact on a huge variety of physiological mechanisms including the production of neurotransmitters and the interaction with brain functions through the gut-brain-axis. Recently, alterations of the gut microbiome in bipolar disorder (BD) became evident. In comparison to controls, BD patients exhibited a methylation of ARNTL (aryl hydrocarbon receptor nuclear translocator like), a clock gene responsible for the activation of monoamine oxidase A (MAOA) transcription. This current study investigated whether the diversity of microbiota correlates with the methylation of the clock gene ARNTL in BD study participants.

**Methods.**– Genomic DNA was isolated from peripheral fasting blood of study participants with BD in euthymic state ( $n = 32$ ). The methylation analysis of the ARNTL CG site cg05733463 was performed by bisulfite treatment of genomic DNA (Epitect kit), PCR and pyrosequencing. In addition, DNA was extracted from stool samples and subjected to 16S rRNA gene analysis. QIIME was used to analyze microbiome data.

**Results.**– Methylation status (in %) of the ARNTL CpG position cg05733463 correlated significantly with bacterial diversity (Simpson Index:  $r = -0.389$ ,  $P = 0.0238$ ) and evenness (Simpson evenness index:  $r = -0.358$ ,  $P = 0.044$ ) in BD patients.

**Discussion.**– The gene expression of ARNTL correlates positively with the gene expression of MAOA (monoamine oxidase A), which explains the concatenation between circadian rhythms and neurotransmitter dysbalances. Metabolism products of diverse microbiota strains may affect the epigenetic regulation of ARNTL and may affect mood swings by interfering with the molecular clock.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Vitamin D levels in adult outpatients with bipolar disorder: A case-control study**

C. Ortigosa Silva  
Hospital Clinico Universitario San Juan, psychiatry department, Alicante, Spain

\* Corresponding author.

*Introduction.*– Several studies show an association between mental disorders and vitamin D. However, there are few studies focus on bipolar disorder.

*Objective.*– To compare vitamin D levels of outpatients with bipolar disorder with healthy controls.

*Methods.*– This case-control study took place in Vitoria (latitude 42°51'N). Sociodemographical data were reported (Table 1). Depressive symptoms were evaluated with the Hamilton Depression Rating Scale (HDRS-17). All clinical and biological assessments were performed in routine practice. SPSS version 23.0 software package was used.

*Results.*– A total of 21 patients and 19 controls were included. The mean levels of 25-hydroxivitamin D showed no significant difference between groups ( $P=0.947$ ). Vitamin D deficiency ( $<10$  mg/ml) was identified only in the case group (Fig. 1). Neither sex, BMI nor smoking status were predictors of vitamin D deficiency. A very mild association was detected between the HDRS-17 score and vitamin D levels ( $rs = -0.022, P=0.88$ ).

*Conclusions.*– Our study showed clinically relevant data that offer support to the prevalence of hypovitaminosis D in bipolar patients. Screening for vitamin D deficiency is a low-cost intervention with the potential to improve general health condition. Future researches are needed to conclude the real role of the vitamin D improving the prognosis of people with bipolar disorder.

Table 1.

	CASE GROUP n=21	CONTROL GROUP n=19	p-value
<b>GENDER (male/female)</b>	52.4%/47.6%	26.3% / 73.7%	$p = 0.17$ (+)
<b>AGE</b>	50.52 (SD=13.28)	37 (SD=11.85)	$p = 0.003^*$ (**)
<b>BMI (kg/m<sup>2</sup>)</b>	28.75 (SD=4.96)	22.77 (SD=3.62)	$p = 0.000^*$ (***)
<b>SMOKING</b>	3 (14.2%)	3 (15.8%)	$p = 0.66$ (****)

**Recognition of facial emotion: A possible endophenotype for bipolar disorder?**

F.D.L. Osório\*, A.L. Dualibe  
São Paulo university, department of neurosciences and behaviour, Ribeirão Preto, Brazil

\* Corresponding author.

*Introduction.*– Bipolar disorder (BD) is associated with high rates of heritability. Studies show that cognitive dysfunction may be a fundamental feature of the BD physiopathology and a strong expression of its genetic component, stimulating the search for specific neuro-cognitive endophenotypes.

*Objectives.*– To assess the recognition of facial emotion expressions – a key facet of social cognition in euthymic BD individuals ( $n=40$ ) and their first-degree relatives (siblings/offspring;  $n=30$ ) compared to a group of healthy subjects without risk of BD ( $n=30$ ).

*Methods.*– A computed black-white dynamic task with six basic emotions was used.

*Results.*– Subjects with BD showed a higher overall impairment in the accuracy regarding the other groups, which did not differ between them. However, as for some specific emotions (happiness:  $P=0.02$ ; fear:  $P<0.001$ ), the subjects at risk of BD also showed less accuracy compared to controls, that is, with a performance comparable to that of BD subjects. The reaction time to recognise the stimulus was longer in both BP and at-risk subjects (relatives) ( $P<0.001$ ).

*Conclusions.*– Subjects at risk of BD showed impairment in the processing time and recognition of specific facial expressions, demonstrating a possible endophenotype for BP

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0328

**The association between depressive residual symptoms and illness course characteristics in a sample of bipolar outpatients**

G. Serafini<sup>1</sup>, F. Santi<sup>1</sup>, G.H. Vazquez<sup>2</sup>, X. Gonda<sup>3</sup>, M. Pompili<sup>4</sup>, Z. Zoltan Rihmer<sup>3</sup>, M. Amore<sup>1</sup>

<sup>1</sup> University of Genoa, neuroscience DINOGMI, Genoa, Italy; <sup>2</sup> McLean hospital, international consortium for bipolar and psychotic disorder research, Belmont, MA, United States, USA; <sup>3</sup> Kutvolgyi clinical center, Semmelweis university, department of psychiatry and psychotherapy, Budapest, Hungary; <sup>4</sup> Suicide prevention center, Sant'Andrea hospital, university of Rome, department of neurosciences, Rome, Italy

\* Corresponding author.

*Introduction.*– Patients with bipolar disorder (BD) presented residual symptoms referring to subsyndromal manifestations between episodes that do not meet the required criteria for episodes definition in 50–70% of cases. However, the impact of these symptoms on the course of BD is still unclear and needs to be more clearly elucidated.

*Objectives.*– Our aim is to explore factors associated with depressive residual symptoms in a sample of 255 currently euthymic BD outpatients on maintenance treatment.

*Methods.*– The sample includes 160 (62.8%) females and 95 (37.2%) males who were consecutively recruited at the Section of Psychiatry, University of Genoa (Italy) and underwent comprehensive

structured interviews, detailed clinical interviews, and clinical record reviews for the assessment of information concerning the course of illness and clinical status. After categorizing subjects according to the presence/absence of residual symptoms, groups were compared according to the most relevant clinical variables and variables associated with residual symptoms were analyzed using multivariate analyses.

**Results.**– Subjects with residual symptoms were less likely to report substance abuse ( $\chi^2_{(2)} = 11.937, P \leq 0.005$ ) and lifetime psychotic symptoms ( $\chi^2_{(2)} = 10.577, P = 0.005$ ), and more likely to report higher illness episodes, longer illness duration ( $t_{253} = 67.282, P \leq 0.001; t_{253} = 10.755, P \leq 0.001$ ), and longer duration of illness episode ( $t_{253} = 7.707, P \leq 0.001$ ) relative to those without residual symptoms. After multivariate analyses, a significant positive contribution to residual symptoms was given only by duration of current illness episode ( $\beta = 0.003; P \leq 0.05$ ), and lifetime psychotic symptoms ( $\beta = 1.041; P \leq 0.05$ ).

**Conclusions.**– Clinicians should aim to attenuate residual symptoms as they may significantly affect the achievement of a full remission.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Evaluation of cognition in a sample of patients affected by bipolar disorder and schizophrenia

E. Stella<sup>1\*</sup>, M. La Montagna<sup>1</sup>, F. Panza<sup>2</sup>, D. Seripa<sup>3</sup>, G. Miscio<sup>3</sup>, C. Gravina<sup>3</sup>, M. Urbano<sup>3</sup>, A. Greco<sup>3</sup>, G. Logroscino<sup>2</sup>, A. Bellomo<sup>1</sup>, M. Lozupone<sup>1</sup>

<sup>1</sup> University of Foggia, department of clinical and experimental medicine, Foggia, Italy; <sup>2</sup> University of Bari "Aldo Moro", department of basic medicine sciences, neuroscience and sense organs, Bari, Italy; <sup>3</sup> IRCSS Casa Sollievo della Sofferenza, department of medical sciences, San Giovanni Rotondo, Italy

\* Corresponding author.

**Introduction.**– Numerous systematic reviews and meta-analyses described cognitive deficits in major psychiatric disorders. Bipolar (BD) and schizophrenic (SC) patients exhibit significant cognitive impairments across a range of standard neuropsychological tests. Moreover, in literature cognitive dysfunction in BD appears to fall between the level of healthy controls and schizophrenic patients.

**Objectives.**– To demonstrate if cognitive dysfunctions are shared by either psychiatric illnesses or specific to each disorder.

**Methods.**– We enrolled 40 bipolar disorder patients, and compared them to 40 patients with schizophrenia. Neurocognitive performance of participants was assessed by a trained clinician, using the Measurement and Treatment Research to Improve Cognition in Schizophrenia Consensus Cognitive Battery (MCCB).

**Results.**– SC patients (mean age 42 years, 58% M) were directly compared with BD (mean age 45 years, 47% M) patients using Student's *t*-test, founding that they were more severely affected in some of the assessed parameters (Working Memory  $P = 0.002$ ; Visual Learning  $P = 0.01$ ; Social Cognition  $P = 0.002$ ). Moreover, schizophrenic compared to the bipolar group exhibited a more pronounced deficit in general measure of task performance (Overall Composite  $P = 0.005$ ).

**Conclusions.**– Our study results are consistent with a growing body of literature suggesting that patients with schizophrenia perform significantly worse than patients with BD across a spectrum of neurocognitive domains. A possible clinical and etiological overlap between schizophrenia and bipolar disorder has long been a matter of discussion. This study proposes that specific neuropsychological deficits may represent significant points of dissociation between

schizophrenia and bipolar disorder. These alterations may help to distinguish the pathophysiological basis of these major psychiatric disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Chronotype in remitted bipolar disorder

A. Tounsi<sup>1\*</sup>, F. Ellouze<sup>1</sup>, S. Ben Fadhel<sup>1</sup>, M. Daoud<sup>1</sup>, M. Karoui<sup>1</sup>, M. Cheour<sup>2</sup>, F. Mrad<sup>1</sup>

<sup>1</sup> Razi hospital, psychiatry ward G, Mannouba, Tunisia; <sup>2</sup> Razi Hospital, psychiatry ward E, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Circadian rhythms deregulations and an evening preference have been associated with bipolar disorder (BD) both during euthymic periods and mood relapses.

**Objectives.**– The aim of this study was to identify possible clinical and sociodemographic correlates of chronotypes during euthymic periods in a sample of patients with BD.

**Methods.**– A sample of 100 patients treated for BD type I or II in euthymic phase were recruited according to predefined inclusion criteria. Sociodemographic and clinical data were collected. Chronotypes were assessed using the HORNE–OSTBERG MORNINGNESS–EVENINGNESS QUESTIONNAIRE (ME).

**Results.**– 56% of patients had an indifferent chronotype while 24% had a morning type and 20% had an evening type.

No significant correlations were found between sociodemographic or clinical data and a specific type of chronotype.

Analysis showed a significant effect of Lithium on the chronotype ( $P < 0.0001$ ) with patients displaying morning preferences.

**Conclusion.**– Chronobiology and circadian vulnerability are important fields of investigation to understand the pathophysiology of BD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0331

### Different clinical characteristics in Italian bipolar I vs bipolar II patients with a previous suicide attempt

M.E.M. Vismara<sup>\*</sup>, B. Grancini, L. Cremaschi, L. Oldani, C. Arici, V. De Carlo, A.C. Altamura, B. Dell'osso

Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, department of psychiatry, university of Milan, Milan, Italy

\* Corresponding author.

**Introduction.**– Bipolar Disorder (BD) is a chronic and highly disabling condition, associated with a conspicuous burden of morbidity and mortality, often related to suicidal behaviours. Approximately 20 to 35% of BD patients attempt suicide during their lifetime. Different socio-demographic and clinical variables have been associated with a higher suicidal risk in the bipolar population. However, little is known about the influence of BD subtypes in relation to suicide and suicide attempt, in particular.

**Objective.**– The present study aimed to investigate the difference between BDI and BDII patients who committed at least one previous suicide attempt (PSA).

**Methods.**– 362 in- and out-patients with a diagnosis of BD type I (BDI) and II (BDII) according to DSM IV-TR criteria were recruited. Only patients with a PSA ( $n = 94$ ) were considered for the analysis and were divided in two subgroups (BDI vs BDII) to compare socio-demographic and clinical variables.

**Results.**– BDI and BDII patients showed a similar PSA rate without differences in socio-demographic variables. BDI versus BDII patients with PSA showed significantly more lifetime psychiatric hospitalizations, more substance abuse comorbidity, a higher rate of psychotic symptoms, and lower Global Assessment of Functioning scale score. In contrast, BDII versus BDI patients with a PSA had a significantly higher frequency of life events at onset, more frequent depressive first and most recent episode polarity, and more current antidepressant use.

**Conclusions.**– The present study pointed out specific clinical differences between BDI and BDII patients with a PSA, contributing to a better characterization of suicidal behaviours in BD subtypes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

psychiatry and human behavior, Providence, USA

\* Corresponding author.

**Introduction.**– Replication is central to scientific study, and, when attempted, is often not achieved. Our group previously reported that patients who screened positive on the Mood Disorders Questionnaire (MDQ) were as likely to be diagnosed with borderline personality disorder (BPD) as with bipolar disorder.

**Objectives.**– In the present report from the Rhode Island Methods to Improve Diagnostic Assessment and Services (MIDAS) project, we attempted to replicate our initial findings in a new sample of psychiatric outpatients, and we also examined the performance of the MDQ in depressed patients.

**Methods.**– 721 psychiatric outpatients were interviewed with the Structured Clinical Interview for DSM-IV (SCID) and Structured Interview for DSM-IV Personality Disorders (SIDP-IV), and completed the MDQ.

**Results.**– More patients who screened positive on the MDQ were diagnosed with bipolar disorder (34.1%,  $n=44$ ) than with BPD (25.6%,  $n=33$ ). BPD was more frequently diagnosed in the MDQ positive group than the MDQ negative group (27.1% vs. 5.8%, OR = 6.0, 95% CI, 3.3–10.9,  $P<.001$ ). We repeated the analyses for the 279 patients who were in a major depressive episode at the time of the evaluation, and the results were the same.

**Conclusions.**– The results of the present study were generally consistent with the original report. The present study found a 4 to 5-fold increase in the frequency of BPD in patients who screened positive compared to patients who screened negative on the MDQ, and this was also true when the analysis was limited to depressed patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Outcomes of delirium in older medical inpatient in six months post-discharge

D. Adamis<sup>1\*</sup>, O. Fitzpatrick<sup>1</sup>, V. Melvin<sup>1</sup>, D. Meagher<sup>2</sup>, G. McCarthy<sup>1</sup>

<sup>1</sup> Sligo mental health services, psychiatry, Sligo, Ireland;

<sup>2</sup> University of Limerick, department of psychiatry, Limerick, Ireland

\* Corresponding author.

**Introduction.**– Delirium is associated with poor outcomes and high mortality in older people.

**Objectives.**– To examine the association of in-hospital delirium with mortality, cognition and functionality 6 months after discharge.

**Methods.**– Prospective, observational, study. Consecutive patients aged (70+) were recruited from the medical wards. Each participant was assessed among other scales with CAM, MoCA, and Barthel Index. Six months later they were reassessed in community with the same scales.

**Results.**– The initial sample was consisted from 198 participants (mean age 80.63, SD:6.8), 92 females. The follow-up sample was 39, (Dead: 33, Decline: 19, Not contactable 25, Not-attended: 82). After exclusion of the in-hospital deaths no significant differences was found in rates of mortality in 6 months between those who developed delirium during the hospitalisation (CAM+) and those who did not ( $n=178$ ,  $\chi^2=.563$ ,  $df:1$ ,  $P=.453$ ). Cognition (MoCA): Overall was significant cognitive improvement (paired  $t$ -test,  $t=5.326$ ,  $df:38$ ,  $P<.001$ ) however those who had delirium during hospitalisation had significantly lower scores in MoCA compared to those who did not. ( $t=2.545$ ,  $df:37$ ,  $P=.0015$ ). Similarly with function (Barthel Index): Overall improvement ( $t=5.074$ ,  $df:38$ ,  $P<0.001$ ), but those who had delirium had lower scores compared to those who did not ( $t=2.382$ ,  $df:37$ ,  $P=.02$ ).

**Conclusions.**– Although the follow-up sample was small it seems that those who had delirium continue to have lower cognitive and functional scores after six months. Delirium did not affect the mortality rates. Perhaps delirium is an epiphenomenon of an underlying cognitive dysfunction of a brain which cannot repair itself.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Prevalence and predictors of depressive symptoms among attendees of a tertiary care dermatology clinic in Muscat, Oman

M. Al Alawi<sup>1\*</sup>, H. Al Sinawi<sup>1</sup>, A.M. Al Qasabi<sup>2</sup>, A.M. Al Mamari<sup>1</sup>, S. Murthi<sup>3</sup>, S. Al-Adawi<sup>4</sup>

<sup>1</sup> Oman medical speciality board, psychiatry training program, Muscat, Oman; <sup>2</sup> Oman medical speciality board, dermatology training program, Muscat, Oman; <sup>3</sup> Oman medical speciality board, studies and research section, Muscat, Oman; <sup>4</sup> Sultan Qaboos university hospital, behavioral medicine, Muscat, Oman

\* Corresponding author.

**Introduction.**– Various studies have suggested that depression is more prevalent among patients with skin disorders than in the general population. Most of the studies addressing this subject involve Euro-American populations.

**Objectives.**– The present study aimed to estimate the prevalence of depressive symptoms among patients with dermatological dis-

orders and, then, to decipher the clinical-demographic factors associated with depressive symptoms.

**Methods.**– A cross-sectional analytical study was conducted among a random sample of patients attending a dermatology clinic in Muscat. The Patient Health Questionnaire-9 (PHQ-9) was used to screen for depressive symptoms. A logistic regression model was used to find the adjusted and unadjusted odds ratios (ORs).

**Results.**– A total of 260 patients participated in this study, with a response rate of 81%. The prevalence of depression symptoms was 24%. According to regression analysis, family history of depression, comorbid medical disorders and treatment with topicals or isotretinoin were significant predictors of depression (OR=9.41, 95% confidence interval [CI]: 2.27–39.05,  $P=0.002$ ; OR=2.0, 95% CI: 1.2–3.21,  $P=0.05$ ; OR=2.28, 95% CI: 1.09–4.76,  $P=0.028$ ; and OR=2.78; 95% CI: 1.08–7.19,  $P=0.035$ , respectively).

**Conclusion.**– This study indicates that depression is common among patients with dermatological disorders in Oman, particularly in those with family history of depression, medical comorbidities and those who use specific dermatological medications. Screening for depression in patients attending dermatology clinics is essential in order to detect and promptly treat patients suffering from depression.

### The role of psychiatry in the approach of neurocardiogenic syncope

M. Arts<sup>1</sup>, S. Petrykiv<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> Mental Health Western Northern Brabant, geriatric psychiatry and neuropsychiatry, Halsteren, The Netherlands; <sup>2</sup> University of Groningen, university medical center Groningen, department of clinical pharmacy and pharmacology, Groningen, The Netherlands;

<sup>3</sup> Mental health care, Friesland GGZ, Friesland, department of geriatric psychiatry, Leeuwarden, The Netherlands; <sup>4</sup> Leonardo scientific research institute, department of geriatric psychiatry and neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

**Introduction.**– Neurocardiogenic syncope, also known as vasovagal syncope, is a sudden transient loss of consciousness with loss of posture, followed by a spontaneous recovery. All age groups can be affected, with a mean prevalence of 22% in the general population and up to 29% in the elderly. Characteristic features include hypotension, bradycardia and peripheral vasodilatation. Typically syncope is treated by a cardiologist. However, a multidisciplinary team comprising a cardiologist, psychiatrist and possibly a psychologist would be of added value can be, especially in patients experiencing recurrent episodes of neurocardiogenic syncope.

**Objectives and aims.**– To investigate and discuss the added value of psychiatry in the treatment of neurocardiogenic syncope.

**Methods.**– An literature search was conducted using Pubmed, EMBASE, searching for studies reporting vasovagal syncope or neurocardiogenic syncope and possible psychiatric treatment strategies.

**Results.**– Several studies show that neurocardiogenic syncope is often accompanied with psychiatric disorders. Therefore, psychiatric evaluation is an essential component in the diagnosis and treatment of this type of syncope. Focused patient education may be helpful in minimize the risk of a syncope. There is also evidence that selective serotonin reuptake inhibitors, tricyclic antidepressants and benzodiazepines may prevent recurrent episodes. There are also studies which recommend cognitive behavioural therapy for the treatment of neurocardiogenic syncope.

**Conclusions.**– Next to physical examination by a cardiologist, a protocol including psychiatric evaluation by a psychiatrist, patient education, psychopharmacotherapy, and cognitive behavioural therapy should be suggested for the treatment of recurrent episodes of neurocardiogenic syncope.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The risk markers for new onsets of the functional somatic syndromes

F. Creed<sup>1</sup>, J. Rosmalen<sup>2</sup>, P. White<sup>3</sup>

<sup>1</sup> Emeritus professor of psychological medicine, neuroscience and mental health, university of Manchester, UK, Hebden Bridge, United Kingdom; <sup>2</sup> Department of psychiatry, interdisciplinary center for psychopathology and emotion regulation ICPE, university medical center, Netherlands, Groningen, The Netherlands; <sup>3</sup> King's College, department of primary care and public health sciences, London, United Kingdom

\* Corresponding author.

**Introduction.**– The risk factors for developing chronic fatigue syndrome (CFS), irritable bowel syndrome (IBS) and chronic widespread pain (also known as fibromyalgia FM) are unclear.

**Objectives.**– In a prospective population-based study we assessed whether the risk markers for developing new onsets of CFS, IBS and FM were similar in the three syndromes.

**Methods.**– We used data from the Dutch Lifelines study, a population-based cohort with 152,170 participants at baseline, and, so far, 91,942 at 3 years follow-up. At baseline extensive biological, psychosocial and medical data were collected, including the presence of general medical illnesses and the MINI interview for psychiatric diagnoses. New onsets of the 3 syndromes were identified at 3 years follow-up by self-report. We excluded participants who, at baseline, reported the relevant syndrome or the key symptom (fatigue/abdominal symptoms/painful muscles) leaving 1082 new onsets of IBS, 208 of CFS and 491 of FM. Chi square or ANOVA were used to assess how the new-onsets differed from the general population. Penalised logistic regression is ongoing.

**Results.**– CFS, IBS, FM share many non-symptom characteristics that precede the illness onset including many socio-demographic features, stressful life events, psychiatric disorder, gastro-intestinal and musculo-skeletal illnesses and health perception, including in multivariate analysis. They differ in terms of age, sex distribution, years of formal education, BMI, the particular preceding general medical illness and prescribed medication.

**Conclusions.**– The similarities of the predictors suggest some common underlying aetiology but there appear also to be syndrome-specific features in both socio-demographic characteristics and general medical illnesses that predict syndrome development.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Neurotic conditions and psychosomatic disorders in highly qualified sportsmen

O. Dobrushina<sup>1\*</sup>, I. Mitin<sup>2</sup>, G. Arina<sup>3</sup>, E. Razumets<sup>2</sup>, A. Trofimova<sup>4</sup>, A. Malyutina<sup>3</sup>, S. Martunov<sup>5</sup>, A. Zholinskii<sup>6</sup>

<sup>1</sup> International institute of psychosomatic health, director, Moscow, Russia; <sup>2</sup> Federal research and clinical center of sports medicine and rehabilitation of federal medical biological agency, medical psychology, Moscow, Russia; <sup>3</sup> M.V. Lomonosov Moscow State university, psychology, Moscow, Russia; <sup>4</sup> International institute of psychosomatic health, psychology, Moscow, Russia; <sup>5</sup> International institute of psychosomatic health, founder, Moscow, Russia; <sup>6</sup> Federal research and clinical center of sports medicine and rehabilitation of federal medical biological agency, director, Moscow, Russia

\* Corresponding author.

**Introduction.**– Highly qualified sportsmen are supposed to be at risk for the development of psychosomatic disorders due to stressful professional activity. Evaluation of the influence of psychological factors on stress-related bodily reaction in this group is of interest. **Objectives.**– To study the association between neurotic conditions and psychosomatic disorders in highly qualified sportsmen.

**Methods.**– Data from annual examination of highly qualified sportsmen, including Yachno-Mendelevich survey for neurotic conditions, underwent retrospective analysis. Medical records were analyzed for disorders with known psychosomatic mechanisms, such as somatoform autonomic dysfunction, irritable bowel syndrome, chronic back/neck pain and other. 645 records on sportsmen with psychosomatic disorders and 255 records on control sportsmen entered the analysis.

**Results.**– Sportsmen with psychosomatic disorders had higher rate of neurotic conditions than the control group (18.2% vs. 12.9%,  $P=0.05$ ); between-group differences in Yachno-Mendelevich survey subscores were seen in subscales “neurotic depression”, “asthenia”, “histrionic type reactions”, “obsessive-compulsive disorder” and “autonomic dysfunction”. Logistic regression revealed significant influence of the particular subscale “histrionic type reactions” on the development of psychosomatic disorders ( $P=0.04$ ). The only association between specific neurotic condition and type of psychosomatic disorder was coexistence of chronic back/neck pain and neurotic depression, with anxiety found to be a significant additional factor in logistic regression.

**Conclusions.**– Neurotic conditions modulate the development of psychosomatic disorders in highly qualified sportsmen.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Neuropsychiatric manifestations Ushering Pellagra

F. Fekih-Romdhane, R. Ridha

Razi Hospital, psychiatry, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Pellagra is a metabolic disorder which is caused by a deficiency of vitamin B3. Its diagnosis is based on the patient's history and the classic triad of dermatitis, diarrhea, and dementia. **Objectives and methods.**– We report through this observation, a rare case of pellagra revealed by neuropsychiatric disorders.

**Results.**– Mr. N.A was a 48-year-old man. He has a past history of chronic alcohol consumption, and a pulmonary tuberculosis diagnosed in 2007 for which he was treated with first line antituberculosis drugs. He has no past history of neuropsychiatric illness.

The patient was diagnosed in 2015 with schizophrenia spectrum disorder and put on long-acting injectable antipsychotic therapy. In January 2017, Mr. N.A was deemed not guilty by reason of insanity following a crime involving Damage to Public Property, and was admitted in our forensic psychiatry department. The first examination revealed that he had aphasia, apraxia and agnosia. The dermatological examination found a Cheilite and photodistributed skin lesions spread over the the face and distal extremities. Biology revealed biological signs of malabsorption. The diagnosis of pellagra was made by a combination of antituberculous agents, chronic ethylism, cutaneous lesions, diarrhea, mental disorders and advanced dementia. Mr. N.A was put on multivitamin complex and supplemental parenteral nutrition. On his third day of hospitalization, he died as a result of septic shock complicating bronchopneumonia.

**Conclusions.**– The occurrence of mental disorders in a subject who had no previous psychiatric history, with a context of chronic ethylism, should lead to earlier consideration of seeking classic clinical triad of pellagra.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Depressive disorders and sexual functioning among Malaysian women with polycystic ovarian syndrome (PCOS): A cross-sectional study

B. Francis<sup>1\*</sup>, K.Y. Wah<sup>2</sup>, R.A. Jawan<sup>3</sup>, A.H. Sulaiman<sup>4</sup>, J.S. Gill<sup>4</sup>

<sup>1</sup> University Malaya, department of psychological medicine, Kuala Lumpur, Malaysia; <sup>2</sup> Hospital Mesra Bukit Padang, psychiatry, Sabah, Malaysia; <sup>3</sup> Hospital KPJ Seremban, obstetrics and gynaecology, Seremban, Malaysia; <sup>4</sup> University Malaya, psychological medicine, Kuala Lumpur, Malaysia

\* Corresponding author.

**Introduction.**– Depressive disorders in females with Polycystic Ovarian Syndrome (PCOS) are common with a prevalence of 25% to 64% [1]. Women with PCOS also showed higher levels of sexual dysfunction compared to control.

**Objectives.**– (i) To assess the prevalence of sexual dysfunction and depressive disorders among Malaysian women who have PCOS (ii) To analyse the correlates of depressive disorders in this population. **Methodology.**– Women with PCOS who fulfilled the Rotterdam Criteria in University of Malaya Medical Center, Kuala Lumpur, Malaysia were enrolled into the study ( $n = 105$ ). Socio-demographic data, Mini International Neuropsychiatric Interview (M.I.N.I) and the Female Sexual Function Index-Malay (FSFI-M) were administered.

**Results.**– A sizeable portion of the population (66.7%) had depressive disorders. The most common depressive disorder was major depressive disorder (25.5%). The Malay race was significantly correlated with depressive disorders. Body mass index, parity, use of oral contraceptive pill and testosterone levels were not significantly correlated. Only 8 subjects (10.1%) reported to have female sexual dysfunction, and 71 subjects (89.9%) reported to have no sexual dysfunction. However, almost half of them (41.8%) were dissatisfied with their sex lives. Sexual dysfunction was significantly correlated with depressive disorders ( $P=0.018$ ).

**Conclusion.**– We recommend that women with PCOS should be screened for depressive disorders and sexual dysfunction as their prevalence is high and are significantly correlated.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Correlates and prevalence of anxiety disorders among women with polycystic ovarian syndrome (PCOS): A Malaysian cross-sectional study**

B. Francis<sup>1\*</sup>, K.Y. Wah<sup>2</sup>, R.A. Jawan<sup>3</sup>, A.H. Sulaiman<sup>4</sup>, J.S. Gill<sup>4</sup>

<sup>1</sup> University Malaya, department of psychological medicine, Kuala Lumpur, Malaysia; <sup>2</sup> Hospital Mesra Bukit Padang, psychiatry, Sabah, Malaysia; <sup>3</sup> Hospital KPJ Seremban, obstetrics and gynaecology, Seremban, Malaysia; <sup>4</sup> Kuala Lumpur, Malaysia

\* Corresponding author.

**Introduction.**– The prevalence of anxiety disorders in females with Polycystic Ovarian Syndrome (PCOS) ranges widely, that is from 14–57% [1]. A recent meta-analysis showed that the odds of women with PCOS having anxiety disorders were 5 times that of control [2]. **Objectives.**– (i) To study the prevalence of anxiety disorders among Malaysian women with PCOS, (ii) To identify the correlates of anxiety disorders in this population.

**Methodology.**– Samples were collected among the women with PCOS who fulfilled the Rotterdam criteria ( $n=105$ ). Socio-demographic data were collected and the Mini International Neuropsychiatric Interview (M.I.N.I) administered. The women were screened for anxiety using the Hospital Anxiety and Depression Scale anxiety subscale (HADS-A).

**Results.**– The HADS-A optimal cutoff was 7.5. Approximately 62.7% had anxiety disorders diagnosed with the M.I.N.I. The most common anxiety disorder was generalized anxiety disorder (30.4%). Age below 30 years was significantly correlated with anxiety. Body mass index, use of oral contraceptive pill, parity and testosterone levels was not significantly correlated.

**Conclusion.**– We recommend that women with PCOS should be screened for anxiety disorders, as their prevalence is much higher than what is expected of the normal population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Bio-psycho-social complexity of patients undergoing pre-orthotopic liver transplant compared to other clients of a consultation-liaison psychiatry service**

G. Mattei<sup>1\*</sup>, S. Ferrari<sup>2</sup>, M. Galletti<sup>2</sup>, G. Rioli<sup>2</sup>, D. Perrone<sup>2</sup>, M. Moscara<sup>2</sup>, S. Cavana<sup>2</sup>

<sup>1</sup> University of Modena and Reggio Emilia & Marco Biagi Foundation, department of economics, Modena, Italy; <sup>2</sup> University of Modena and Reggio Emilia, department of diagnostics, clinical and public health medicine, Modena, Italy

\* Corresponding author.

**Introduction.**– The Modena Psychiatric Consultation–Liaison Psychiatric Service (MCLPS) provides consultations for medical-

surgical in- and out-patients, including psychiatric assessment of patients waiting for Orthotopic Liver Transplantation (pre-OLT).

**Objectives.**– To measure bio-psycho-social complexity, anxiety-depressive symptoms and their possible association among pre-OLT patients referred to the MCLPS.

**Methods.**– All patients referred to the MCLPS for pre-OLT screening from 01/02/2017 to 01/08/2017 were assessed by means of Intermed-Self Assessment (IMSA) and Hospital Anxiety and Depressive Scale (HADS), besides routine psycho-diagnostic examination, and compared to other, non pre-OLT, medically-ill patients referred to the MCLPS. Clinical and demographics variables were collected for each patient. Statistics was performed by means of regression models and Fisher's Exact test.

**Results.**– Twenty-five pre-OLT patients (76% males, mean age  $55 \pm 9.0$  years) were enrolled and matched to 31 controls (80% females, mean age  $58 \pm 16.6$  years). A caregiver was present for all pre-OLT patients and for 70% of controls. One pre-OLT candidate and 9 controls scored  $> 21$  on the IMSA, indicating bio-psycho-social complexity. Four pre-OLT patients (16%) and 20 (65%) controls reported symptoms of anxiety and depression. IMSA total score was higher among controls ( $P=0.03$ ) and lower when a caregiver was present ( $P=0.04$ ). Levels of anxiety, depression, and anxiety-depression symptoms were significantly higher among controls (OR 6.28,  $P < .01$ ; OR 5.19,  $P \leq .01$ ; OR 9.54,  $P < .01$  respectively).

**Conclusions.**– According to our preliminary results, pre-OLT patients reported lower levels of bio-psycho-social complexity and anxious-depressive symptoms in comparison to other MCLPS clients. The presence of a caregiver could reduce the level of bio-psycho-social complexity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Childhood trauma and psoriasis, as a psychosomatic disease**

Y. Gorgulu<sup>\*</sup>, R. Kose Cinar, M.B. Sonmez

Trakya university, faculty of medicine, psychiatry, Edirne, Turkey

\* Corresponding author.

**Introduction.**– Psychiatric disorders sometimes may be related to childhood psychological trauma. Recent studies have associated childhood exposure to trauma to some skin diseases, too.

**Objectives.**– Our study aimed at exploring whether psoriasis is related to the reported childhood traumatic life events. On the other hand, we investigated the relation between depression, dissociation experiences and psoriasis.

**Methods.**– Fifty-eight patients with psoriasis and 38 voluntary healthy controls were enrolled in the study. All participants completed a specific questionnaire measuring traumatic life experiences (Childhood Traumatic Questionnaire, CTQ), Beck depression inventory (BDI) and Dissociative experiences scale (DES). The CTQ assesses emotional and physical neglect and emotional, physical and sexual abuse in the childhood.

**Results.**– The mean age of the patients and controls was 39.81 ( $\pm 15.12$ ) and 37.13 ( $\pm 12.28$ ) years, consecutively. The sociodemographic characteristics of the patients and controls was not different ( $P > 0.05$ ). The mean scores of patients were 37.06 ( $\pm 7.04$ ) for CTQ; 13.07 ( $\pm 9.44$ ) for BDI and 312.91 ( $\pm 350.50$ ) for DES. The mean scores of controls were 33.63 ( $\pm 9.13$ ) for CTQ; 7.82 ( $\pm 7.10$ ) for BDI and 207.95 ( $\pm 210.75$ ) for DES. CTQ and BDI scores were significantly different between the two groups ( $P < 0.05$ ). Although the DES score of patients group was higher than the score of control group, but it was not statically significant. On ROC analysis, the AUC for CTQ was 0.678 ( $P=0.003$ ), (sensitivity % 62.9 and specificity % 76.9) with optimal cutoff of  $\leq 32$ .

**Conclusions.**– Our findings suggest a relationship between childhood traumatic experiences and psoriasis.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0343

### Prevalence of delirium in tertiary general hospital patients

A. Kandeger<sup>1</sup>, F. Kayhan<sup>2</sup>

<sup>1</sup> Isparta City hospital, psychiatry, Isparta, Turkey; <sup>2</sup> Freelance physician, psychiatry, Konya, Turkey

\* Corresponding author.

**Introduction.**– Delirium is a multifactorial syndrome involving interactions between predisposing factors, such as severe illness, poor vision, and cognitive disorders, and precipitating factors, such as infections and surgical interventions. Furthermore, delirium is associated with prolonged hospitalization, increased mortality, and greater functional and cognitive impairment. Despite its prevalence in hospital patients, delirium is often undiagnosed or misdiagnosed.

**Objectives.**– Studies performed in the general hospital population have been limited to elderly patients. To our knowledge, no previous prevalence studies in a hospital setting have used psychiatric interviews to diagnose delirium in patients with a wide age range who were hospitalized in several different wards. We aimed to investigate the prevalence of delirium in tertiary hospital patients.

**Methods.**– The study included 741 of 800 randomly selected patients on all hospital wards except pediatrics, psychiatry, and intensive care.

**Results.**– Delirium was diagnosed in 48 (6.5%) patients. The prevalence of delirium was higher among patients with a low educational level, an older age, chronic obstructive pulmonary disease (COPD), and diabetes mellitus (DM), as well as those on surgical wards (e.g., orthopedics) and those with longer hospital stays. Delirium had not been recognized by health care professionals in 14 (29.8%) cases, and psychiatric consultation was not requested.

**Conclusions.**– Our findings indicate that delirium was more common among inpatients and postoperative patients and tended to be underdiagnosed. Early diagnosis of delirium by healthcare professionals may decrease the length of hospital stay and the mortality and morbidity rates. Educational interventions to improve understanding of delirium may help reduce misdiagnosis of delirium.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Somatic and mental complaints in the normative population: General “ill-being” or somatic “mask” of mental problems?

S. Khrushchev<sup>1</sup>, E. Rasskazova<sup>2</sup>, A. Tkhostov<sup>3</sup>, V. Guldán<sup>4</sup>

<sup>1</sup> National research center for hematology, laboratory studying mental and neurological disorders, Moscow, Russia; <sup>2</sup> Lomonosov Moscow state university / mental health research center, associate professor / senior researcher, Moscow, Russia; <sup>3</sup> Lomonosov Moscow state university, the head of the clinical psychology department, Moscow, Russia; <sup>4</sup> Moscow region center of social and forensic psychiatry, head of psychology laboratory, Moscow, Russia

\* Corresponding author.

**Introduction.**– The assumption that somatic symptoms can express psychological conflict is the basis of psychosomatic medicine, but the relationship between somatic and mental complaints in healthy people is not well-investigated.

**Objectives.**– There are two alternative hypotheses compared in the study: according to the “general distress factor” hypothesis one can expect positive correlation between somatic and mental complaints. Alternatively, if somatic symptoms “mask” or express mental ill-being correlation should be zero or negative one.

**Methods.**– Data on 1443 healthy adults from Russian MMPI-2 validation project were used (Butcher et al., 2001, Rasskazova et al., 2013). Content scales reflecting mental and somatic complaints were factorized revealing “general distress” factor (explained 61% of variance with factor loadings .63–.91). Then each scale was regressed on general factor to differentiate specific complaints.

**Results.**– Complaints on somatic symptoms correlates positively to complaints on mental symptoms ( $r = .33-.62$ ). Their relationship with personality characteristics is largely a non-specific manifestation of the general psychological distress ( $r = .32-.69$  versus  $r < .34$  for all clinical scales except for Hs and Mf). Hypochondriacal and hysterical traits are associated with a variety of specific somatic complaints, depressive traits – with a common concern for the health, schizoid traits – with gastrointestinal complaints ( $r = .24-.48$ ).

**Conclusions.**– Data are in line with “general distress factor” hypothesis. A number of specific physical and mental complaints observed in different personality profiles should be taken into account in diagnostics and treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### A case study of Munchausen syndrome: Developing a self-assessment scale

C. Lazzari\*, A. Shoka, B. Papanna, G. Mousailidis

Essex partnership university NHS foundation trust, United Kingdom, general adult psychiatry, Colchester, United Kingdom

\* Corresponding author.

**Introduction.**– In United Kingdom, Munchausen Syndrome (MS) is becoming common within female patients, often comorbid with borderline personality disorder, and presenting with multiple admissions both to psychiatric and general hospitals.

**Objectives.**– To create a self-assessment tool for Munchausen Syndrome.

**Methods.**– A Delphi group of psychiatrists created a 23-item questionnaire with a 5-point Likert scale, The Munchausen Syndrome Self-Assessment Scale (MSAS), which reported major concerns and themes of presentation of a 21-year-old female being the case study. The MSAS was compared to results on standardized psychiatric scales (Table 1 and Fig. 1) by using meta-analysis and the coefficient of heterogeneity  $I^2$  to search for sensitivity of MSAS.

**Results.**– There was a statistically significant heterogeneity within all the scales ( $I^2 = 94.53\%$ ;  $P < 0.001$ ). However, the MSAS did not show higher sensitivity compared to the other standardized scales. Nevertheless, PHQ-9 and GAD-7 were highly sensitive in spotting MS.

**Conclusions.**– Anxiety and depression with multiple physical symptoms are the most co-morbid psychiatric conditions in patients with MS. Special management is needed in MS as liaison psychiatry seems a promising way to improve quality of life in MS.

Table 1.

Psychiatric Scale	Total Score in the patient	Degree of severity	Total possible in the Scale	Proportion (95%CI) at meta-analysis
BPRS (Brief Psychiatric Rating Scale)	27	Low	126	0.21 (0.14-0.29)
MADRS (Montgomery-Asberg Depression Scale)	24	Moderate	60	0.40 (0.27-0.53)
HAM-D (Hamilton Depression Rating Scale)	22	Severe	44	0.50 (0.35-0.64)
KPS (Karnoofsky Performance Status Scale)	40	Moderate to severe	100	0.40 (0.30-0.49)
PHQ-15 (Physical Health Questionnaire 15)	16	Moderate	30	0.53 (0.34-0.71)
PHQ-9 (Physical Health Questionnaire 9)	24	Severe	27	0.88 (0.70-0.97)
GAD-7 (Generalized Anxiety Disorder 7)	21	Severe	21	1.00 (0.83-1.00)

### Socio-demographic, tumor characteristics and presence of psychiatric diagnostic in patients with primary brain tumor

L. Martínez Sadurní<sup>1</sup>\*, B. Samsó<sup>1</sup>, M. Martínez-García<sup>2</sup>, G. Vallalba<sup>3</sup>, E. Sarsanedas<sup>4</sup>, I. Ruiz-Ripoll<sup>1</sup>

<sup>1</sup> Hospital del Mar-Parc de Salut Mar, Institut de Neuropsiquiatria i Addiccions, Barcelona, Spain; <sup>2</sup> Hospital del Mar, department of oncology, Barcelona, Spain; <sup>3</sup> Hospital del Mar, department of neurosurgery, Barcelona, Spain; <sup>4</sup> Hospital del Mar, department of clinica documentation, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Patients with brain tumor present high risk of emotional, cognitive, psychiatric and behavioral symptoms. In these patients we can find stress reaction towards the health and the loss in their neurologic and cognitive function added to the burden of the direct effect of the tumor and the side effects of neurosurgery, chemotherapy, radiotherapy and pharmacological treatments. However, observational studies show heterogenic results about the frequency of psychiatric disorders, their characteristics and the relationship with socio-demographic aspects in relationship with the tumor.

**Aims.**– The aim of this study is to assess the socio-demographic, tumor characteristics and psychiatric symptoms of presentation of the patients with brain tumors diagnosed in Hospital del Mar.

**Methods.**– A sample of 148 patients with primary brain tumor diagnosis between 2008 and 2011 in Hospital del Mar in Barcelona was analyzed retrospectively. Socio-demographic, neuroimaging and histological data was collected. A psychiatric evaluation was

carried out by consultation-liaison. A descriptive approach of the obtained data is presented.

**Results.**– No great differences were observed in the gender proportion. The majority of the tumors were located in frontal or temporal areas. Astrocytoma was the most prevalent histological type of tumor. A psychiatric disorder could be established in 38,5% of the patients with predominance of depression.

**Conclusions.**– Further research to better define the socio-demographic and tumor characteristics in the patients with brain tumor and determine its association with psychiatric symptoms would be of great interest to improve the clinical management and to provide stronger evidence on the importance of suspicion of brain tumors in new-onset psychiatric symptoms.

### Cognitive impairments in type II diabetic patients

Z. Sepehrmanesh

Kashan university of medical sciences, psychiatry department, medical faculty, Kashan, Iran

\* Corresponding author.

**Background.**– Diabetes mellitus has a high prevalence in the world and is causing complications for patients, such as brain dysfunction and dementia which is less well-known. The aim of this study was to assess cognitive status in patients with type II diabetes compared with people without diabetes.

**Methods.**– The study included 60 type II diabetic patients and 60 healthy volunteers. After recording demographic information and obtaining consent, MMSE scale was recorded for all patients. *T* tests, Chi<sup>2</sup>, ANOVA and multiple logistic regressions were used to compare the studied variables.

**Results.**– The mean MMSE in diabetic patients was 24.13 and in the control group was 27.6 ( $P < 0.001$ ) that this relationship remained significant by eliminating confounding factors. The mean MMSE in diabetic patients with poor diabetes control was 22.64 and in diabetic patients with good control of the diabetes was 24.58 ( $P < 0.001$ ). Mean MMSE in diabetic patients with disease duration more than 15 years' was 22.86 in diabetic patients with duration less than 10 years was 26.16 ( $P < 0.001$ ).

**Conclusion.**– Results of this study showed that individuals with type II diabetes have poor cognitive function compared to healthy controls and these impairments worsens with increasing disease duration, age and lack of proper control of diabetes.

**Keywords:** Diabetes; Cognitive impairment; MMSE

### Anxiety-depressive spectrum and cognitive disorders rates in inflammatory rheumatic diseases

D. Veltishchev<sup>1</sup>\*, T. Lisitsyna<sup>2</sup>, O. Kovalevskaya<sup>1</sup>, O. Seravina<sup>1</sup>, A. Abramkin<sup>2</sup>, P. Ovcharov<sup>2</sup>

<sup>1</sup> Moscow research institute of psychiatry, NMRC PN MoH RF, stress related disorders, Moscow, Russia; <sup>2</sup> Nasonova research institute of rheumatology, systemic rheumatic diseases, Moscow, Russia

\* Corresponding author.

**Introduction.**– Mental disorders (MDs) are frequent comorbid diagnoses for Inflammatory Rheumatic Diseases (IRDs) patients. The

structure of MDs diagnoses and comparison of their rates in different IRDs have not been evaluated still.

**Objective:** comparative analysis of MDs: Anxiety-Depressive Spectrum (ADS) and Cognitive Disorders (CDs) rates in Inflammatory Rheumatic Diseases (IRDs) patients: rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), primary Sjögren syndrome (SjS) and Behçet's disease (BD).

**Methods.**– 613 IRDs patients were enrolled in the study. All of them had reliable diagnoses of IRDs: RA ( $n = 128$ ), SLE ( $n = 180$ ), SSc ( $n = 110$ ), SjS ( $n = 80$ ), BD ( $n = 115$ ). MDs were diagnosed in accordance with the Hospital Anxiety and Depression Scale (HADS) for screening and semi-structured (ICD-10) interview. CDs were diagnosed with psychology and neuropsychology methods.

**Results.**– Among diagnosed MDs in IRDs patients ADS (78.4%) and CD (70.0%) were significantly prevailed comorbid MDs. Depressive disorders (single, recurrent depression and dysthymia) were diagnosed in 73% of RA, 64.5% – SSc, 60% – BD, 50% – SLE, 49% – SjS-pts; anxiety disorders (GAD and adjustment disorder) – in 25% of SjS, 24.5% – SLE, 23% – RA, 17% – BD, 6.4% – SSc-pts. CDs of different severity were diagnosed in all SSc (100%) patients, less often in BD (77.4%), pSS (68.7%), RA (68.7%) and SLE (36.1%) patients. The chronic/recurrent depressions had preceded IRDs in most cases.

**Conclusion.**– Anxiety-Depressive Spectrum and Cognitive disorders are typical for the majority of IRDs patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Use of information and communications technologies among psychiatric population: A comparison between individuals with and without serious mental illness

Z. Abu Rahal<sup>1,2\*</sup>, L. Vadas<sup>2</sup>, B. Bloch<sup>2,3</sup>, A. Avital<sup>4,5</sup>

<sup>1</sup> Clalit health services, Northern District, Israel, psychiatry, Turan, Israel; <sup>2</sup> Emek medical center, psychiatry department, Afula, Israel;

<sup>3</sup>Technion, Israel institute of technology, Rappaport faculty of medicine, Haifa, Israel; <sup>4</sup>Technion, Israel institute of technology, behavioral neuroscience lab, department of physiology, Rappaport faculty of medicine, Haifa, Israel; <sup>5</sup>Emek medical center, psychiatry department, Afula, Israel

\* Corresponding author.

**Introduction.**– There is a growing interest in utilizing ICT (Information and Communications Technologies) for mental health related purposes. Despite the increasing evidence base for the efficacy of the technology-based intervention, little is known about the current rates of ICT use among the psychiatric population in general and the serious mental illness population in particular.

**Methods.**– We surveyed 427 psychiatric patients from different clinical settings (outpatient, inpatient and ER) in Emek Medical Center, Northern Israel. The self-report surveys included questions about demographics, access to and use of ICT (Computer, Internet, Facebook, Mobile phone, Smartphone).

**Results.**– The total computer use was 59.3% and 77.3% reported internet use and access. Overall 92.7% reported owning a mobile phone and 67.9% reported owning a smartphone. 63% of the participants reported owning a Facebook account. More than half of the participants who use ICT reported that they have used these technologies at least once a day. 50.5% ( $n = 216/427$ ) of the patients had a serious mental illness (SMI): Mainly psychotic and affective dis-

orders. Except of mobile phone, there were statistically significant differences between individuals with and without serious mental illness in using and accessing computer, Internet, Facebook and smartphone.

**Conclusions.**– A majority of our psychiatric patients are accessing and using ICT. Despite the relatively low frequency, access to and use of ICT among people with serious mental illness, we illustrate that their access and use are increasing and already extended. Future studies will be essential in evaluating potential barriers and challenges in utilizing ICT among SMI populations

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Real-time schizophrenia monitoring using wearable motion sensitive devices

M. Bazhmin<sup>1\*</sup>, T. Tron<sup>2</sup>, Y. Resheff<sup>2</sup>, A. Peled<sup>3</sup>, A. Grinshpoon<sup>3</sup>, D. Weinshtal<sup>2</sup>

<sup>1</sup> Technion university, Haifa, Israel, Shaar Menashe MHT, Shaked, Israel; <sup>2</sup> Hebrew university of Jerusalem HUJI, Israel, The Edmond and Lily Safra center ELSC for brain science, Jerusalem, Israel; <sup>3</sup>Technion university, Haifa, Israel, Shaar Menashe MHT, Hadera, Israel

\* Corresponding author.

**Introduction.**– The current subjective non-quantitative evaluation of motor disturbances in schizophrenia leads to multiple inaccurate interpretations of phenomenology which impairs the reliability and validity of psychiatric diagnosis.

**Objectives.**– Our objective is to quantitatively measure motor behavior in schizophrenia patients, and develop automatic tools and methods for patient monitoring, follow-up and treatment adjustment.

**Methods.**– Wearable devices were distributed among 25 inpatients in the closed wards of a Mental Health Center. Motor activity was measured using embedded accelerometers, as well as light and temperature sensors. The devices were worn continuously by participants throughout the duration of the experiment. Participants were also clinically evaluated twice weekly, for mental, motor, and neurological symptom severity using common accredited evaluation scales. Medication regimes and outstanding events were also recorded by hospital staff.

**Results.**– Results show significant correlations between features of activity in various daily time-windows, and measures derived from the psychiatrist's clinical assessment or abnormal events in the patients' routine. Correlation analysis between steps count per minute, averaged sum of point-wise acceleration, variance and square acceleration, indicate a predictive benefit with respect to the PANSS factors. Daily step counts of a patient dramatically increased 5-fold, as a significant change in medication dosage. Measures in this study can track changes in the patient's condition as compared to normal baseline, and may identify external events which are correlated with the departure from normality.

**Conclusions.**– Sensors monitoring of motor activity in schizophrenia patient can be a proven additional valuable tool for clinical assessment, in schizophrenia inpatients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0351

### **Voice user interfaces (VUI) and mental health**

J. Diederich

American university of Beirut, department of psychology, Beirut, Lebanon

\* Corresponding author.

*Introduction.*– Attention economy is a concept in information management that treats human attention as a limited commodity. Herbert A. Simon is considered to be the first person having introduced the concept of attention in economics. Simon outlined that in an information rich world, there is a limitation of the resource that consumes information: human attention. Almost half a century later, there is a need for a form of human-computer interaction that does not consume visual attention and allows multi-tasking.

*Objectives.*– A mobile, artificial intelligence (AI) system that uses Voice User Interfaces (VOI) only, that is, the system responds to speech commands and answers questions in natural languages such as English, French or Arabic. This enables the user to simultaneously direct attention to other information sources and to perform physical actions while using the program.

*Methods.*– A system was generated by use of Artificial Intelligence Markup Language (AIML) that answers questions about mental health topics or neuro-developmental problems such as Attention Deficit Hyperactivity Disorder (ADHD). The system uses reliable, publicly available information sources to answer questions about psychological disorders.

*Results.*– The system allows an ongoing, uninterrupted dialogue about topics such as ADHD, refers the user to publicly available trustworthy information whenever possible and does not respond to inappropriate questions. In the event questions are asked that are not covered by its knowledge sources, the dialogue is appropriately re-directed to areas of competence.

*Conclusions.*– Voice User Interfaces are candidates for effective psycho-education in mental health informatics.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

PW0352

### **An artificial intelligence system for diagnostic mental health interviews**

J. Diederich

American university of Beirut, department of psychology, Beirut, Lebanon

\* Corresponding author.

*Introduction.*– Assessment interviews are highly structured; the examiner asks a set of questions in a prescribed order. If the clinician specialises on a certain condition such as Attention Deficit Hyperactivity Disorder (ADHD), interviews with parents and clients may become routine. Fatigue and other human factors can have an impact on the result of the interview if responses are not accurately recorded.

*Objectives.*– The development of an artificial intelligence (AI) system that uses voice user interfaces (VUI) to ask diagnostic interview questions in natural languages such as English, French or Arabic. The responses of the interviewee are recorded and transcribed. Importantly, the interviewee can ask for clarifications and explanations, the system then explains why certain questions have been asked.

*Methods.*– A system was built by use of Virtual Basic and the Microsoft Speech Engine that asks diagnostic questions about mental health or neuro-developmental problems such as ADHD. Tests runs of the system including free and complex responses by the

interviewee were analysed to answer the core research question: Is it possible to have a coherent, diagnostic interview by an AI system if there are free responses and intermittent questions by the interviewee? Are the results of the interview an acceptable outcome from the viewpoint of current clinical practice?

*Results.*– The system allows an ongoing, uninterrupted diagnostic dialogue and responds appropriately to complex responses including questions. The completely recorded and transcribed interview is forwarded to human clinicians for review.

*Conclusions.*– AI systems are candidates for routine interviews in mental health assessments.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Validation and reliability of a set of stimuli of facial expressions of babies' emotions**

M. Donadon<sup>1\*</sup>, D.L. Osório<sup>2</sup>, R. Martin Santos<sup>3</sup>

<sup>1</sup> Medical school at Ribeirao Preto, neuroscience and behavior, Ribeirao Preto, Brazil; <sup>2</sup> University of São Paulo, Neurociências e Ciências do comportamento, Ribeirão Preto, Brazil; <sup>3</sup> Universidade Autònoma de Barcelona, Psiquiatria, Barcelona, Spain

\* Corresponding author.

*Introduction.*– Studies aiming to construct, validate or analyze reliability of sets of stimuli of facial expressions of basic emotions in infants are not explored by the literature.

*Objectives.*– describe the process of validation and reliability of a set of basic emotions stimuli of 12 babies.

*Methods.*– We used 72 photographs of infants, expressing the basic emotions (joy, sadness, fear, anger, surprise and neutral), elaborated in a previous study, which were inserted in a computational program. For this purpose, 119 subjects from the general population, from different age groups, levels of education, and ethnicities were selected to answer the task, and 31 subjects were randomly selected to redo the task in order to test reliability. The internal consistency of the stimuli was evaluated using the Cronbach's alpha, the difficulty index of each stimulus was calculated by means of the floor and ceiling effect, and the test/retest reliability analyzes were done through the McNemar test. The  $P < 0.05$  was adopted.

*Results.*– It was observed that the 71 stimuli presented satisfactory test/retest reliability. Regarding the validity parameters, it was observed that the Cronbach's alpha of the different groups of emotions ranged from 0.44 to 0.76, confirming the adequacy of the set of stimuli. Finally, regarding the index of difficulty of the stimuli, it was observed that six stimuli were considered very easy and eight stimuli, considered very difficult.

*Discussion/Conclusion.*– The stimulus set showed evidence of validity and reliability and is an important instrument for the evaluation of social cognition in different clinical groups.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **A systematic review of the effectiveness of mobile apps for common mental health disorders: Policy implications and future recommendations**

A. Ferretti<sup>1\*</sup>, S.J. Kim<sup>2</sup>, J.L. Haushalter<sup>3</sup>, G. Hopkin<sup>2</sup>

<sup>1</sup> ETH Zurich, health ethics and policy lab, department of health sciences and technology, Zurich, Switzerland; <sup>2</sup> London school of economics and political science, department of health policy, London, United Kingdom; <sup>3</sup> Vanderbilt law school, department of criminal justice, Nashville, USA

\* Corresponding author.

**Introduction.**– Mental health apps (MHapps) hold the potential to improve access to mental health services. IMS Institute reported that more than 4000 MHapps were available in 2015. However, it is unclear whether the effectiveness of MHapps is supported by evidence; this might generate uncertainty on technologies' adoption. **Objective:** This review examined the available evidence supporting the effectiveness of MHapps. Research's results might help to formulate considerations about this early stage of MHapps possibilities.

**Methods.**– A comprehensive literature search on relevant databases was conducted. Based on inclusion criteria, the synthesis included only randomised controlled trials that compared the effects of MHapps in reducing symptoms in people diagnosed with common mental disorders to a waiting-list or treat-as-usual control group. Furthermore, only outcomes measured by a validated scale were considered.

**Results.**– A total of 5,867 publications were identified but only 7 papers, describing 6 apps (concerning depression, anxiety, alcohol use, post-traumatic stress disorder (PTSD), and autism spectrum disorder), met inclusion criteria. There were mixed findings about the effectiveness of the MHapps with one proving ineffective and the remainder providing mild-to-moderate effectiveness in reducing the primary symptoms of mental illness at post-test and at follow-up.

**Conclusions.**– Few MHapps have published evidence of their effectiveness and where evidence is available, it suggests their effect is limited. Mental health professionals should be cautious about recommending unevicenced MHapps and policies that regulate the health app market should be considered. In addition, more rigorous evaluations that use comparable outcomes and consider both benefits and harms should be embedded in future research.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Printemps project: E-health intervention for suicide prevention and mental health promotion in the French general population**

G. Coralie, T. Kathleen, V. Marie-Amélie, L.J. Anaïs, J.B. Hazo<sup>\*</sup>, C. Karine

INSERM, UMR-S 1123, Eceve, Paris, France

\* Corresponding author.

The development of web-based interventions to prevent suicide, self-harm and psychological distress has been recommended and the French national plan for actions against suicide has supported the development of reference websites for suicide prevention. However, web-based interventions must be associated with promotional efforts.

Our primary objective is to assess the efficacy of a web-based intervention "StopBlues<sup>®</sup>" for primary prevention of suicide and promotion of mental health, promoted by cities and general practitioners (GPs). Secondary objectives include measures of quantitative and qualitative effects of StopBlues<sup>®</sup> and its promotion.

StopBlues<sup>®</sup> features include: general information on mental health and care, questionnaires and mood-followers, mapping of the (mental) health care, initiatives and structures, positive psychology exercises, emergency button and personal safety plan. StopBlues<sup>®</sup> will be available as a website and a free app.

It is a cluster randomized-controlled trial where clusters are 42 French district local areas randomized in 3 groups with distinct types of promotions of StopBlues<sup>®</sup>. Ancillary qualitative studies would be conducted to examine the conditions that favour such e-health prevention at local level.

Endpoints will include: total number of suicidal acts (before/after and between cities), users' psychological distress, suicidal risk, attitudes toward seeking help, feedback and comments of the web-app and, at cities level, the number and type of additional prevention measures developed by the cities, barriers to implementation, variability and types of promotion actions, quality of their mapping, resources allocated to the promotion.

If efficacy is proven, we would expand the intervention to the national and European levels with qualitative recommendations for such extension.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0356

### **European comparative effectiveness research on internet-based depression treatment (E-Compared-France). A study protocol**

H. Jéôme<sup>1</sup>, J.B. Hazo<sup>2\*</sup>, P. Amélie<sup>2</sup>, M. Morgane<sup>2</sup>, D. Maya<sup>2</sup>, C. Karine<sup>2</sup>

<sup>1</sup> Centre hospitalier universitaire de Grenoble, psychiatrie, Grenoble, France; <sup>2</sup> INSERM, UMR-S 1123, ECEVE, Paris, France

\* Corresponding author.

The epidemiological and economic burden of depression challenge European health care systems in terms of access to cost-effective treatments. Internet-based depression treatment is considered as a promising alternative to current strategies. The aim of this project, as part of the E-Compared project conducted in eight European countries, is to assess the clinical and cost-effectiveness of blended Cognitive Behavioral Treatment (CBT) i.e. combining Internet-based with face-to-face CBT, compared to treatment as usual (TAU) for major depressive disorder (MDD) in France.

A two-arm randomized controlled trial was carried out in 10 specialized major depression centers in different French cities. Adult patients who met DSM-IV criteria for MDD and a PHQ-9 score  $\geq 5$  were included either in the blended CBT arm, mixing face-to-face to internet-based CBT delivered through an online platform, or in the control group, consisting in 18 sessions of face-to-face CBT. The depressive symptoms, assessed by the PHQ-9 (primary outcome), QIDS, MADRS and MINI, as well as health-related QoL (EQ-5D-5L) and economic impact information were taken at baseline, 3 months, post-treatment, 6 and 12 months. Cost-effectiveness will be assessed at five years from different perspectives using a cost-effectiveness analysis.

105 patients were included. Analyses and results of the French trial will be displayed in early 2018.

The results of this study are expected to provide knowledge to decision-makers on whether blended CBT is a cost-effective innovative solution to treat MDD.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0357

### **Automatic detection of emotions in depressed patients and healthy subjects: A mobile application study**

G.C.L. Hung

Taipei City Hospital, Songde Branch, department of psychiatry, Taipei, Taiwan R.O.C.

\* Corresponding author.

*Objective.*– Improving the recognition and management of momentary emotion is crucial for mental health, both in depressed patients and in normal population. The objective of this study is to examine the performance of a mobile phone system regarding the detection of real-time emotion.

*Methods.*– A mobile phone application, iHOPE, was developed for detecting emotion. A Bayesian network with 15 nodes was used for inferring momentary emotion based on contextual factors and smartphone use patterns. Five patients with major depressive disorder and seven normal participants were recruited. Participants used the Circumplex model to label their daily emotions for 8 consecutive weeks, which were used for model training and validation. *Results.*– Depressed patients spent 77% more time with smartphone than healthy subjects. In comparison with accuracy of 25% by random guessing, our detection algorithm achieved an accuracy of 54% in all participants, as demonstrated by 10-fold cross validation. Predictive accuracy was better in patients than in healthy subjects. In depressed patients, using data 180 minutes prior to emotion tags achieved the best performance, whereas for healthy subjects, the optimal time window was 30 minutes. We also find that using more recent data (i.e. the past 2 weeks vs. the first 2 weeks or all data) resulted in better performance. The contribution of individual variable on predictive accuracy demonstrated significant inter-subject variability

*Conclusions.*– The findings here suggest that, both in depressed patients and in healthy subjects, it is possible to infer momentary emotion with individualized detection algorithm, while identifying personal attributes to improve emotional awareness.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0358

### **Multi-media intervention for preventing drug use among at-risk youth in Kazakhstan: Results on a pilot RCT**

L. Ismayilova<sup>1</sup>, A. Terlikbayeva<sup>2</sup>

<sup>1</sup> University of Chicago, school of social service administration, Chicago, USA; <sup>2</sup> Columbia university, global health research center of Central Asia, Almaty, Kazakhstan

\* Corresponding author.

*Purpose.*– Located on major drug trafficking routes from Afghanistan to Russia, some former Soviet Union countries, including Kazakhstan, are experiencing skyrocketing rates of drug use, disproportionately affecting young people. The study is the first randomized controlled trial (RCT) adapting an evidence-based intervention to prevent drug use among at-risk adolescents from

communities highly affected by heroin trade and use in Almaty, Kazakhstan.

*Methods.*– This pilot trial, funded by the U.S. National Institute of Health, included 181 at-risk adolescents (ages 14–17), recruited through police officers ('inspectors') from public schools, and 181 of their caregivers (parents or other adult family members). Eligible youth had to have at least one risk factor (i.e., substance-using friends or family members, parental criminal history). In addition to the standard school-based health education program, intervention arm adolescent-caregiver dyads received pilot computerized sessions with interactive avatars customized to participants' gender that focused on building youth's assertiveness, refusal and coping skills as well as strengthening family communication and support. Electronic surveys in Russian were conducted at baseline, 3 and 6 months.

*Results.*– Compared to the control arm, intervention arm parents reported a reduction in harsh discipline practices (Cohen's  $d = -.35$ ,  $P = .026$ ) and an increase in positive and supportive parenting ( $d = 0.26$ ,  $P = .042$ ). Adolescents reported an increase in self-esteem ( $d = .22$ ), assertiveness ( $d = .22$ ) and reduction in peer pressure for substance use ( $d = 0.26$ ).

*Conclusions.*– In middle-income countries like Kazakhstan, interventions that combine empirically tested skills-based and family involvement approaches and utilize interactive technologies may represent a potentially engaging and cost-effective tool with high fidelity and easy scalability.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0359

### **Telepsychiatry: Acute care in the suicidal adolescent – utility of off-site consultation and outcome**

U. Jain<sup>1</sup>, D. Willis<sup>2</sup>

<sup>1</sup> SMS medical college, psychiatry, Jaipur, India; <sup>2</sup> Hospital for sick children, psychiatry, Toronto, Canada

\* Corresponding author.

Imminent danger requires assessment to determine the risk of lethality. With a considerable under-representation of child and adolescent psychiatrists, this problem is endemic even in urban areas let alone remote communities. One of the common concerns about Telepsychiatry has been whether this medium is able to make an assessment of high risk adolescent youth in a manner that is both expeditious and competent that leads to disposition strategies that would be similar to that of face to face management. The data from the Hospital for Sick Children, one of the largest Telehealth Networks in the world, are presented.

*Methods.*– Fifty five youth (12–17) were assessed for their suicidal risk through the medium of Telepsychiatry while they were admitted at the Timmins District Hospital. They were followed by the local mental health agency after discharge and a follow-up was made between 1-3 months after discharge through Telepsychiatry. *Results.*– All of the patients (M:F: 4:51) came into hospital with suicidal ideation or an attempt. 27% were of aboriginal origin. 44/55 were deemed capable of being released. None of the patients died. 15/55 had multiple hospitalizations after discharge with a presumptive concurrent diagnosis of Borderline Personality Traits.

*Conclusion.*– While this is a retrospective study, the compelling story is that Telepsychiatry is an effective method of doing intricate and safe assessments in at-risk youth. The belief that the nuances of non-verbal communication or making a competent assessment are simply unfounded. A randomized control study is warranted to show this with definiteness.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

**The impact of 15 minutes daily online self-help on stress, anxiety, depression and life satisfaction subscores measured over 6 years after treatment on 5000+ patients**

P. Koeck

15Minutes4Me.com, Coachteam BVBA, Antwerpen, Belgium

\* Corresponding author.

We measured every 7 days DASS-21 subscores on Stress, Anxiety and Depression during participation in a 15 minutes daily online Self-Help Program on over 5000 patients. A follow-up measurement was done between 3 months and 6 years after their participation. In this presentation we will discuss the evolution of the weekly decrease in specific subscores on Stress, Anxiety and Depression during participation.

During the program, mean depression scores drop with 42% after 7 days, 49% after 14 days, 67% after 21 days, 75% after 35 days, 82% after 49 days. Stress subscores decrease with 36% after 7 days, 43% after 14 days, 51% after 21 days, 57% after 35 days, 64% after 49 days. Anxiety scores decrease with 33% after 7 days, 56% after 14 days, 67% after 49 days. Changes in Life Satisfaction were measured on a 0-10 subjective scale, resulting in a 20% increase after 7 days, 30% increase after 14 days and 40% after 21 days, whereafter remaining stable.

Detailed tables and graphs together with the follow-up measurement will be discussed and interpreted during the oral presentation. In this longitudinal descriptive research the 15Minutes4Me.com program was used to measure the DASS-21 subscores. The program delivers a weekly report with evolution graphs to the patient for sharing and discussion with his own General Physician or psychiatrist, who is responsible for medical diagnosis and overall follow-up of the patient, complimentary to his participation in the daily online Self-Help Autotherapy Program. *Disclosure of interest.*– The author has not supplied a conflict of interest statement.

**Introduction.**– Eating disorders (EDs) are characterized by disturbed eating patterns and undue influence of body shape and weight on self-evaluation. Four prominent symptoms in EDs are: restrictive eating, binge eating, purging and excessive exercise. Research has shown that app-based treatment can reduce ED-pathology and that symptom reduction is similar to traditional face-to-face treatment. An app-intervention based on cognitive behavioral therapy (CBT) combined with regular video consultations has not previously been developed and used for these four ED-symptoms.

**Objectives.**– The aim of the study was to develop a CBT app-intervention supplemented by weekly video-consultations with a psychologist for persons suffering from restrictive eating, binge eating, purging or excessive exercise.

**Methods.**– We conducted a feasibility study aiming to develop and pilot-test the treatment model consisting of a 10-week CBT program with app-interventions and psychotherapeutic video consultations.

**Results.**– The psychotherapeutic content of the app (including assessment, psychoeducation, exposure therapy and motivation to change) and the development of the app-design will be presented, as will the preliminary results of the pilot-test on 10 patients.

**Conclusions.**– The combination of an app and psychotherapeutic video consultations may be effective in the treatment of restrictive eating, binge eating, purging or exercise addiction. Furthermore, Internet-based ED-treatment makes treatment accessibility easier and may spare economical costs and travel time. The next part of this study is designed to evaluate the effect of the treatment in a randomized controlled trial addressing symptom reduction, quality of life and the participants' experience with technology-based treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Intra-individual variability (IIV) as a behavioral marker for detecting senior adults at risk of cognitive decline: Implications for telegeriatric healthcare

H. Lu\*, S.S.M. Chan, L.C.W. Lam

The Chinese university of Hong Kong, psychiatry, Hong Kong, Hong Kong S.A.R.

\* Corresponding author.

**Backgrounds.**– Emerging from “aged” society to “super-aged” society (Chan & Liang, 2012), Hong Kong is expected to face a looming tsunami of gerontological issues in the coming decades. There is no satisfied medication for dementia and other major neurodegenerative diseases so far. Hence, a critical issue in geroscience will be lead by detecting the impending biomarkers of healthy and pathological ageing. Intra-individual variability (IIV) represents the facet of within-person changes as a measure of short-term fluctuations. IIV has been proven to be a promising phenotype of neurodegenerative changes.

**Objectives.**– This study was aimed to investigate the IIV of reaction time (RT) in the healthy senior adults and adults with mild neurocognitive disorders (NCD).

**Methods.**– 67 NCD patients and 137 healthy controls completed a neuropsychological battery and a computerized reaction time based test. IIV was evaluated by two indices: intraindividual standard deviations (iSD) and intraindividual coefficient of variation of reaction time (ICV-RT).

**Results.**– Compared to healthy controls, NCD group demonstrated greater IIV (iSD:  $t = 11.803$ ,  $P < 0.001$ ; ICV-RT). The IIV indices presented a moderate power to differentiate NCD subgroups (NCD-Alzheimer's disease: AUC value = 0.677–0.687; NCD-vascular disease: AUC value = 0.615–0.631) from healthy group.

**Conclusions and implications.**– The findings emphasize the importance of short-term fluctuations in differentiating the individuals with different cognitive status. Beyond cognitive performance, the perspective of IIV brings the insights into collecting and monitoring the cognitive status through cell phone app and wearable devices instantly and individually, which will lead dramatic changes in geriatric healthcare delivery.

### Help information-seeking behavior of American veterans: A cluster analysis of health concerns most frequently discussed on the Internet

D. Sendler\*, M. Duplaga

Jagiellonian university medical college, department of health promotion, Cracow, Poland

\* Corresponding author.

**Introduction.**– This study investigates what kinds of health information US veterans with PTSD seek on the internet.

**Methods.**– First, using DEVONagent Pro, we selectively screened entire Internet to identify discussion sites, where U.S. veterans exchange health information. Second, we archived and qualitatively analyzed all data, using grounded theory.

**Results.**– We identified several theme clusters that capture what health information veterans with PTSD seek on the Internet. “Mental diagnosis and going back to work” – this group of forums concerns those veterans wishing to return to full-time employment after military service. “Vitamin B12 deficiency and changes in mood” – self-described experience of veterans diagnosed with Vitamin B12 deficiency and how it affects their daily mood and activities. “Diabetes and treatment” – treatment-related experiences of veterans diagnosed with diabetes. “Treatment with Prazosin for post-combat nightmares” – self-reflections of veterans receiving treatment with Prazosin for night terrors and dealing with associated side effects. “Training a rescue dog for service role” – these forums look at how veterans who own a rescue dog privately train them to become a support service dog. “PTSD and marijuana addiction” – reflects veterans who claim that addiction to marijuana helps in alleviating PTSD symptoms. “PTSD and anger” – management of anger problems, including tips on stress management.

**Conclusions.**– These data show that U.S. veterans with PTSD utilize online spaces to seek health information about a wide array of medical problems.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### What are the facilitators and barriers for the uptake and adherence to digital therapies for depression in adults? A systematic review of qualitative literature

V. Soundararajan<sup>1\*</sup>, E. Fearon<sup>2</sup>, J. Brown<sup>3</sup>

<sup>1</sup> London school of hygiene and tropical medicine, public health, Norwich, United Kingdom; <sup>2</sup> London school of hygiene and tropical medicine, department of social and environmental health research, London, United Kingdom; <sup>3</sup> King's college london, department of psychology, London, United Kingdom

\* Corresponding author.

**Introduction.**– Depression is a growing global burden that is compounded by several factors, including the existence of a “treatment gap.” Although digital therapies offer a potential solution, effectiveness trials experience high drop-out rates, with limited understanding of facilitators and barriers that determine uptake and adherence.

**Objectives.**– This review aims to provide an up-to-date synthesis of qualitative evidence by systematically identifying and reviewing literature exploring the facilitators and barriers for the uptake and adherence of digital therapies, as expressed by adults with depression.

**Methods.**– A systematic literature search was conducted in June and August 2017 using three scientific databases. A meta-ethnographic approach was used to synthesise data into key themes and lines of argument.

**Results.**– 542 studies were identified and refined to 8 studies for inclusion. Four main lines of arguments emerged, which encompassed key facilitators and barriers: (1) Virtual platform as a replacement of face-to-face therapy (2) Relationships with professionals, family and friends (3) Identifying “self” in content and structure of interventions (4) Patient expectations of therapy process and outcome.

**Conclusions.**– Facilitators and barriers were found to lie on a continuum rather than function as discrete, unchanging factors. A theme could act as a facilitator or a barrier depending on individual preferences and needs. Adequate therapist support and aligning patient expectations with therapy process and outcomes were identified as key facilitators. In the future, there is a need for research in low-to-middle income settings and broadening of participant characteristics for wider generalizability of results.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### When do people turn to Internet counselling? Exploring the time patterns of turning to initial Internet counselling consultations on a large sample

M. Tirel<sup>1\*</sup>, D. Rozgonjuk<sup>1</sup>, M. Purre<sup>2</sup>

<sup>1</sup> Institute of psychology, institute of psychology, Tartu, Estonia;

<sup>2</sup> Institute of social studies, department of social studies, Tartu, Estonia

\* Corresponding author.

**Introduction.**– Unlike traditional face-to-face counselling, internet counselling is easily accessible and not dependent on the time and location, potentially having the capability to provide mental health services to economically disadvantaged groups and people in remote or underserved areas. As its round-the-clock availabil-

ity is one of its strongest advantages, it is important to study the temporal patterns of consultations. This paper is the first to study the temporal patterns of internet counselling consultations.

**Objectives.**– The aim of the paper was to explore when people write to internet counsellors for the first time and to ascertain whether there are temporal patterns in the initial consultations.

**Methods.**– The sample comprises 3291 first-time advice-seekers who contacted the Internet counsellors of the two largest Estonian internet counselling providers. Nonparametric graphic approach (heatmap analysis) was used to graphically represent the number of consultations at different times (e.g., the variability of first-time contacting in times of day, days of week, and seasons). Multinomial logistic regression was used to predict the time, day of the week and season of the consultations.

**Results.**– The preliminary findings showed that most of the initial consultations take place on Mondays, during evenings and darker seasons (autumn, winter).

**Conclusions.**– Most of the initial consultations take place during darker times: in the evening and in autumn and winter. This information can be used in planning the work of internet counsellors and ensuring that enough counsellors are available during peak times.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Predictors of engagement with a digital intervention for promoting personal recovery in persisting psychosis

K.A. Villagonzalo<sup>1\*</sup>, D. Meyer<sup>2</sup>, C. Arnold<sup>1</sup>, F. Foley<sup>1</sup>, R. Bruno<sup>3</sup>, J. Farhall<sup>3</sup>, N. Thomas<sup>1</sup>

<sup>1</sup> Swinburne university of technology, centre for mental health,

Hawthorn, Australia; <sup>2</sup> Swinburne university of technology,

department of statistics, Hawthorn, Australia; <sup>3</sup> La Trobe university, department of psychology and counselling, Bundoora, Australia

\* Corresponding author.

**Introduction.**– Given the increasing popularity of e-mental health interventions, including their use as an adjunct to routine care, understanding how engagement with such tools may be predicted and enhanced is important.

**Objective** This study aimed to identify patterns and predictors of engagement with online resources promoting personal recovery, which focused on lived experience content and peer-to-peer learning for adults with persisting psychosis.

**Methods.**– A randomised trial was conducted as part of the Self-Management and Recovery Technology (SMART) research program, to evaluate the efficacy of a digitally-assisted intervention using online resources in individual sessions with a mental health worker, compared to befriending control sessions. In this study, optional independent use of the online resources was examined, and survival analysis conducted to identify demographic and baseline predictors of length of time engaged with the resources.

**Results.**– Of 73 participants, 51 (69.9%) used the resources independently at least once, with 14 (19.2%) continuing to access the resources over 12 months post-baseline. Lower baseline scores on anxiety and intrapersonal domains of recovery significantly predicted longer engagement with the resources, as did female gender. Psychotic symptom levels, age, and internet use abilities were not associated with engagement.

**Conclusions.**– These results suggest that independent engagement with online, recovery-focused resources, following supported use, is possible for people of varying age, internet use abilities and symptom severity. People with higher baseline scores on recovery may be less motivated to engage with such resources. Developers of e-

mental health interventions could consider gender and anxiety as factors influencing engagement.

### **Preferred design features of E-mental health programs for prevention of major depression in male workers: Results from a Canadian national survey**

J. Wang

*Ottawa institute of mental health research, work and mental health research unit, Ottawa, Canada*

\* Corresponding author.

*Introduction.*– E-mental health programs hold potential for early prevention of major depression. However, we have a little knowledge about men's preferences for design features of e-mental health programs.

*Objectives.*– Amongst Canadian male workers, to (1) estimate and compare the proportions of Internet use for medical information, preferred design features and likely use of e-mental health programs, (2) examine factors associated with the likely use of e-mental health programs.

*Methods.*– A cross-sectional survey in 10 provinces in Canada was conducted between March and December, 2015. Random digit dialing method was used to collect data from 511 working men who were at high risk of having MDE and 330 working men who were at low risk of having MDE.

*Results.*– High risk men were more likely to endorse the importance of accessing health resources on the Internet than low risk men. The top three features most likely to be used by high risk men were: "information about improving sleep hygiene" (61.3%), "practice and exercise to help reduce symptoms of stress and depression" (59.5%) and "having access to quality information and resources about work stress issues" (57.8%). Compared to men at low risk for MDE, men at high risk for MDE were much more likely to consider using almost every one of the different design features.

*Conclusions.*– E-mental health programs may be a promising strategy for prevention of depression in working men. Development of e-mental health programs should consider men's preferences and perceived barriers to enhance the acceptability of this approach.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

## **Eating Disorders / Sleep Disorders and Stress**

### **PTSD symptoms associated with myocardial infarction: Practical clinical implications**

W. Akosile\*, R. Young, D. Colquhoun, J. Voisey, B. Lawford  
*Queensland university of technology, school of psychology and counselling, health, Kelvin Grove, Australia*

\* Corresponding author.

*Introduction.*– Several studies have demonstrated an association between myocardial infarction (MI) and post-traumatic stress disorder (PTSD). Some studies have established that individuals who have PTSD are vulnerable to developing cardiovascular diseases (CVD) like MI. For unclear reasons, individuals with PTSD are at a

higher risk of developing MI and other coronary heart diseases. Previous researchers have also noted that individuals with PTSD have a preponderance of known risk factors for MI. Also, sleep disturbance, somatic and anxiety symptoms could be prodromal symptoms for MI.

*Objectives.*– What phenotypic features or symptom profile associated with cardiovascular disease may help with early detection and intervention?

*Methods.*– This study cross-sectionally examined a well characterised trauma exposed post-Vietnam veterans with or without PTSD to explore symptoms associated with a positive history of MI.

*Results.*– Variables significantly associated with myocardial infarction from the bivariate analysis are avoidance memories; avoidance reminders and sleep disturbance. These variables were put into a logistic regression with known risk factors for myocardial infarction. Only sleep disturbance retained its effect with a p-value of 0.015.

*Conclusion.*– Sleep disturbance may be a modifiable risk factor in the treatment and prevention of myocardial infarction.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **How are eating disorders being portrayed in mass media outlets?**

M. Alvarez de Mon Gonzalez<sup>1</sup>, V. Pereira<sup>1</sup>, T. Dot<sup>1</sup>, H. Saiz<sup>2</sup>, G. Lahera<sup>3</sup>, I. Alberdi<sup>4</sup>, F. Ortuño<sup>1</sup>

<sup>1</sup> *Clinica Universidad de Navarra, psychiatry, Pamplona, Spain;*

<sup>2</sup> *Complejo Hospitalario de Navarra, psychiatry, Pamplona, Spain;*

<sup>3</sup> *Universidad de Alcalá, Madrid, Spain;* <sup>4</sup> *Hospital Clínico San Carlos, Madrid, Spain*

\* Corresponding author.

*Introduction.*– In today's world, mass media outlets play a key role in the way we perceive different aspects of our lives such as beauty, fashion, and standards of living. This ultimately affects our self-esteem, confidence, and the way we view society.

*Objective:* To conduct a qualitative analysis on the Tweets that refer to eating disorders, such as anorexia and bulimia nervosa, from the Twitter accounts of prominent US mass media outlets.

*Method.*– 15 US news media outlets were selected and analyzed. These outlets were chosen based on the number of followers on their Twitter accounts and were narrowed down to those with the most followers. Some major news outlets (ex. Wall Street Journal) were excluded for not having a section on health. The Tweets were selected if they made any reference to anorexia and/or bulimia nervosa (ex. anorexia from @latimes). This study focused on the Tweets from 2007–2016.

*Results.*– 275 Tweets were selected and divided into four categories. 26% focused on general interest ("Eating Disorder Roulette: Why do teens get eating disorders?"), 65% were testimonies from patients, 8% revolved around scientific advancements ("A look into an innovative eating disorder treatment"), and the rest were Tweets that had a condescending tone towards these disorders.

*Conclusions.*– People from different backgrounds are turning to Twitter to be used as an outlet for personal statements and recounts. Although only a small percentage of Tweets have a condescending tone, there still exists a need to eliminate completely this disrespectful attitude.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### “It’s high time to go to bed” – Bedtime set by caregivers is still important, especially for older adolescents

N. Kalak<sup>1</sup>, M. Gerber<sup>2</sup>, U. Pühse<sup>2</sup>, D. Sadeghi Bahmani<sup>1</sup>, E. Holsboer-Trachsler<sup>1</sup>, S. Brand<sup>3\*</sup>

<sup>1</sup> University of Basel, psychiatric clinics, Basel, Switzerland;

<sup>2</sup> University of Basel, department of sport, exercise and health, Basel, Switzerland; <sup>3</sup> Psychiatric university hospital, center of affective, stress and sleep disorders, Basel, Switzerland

\* Corresponding author.

**Background.**– Later bedtimes in adolescence result in decreased sleep duration. However, sufficient and restoring sleep duration is important for psychological health. To investigate the connection, we assessed adolescents attending boarding schools with the same school schedules, but different set bedtimes.

**Methods.**– We examined a total of 1571 adolescents (mean age, 16.51 years; SD = 1.83; 55% females) attending boarding schools in German-speaking Switzerland. We compared those who slept at the boarding schools ( $n = 1013$ , 64%; INTERNS) with adolescents attending the same schools but who slept at home ( $n = 558$ ; 36%; EXTERNS). For the INTERNS uniform bedtimes were set by school staff. For the EXTERNS caregivers set variable bedtimes. All adolescents reported their sleep duration and sleep quality on school days; psychological functioning was assessed by questionnaire.

**Results.**– Overall, adolescents in the EXTERNS group reported slightly shorter sleep duration, and had slightly better sleep quality and psychological functioning than adolescents in the INTERNS group. However, for older adolescents aspects of this pattern reversed; for the INTERNS sleep and psychological functioning was poorer while the INTERNS had better sleep quality and psychological functioning. There was a U-shaped association between sleep duration and sleep quality, and an inverse U-shaped association between sleep duration and psychological functioning.

**Conclusion.**– Among a large sample of adolescents attending boarding schools, earlier set bedtimes were associated with both better sleep schedules and psychological functioning. Therefore, caregiver should be encouraged to set prior bedtime limits, especially for their older adolescents.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### What sexuality tells us about long-term outcome of eating disorders: A three year follow-up study

G. Castellini\*, L. Lelli, C. Emanuele, V. Ricca

University of Florence, department of neuroscience, psychology, drug research and child health, Florence, Italy

\* Corresponding author.

**Introduction.**– The present study attempted to identify psychopathological and clinical factors associated with restoration of regular menses and sexual function in Eating Disorders (EDs) patients, and to evaluate the role of sexuality as a moderator of the recovery process after an individual Cognitive Behavioural Therapy (CBT).

**Methods.**– 39 Anorexia Nervosa (AN) and 40 Bulimia Nervosa (BN) female patients were evaluated by means of a face-to-face interview, self-reported questionnaires, including Eating Disorder Examination Questionnaire and Female Sexual Function Index, and blood sample for hormonal levels and biomarkers. The same assess-

ment was repeated at baseline (T0), at one year follow up (T1), and at three years follow up (T2).

**Results.**– After CBT, both AN and BN patients showed a significant improvement of sexual functioning, which was associated with a reduction of core psychopathology, in particular with body uneasiness reduction. AN patients who recovered regular menses demonstrated a better improvement across time of both psychopathological and clinical features, and they were more likely to maintain these improvements at three years follow up. Recovery of regular menses and improvement of sexuality at the end of CBT were associated with a higher probability to have a full recovery at three years follow up (Fig. 1).

**Conclusions.**– The results of the present study challenges a concept of recovery in EDs, exclusively based on weight restoration or behavioral changes. A psychopathological assessment including sexual functioning and core psychopathology might identify the residual pathological condition, and it is able to provide information regarding the long term recovery process.

### Facebook addiction, depression and sleep disorders in Tunisian medical students

N. Messedi, M. Chakroun\*, N. Smaoui, F. Charfeddine, L. Aribi, O. Amami

Hedi Chaker university hospital, psychiatry “B”, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Facebook (fb) is become a new living environment, mainly for young people; but the relationship between internet addiction specially (fb), sleeping and mood disorders was little studied.

**Objectives.**– To study fb addiction prevalence, to assess depression, anxiety and sleeping disorders among medical students, and determine the relationship between these different entities.

**Methods.**– A cross-sectional, analytical study of 100 students of Sfax’s medicine faculty, in Tunisia, during the month of January 2017. The Hospital Anxiety and Depression Scale (HADS); to assess anxiety and depressive symptoms, the Facebook addiction scale test (FAST) and The Insomnia Severity Index (ISI).

**Results.**– The average age of students was  $22.94 \pm 2.7$  years. The sex ratio (M/W) was 0.7. They were single (78%).

The average age of the first connection was  $14.45 \pm 2.7$  years, with a connection’s duration of 227.45 min/day.

A sleeping dissatisfaction was founded in 38% of the students, and difficulty in falling asleep in 53%.

An addiction to (fb) was present in 26% of the students.

The depression was founded in only 11% of students but anxiety in 16% of them.

The prevalence of insomnia was 53%.

fb addiction was related to: younger age  $\leq 21$  years ( $P=0.002$ ), connection's duration  $\geq 300$  min/day ( $P<0.00$ ); insomnia ( $P<0.00$ ); and depression ( $P=0.01$ ).

**Conclusion.**– Our study reports that young students high in fb addiction are more vulnerable to depression, and sleeping disorders. The research needs to be more developed to improve prevention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cortical complexity in anorexia nervosa (AN): A study by means of fractal dimensionality (FD)**

E. Collantoni<sup>1</sup>, I. Chiappini, P. Meneguzzo, S. Michelon, M. Solmi, E. Tenconi, R. Manara, P. Santonastaso, A. Favaro

University of Padua, department of neurosciences, Padua, Italy

\* Corresponding author.

**Introduction.**– In recent years several efforts have been focused on the study of the cortical structure in AN, trying to disentangle the relationship between any cortical alterations and the course of the disorder. A novel way to analyze the cortical structure has been offered by Fractal Dimensionality (FD), a technique that is designed for the analysis of complex structural patterns.

**Objectives.**– With the present study we used FD to examine the cortical complexity in a sample of patients with acute AN and in a sample of patients with AN in full remission (REC-AN).

**Methods.**– 38 patients with acute AN, 38 healthy controls (HC) and 20 patients recovered from AN underwent MRI scanning. Surface extraction was completed using FreeSurfer package. FD was computed with a specific Matlab toolbox (Madan et al., 2016).

**Results.**– A comparison between the AN group and HC revealed a global FD reduction. Total FD significantly correlated with BMI and duration of illness in patients. Regression analyses showed a relationship between FD and age, BMI, cortical volume and gyrification index in the AN group.

**Conclusions.**– Our findings support the hypothesis that cortical alterations in AN are complexly determined by several variables and confirm the importance of age in determining cortical complexity. FD represents a method to explore cortical complexity that demonstrated to be sensitive to the effects of malnutrition.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Confirmatory factor analysis of the body image shame scale in overweight and obese women participating in a weight management programme**

C. Duarte<sup>1\*</sup>, J. Pinto-Gouveia<sup>1</sup>, C. Ferreira<sup>1</sup>, C. Stalker<sup>2</sup>, F. Catarino<sup>2</sup>, J. Basran<sup>2</sup>, P. Gilbert<sup>2</sup>, H. Graham<sup>3</sup>, L. Morris<sup>4</sup>, J. Stubbs<sup>5</sup>

<sup>1</sup> University of Coimbra, CINEICC, cognitive and behavioural centre for research and intervention, faculty of psychology and educational sciences, Coimbra, Portugal; <sup>2</sup> University of Derby, college of life and natural sciences, Derby, United Kingdom; <sup>3</sup> Rowett institute of nutrition and health, biomathematics and statistics Scotland, Aberdeen, United Kingdom; <sup>4</sup> Slimming World, slimming world, Alfreton, United Kingdom; <sup>5</sup> University of Leeds, appetite control and energy balance research group, school of psychology, Leeds, United Kingdom

\* Corresponding author.

**Introduction.**– Body image-focused shame plays an important role in the development and maintenance of eating and weight-related problems. The Body Image Shame Scale (BISS; Duarte, Pinto-Gouveia, Ferreira, & Batista, 2015) was developed to assess body image shame as external and internal constructs. These are (i) fears and evaluations of other people's negative perceptions of oneself based on one's physical appearance and (ii) negative self-evaluations of one's own physical appearance.

**Objectives.**– The current study examined the factor structure and psychometric properties of the BISS in obese and overweight women participating in a commercial weight management programme.

**Methods.**– Six hundred and eighty three women, aged 19–65 years ( $M=45.07$ ;  $SD=11.27$ ) and with BMI ranging from 25.06–66.14 ( $M=32.83$ ;  $SD=6.40$ ), completed self-report measures of body image shame, weight-related self-criticism, loss of control of eating, and depressive, anxiety and stress symptoms.

**Results.**– Results of the Confirmatory Factor Analysis indicated that the BISS 2-factor structure presents a good model fit ( $\chi^2_{(74)}=460.78$ ;  $CFI=0.95$ ;  $TLI=.94$ ;  $PCFI=0.77$ ;  $RMSEA=0.09$ ;  $SRMR=0.04$ ). The total scale (.97) and the subscales External (.96) and Internal (.97) body image shame presented high internal reliability. Correlation analyses confirmed the scale's convergence with weight-related self-criticism, symptoms of depression, anxiety and stress and loss of control of eating.

**Conclusions.**– Results confirmed the adequacy of the BISS two-factor structure, supporting that this is a useful measure to assess body image shame in this specific population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Changes in depression and quality of life after a mindfulness, compassion and values-based intervention for BED – Who may benefit the most?**

J. Pinto-Gouveia, C. Duarte<sup>\*</sup>, S. Carvalho, L. Palmeira, P. Castilho, C. Ferreira, J. Duarte, M. Cunha, M. Matos, J. Costa

CINEICC - Cognitive and Behavioural Centre for Research and Intervention, Faculty of Psychology and Educational Sciences, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Binge Eating Disorder (BED) is highly associated with depressive symptoms and poorer quality of life (QoL), which influence BED maintenance and treatment. Shame, self-criticism, and psychological inflexibility also play an important role in this condition. BEfree is a novel 12-session compassion, mindfulness and values-based group intervention for BED in obesity that target these processes.

**Aims:** This study aims to explore whether patients that presented higher levels of shame, self-criticism and psychological inflexibility at pre-intervention, were those who showed greater improvements in depressive symptoms and QoL at post-intervention.

**Methods.**– Participants were 31 overweight/obese women with the diagnosis of BED who were enrolled in BEfree ( $M(\text{age})=39.68$ ,  $SD=10.29$ ;  $M(\text{BMI})=35.35$ ;  $SD=6.07$ ), and asked to fill a set of self-report measures at pre and post-intervention. ANOVA repeated measures were conducted, and two groups were formed according to the median in shame, self-criticism and psychological inflexibility: (i) below the median; (ii) equal/above the median.

**Results.**– Changes in depression and QoL differed according to pre-intervention levels of shame, self-criticism and psychological inflexibility. Participants with higher levels of shame, self-criticism and psychological inflexibility were those who showed greater

decreases in depression from pre to post-intervention. Similar results were found for changes in QoL.

**Conclusions.**– Results suggest that patients with higher levels of shame, self-criticism and psychological inflexibility are those who may benefit the most from BEfree in improving psychological functioning. Findings highlight the importance of targeting these processes, while promoting self-compassion and values-based actions, in this clinical condition.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Alterations in the ghrelinergic system in anorexia nervosa patients: Inputs from animal models**

P. Duriez<sup>1,2\*</sup>, O. Viltart<sup>2</sup>, V. Tolle<sup>2</sup>

<sup>1</sup> *Clinique des maladies mentales et de l'encéphale, centre hospitalier Sainte-Anne, Paris, France;* <sup>2</sup> *Centre de psychiatrie et neurosciences, Inserm U894, Paris, France*

\* Corresponding author.

**Introduction.**– The physiological mechanisms involved in the adaptation to chronic food restriction could constitute an perpetuation factor in anorexia nervosa (AN) and favoring relapse. We aim to decipher whether ghrelin is a valuable biomarker of relapse after nutritional recovery. In a translational perspective, we have developed a preclinical mouse model.

**Methods.**– 8-week old female mice ( $n=6$ /group) were placed in a cage containing a wheel (FRA) or not and were fed ad libitum (AL) or subjected to a progressive food restriction from 30 to 50% (FR) for a 2-weeks or 10-weeks protocol, followed or not by 20 days of refeeding. Blood samples were performed during the restriction and refeeding periods. Clinical data were obtained during inpatient weight restoration and at post-discharge period. Blood collection for ghrelin assays were performed at admission, after weight restoration and one month post-discharge.

**Results.**– As in AN patient, this mouse model displayed similar weight loss and inappropriate physical activity. Acylated ghrelin (AG) plasma concentrations increased throughout the undernutrition both in mouse model and AN patient. In mice, AG and DAG were differentially impacted by physical activity in the early stage of caloric restriction. The refeeding period did not permit to properly restore the plasma AG and DAG levels. Preliminary clinical data in AN showed that AG and DAG concentrations did not present similar periprandial kinetics.

**Conclusion.**– The FRA model appears to be a preclinical model useful to clarify how the ghrelinergic system can influence or reflect the duration of recovery and predict relapse.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Schema therapy and appetite-focused cognitive behaviour therapy versus cognitive behaviour therapy for transdiagnostic binge eating: A two year follow-up of a randomised controlled trial**

J. Jordan<sup>1\*</sup>, V.V. McIntosh<sup>2</sup>, J.D. Carter<sup>2</sup>, C.M. Frampton<sup>1</sup>, P.R. Joyce<sup>1</sup>

<sup>1</sup> *University of Otago, Christchurch, psychological medicine, Christchurch, New Zealand;* <sup>2</sup> *University of Canterbury, psychology, Christchurch, New Zealand*

\* Corresponding author.

**Introduction.**– Limited outcomes of current psychotherapies for bulimia nervosa (BN) and binge eating disorder (BED) has prompted the trialling of innovative psychotherapies. Our randomised trial compared cognitive behaviour therapy (CBT) with Jeffrey Young's schema therapy (ST, emphasising early life experiences related to eating disorders); and CBT-A (incorporating retraining awareness of appetite) to try to improve outcomes for BN and BED.

**Objectives.**– To examine outcomes 2 years post-therapy.

**Methods.**– 112 women aged 16–65 years participated in a 12 month randomised psychotherapy trial for binge eating (current BN or BED diagnoses) (McIntosh et al., 2016). Outcomes were eating disorder diagnoses, objective binge frequency and global assessment of functioning (GAF). Statistics were ANOVAS, paired *t* tests (Cohen's *d*) and Chi<sup>2</sup>.

**Results.**– Of the 76% attending at 2 years, 66% were abstinent from bingeing (past month) while others were still symptomatic (BN 8%, BED 8%, anorexia nervosa 1%, eating disorder not otherwise specified 16%). Effect sizes for reduction in binge frequency from pre-treatment were large ( $d=1.26$ ). GAF mean scores of 72 were in the transient expectable reactions to psychosocial stressors range. There were no significant differences among therapies for these outcomes.

**Conclusions.**– All therapies were effective (but not significantly different) at 2-year follow-up, with good maintenance of change across treatments. The small sample size limits the power to detect statistically significant differences, despite the satisfactory follow-up rate. Although these innovative treatments, ST and CBT-A, did not improve outcomes by 2-year follow-up, they may offer alternative therapies addressing therapy matching and patient preferences.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Developing and validating clinical efficacy for obesity digital CBT model**

M. Kim<sup>1\*</sup>, S. Choi<sup>1</sup>, H. Choi<sup>2</sup>, Y. Lee<sup>2</sup>, S. Lee<sup>3</sup>, Y. Kim<sup>4</sup>

<sup>1</sup> *Duksung Women's university, clinical psychology, Seoul, Republic of Korea;* <sup>2</sup> *Seoul national university hospital, functional neuroanatomy of metabolism regulation, Seoul, Republic of Korea;* <sup>3</sup> *Seoul national university, food and nutrition, Seoul, Republic of Korea;*

<sup>4</sup> *Noom Korea, medical director, Seoul, Republic of Korea*

\* Corresponding author.

It is markedly distressful for people with obesity to maintain a new lower weight from weight loss. The aim of the present study is to develop and validate the effects of a new cognitive behavioural therapy (CBT) using digital healthcare mobile apps such as Noom Coach and InBody. Seventy-five female participants whose BMI scores were above 25 and who had no other clinical problem except obesity were randomized into an experimental and a control group. Fifty people in the experimental group were connected with the therapist using digital healthcare apps, so they got daily feedbacks and assignments for 8 weeks. Twenty-five people in the control group also used digital healthcare apps but they were asked to do self-care without intervention. The main findings of this study are as follows. First, BMI scores for the experimental group decreased significantly at the post-assessment, resulting in an average weight loss of about seven percent of initial weight. Second, after implementing the intervention, the experimental group reported remarkably decreased in level of depression and anxiety compared to the control group. Moreover, the self-esteem became higher in experimental group than in control group. Third, the biological markers (e.g. leptin, glucose, cholesterol, AST, ALT and GGT) showed that experimental group became closer to the healthy level

than the control group after the intervention. These findings lend further report to the notion that obesity is closely related to psychological problems which requires psychological intervention like the CBT in this research to manage the weight in healthy lifestyle.

### Trajectory of maturation of neuropsychological functions in anorexia nervosa

P. Meneguzzo\*, E. Collantoni, E. Bonello, D. Degortes, M. Solmi, T. Catapano, E. Tenconi, P. Santonastaso, A. Favaro  
*Psychiatric unit, department of neurosciences, Padova, Italy*  
\* Corresponding author.

*Background.*– Many studies have reported the presence of specific types of cognitive dysfunction in Anorexia Nervosa (AN), particularly cognitive inflexibility and visual-spatial difficulties. However, the developmental trajectories of these types of cognitive difficulties in patients with AN are unknown. The present study aims at investigating various types of executive functions, in order to assess the impact of the presence of AN on the trajectories of their maturation.

*Materials and methods.*– We recruited 269 female patients with a lifetime diagnosis of AN and a control group consisting of 247 healthy women. All participants were administered a series of neuropsychological tests: Wisconsin Card Sorting Test (WCST), Iowa Gambling Task (IGT), Stop Signal Task (SST), Rey-Osterrieth Complex Figure Test (ReyCFT), and Reading-the-Mind-in-the-eyes task (RMET).

*Results.*– All cognitive functions were found to be impaired in adult AN patients compared to non-affected women, whereas adolescent patients performed similarly than adolescent controls. By studying the relationship between cognitive performance and age we observed qualitative and quantitative differences between patients and controls in the developmental trajectories of many executive tasks, in particular WCST, SST, ReyCFT and RMET.

*Conclusions.*– AN patients showed a disruption of developmental trajectories of empathy, central coherence and set-shifting abilities from adolescence to adulthood. These alterations might be partially due to the effects of malnutrition, but are more likely attributable to the pathogenetic role of early risk factors in interaction with genetic factors.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The effects of clinical and psychological maternal problems during pregnancy on the onset of sleep disturbances in infants at 3 months of age

I. Morales-Muñoz<sup>1</sup>\*, O. Saarenpää-Heikkilä<sup>2</sup>, A. Kylläinen<sup>3</sup>, P. Pölkki<sup>4</sup>, T. Porkka-Heiskanen<sup>5</sup>, T. Paunio<sup>6</sup>, J. Paavonen<sup>1</sup>  
<sup>1</sup> National institute for health and welfare, department of health, Helsinki, Finland; <sup>2</sup> Tampere university hospital, pediatric clinics, Tampere, Finland; <sup>3</sup> University of Tampere, department of psychology, school of social sciences and humanities, Tampere, Finland; <sup>4</sup> University of Eastern Finland, department of social sciences, Kuopio, Finland; <sup>5</sup> University of Helsinki, department of physiology, Helsinki, Finland; <sup>6</sup> University of Helsinki and Helsinki university hospital, department of psychiatry, Helsinki, Finland  
\* Corresponding author.

*Introduction.*– Sleep disturbances in early childhood are linked to several behavioral and psychological problems. Moreover, some prenatal factors have been found to influence infants' sleep. Among them, most of the studies have been focused on prenatal depression and/or anxiety, whereas other relevant psychological factors during pregnancy have not been acknowledged.

*Objectives.*– We aimed to examine the effect of several clinical and psychological maternal problems during pregnancy (i.e., anxiety, depression, sleep problems, alcohol abuse, seasonality, attention deficit and hyperactivity disorder-ADHD, and/or trauma) on the onset of sleep problems (i.e., short sleep, night awakenings, circadian rhythm and self-shooting problems, and irregular sleeping routine) in infants at 3 months of age.

*Methods.*– A sample of 1221 cases was recruited, with subjective measures during pregnancy in mothers, and at 3 months after birth in infants.

*Results.*– We found that some maternal problems during pregnancy were able to explain the onset of some sleep disturbances in infants at 3 months of age. Interestingly, ADHD symptomatology in mothers was the variable that predicted the highest number of sleep disturbances at 3 months.

*Conclusions.*– To the best of our knowledge, this is the first study reporting the effect of several maternal prenatal factors on child sleep, and not exclusively anxiety and depression.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Burnout among Tunisian geriatric caregivers

A. Mrad\*, S. Fathallah, M. Kraoui, G. Lotfi  
*Faculty of medicine of Monastir, university of Monastir, department of psychiatry, Monastir, Tunisia*  
\* Corresponding author.

*Introduction.*– Previous studies have demonstrated that geriatric caregivers are exposed to significant fatigue and stress that can lead to the development of burnout.

*Objectives.*– The aim of this study was to identify the prevalence of burnout and to examine individual and professional factors to predict burnout among caregivers in nursing homes.

*Methods.*– An exploratory descriptive study was conducted in 10 geriatric care centers in Tunisia. A total of 272 caregivers (nurse, nurse's aide and physiotherapist) were informed prior to the study and consenting. We have administered an anonymized self questionnaire including sociodemographic features, the Maslach Burnout Inventory (MBI) and a list of questions targeted to identify factors related to the professional burnout.

*Results.*– Thirty percent of the nursing staff had a burnout. 65% of them had a high level of emotional exhaustion, 39% had depersonalization and 19% had a feeling of inefficacy. Associated factors to burnout were male gender ( $P=0.05$ ), experience in the work more than 10 years ( $P=0.035$ ), exhibition to inadequate physical environment ( $P=0.008$ ), overload in the work ( $P=0.04$ ), relationship difficulties with the elderly ( $P=0.01$ ), depressive symptoms ( $P=0.01$ ) and the lack of specialist training in geriatrics ( $P=0.011$ ).  
*Conclusions.*– Working with elderly people is physically and emotionally demanding, so it could lead to burnout, especially in bad professional conditions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Frequency of burn-out among Moroccan medical residents

H. Nafaa<sup>1</sup>\*, A. ouanass<sup>2</sup>

<sup>1</sup> Mohammed V university, faculty of medicine and pharmacy, Arrazi psychiatric hospital, sale, Morocco; <sup>2</sup> Mohamed V university, faculty of medicine and pharmacy, Arrazi hospital, psychiatry, Salé, Morocco

\* Corresponding author.

**Introduction.**– Burnout is a professional disorder, that could be either physical or mental, which mostly affects people who help others (caregivers, teachers, social workers, etc.).

**Objective.**– Determine the frequency of severe burnout in a population of resident doctors practicing in the various departments of the Ibn Sina hospital in Rabat, Morocco and to assess its impact on their performance.

**Methodology.**– A cross-sectional study of resident physicians in various specialties.

The evaluation of the Burn-out is done through the Maslach scale. We chose the Burn Out inventory test of Maslach and Jackson because it is one of the descriptive models of burn out that evaluates the psychological impairment at work by studying the consequences of chronic stress. It explores three dimensions: emotional exhaustion, dehumanization or depersonalization, and its degree of personal achievement at work.

**Results.**– Severe burnout was 18%. Several personal and occupational stressors were attributed to severe burnout, including personal and family history, lifestyle, hostile atmosphere, poor working conditions, and the relationship between staff and patients.

**Conclusion.**– the burn-out in the resident doctor is strongly linked to several factors, as just mentioned. It is therefore important to take action on modifiable factors in order to avoid the harmful consequences of burnout, both on the professional performance and on the personal life of the physician, who, to the detriment of his own health, is exhausted at work without realizing that he exposes himself to complications such as depression or drugs misuse.

**Keywords:** Burn-out; Exhaustion; Doctor; Stress

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The influence of the dysmorphofobia on the affective state and the life quality of female patients with eating disorder

E. Okonishnikova\*, I. Belokrylov, A. Bryukhin, T. Lineva, V. Karnozov, G. Kirsanova

Peoples' friendship university of Russia, RUDN university, department of psychiatry and medical psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Anorexia nervosa (AN) and bulimia nervosa (BN) take one of the first places in the risk of fatal outcome among eating disorders, have a tendency to chronicity and high suicidal risk. Psychopathological basis for AN and BN is a dysmorphofobia or a pathological dissatisfaction with one's body, characterized by intrusive, overvalued or delusional ideas of physical disability. Dysmorphofobia affects the formation of affective pathology and reduces the life quality.

**Objective.** The study of the correlation between the degree of dissatisfaction with one's bodies, affective disorders and life quality of patients with AN and BN.

**Methods.**– 50 female patients with AN and BN at the age of 16–30 years (the average age is 21). The disease duration from 6 months to 12 years. Validated Questionnaire image of one's own body (QIOB) and the Scale of satisfaction with one's body (SSOB), O. Scogarevsky's technique; Hospital anxiety and depression scale (Zigmond A., Snaith R.); Questionnaire for the assessment of life quality (SF-36); Microsoft Excel standard correlation calculation.

**Results.**– Dissatisfaction with one's body based on QIOB and SSOB tests has a significant correlation with anxiety, a moderate correlation with depression, a significant correlation with the psychological component of health, a weak correlation with the physical component of health.

**Conclusions.**– Dissatisfaction with one's body or dysmorphofobia of patients with AN and BN significantly affects their affective state and psychological component of life quality that leads to social maladjustment.

**Disclosure of interest.**– The publication was prepared with the support of the "RUDN University Program 5-100".

PW0385

### The assessment of life quality of patients with eating disorders

E. Okonishnikova\*, A. Bryukhin, T. Lineva, I. Belokrylov, V. Karnozov, G. Kirsanova

Peoples' friendship university of Russia, RUDN university, department of psychiatry and medical psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– The life quality assessment of patients provides an opportunity to recognize and prevent medical, psychological, social and economic risks for the health and social functioning. Patients with eating disorders suffer physical, psychological and social adaptation. The life quality study of this group of patients helps to choose a more rational method of medication treatment, psychotherapy and rehabilitation.

**Objective.** To study life quality indicators of patients with anorexia nervosa (AN) and bulimia nervosa (BN).

**Methods.**– The study of 50 female patients with AN and BN at the age of 16–30 years (average age is 21). The disease duration from 6 months to 12 years. Non-specific questionnaire to assess life quality, created on the basis of the WHO methodology (SF-36).

**Results.**– The following regularities of the evaluation of physical (PH) and psychological (MH) health components are established. The reduced PH value (21 to 40 out of 100 points) is identified in 30% of patients; the average PH value (from 41 to 60 points) in 64% of patients; the increased PH value (from 61 to 80 points) in 6% of patients. The low MH value (0 to 20 points) is identified in 30% of patients; the reduced MH value (21 to 40 points) in 42% of patients; the average MH value (41 to 60 points) in 28% of patients.

**Conclusions.**– AN and BN worsen life quality of patients and affects physical, emotional and social spheres of life.

**Disclosure of interest.**– The publication was prepared with the support of the "RUDN University Program 5-100".

PW0386

### Features of obsessive-phobic disorders of patients with anorexia nervosa

E. Okonishnikova\*, T. Lineva, A. Bryukhin, I. Belokrylov, V. Karnozov, G. Kirsanova

Peoples' friendship university of Russia, RUDN university, department of psychiatry and medical psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Obsessive-phobic disorders, often observed in patients with anorexia nervosa (AN), significantly increase the disease, complicate treatment and worsen the prognosis.

**Objective.** To study the clinic and the dynamics of the obsessive, compulsive and phobic disorders of patients with AN.

**Methods.**– Examined 250 patients with AN, ages 12 to 35 years. Applied clinical, psychometric, experimental-psychological and statistical methods. The presence and severity of obsessive, compulsive and phobic symptoms were determined using the Yale-Brown Obsessive-compulsive Scale, the Questionnaire “Hierarchical structure of the actual fears of the person” (Shcherbatykh Y., Ivleva E.).

**Results.**– Obsessive compulsive disorder at different stages of AN was diagnosed in 227 (90.8% of) patients. Obsessive-phobic disorders were divided into two groups: I group - related to dietary issues and the appearance correction (100%) and II group (23%) were not associated with such. Obsessions, compulsives and phobias from the first group had a number of features, including the frequent lack of criticism in obsessive thoughts, lack of vegetative component in the structure of phobias. Traced the close relationship of the dynamics of obsessive-phobic symptoms with violation of the food reflex and eating behavior of patients. Polymorphism of obsessive disorders indicated the severity of condition of patients.

**Conclusions.**– Obsessive-phobic disorders related to food theme and the appearance correction are a special type of obsessions in AN, largely related to the specifics of this disease, including a combination of psychological and somato-endocrine disorders.

**Disclosure of interest.**– The publication was prepared with the support of the “RUDN University Program 5-100”.

PW0387

### **The severity of depression in anorexia nervosa**

E. Okonishnikova\*, A. Bryukhin, T. Lineva, I. Belokrylov, G. Kirsanova, V. Karnozov, E. Onegina

Peoples' friendship university of Russia, RUDN university, department of psychiatry and medical psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Previously it was thought that depression in anorexia nervosa (AN) is often mild or moderate because of the possibility easily correct the body weight and figure. However, emotional disorders may indicate the severity of mental disorders in AN, being the cause of relapse and chronification of the disease.

**Objective.** To identify the prevalence and severity of depressive disorders of patients depending on the body mass index and age of patients

**Methods.**– Study of 27 patients in AN, the age from 15 to 36 years (average age is 20.6). Research methods: clinical, anthropometric, catamnestic, psychometric scaling (HAMD, MADRS), statistical

**Results.**– Premorbid 23 (85.2%) patients mentioned depression and subdepression. In 19 patients (70.4%) body mass index was  $>23 \text{ kg/m}^2$  (excess). At admission, 18 (66.7%) patients had hypotrophy of the 3rd degree, 7 (25.9%) patients had hypotrophy of 1 and 2 degrees. 20 patients (74.1%) had severe degree of depression, 3 patients (11.1%) – moderate, 4 (14.8%) – easy. Severe depression is diagnosed in young patients, light or the lack of it in older. A positive significant relationship (correlation coefficient of 0.96) between severity of depression and the average proportion of age and body mass index was identified.

**Conclusions.**– Depressive disorders are often marked up before the period of development of AN, are expressed in the manifestation and further course of the disease, correlating with the age of patients and the degree of exhaustion.

**Disclosure of interest.**– The publication was prepared with the support of the “RUDN University Program 5-100”.

### **Impulsivity, trauma and insecure attachment as mediators of suicidality in eating disorders**

G. Patricello<sup>1\*</sup>, U. Volpe<sup>1</sup>, A.M. Monteleone<sup>1</sup>, R. Amodio<sup>1</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> University of Campania “Luigi Vanvitelli”, psychiatry, Naples, Italy;

<sup>2</sup> University of Salerno, medicine, surgery and dentistry

“Scuola Medica Salernitana”, section of neuroscience, Salerno, Italy

\* Corresponding author.

**Introduction.**– Suicide is recognized as one of the major causes of mortality in eating disorders (ED); however, evidence on this subject are scarce yet. Particularly, risk and protective factors for suicide in ED have been not satisfactorily investigated.

**Objectives.**– In the present study, we aimed to explore the influence of impulsivity, childhood trauma and attachment styles on suicidal ideation and behaviors in ED subjects.

**Methods.**– We recruited 65 outpatients with a DSM-5 diagnosis of ED (25 with anorexia nervosa; 18 with bulimia nervosa; 10 with binge eating disorder; 14 with other specific eating disorders). Psychometric evaluations included questionnaires about eating symptoms (EDI-2), affective symptoms (HDRS), suicide severity (C-SSRS), childhood trauma (CTQ) and adult attachment style (ECR), as well as ad hoc schedule, to gather information about basic socio-demographic and clinical status. Furthermore, follow-ups at 6 and 12 months after intervention were planned.

**Results.**– Impulsivity resulted to exert the strongest influence over lifetime suicide behaviors, while clinical severity was not related to suicide ideation or behavior. Preliminary mediation analyses tend to confirm that insecure attachment and childhood trauma/abuse may significantly influence suicide behavior.

**Conclusions.**– Even if these results need to be replicated in a larger sample and over a longer period of observation, they suggest that attachment and childhood trauma/abuse may play an important role in increasing the risk of suicide. These findings highlight that therapeutic approaches should include specific elements for ED subjects at high risk of suicide.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Impact of mindfulness-based cognitive therapy (MBCT) on eating impulsivity, hunger sensations and mental ruminations in bulimia or binge eating disorder**

L. Sala<sup>1\*</sup>, C. Vindreau<sup>1</sup>, P. Gorwood<sup>2</sup>

<sup>1</sup> Sainte-Anne hospital, clinic of mental illnesses & brain disorders,

Paris cedex 14, France; <sup>2</sup> Inserm U894, centre of psychiatry and neuroscience, Paris, France

\* Corresponding author.

**Introduction.**– An increasing number of protocols incorporating mindfulness exercises are offered to people with eating disorders (ED) but, paradoxically, few studies exist on this subject. Since 2014, the Sainte-Anne Hospital has established eight-session MBCT groups for patients suffering from bulimia and binge eating disorder (BED). The programme has been tailored appropriately in the choice of cognitive tools and the duration of meditation practices.

**Objectives.**– To study the effect of MBCT on eating impulsivity on the one hand, and the ability to distinguish hunger from other sensations on the other hand, and finally on mental ruminations.

**Methods.**– Participants comprised forty-seven subjects attending our ED day hospital. Each participant was evaluated before and after the programme using the following self-report questionnaires: the Three Factor Eating Questionnaire (TFEQ), the Ruminative Response Scale for Eating Disorder (RRS-ED), the Bulimia Inventory Test, Edinburgh (BITE), the Body Shape Questionnaire (BSQ), and the Five Facets Mindfulness Questionnaire (FFMQ).

**Results.**– A significant improvement in cognitive restraint of eating ( $t = 3.05, P = 0.004$ ) and disinhibition ( $t = 2.37, P = 0.02$ ) as measured by the TFEQ was observed but not hunger ( $t = 1.04, P = 0.30$ ). Likewise a significant reduction in ED-specific ruminative processes ( $t = 2.67, P = 0.01$ ) was measured by the RRS-ED.

**Conclusions.**– Our results provide new and interesting perspectives for patient care for which few studies have been published in literature to date.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0390

### **Weight suppression and weight suppression speed are associated with clinical characteristics before and at the end of treatment**

M. Solmi\*, P. Meneguzzo, E. Collantoni, A. Favaro, E. Tenconi  
University of Padua, neurosciences department, Padua, Italy

\* Corresponding author.

**Background.**– Growing evidence suggests a role of weight suppression (WS), namely the difference between life-time highest weight and current weight, in determining the severity of symptoms in the context of specific Eating Disorders (ED), and in the whole ED group. However, no study has investigated whether WS speed (WSS), is associated with symptoms in ED.

**Methods.**– Prospective cohort study including patients with ED, with diagnoses made according to DSM5 criteria, in the context of out-patients multidisciplinary treatment. ED symptoms were measured with Eating Disorder Inventory (EDI), and with binge, restriction, purging-wide behaviors, general psychopathology with Symptom Check List 90 (SCL-90), self-esteem with Rosenberg Self-Esteem Scale (RSES), and personality with Tridimensional Personality Questionnaire (TPQ), at baseline. Symptoms frequency, response, remission, and drop-out rates were evaluated at the end of treatment.

**Results.**– We included 414 patients with ED, 146 with restrictive Anorexia Nervosa (AN-R), 62 bulimic-purgative AN (AN-BP), 206 bulimia nervosa (BN). At baseline, WS was associated with restriction ( $P = 0.027$ ) and drive for thinness ( $P = 0.008$ ) in AN-R group only, WSS with body dissatisfaction in AN-BP ( $P = 0.02$ ), with novelty seeking in AN-R ( $P = 0.046$ ), while inversely with novelty seeking in BN ( $P = 0.012$ ). After treatment, WS was associated with weight increase in AN-R ( $P = 0.031$ ), and BN ( $P = 0.001$ ). WSS was associated with purging ( $P = 0.003$ ) in AN-BP, with BMI increase in AN-R ( $p = 0.035$ ), and inversely with drop-out rates in BN ( $P = 0.014$ ).

**Conclusion.**– At baseline WS was associated with symptoms in AN-R, while WSS in AN-BP, the latter with personality features in AN-R and BN. After treatment, WS and WSS predicts BMI increase in AN-R, WS in BN, WSS in AN-BP, the latter protecting against drop-out in BN.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0391

### **Examining food craving: The relationship with BMI and food addiction**

E. Sönmez<sup>1\*</sup>, C. Çelebi<sup>2</sup>, Y. Akvardar<sup>3</sup>

<sup>1</sup> Caycuma state hospital, psychiatry, Zonguldak, Turkey;

<sup>2</sup> Afyonkarahisar state hospital, psychiatry, Afyon, Turkey;

<sup>3</sup> Marmara university school of medicine, psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Particular foods are linked with greater pleasure and therefore attributed to have reward-like properties. When frequently consumed, such foods reinforce their own consumption, resulting in an addiction-like eating pattern, despite negative consequences such as excessive caloric intake and weight gain.

**Objectives.**– This case-control study aimed to evaluate food cravings, with regard to its contribution in food addiction and obesity.

**Methods.**– The case group consisted of pre-operative bariatric surgery patients ( $n = 40$ ) and matched-controls from other other BMI subgroups (normal, pre-obese and obese) were enrolled. Yale Food Addiction Scale (YFAS) was used to assess food addiction symptoms and diagnosis. Food craving was examined by Food Craving Questionnaire – Short Form. Moreover, subjective perceptions of food craving (intensity, duration, frequency and capacity to resist) were assessed using visual analogue scales.

**Results.**– Food addiction prevalence was 15% in the case group, significantly higher than among controls ( $\chi^2: 11.62, P < 0.01$ ). Food craving scores differed between groups, obesity and morbid obesity groups scored significantly higher as compared to individuals with a lower BMI ( $22.32 \pm 15.24$  vs  $9.39 \pm 10.62, P < 0.01$ ). Those with food addiction reported to have more intense, long-lasting and more frequent cravings when compared to those without, this association was more prominent for women with a BMI of  $30 \text{ kg/m}^2$  or more ( $z = -2.37, P < 0.01$ ;  $z = -2.31, P < 0.01$ ;  $z = -1.43, p < 0.05$ ; respectively).

**Conclusions.**– It can be interpreted that food craving constitutes a critical dimension of food addiction phenomenon, especially for female obesity patients. Targeting cravings might help achieving better treatment outcome in food addiction-related obesity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0392

### **Clinical features in patients in Parkinson's disease with REM sleep behavior disorder**

K. Yaich\*, S. Sakka, N. Farhat, O. Hdiji, H. Hadjkacem, M. Dammak, C. Mhiri

Habib Bourguiba hospital, neurology department, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– REM sleep behaviour disorder (RBD) is one of the most common non-motor symptoms of Parkinson's disease (PD) and have a significant negative impact on quality of life. It has been proven to be a predictor of development of PD. Furthermore, the identification of a significant relationship between RBD and severity of parkinsonian motor signs in corroborates this idea.

**Method.**– Thirty nine Parkinsonian patients, with an average age of 69 years, followed in our neurology department were retrospectively included. The sex ratio male / Female was 0.56. Patients were tested in the Off period using part III of the Unified Parkinson's Disease Rating Scale For each UPDRS MDS III, GDS (Geriatric depression score) and REM SBD SQ (Rapid Eye Movement Sleep Behavior Disorder Screening Questionnaire). Patients were divided according to severity of severe motor signs if MDS UPDRS III > 60, Moderate if

MDS UPDRS between 25 and 60 and mild if MDS UPDRS is less than 25.

**Result.**– 41% of our patients were at the severe stage, 48.75% of cases at the moderate stage and only 10.26% of cases at the light stage of the disease. Depression was retained in 84.62% of patients with GDS score  $\geq 5$ . RBD were found in 53.85% when REM SBD SQ  $\geq 5$ . There was a significant correlation between the severity of the motor signs of the disease and RBD ( $P=0.008 < 0.05$ ).

**Conclusion.**– Our findings demonstrated that patients with RBD showed higher motor examination (UPDRS-III) score compared to PD patients with normal REM sleep behavior.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Epidemiology and Social Psychiatry - Part I / Pain and Treatment Options

### Psychiatric disorders in Iranian children and adolescents

N. Ahmadi<sup>1</sup>, M.R. Mohammadi<sup>2</sup>

<sup>1</sup> Yazd cardiovascular research center, Shahid Sadoughi university of medical sciences, Yazd, Iran; <sup>2</sup> Psychiatry and psychology research center, Tehran university of medical sciences, Tehran, Iran

\* Corresponding author.

**Introduction.**– There has been a growing need to better understand the prevalence and associated factors for mental health problems in children and adolescents in Iran.

**Objective.**– The aim of the present study was to investigate the epidemiology of psychiatric disorders in children and adolescents in five provinces of Iran: Tehran, Shiraz, Isfahan, Tabriz and Mashhad. **Method.**– In the present study, we selected 9636 children and adolescents aged 6–18 years through multistage cluster random sampling method from five provinces of Iran. We instructed the clinical psychologists to complete the Strengths and Difficulties Questionnaire (SDQ) for the participants, and those who received a high score on SDQ, completed the Persian version of Kiddie-SADS-Present and Lifetime Version (K-SADS-PL).

**Results.**– Based on the results, oppositional defiant disorder (ODD) (4.45%) had the highest prevalence of psychiatric disorders in the five provinces. In addition, attention deficit hyperactivity disorder (ADHD) had the most prevalence in boys (5.03%) and ODD had the most prevalence in girls (4.05%). Among the three age groups, 6 to 9 year olds had the highest rates of ADHD (5.69%); 10 to 14 and 15 to 18 year olds had the highest rates of ODD (4.32% and 4.37% respectively). Among the five provinces, Tehran and Mashhad allocated the highest rates of ODD; Isfahan and Shiraz had the highest rates of ADHD.

**Conclusion.**– The current study revealed that the overall frequency of psychiatric disorders based on Kiddie-SADS-Present and Lifetime Version (K-SADS-PL) was higher than a similar study.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Adolescent affective problems and premature mortality: A fifty-three year follow-up of a British National Birth Cohort Study

G. Archer<sup>1</sup>, D. Kuh<sup>1</sup>, M. Hotopf<sup>2</sup>, M. Stafford<sup>1</sup>, M. Richards<sup>1</sup>

<sup>1</sup> University College London, MRC unit for lifelong health and ageing at UCL, London, United Kingdom; <sup>2</sup> Institute of psychiatry, psychology & neuroscience, Kings College London, psychological medicine, London, United Kingdom

\* Corresponding author.

**Introduction.**– Little is known about the association between adolescent affective problems (anxiety and depression) and mortality.

**Objectives.**– To examine whether adolescent affective problems are associated with premature mortality, and to assess whether this relationship is independent of other early-life factors.

**Method.**– In Britain's oldest birth cohort, the MRC National Survey of Health of Development, adolescent affective problems were rated by teachers at ages 13 and 15. Scores were summed and categorised into 'mild or no', 'moderate', and 'severe' problems (1–50th, 51–90th and 91–100th percentiles, respectively). Mortality data were obtained from the NHS Central Register up to age 68 years. Potential confounders were parental social class, childhood health and cognition, and adolescent externalising behaviours. Survival analysis was used to examine the association between adolescent affective problems and mortality in 3884 study members.

**Results.**– Over the 53 year follow-up, 12.2% ( $n=472$ ) of study members died. Severe adolescent affective problems were associated with an increased rate of mortality compared to those with mild or no problems (hazard ratio (HR)=1.76, 95% CI 1.33–2.33, adjusted for sex). This association was only partially attenuated following adjustment for potential confounders (HR<sub>adj</sub> = 1.61, 95% CI 1.20–2.15). Severe problems were associated with deaths from cancers and cardiovascular disease; however the strongest associations were observed with respect to 'other' causes (sub-distribution HR<sub>adj</sub> = 2.03, 95% CI 1.07–3.85). Moderate problems were not associated with mortality.

**Conclusion.**– Severe adolescent affective problems are associated with an increased rate of premature mortality over a fifty year follow-up, independent of potential confounders. These findings underscore the importance of early mental health interventions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Investigation of neuroprotective effect of Fisetin in a reserpine-induced fibromyalgia in rats

A. Kandhare, A. Mukherjee, S. Bodhankar\*

Poona College of pharmacy, department of pharmacology, Bharati Vidyapeeth Deemed university, Pune, India

\* Corresponding author.

**Introduction.**– Fisetin (FST) (3, 3', 4', 7-tetrahydroxy flavone), a flavonoid have been reported to possess potent antioxidant and anti-inflammatory activities. Fibromyalgia is a complex disorder characterized by chronic widespread pain and complex comorbid symptoms.

**Objective.**– To evaluate the efficacy and possible mechanism of action of FST against reserpine-induced fibromyalgia (RIF) in rats.

**Methods.**– RIF was induced in male Wistar rats (180–220 gm) by administration of reserpine (1 mg/kg, s.c., once daily, for three consecutive days). Rats were treated with either FST (5, 10 and 25 mg/kg) or vehicle (10 mg/kg) p.o. for 21 days. Various behavioral,

biochemical, molecular and histological parameters were evaluated.

**Results.**– RIF causes a significant decreased ( $P < 0.05$ ) in the hyperalgesia and mechano-tactile allodynia whereas administration of FST (10 and 25 mg/kg) showed a significant increase ( $P < 0.05$ ) in hyperalgesia and allodynia. RIF-induced decreased in the brain (thalamus), and spinal cord monoamines (serotonin, dopamine, and noradrenaline) levels were significantly increased ( $P < 0.05$ ) by FST (10 and 25 mg/kg) treatment. FST (10 and 25 mg/kg) also significantly attenuates ( $P < 0.05$ ) RIF-induced alteration in oxido-nitrosative stress in brain and spinal cord. FST administration also decreased RIF-induced histological aberration in the brain and spinal cord.

**Conclusion.**– The results of present investigation demonstrated that fisetin possessed potent neuroprotective property against RIF-induced fibromyalgia via modulation of the central monoamines and oxido-nitrosative stress. Thus, our findings may open novel landscapes in the therapeutic potential of this dietary flavonoid in CNS disorders especially fibromyalgia and neuropathic pain.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Adverse childhood conditions as risk factors for cognitive impairment: Cohort study of ~ 55,000 persons from 13 European countries

P. Cermakova<sup>\*</sup>, T. Formanek, P. Winkler

National institute of mental health, social psychiatry, Klecany, Czech Republic

\* Corresponding author.

**Introduction.**– Disadvantaged conditions in childhood may lead to cognitive impairment in old age.

**Objectives.**– To investigate the association of adverse childhood conditions (socioeconomic hardship, poor school performance and poor health) with cognitive performance and cognitive decline in older adults. Secondary aim was to determine the role of a country in these associations.

**Methods.**– Observational longitudinal cohort study of 55,196 older individuals (mean age 67 years, 56% women) from the Survey on Health, Ageing and Retirement in Europe (SHARE). Simple and hierarchical linear regression was applied.

**Results.**– Indicators of adverse socioeconomic circumstances and poor school performance were associated with lower cognitive functions, adjusting for demographic, psychosocial and cardiovascular risk factors. History of most childhood diseases was associated with better cognitive performance. In the final, fully adjusted model, overall socioeconomic hardship [ $\beta$  -0.39; 95% confidence interval (CI) -0.44; -0.34] and poor school performance ( $\beta$  -0.63; 95% CI -0.68; -0.58) were associated with lower cognitive performance, while overall poor childhood health was linked to better cognition ( $\beta$  0.22; 95% CI 0.14; 0.29). Belonging to a specific country explained 14% of the variance in cognitive performance, but the effects of childhood conditions within each country were small. No indicator of childhood conditions was associated with the change in cognitive performance.

**Conclusions.**– Variation in childhood circumstances explain the differences in cognitive performance between older people, but does not protect against the decline from their previous level of cognitive

functions. The role of childhood diseases is less clear and should be investigated in future studies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Individual effectiveness of neurofeedback in migraine: The role of personality and emotional state

G. Arina<sup>1</sup>, O. Dobrushina<sup>2\*</sup>, E. Osina<sup>3</sup>, G. Aziatskaya<sup>4</sup>, A. Trofimova<sup>3</sup>

<sup>1</sup> M.V. Lomonosov Moscow state university, psychology, Moscow, Russia; <sup>2</sup> International institute of psychosomatic health, director, Moscow, Russia; <sup>3</sup> International institute of psychosomatic health, psychology, Moscow, Russia; <sup>4</sup> Neurology research center, neurorehabilitation, Moscow, Russia

\* Corresponding author.

**Introduction.**– Effectiveness of headache treatment interventions, in particular, of neurofeedback, may be influenced by psychological factors. Information regarding individual effectiveness, important for clinical practice, is usually negotiated in group studies.

**Objectives.**– Assess the influence of personality and emotional state on individual effectiveness of neurofeedback in migraine in a single-case study.

**Methods.**– A single case design cross-over sham-controlled study with blinded evaluator included 8 females aged 19–32 years with frequent migraine. The study consisted of 4 phases: pre-evaluation ( $\geq 2$  weeks), treatment 1 (5 weeks), treatment 2 (5 weeks), post-evaluation ( $\geq 2$  weeks). Treatment 1 and 2 included 10 infra-low frequency neurofeedback and 10 sham-neurofeedback sessions at T3T4 site in randomized order. Baseline psychological assessment included Minnesota Multiphasic Personality Inventory (MMPI), Beck's Depression Inventory, The State-Trait Anxiety Inventory.

**Results.**– Real, but not sham neurofeedback resulted in significant reduction of migraine attacks frequency of six participants ( $P < 0.03$ ). The rest two participants were characterized by high MMPI profile (see image) and severe depression, while no such abnormalities were detected in participants with high effectiveness of treatment. The anxiety level had no influence on therapeutic effects of neurofeedback (Fig. 1).

**Conclusions.**– High MMPI profile and severe depression interfere with neurofeedback effectiveness in migraine. It is worth to perform assessment of personality and depression level in migraine patients prior to treatment to prevent the inherently inefficient treatment approach.

### Reduction of intensive negative emotions in everyday life during the treatment of migraine with neurofeedback

O. Dobrushina<sup>1\*</sup>, G. Arina<sup>2</sup>, E. Osina<sup>3</sup>, G. Aziatskaya<sup>4</sup>, A. Trofimova<sup>3</sup>

<sup>1</sup> International institute of psychosomatic health, Director, Moscow, Russia; <sup>2</sup> M.V. Lomonosov Moscow State university, psychology, Moscow, Russia; <sup>3</sup> International institute of psychosomatic health, psychology, Moscow, Russia; <sup>4</sup> Neurology research center, neurorehabilitation, Moscow, Russia

\* Corresponding author.

**Introduction.**– Several relations between emotions and migraines are proposed: negative emotions may arise as a response to pain and disadaptation, may provoke the migraine attacks, and/or may be caused by the same neurophysiological mechanism as migraines do. Longitude studies assessing dynamics of emotional state during migraine treatment are of interest.

**Objectives.**– To study the dynamics of emotions in everyday life during the treatment on migraine with neurofeedback.

**Methods.**– During a single case design cross-over sham-controlled study of neurofeedback 6 females with frequent migraines filled an everyday electronic diary regarding headache, stress, emotions, coping-strategies. The study consisted of 4 phases: pre-evaluation ( $\geq 2$  weeks), treatment 1 (5 weeks), treatment 2 (5 weeks), post-evaluation ( $\geq 2$  weeks), where treatments 1 and 2 were 10 infra-low frequency neurofeedback/sham-neurofeedback sessions at T3T4 site in randomized order.

**Results.**– Real, but not sham neurofeedback resulted in a decrease of the frequency of migraine attacks ( $29.5 \pm 14.5\%$  during neurofeedback vs.  $37.7 \pm 16.8\%$  during pre-evaluation,  $P=0.04$ ). No significant changes were observed in the level of stress and the use of different coping-strategies during the study phases. A reduction of the percentage of days with intensive negative emotions was seen during neurofeedback:  $8.6 \pm 9.1\%$  vs.  $16.7 \pm 13.2\%$  during pre-evaluation ( $P=0.03$ ) and vs.  $15.1 \pm 11.3\%$  during the sham phase ( $P=0.03$ ). We failed to find any correlations between the headaches frequency and emotional state both at individual and group level.

**Conclusions.**– Neurofeedback results in concomitant reduction of the frequency of migraine attacks and of the frequency of intensive negative emotions.

### Long-run impact of prenatal exposure to the Chinese famine on risk of schizophrenia in adulthood

P. He\*, X. Zheng

Peking university, institute of population research, Beijing, China

\* Corresponding author.

**Introduction.**– Schizophrenia is a common major mental disorder and prenatal nutritional deficiency may increase its risk.

**Objectives.**– We aimed to investigate long-term impact of prenatal exposure to the Chinese famine of 1959–1961 on risk of schizophrenia in adulthood.

**Methods.**– We obtained data from the Second National Sample Survey on Disability implemented in 31 provinces in 2006, and restricted our analysis to 369,949 individuals born from 1956 to 1965. Schizophrenia was ascertained by psychiatrists based on the International Statistical Classification of Diseases, Tenth Revision. Famine severity was defined as cohort size shrinkage index. The famine effect on adult schizophrenia was estimated by difference-

in-difference models, established by examining the variations of famine exposure across birth cohorts.

**Results.**– Compared with the reference cohort of 1965, famine cohorts (1959–1962) had 101% higher odds (OR: 2.01; 95% CI: 1.21, 3.33;  $P=0.007$ ) of schizophrenia in the rural population. After adjusting for multiple covariates, this association remained significant and substantial (OR: 1.97; 95% CI: 1.17, 3.32;  $P=0.011$ ). We did not observe statistically significant differences in odds of schizophrenia among famine cohorts compared with the reference cohort in the urban population.

**Conclusion.**– Our study strongly supports the view that prenatal exposure to famine increased risk of schizophrenia in later life, and confirms urban-rural difference in the famine effect on schizophrenia. Further studies were needed to investigate corresponding mechanisms on this topic.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Illness and treatment representation in patients with primary headache and headache secondary to psychiatric disorders

M. Kovyazina<sup>1,2\*</sup>, J. Migunova<sup>1</sup>, E. Rasskazova<sup>1,3</sup>, A. Tkhostov<sup>1</sup>, N. Varako<sup>1,2</sup>, V. Barabanshchikova<sup>1</sup><sup>1</sup> Lomonosov Moscow state university, psychology, Moscow, Russia;<sup>2</sup> Research center of neurology, neurorehabilitation and physiotherapy, Moscow, Russia; <sup>3</sup> Mental health research center, psychosomatics and psychotherapy, Moscow, Russia

\* Corresponding author.

**Introduction.**– Differentiation of patients with primary and secondary to mental illness pain is an important diagnostic task of general clinics and emergency centers (Radat et al., 2011). Emotional and cognitive factors that predict avoidance behaviour and quality of life decline in patients with chronic pain (Smitherman et al., 2015, Norton, Asmundson, 2004) could possibly help for differentiation.

**Objectives.**– The aim was to compare illness representation in patients with headache secondary to psychiatric disorders and other chronic headaches.

**Methods.**– 30 patients with headache secondary to personality and affective disorders and 74 patients with chronic migraines and tension-type headaches filled Migraine Disability Assessment Test (Stewart, 2001), Cognitions About Body and Health Questionnaire (Rief et al., 1998), Illness Perception Questionnaire (Moss-Morris et al., 2002) and Quality of Life and Enjoyment Questionnaire (Rit-sner et al., 2005), Morisky-Green Test (Morisky et al., 1986).

**Results.**– Comparing to primary headaches, in patients with secondary pain intensity is more related to dissatisfaction with health and emotions ( $r=-.69$ ;  $-.66$  versus  $r=-.39$ ;  $-.31$ ). They almost never reported neutral relationship to headache from relatives ( $\chi^2=6.51$ ,  $P<.05$ ) but reported higher limitations in work, personal control of illness, more fears about diagnosis and better adherence ( $t=-2.56$ ;  $-1.96$ ,  $P<.05$ ).

**Conclusions.**– Higher sensitivity to pain intensity, feeling of control and adherence reported by patients with headaches if accompanied by fears about diagnosis, emotional reactions of relatives and limitations at work allow suspecting mental illnesses underlying chronic pain.

**Funding.**– The reported study was funded by RFBR according to the research project no. 17-29-02169.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Stress urinary incontinence (SUI) and suicidality seen in the United Kingdom clinical practice research datalink (CPRD)

H. Li<sup>1</sup>\*, M. Bangs<sup>2</sup>, D. Ruff<sup>3</sup>, L. Mitchell<sup>4</sup>, S. Jonathan<sup>2</sup><sup>1</sup> Eli Lilly, GPS, Indianapolis, USA; <sup>2</sup> Eli Lilly, patient safety, Indianapolis, USA; <sup>3</sup> Eli Lilly, global statistics, Indianapolis, USA;<sup>4</sup> Eli Lilly, patient safety, Erl Wood, United Kingdom

\* Corresponding author.

Following authorisation of duloxetine in 2004 for stress urinary incontinence (SUI), the issue of suicidality and use of antidepressants became a topic of intense scrutiny around the world.

To assess the association between duloxetine and suicidality in women with SUI.

The analysis included eligible women with SUI aged  $\geq 18$  years, prescribed with duloxetine or other antidepressants, and an untreated cohort matched 4:1 to duloxetine cohort. Cox proportional hazard models were used to estimate adjusted hazard ratios (HR) comparing duloxetine treated (as-treated, intent-to-treat) to untreated and other antidepressant cohorts.

5255 duloxetine-treated and 20,674 untreated patients with SUI were identified, aged 56.42 ( $\pm 13.92$ ) and 56.40 ( $\pm 13.81$ ) years respectively. Duloxetine-treated patients had more suicidality risk factors compared to the untreated: baseline depression (14.44% vs. 9.95%); and were similar compared to antidepressant cohort: baseline depression (10.7% vs. 10.9%). Comparing to untreated patients, using different follow-up time of untreated cohort (entire vs. matched), the adjusted HRs of suicidal attempts were 2.92 (1.44, 5.95,  $P=0.003$ ) and 5.06 (1.56, 16.45,  $P=0.007$ ); and adjusted HR of suicidal ideation were 3.32 (1.63, 6.78,  $P=0.001$ ) and 3.89 (1.46, 10.43,  $P=0.007$ ). However, comparing to antidepressant cohort, the adjusted HR of suicide attempt and ideation was not statistically significant: 1.94 (0.63, 5.95,  $P=0.25$ ), and 0.51 (0.16, 1.67,  $P=0.27$ ) respectively.

Although a statistically significant association was observed, there are concerns of biases due to confounding by indication and incomplete capture of depression diagnoses in CPRD. The study findings were not sufficient to change benefit risk of using duloxetine for the treatment of SUI.

### Evaluation of the effect of aromatherapy with rosa damascena mill on postoperative pain intensity in hospitalized children

M. Marofi<sup>1</sup>\*, M. Sirousfard<sup>2</sup>, M. Moini<sup>3</sup>, A. Ghanadi<sup>4</sup><sup>1</sup> Isfahan university of medical sciences, nursing, Isfahan, Iran;<sup>2</sup> Isfahan university of medical sciences input required, pediatric and neonatal, Isfahan, Iran; <sup>3</sup> Isfahan university of medical sciences,medical-surgical, Isfahan, Iran; <sup>4</sup> Isfahan university of medical sciences, faculty of pharmacy, Isfahan, Iran

\* Corresponding author.

*Background.*– Pain is the common complication after a surgery. The aim of this study was to evaluate the effect of aromatherapy with Rosa damascena Mill. on the postoperative pain in children.

*Materials and methods.*– In a double-blind, placebo-controlled clinical trial, we selected 64 children of 3–6 years of age through convenient sampling and divided them randomly into two groups. Patients in group A were given inhalation aromatherapy with R. damascena Mill., and in group B, the patients were given almond oil as a placebo. Inhalation aromatherapy was used at the first time of subjects' arrival to the ward and then at 3, 6, 9, and 12 h afterward. Common palliative treatments to relieve pain were used in both groups. Thirty minutes after aromatherapy, the postoperative pain in children was evaluated with the Toddler Preschooler Postoperative Pain Scale (TPPPS). Data were statistically analyzed using Chi<sup>2</sup> test, one-way analysis of variance (ANOVA), and repeated measures ANOVA.

*Results.*– There was no significant difference in pain scores at the first time of subjects' arrival to the ward (before receiving any aromatherapy or palliative care) between the two groups. After each time of aromatherapy and at the end of treatment, the pain score was significantly reduced in the aromatherapy group with R. damascena Mill. compared to the placebo group.

*Conclusions.*– According to our results, aromatherapy with R. damascena Mill. can be used in postoperative pain in children, together with other common treatments without any significant side effects.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The effect of pain on cognitive flexibility assessed with Stroop task

C. Dondas<sup>1</sup>, C. Munteanu<sup>2</sup>\*, M. Iorga<sup>3</sup>, A. Rey<sup>4</sup>, M. Thar<sup>4</sup>, S. Mazza<sup>4</sup><sup>1</sup> University 'Alexandru Ioan Cuza', psychology and educationsciences, Iasi, Romania; <sup>2</sup> "Gr. T. Popa" university of medicine and pharmacy, general medicine, Iasi, Romania; <sup>3</sup> University of medicine

and pharmacy "Grigore T. Popa", behavioral sciences, Iasi, Romania;

<sup>4</sup> University Lyon 2, psychology, Lyon, France

\* Corresponding author.

*Introduction.*– Cognitive flexibility has been shown to modulate pain perception, but the relationship between cognitive flexibility and pain perception is still not clearly understood.

*Objectives.*– The aim of the study is to identify the manner in which acute experimental pain influences the level of cognitive flexibility of our participants.

*Methods.*– A number of 40 subject were included in this study. We used the Stroop task as a measure for cognitive flexibility. The test consists of three tasks: naming the color, reading the name of the color and the interference condition. Every subject had to read each of the three sheets two times, the first two sheets were performed in the nonpainful condition (cold pressor task, ambient temperature) and only the interference sheet had to be read depending of the experimental condition, either in the painful condition (cold pressor test, 12°Celsius) or the non painful one. The order of the hands was counterbalanced.

*Results.*– The results show that there are no significant differences at the Interference task for the time (M<sub>pain</sub>=85.12 s, M<sub>non-pain</sub>=83.76), the number of corrected errors (M<sub>pain</sub>=1.90, M<sub>non-pain</sub>=1.9) or non-corrected errors (M<sub>pain</sub>=0.55, M<sub>non-pain</sub>=0.39). The results are presented in Fig. 1.

*Conclusions.*– Acute experimental pain does not influence the performance for cognitive flexibility task.

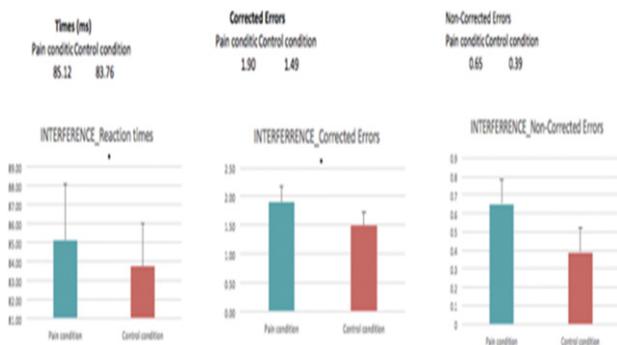

Fig. 1 Results for the interference condition.

*Disclosure of interest.*— The authors have not supplied a conflict of interest statement.

\* Corresponding author.

*Introduction.*— While many researches show an excess psychiatric morbidity in incarcerated populations, there has been no recent study in France.

*Objectives and methods.*— The study of health in prison populations (SPC) is a multicentric retrospective survey aimed at measuring mental disorders according to the MINI. The sample includes adults arriving in prison between March 2014 and April 2017 in the following French departments: Nord and Pas-de-Calais. A comparison of the levels of disorder was conducted between the men in the study (96% of the population) and a matched sample of men interviewed with the same protocol in the Mental Health in General Population study (SMPG).

*Results.*— 630 men were included. Most of them are young (average 32) and in precarious social condition (half unemployed, half with an income of less than 850€ per month and half without any degree) (Table 1).

*Conclusion.*— Our study confirms the high prevalence of mental disorders among prison populations and confirms the need for strengthening specific actions before the incarceration.

Table 1.

	% SPC	% SMPG	P
Depressive episode last 2 weeks	27.2	13.6	<.001
Major depressive disorder recurrent	15.7	6.9	<.001
Panic disorder current	12.3	5.0	<.001
Social phobia current	6.1	4.0	<.001
Generalized anxiety disorder last 6 months	25.7	13.9	<.001
Post-traumatic stress disorder current	4.8	0.5	<.001

### Serotonin syndrome as an interactions between SSRIs and Opiates

S. Petrykiv<sup>1\*</sup>, M. Arts<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>  
<sup>1</sup> University of Groningen, university medical center Groningen, department of clinical pharmacy and pharmacology, Groningen, The Netherlands; <sup>2</sup> Mental health care, West North Brabant GGZ-WNB, department of geriatric psychiatry and neuropsychiatry, Bergen op Zoom, The Netherlands; <sup>3</sup> Mental health care Friesland GGZ-Friesland, department of geriatric psychiatry, Leeuwarden, The Netherlands; <sup>4</sup> Leonardo scientific research institute, department of geriatric psychiatry and neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

*Introduction.*— Depression and somatic pain are two of the most commonly treated conditions in the developed countries, while the antidepressants and opioids are among the most widely prescribed drugs in the world. There is a growing concern that SSRIs/SNRIs in combination with opioids might cause potentially life threatening serotonin syndrome (SS). However, the supporting evidence originates from several case reports and the magnitude of pharmacodynamic interaction between SSRIs/SNRIs and opioids is unclear. *Objectives and aims.*— Review on iatrogenic complication from therapeutic use effects of SSRIs/SNRIs and opioid drugs.

*Methods.*— Detailed literature review through PubMed, EMBASE and Cochrane's Library to assess the clinical relevance of combined SSRIs/SNRIs and opioid use. In addition, we used the results of a Dutch survey performed in hospital pharmacies and general pharmacies accessing the incidence of SS in patients using the combination of different opioids and SSRIs/SNRIs.

**Results.**– Identified cases involved combining tramadol with citalopram, fluoxetine, paroxetine, nefazodone, sertraline, and venlafaxine. From the Dutch survey, eleven hospital pharmacies and 18 general pharmacies described an action when an SSRI/SNRI was combined with fentanyl or oxycodone, whereas more than 80% reacted when an SSRI/SNRI was combined with tramadol.

**Conclusion.**– Clinicians should be aware of interaction and the risk of serotonin syndrome when a patient receives a combination of different opioids and SSRIs/SNRIs. If an SSRI/SNRI is prescribed together with tramadol, prescribers and patients would be informed by the pharmacy and receive advice about alternative drugs.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Treatment dropout at age of transition of care from child and adolescent psychiatric services to adult services (CRECER Project)**

B. Reneses<sup>1\*</sup>, N. Tur<sup>1</sup>, A. Escudero<sup>2</sup>, I. Cruz<sup>2</sup>, A.L. Del Rey<sup>3</sup>, E. Jose Carlos<sup>4</sup>, L. Agüera<sup>4</sup>, M.D. Moreno<sup>5</sup>, N. Szerman<sup>6</sup>, G. Seara<sup>3</sup>

<sup>1</sup> Hospital Clínico San Carlos, institute of psychiatry, Madrid, Spain;

<sup>2</sup> Hospital Clínico San Carlos, institute of research, Madrid, Spain;

<sup>3</sup> Hospital Clínico San Carlos, institute of research, innovation unit, Madrid, Spain;

<sup>4</sup> Hospital Universitario 12 de Octubre, department of psychiatry, Madrid, Spain;

<sup>5</sup> Hospital Universitario Gregorio Marañón, department of child and adolescents psychiatry, Madrid, Spain;

<sup>6</sup> Hospital Universitario Gregorio Marañón, department of psychiatry, Madrid, Spain

\* Corresponding author.

**Background.**– Adolescence is a critical period in the detection and treatment of many psychiatric disorders. Recent research suggests that a proportion close to 50% of patients experience a poor transition from child and adolescent mental health services (CAMHS) to adult services (AMHS).

**Objective.**– To study the transition process from CAMHS to AMHS and to identify and characterize patients who dropout from treatment around transition age.

**Methods.**– Retrospective study of a cohort of individuals who reached age of 18 (or over) in a 12-month period and received treatment at CAMHS in 3 General Hospitals in Madrid (Spain) without a medical discharge. Subjects were studied two years before transition and until 6 months after having received care at AMHS. Variables: socio-demographic, clinical and related to transition process. Three groups of subjects were analyzed: Group 1: patients who dropped-out CAMHS just before transition without a medical discharge, Group 2: patients who were transferred to AMHS but did not attend the first visit and Group 3: patients who were transferred and attended their first visit at AMHS.

**Results.**– Sample: 234 subjects. Group 1:  $n = 138$  (59%), Group 2:  $n = 26$  (11,1%) and Group 3:  $n = 70$  (29,9%). No significant differences in socio-demographic variables were found between groups. Emotional disorders and emerging personality disorders had the greater proportion of drop-outs before transition, Eating and neurodevelopmental disorders and patients receiving pharmacological treatment have less proportion of drop-out.

**Conclusions.**– Drop-out of care before transition is a crucial issue to bear in mind to improve youth people mental health care.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– Pediatric chronic pain can lead to serious consequences in terms of daily functioning (school absenteeism and loss of social interactions) and global quality of life. Mindfulness-based interventions (MBI's) approaches have shown efficacy in treating adults with chronic pain, but their effectiveness in pediatric population is still poorly understood (Ruskin et al., 2015).

**Objectives.**– To study the feasibility of a group MBI for adolescents (MBI-A) with chronic pain and its initial effectiveness in terms of pain reduction, chronic pain acceptance, activity limitation, quality of life, anxiety and depression levels' reduction.

**Methods.**– A prospective pre-/post-interventional study is currently being conducted in adolescents aged 12–18 years old, followed in Toulouse Pediatric Hospital. 20 adolescents have been included, across 2 groups of 8 weeks. Treatment acceptability is assessed through participation in group activities, compliance with the home practice and global level of satisfaction (Ruskin et al., 2017). Different scales are used to assess level of pain (Visual Analog Scale), activity limitation (Functional Disability Index), quality of life (Perceived Experience and Health for Adolescent 12), pain acceptance (Chronic Pain Acceptance Questionnaire for Adolescent) and anxiety and depression (Revised Children's Anxiety and Depression Scale).

**Results.**– Based on group therapists' first clinical impressions, feasibility and acceptability appear to be good. Treatment's acceptability and its initial effectiveness will be assessed at the end of the first MBI-A group.

**Conclusions.**– MBI-A group therapy could constitute a promising new therapeutic approach for adolescent with chronic pain, not expensive, easy to implement and well-accepted by adolescents and their parents.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>5</sup> Geneva university hospitals & university of Geneva, division of clinical pharmacology and toxicology, multidisciplinary pain centre, Geneva, Switzerland

\* Corresponding author.

**Purpose.**– To examine the associations between the physical component summary score of SF-36, pain intensity measured by Visual Analogue Scales (VAS), Pain Drawing characteristics (PD), Pain Words (PW), psychological and sociodemographic variables.

**Methods.**– Cross-sectional study design with chronic pain patients referred to the Geneva University Hospital Pain Center (2013–2015). Self-administered questionnaires included SF-36 (Physical Component Summary-PCS, Mental Component Summary-MCS), McGill Pain Questionnaire, VAS, Hospital Anxiety and Depression Scale, sociodemographic. The number of PD (lines, arrows and crosses) was summed as an indicator of the patient's depiction of the extent of pain.

Full data were available for 82.8% ( $n=236/285$ ); 63% women, 65%  $\leq 10$  years of education; 51% with French as their mother-tongue. Mean pain duration: 8 years  $SD \pm 11$ ; 34% had mixed (nociceptive and neuropathic) pain, 26% nociceptive pain, 14% chronic pain syndromes, 13% facial pain, and the rest neurogenic pain.

**Results.**– Sociodemographic variables (gender, age, education level, and living conditions) and pain duration were not related to PCS levels. PCS was negatively correlated with PD ( $r = -.238$ ,  $P = 0.000$ ), PW ( $r = -.315$ ,  $P = 0.000$ ), HADS anxiety and depression ( $r = -.238$ ,  $P = 0.000$ ;  $r = -.601$ ,  $P = 0.000$ , respectively), and VAS ( $r = -.458$ ,  $P = 0.000$ ). PCS and MCS were strongly correlated ( $r = .80$ ;  $P = 0.000$ ). Our final model explained 47.9% of the variance in PCS with those using more PD ( $P = .0000$ ) higher VAS ( $P = .0000$ ) and expressing higher level of depression ( $P = .000$ ) displaying lower PCS scores.

**Conclusions.**– By using numeric, semantic, and graphic facets of pain appraisal we assessed the effects of linguistic and symbolic ways patients used to define their suffering and their ability to function.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparing stigma towards alcohol abuse from healthcare workers with the general population

K.C. Soh\*, W.S. Lim, K.M. Cheang, K.L. Chan

Khoo Teck Puat Hospital, Singapore,

department of psychological medicine, Singapore, Singapore

\* Corresponding author.

**Introduction.**– In the domain of alcohol use disorders, stigma poses an “invisible” barrier in the way of efforts by individuals and their families to reach out for help. During 2014–2015, Singapore had conducted a multi-ethnic, cross-sectional study on mental health literacy at the population level, which revealed that alcohol abuse was perceived as a form of weakness rather than an actual illness. No corresponding data is currently available about the corresponding attitudes of hospital-based healthcare workers.

**Objectives.**– This study looks to examine a segment of hospital-based healthcare workers' attitudes towards patients with alcohol abuse, in comparison to the population's perspective. The authors hypothesized that coming from a more empathic and understanding role, healthcare workers would demonstrate less stigmatizing beliefs towards this group of patients.

**Methods.**– Doctors and inpatient nurses were administered the Depression Stigma Scale and Social Distance Scale. The questions for both scales were appropriately modified to suit the context for person(s) with alcohol abuse. The scales were administered via electronic forms or hard-copy questionnaires.

**Results.**– Data collection remains ongoing, but preliminary results appear to suggest that healthcare workers may actually have stronger negative attitudes towards alcohol abuse than the general population. Those with experiences of alcohol abuse, either

firsthand or by means of a family/friend, appeared to have less stigmatizing responses.

**Conclusion.**– Compared to the public, healthcare workers have different experiences in clinical encounters with patients suffering from alcohol abuse; this may adversely shape their attitudes towards this group. It remains to be seen how this ultimately translates to clinical care and patient outcomes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Laser activated analgesic effects of opioid receptor agonists in integrated algorithms of modern addictology

I. Sosin\*, Y. Chuev, O. Goncharova

Kharkiv medical academy of postgraduate education,

department of narcology, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**– Nowadays, minimization of daily dosages for opioid receptor agonists in treatment programs of opioid dependent patients is an important issue of modern addictology.

**Objectives.**– To study the features of integrated application of intravascular laser therapy (ILT) technique targeted to reduce Tramadol therapeutic load for pain syndrome (PS) management at opioid dependence (OD).

**Methods.**– Laser therapy unit (LTU), disposable optic polymer-polymer probes, disposable needles were used. Needle was injected into cubital vein by transdermal puncture, disposable probe was inserted at 3–5 mm intravascular depth into the lumen of the needle. Disposable probe was connected to the LTU: red spectrum range, 0.63  $\mu\text{m}$  wavelength, 1.5 mW capacity, exposure duration of 30–40 minutes, 6-treatment course, 1 treatment daily. “Visual analogue scale” pre- and post-treatment clinical psychopathological monitoring and screening of pain disorders were performed.

**Results.**– 28 opioid dependent patients with marked PS were examined. 16 patients were referred to main group (MG), treated by ILT against the background of 100 mg intramuscular Tramadol, twice per 24 hours, 60-day course (Patent of Ukraine 14322). 13 patients were included to observation group (OG), treated conforming to addictology conventional therapeutic standards with 100 mg intramuscular Tramadol, thrice per 24 hours, 6-day course. Average results of analgesic effects: pretreatment MG –  $8.10 \pm 0.32$  point, OG –  $8.20 \pm 0.41$  point; posttreatment: MG –  $3.40 \pm 0.32$  point, OG:  $4.90 \pm 0.29$  point, differences between groups and with the first testing examination are valid ( $P < 0.05$ ).

**Conclusions.**– The work discussed mechanisms of laser activation and potentiation of Tramadol analgesic effects at OD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Causes of death in Japanese schizophrenia patients

A. Takeda\*, S. Furukawa, M. Takasou, M. Hitosugi

Shiga university of medical science, legal medicine, Otsu, Japan

\* Corresponding author.

**Introduction.**– Schizophrenia is a chronic and one of the most severe mental disorders. From many years studies regarding mortality among people suffering from schizophrenia are being conducted as a way of controlling indirectly the effectiveness of medical care and therapy.

**Objectives.**– Neuroscientists have been trying to identify risk factors for sudden death in individuals with schizophrenia, but the knowledge is still limited. This study examined all-cause and suicide mortality rates diagnosed with schizophrenia.

**Methods.**– Patients aged more than 17 years at Osaka examiner office during the period of January 2014 to December 2016 were included in the study. The history of schizophrenia was confirmed from other hospital's records through our clinical history sheets.

**Results.**– Primary profiling of 401 patients revealed that 246 were males and 155 were females. Mean age distribution was 56.1 years in male and 58.5 in female. Causes of death among people with schizophrenia were analyzed. Common causes of death due to disease included heart disease 125, pneumonia 17, cerebral hemorrhage, liver cirrhosis, and malignant cancer 8 each. The number of suicide death was 122. The way of suicide was jumping (61 cases), hanging (34 cases) and others (27 case).

**Conclusion.**– We could not decide the suicide in 42 cases. We showed statistic investments about causes of death in schizophrenia patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Comorbidity of mental and physical illness in middle age: Impact on service utilisation**

C.S. Wong<sup>1\*</sup>, W.C. Chan<sup>1</sup>, E.Y. Chen<sup>1</sup>, L.C. Lam<sup>2</sup>

<sup>1</sup> The University of Hong Kong, department of psychiatry, Hong Kong, Hong Kong S.A.R.; <sup>2</sup> The Chinese university of Hong Kong, department of psychiatry, Hong Kong, Hong Kong S.A.R.

\* Corresponding author.

**Introduction and objectives.**– Comorbidity of mental and physical illness is prevalent among middle-aged adults. It is of public health importance to understand the impact of comorbidity on the use of mental health services. The aim of this study was to examine the prevalence of mental-physical comorbidity in middle age, and its association with mental health service utilisation.

**Methods.**– Data were extracted from the Hong Kong Mental Morbidity Survey. A total of 3075 community-dwelling Chinese adults aged 40–64 years were interviewed from November 2010 to May 2013. Psychiatric diagnoses of common mental disorder (CMD) were established using the Revised Clinical Review Schedule, and the severity of physical illness was assessed by the Cumulative Illness Rating Scale. Participants were asked to report whether they had used any mental health services in the past year and lifetime.

**Results.**– After adjusting for other confounders, participants with CMD were associated with a higher risk of any chronic physical illness (OR = 1.93, 95% CI 1.08–3.43), in particular neurological, cardiac, musculoskeletal, genitourinary and upper gastrointestinal conditions (OR = 2.31 to 4.13). Comorbid mental and physical illnesses increased the likelihood of mental health service use both in the past year (OR = 2.06, 95% CI 1.01–4.29) and in lifetime (OR = 2.45, 95% CI 1.44–4.18). Participants with comorbid conditions were more likely to seek help from psychiatrists but not from general practitioners.

**Conclusions.**– CMD in midlife that is comorbid with physical health conditions increased the mental health service utilisation. The results emphasise the need for integrated general medical and mental healthcare in this population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The behavioural consequences of chronic mild unpredictable stress measured in animal models**

G. Biala<sup>\*</sup>, K. Pekala, K. Sabara, B. Budzynska

Medical university of Lublin, department of pharmacology and pharmacodynamics, Lublin, Poland

\* Corresponding author.

**Objective.**– Stress is related to neurobiological disturbances, and can be described as a state of an organism characterized by an increase in emotional tension caused by threatening factors. Among animal models, the chronic unpredictable mild stress (CUMS) model is the most frequently used and considered one of the most perfect models of depression and stress-related disorders. Our experiments aimed to evaluate the behavioral changes in mice and rats submitted to the CUMS procedure, especially anhedonia-related, cognitive and rewarding effects.

**Method.**– Male Swiss mice and Wistar rats were submitted to the procedure of CUMS for 4 weeks, 2 hours per day, after which the behavioural tests were performed.

**Results.**– CUMS-exposed mice exhibited anxiety disorders in the elevated plus maze (EPM) test, the disturbances in memory in the passive avoidance (PA) test and depressive effects in the forced swim test (FST). In rats, only CUMS-exposed animals exhibited the conditioned place preference (CPP) after only 2 days of conditioning with nicotine indicating that stressed rats were more sensitive to the rewarding properties of nicotine, i.e., chronic stress exacerbates nicotine preference. An acute mild stress also provoked the reinstatement of the nicotine CPP after extinction.

**Conclusion.**– The results suggest that recent exposure to a stressor may induce anhedonia-related disorders in rodents, such as depression- and anxiety-like behavior and memory disturbances as well as it may augment the rewarding conditioned effects of nicotine. Our study contributes to the understanding of behavioral mechanisms involved in stress-induced disorders in animal models. (Statutory Activity of the MU of Lublin no. 23).

<sup>6</sup> Danish research institute of translational neuroscience, Aarhus university, department of biomedicine, Aarhus, Denmark

\* Corresponding author.

**Introduction.**– The amygdala (AMY), hippocampus (HPC), and prefrontal cortex (PFC) process emotional information, and their dysfunction may result in anxiety disorders. Neuronal oscillations play a critical role in coordinating brain activities. In particular,

theta-band (4–12 Hz) oscillations have been suggested to support emotional memory formation, consolidation and retrieval. GABAergic interneurons (IN) powerfully coordinate oscillatory activities of neural ensembles. A variety of IN with distinct structures and neurochemical profiles can fulfill distinct roles. How distinct IN classes control neural activities in limbic systems and PFC during emotional information processing remains largely unknown.

**Objectives.**– To define roles of AMY, and PFC IN, and their interactions with the HPC in emotional memory processing.

**Methods.**– We used a combination of behavioral (fear conditioning), electrophysiological (extracellular and juxtacellular recordings), optogenetic and histological techniques in rodent animal models.

**Results.**– Parvalbumin (PV)-expressing, perisomatic-targeting IN within AMY and PFC, including basket and axo-axonic cells, were found to control fear memory formation and retrieval through integration of sensory stimuli and coordination of at least two distinct theta-band oscillations. Moreover, online closed-loop optogenetic control of PV IN in PFC on the basis of local field potential oscillations was sufficient to significantly reduce fear expression in mice. **Conclusions.**– PV-expressing IN play major roles in encoding and expressing emotional memories through the coordination of neural ensembles. Studies are required to clarify the respective contributions of PV axo-axonic and basket IN in synchronizing PFC and AMY activities. Future work could open new perspectives by investigating pathological brain oscillations, leading to potential therapeutic applications for anxiety disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Deletion of nuclear xenobiotic receptors Pxr and Car modifies recognition memory and electroencephalographic activity

B. Boussadia<sup>1\*</sup>, L. Laïla<sup>2</sup>, G. Giuseppe<sup>3</sup>, P. Jean-Marc<sup>4</sup>, M. Nicola<sup>1</sup>

<sup>1</sup> Institut de génomique fonctionnelle, université de Montpellier, neuroscience, Montpellier, France; <sup>2</sup> INRA Toxalim, toxicologie intégrative & métabolisme, Toulouse, France; <sup>3</sup> Université Paris Diderot, unité de biologie fonctionnelle et adaptative, Paris, France; <sup>4</sup> Institut de génomique fonctionnelle, université de Montpellier, cancer biology, Montpellier, France

\* Corresponding author.

Nuclear Xenobiotic Receptors (NXR) are a group of transcription factors emerging as players in normal and pathological CNS development. Clinically the association between NXR and cognitive impairment was postulated. While a number of NXR has been studied, it is unknown whether invalidation of the Pregnane Xenobiotic Receptor (PXR, NR1I2) and the Constitutive Androstane Receptor (CAR, NR1I3) correspond to neurological modifications in the adult brain. We have tested the hypothesis that the impact of PXR or CAR on neurophysiology and behavior is underlined by neurovascular modifications.

PXR<sup>-/-</sup>, CAR<sup>-/-</sup> and wild-type mice were used to investigate: (i) recognition memory, motor coordination, and anxiety-like behaviors; (ii) longitudinal video-electroencephalographic (EEG) recordings and frequency wave analysis; (iii) neurovascular structures by histological evaluation and expression of the cerebrovascular tight junctions ZO1 and CLDN5.

PXR<sup>-/-</sup> and CAR<sup>-/-</sup> mice were associated with anxiety-like behavior and recognition memory impairment in adulthood. Concomitantly to memory deficits, EEG monitoring revealed a decrease in 3.5–7 Hz waves during the awake/exploration and sleep periods. Neurophysiological changes did not correspond to significant structural changes in PXR<sup>-/-</sup> adult brain, except for a localized and minor increase in the fronto-parietal neurovascular density. PXR<sup>-/-</sup> and CAR<sup>-/-</sup> show reduced ZO1 expression in isolated brain capillaries. Our results indicate that behavioral and electroencephalographic changes in adult PXR<sup>-/-</sup> and CAR<sup>-/-</sup> mice are concomitant to discrete developmental or structural brain defects. The possibility that interfering with NXR during developmental stages could contribute to adulthood brain abnormal physiology is proposed. The latter may constitute a pathophysiological entry point or a molecular target for brain diseases.

### University students with overweight and obesity would yield lower than their peers in executive functions

K. Cabas-Hoyos<sup>1\*</sup>, Y. Gonzalez-Bracamonte<sup>2</sup>, S. Mendoza<sup>2</sup>

<sup>1</sup> Universidad del Magdalena, Facultad de Salud, Programa de Psicología. Grupo de Investigación Cognición y Educación., Santa Marta, Colombia; <sup>2</sup> Universidad Pontificia Bolivariana, Sede Montería, Facultad de Psicología. Grupo de Investigación CAVIDA, Montería, Colombia

\* Corresponding author.

**Introduction.**– A relationship between obesity and executive functions has been found. It has been pointed out that at a higher Body Mass Index, there are difficulties in changing focus, alternation and sustained attention (Gunstad, Paul, Cohen, Tate, Spitznagel & Gordon, 2007; Boeka & Lokken, 2008; Cserjési, Luminet, Poncet & Lénárd, 2009). It was also evidenced with the WCST (Wisconsin Card Sorting Test) that obese patients showed more persevering errors than their controls (Volkow & Wise, 2005; Boeka & Lokken, 2008). The objective of this research was to evaluate the executive functioning in a group of university students with normal weight, overweight and type I obesity.

**Method.**– Participated 45 university students distributed in three groups previously formed. The weight and height of the subjects were recorded using a conventional scale. The Body Mass Index (BMI) was calculated and transformed into percentiles using the World Health Organization growth charts. A frontal neuropsychological battery was administered. An ANOVA was used to compare intergroup performance.

**Results and discussion.**– An ANOVA analysis showed significant differences in TMT-B run times in obese adolescents. Overweight individuals had a lower performance on the subtest of “inverse digits”, “similarities” and “letters and numbers” reaching statistical differences between the three groups. There were no significant differences in the other components. Both overweight and obesity are considered problems of food deregulation in which patients report difficulties in controlling the intake, quantity and quality of what they eat, which would lead us to propose a design profile.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Longitudinal changes of fMRI connectivity in OCD patients undergoing cognitive-behavioral therapy

C. Tezenas du Montcel<sup>1,2\*</sup>, M. Morgièvre<sup>1,2,3</sup>, L. Mallet<sup>1,2,3</sup>, K. N'Diaye<sup>1,2,3</sup>

<sup>1</sup> Institut du Cerveau et de la Moelle épinière, université Pierre-et-Marie-Curie UPMC, Inserm U1127, CNRS UMR 7225, CHU Pitié-Salpêtrière, Paris, France, behaviour, emotion and Basal Ganglia, Paris, France; <sup>2</sup> Henri-Mondor–Albert-Chenevier hospital, psychiatry department, Créteil, France, psychiatry, Créteil, France;

<sup>3</sup> Albert-Chenevier hospital, FondaMental foundation, Créteil, France, psychiatry, Créteil, France

\* Corresponding author.

Along with pharmacological, cognitive behavioral therapy (CBT) is a first line treatment for Obsessive compulsive disorder (OCD). However, its neuro-psychological mechanisms remain poorly known despite evidence that event-related functional MRI (fMRI) responses to symptom provocation evolve through the course of psychotherapy while resting-state fMRI (rs-fMRI) reveals task-independent functional networks whose connectivity may be altered in OCD.

The current study compares the evolution of functional connectivity alterations measured in  $n=35$  patients (5 excluded) suffering from moderate OCD (Yale-Brown Obsessive and Compulsive Scale: YBOCS > 16) with resting-state fMRI (10-min, 200 EPI whole-brain volumes, 3T Trio) as they follow a 12-weeks CBT program: immediately before, halfway through, at the end, as well as 6 months after. rs-fMRI was processed using the SPM and the CONN toolbox to extract networks related to a priori seed-regions based on the activations observed in these patients in response to symptom provocation and in the so-called default-mode network (DMN). Parametric ANOVA are being conducted to compare functional connectivity across time within patients and in relation to clinical scores.

Preliminary analyses of rs-fMRI suggest a correlation between DMN hyperactivity and Y-BOCS score and decrease of functional connectivity within DMN regions after following CBT, in correlation with decrease of OCD symptoms (YBOCS scores reduced by 46% as reported in). Further analysis will assess the dynamics of changes in functional connectivity abnormalities associated with psychotherapeutic interventions. These changes, if confirmed, could lead to potential neuromarkers of response to CBT as well as possible response predictors across patients.

### Supporting social workers in promoting adaptive skills in persons with intellectual disabilities in a daily centre in Serbia: A case study in a psychosocial perspective

F. Draghelli<sup>1\*</sup>, V. Langher<sup>1</sup>, G. Martino<sup>2</sup>, V. Nannini<sup>1</sup>, G. Scurci<sup>3</sup>

<sup>1</sup> Sapienza university of Rome, department of dynamic and clinical psychology, Rome, Italy; <sup>2</sup> Messina university, department of cognitive-psychological-pedagogical sciences and cultural studies, Messina, Italy; <sup>3</sup> Psy+ Onlus, department of dynamic and clinical psychology, Rome, Italy

\* Corresponding author.

*Introduction.*– The present contribution is part of a collaboration between an Italian association of psychologists and a daily centre

in Belgrade that teaches job skills to its 10 guests with intellectual disability to help them become active participants in society and be responsible for their own life.

*Objective.*– Elaborating qualitative evaluations of the 10 subjects attending the centre, for helping it to face an impasse situation in the working process and answer to their growing needs.

*Methods.*– Direct observation of subjects and Vineland Adaptive Behavior Scale-II (Survey Form), given to social workers and to guests' families, were used for investigating communicative, social and daily skills.

*Results.*– An overview of limits and strengths of each guest was outlined. 5 subjects showed a higher functioning in Communication, 3 in Socialization and 2 in Daily skills. We observed different competences according to the context and people with whom they have significant relationships (parents, personal assistants), especially in "Community" area (Daily abilities). Families had more information about "Writing" (Communication) and "Personal" (Daily abilities) areas, while workers showed in general better considerations or more information as regards Socialization. Some of the respondents (both from families and daily centre) weren't able to answer some items of Communication and Daily Abilities Scales, meaning that they were not aware of potential resources present in the subjects observed.

*Conclusions.*– Apart from exploring the functioning and potentials of the subjects, discussion of results enhanced the possibility of reflecting on workers' and relatives' representations of them and on the close interdependence between the individuals and their contexts. A bio-psycho-social model that goes beyond diagnosis and considers more variables in a development perspective could be useful in present and future projects and actions, that started to be defined.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Intellectual disability and psychopathology: Analysis of cognitive functioning in a psychiatric sample

D. Galletta\*, F. Micanti, A.I. Califano

University of Naples Federico II, neuroscience, Naples, Italy

\* Corresponding author.

*Introduction.*– Intellectual disability is the impairment of global mental abilities, which affects an individual's functioning in everyday life. According to DSM-5, ID has an impact on 3 broad domains in a person's life: conceptual, social and practical. Individuals with intellectual disabilities are more vulnerable to developing psychiatric disorders, such as the scientific literature highlighted several times.

*Objectives.*– Analyze the intellectual-specific functioning of a psychiatric sample with intellectual disability, highlighting its prevalence of psychopathology, cognitive deficits and gender differences.

*Methods.*– 125 subjects with intellectual disability were extrapolated from a wider psychiatric sample of 450 subjects assessed in the psychiatric clinic from 2004 to 2014. Tool used to assess cognitive functioning is the WAIS-R.

*Results.*– Within the sample, psychopathologies are distributed as follows: 51.2% consists of psychosis (22M, 42F), 22.4% consists of intellectual disability on an organic basis (17M, 11F), 8% consists of autistic spectrum disorder (10M), 8% consists of bipolar disorder (7F, 3M), 4.8% consists of borderline personality disorders (5F, 1M), 3.2% consists of schizoid personality disorder (4M), 0.8% consists of narcissistic personality disorder (1M), 0.8% consists of antiso-

cial personality disorder (1M), 0.8% consists of depressive disorder (1F). Analyzing the deficits in the various cognitive domains, it is observed within the psychoses a greater impairment of visual-spatial abilities, as well as in depressive disorders and schizoid and narcissistic personality disorders. Theoretical-abstract abilities are more impaired in borderline and anti-social personality disorders, as well as in bipolar disorders.

*Conclusions.*– Within intellectual disabilities psychoses have a higher weight as literature underlines. Each psychopathology seems to have its own cognitive functioning also in relation to gender. Future research should commit itself to achieving a more precise phenotyping of the sample.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Reduction of aggressive behavior in people with an intellectual disability by supplementation of vitamins, minerals and n-3 fatty acids**

D. Gast<sup>1</sup>, E. Giltay<sup>1</sup>, R. Didden<sup>2</sup>, O. van de Rest<sup>3</sup>

<sup>1</sup> Leiden university medical center, psychiatry, Leiden, The Netherlands; <sup>2</sup> Radboud university, psychology, Nijmegen, The Netherlands; <sup>3</sup> WUR, human nutrition, Wageningen, The Netherlands

\* Corresponding author.

*Background.*– The prevalence of aggression among people with an intellectual disability is high. Previous studies have demonstrated the potentials of multivitamin-, mineral-, and n-3 fatty acids (n-3FA) supplementation to reduce antisocial behavior and aggression among schoolchildren and prisoners.

*Objective.*– To test the hypothesis that multivitamin-, mineral-, and n-3 FA supplementation reduces aggression among adolescents and young adults with an intellectual disability.

*Study design.*– Pragmatic, randomised, double blind, placebo controlled, multicentre intervention study.

*Study population.*– People with an intellectual disability aged between 11–40 years, living at a care or treatment facility or having day care, who have shown aggressive behaviour. Two hundred participants will be recruited. The ratio placebo/supplement is 1:1. *Intervention.*– During 16 weeks, people in the active condition receive 4 supplements daily: 2 Bonusan Multi Vital Forte Actief (Multi vitamin and mineral) and 2 Bonusan Omega-3 Forte (n-3 fatty acids), while people in the placebo condition receive 4 placebo capsules.

*Main study parameters/endpoints.*– The main study parameter is the number of aggressive incidents from baseline to endpoint (16 weeks post baseline), as measured using the Dutch version of the Modified Overt Aggression Scale (MOAS).

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0421

### **New technical solutions in the training of various skills and in improving integration in the real world of patients with intellectual disability and developmental disorders**

K. Krysta

Medical university of Silesia, department of rehabilitation psychotherapy, Katowice, Poland

\* Corresponding author.

*Background.* Intellectual disability is a disorder with the onset during the developmental period that includes both intellectual and adaptive functioning deficits in conceptual, social and practical domains. Developmental disorders is a group of disorders, which embrace cognitive, communication, social and motor impairments, which appear in the developmental period. Treatment and rehabilitation of people with intellectual and developmental disabilities is a multidisciplinary challenge, which require implementing new attitudes. The use of modern technology solutions like telepsychiatry or virtual reality may be a valuable addition to the traditional methods.

*Objective.*– The objective of this review was to explore the usability of new technological solutions in this special population of patients.

*Methods.*– The search in the PubMed was conducted using the following terms: (intellectual disability, developmental disability, learning disorder, virtual reality, telepsychiatry, telemedicine, e-mental health).

*Results.*– Telepsychiatry may be a useful tool in situations, when the direct access to professional assistance is limited, in solving particular problems like e.g. managing challenging behavior, also to support patients' parents and for diagnostic and educational purposes. Virtual reality can be a safe and effective method of improving different skills, developing physical fitness, and enriching the ways of spending the leisure time.

*Conclusions.*– Using modern technology is a relatively new and promising field in which new ideas may develop to support the already existing services for patients with intellectual and developmental disabilities.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **“Pop-out” effect findings in premature and normative children**

O. Lvova<sup>1</sup>, K. Kunnikova<sup>2</sup>, A. Kotyusov<sup>2</sup>, N. Pavlova<sup>1</sup>

<sup>1</sup> Ural federal university named after the first President of Russia B.N. Yeltsin, laboratory of brain and neurocognitive development, Yekaterinburg, Russia; <sup>2</sup> Ural federal university named after the first President of Russia B.N. Yeltsin, clinical psychology and psychophysiology department, Yekaterinburg, Russia

\* Corresponding author.

*Introduction.*– The “pop-out” effect refers to faster search for a unique target among the distractors and considered to be the significant index of visual perception in children allows obtaining the data on the general mechanisms of the visual functions in the early stages of development.

The aim of the study was to find the features of visual search in normal and premature children.

*Methods.*– Case-control study. The experimental group: 12 preterm infants (8 males, 4 females) 12.18 ± 3.30 months old (corrected age), gestation age 30–35 weeks. Controls: 21 full-term infants (14 males, 7 females) 12.68 ± 2.69 months old. Eye-tracker SMI RED500 with contactless remotely controlled by the infrared camera was used for eye-movements detecting. There were two types of tasks: 8 images with complicated stimuli (social tasks, the stimuli were identical to those used by Elsabbagh et al., 2012) and 16 images with textones (non-social tasks, 8 “+” and 8 “O”; identical to those used by Gliga et al., 2015).

*Results.*– The proportion of first sight at the social stimuli was much higher in both groups than first sight at the textones “O” and “+” ( $P=0.000$ ,  $d=1.097$ ;  $P=0.000$ ,  $d=1.478$  in full-term group respectively;  $P=0.000$ ,  $d=1.38$ ;  $P=0.000$ ,  $d=1.55$  in preterm group respectively). Saccade latency was lower in social tasks in the control group ( $P=0.035$ ,  $d=0.638$ ).

**Conclusion.**– the performance of visual search was higher in social context compared with non-social. No difference in the “pop-out” effect in both groups has been found.

**Disclosure of interest.**– This work was supported by grant Russian Science Foundation Russian Science Foundation 16-18-10371.

### Correlations between diffusion parameters and neurometabolic status in the left frontal lobe in UHR subjects

P. Menshchikov<sup>1\*</sup>, I. Lebedeva<sup>2</sup>, T. Akhadov<sup>1</sup>, N. Semenova<sup>1</sup>, M. Ublinskiy<sup>1</sup>, A. Manzhurtsev<sup>1</sup>, A. Tomyshev<sup>2</sup>, V. Kaleda<sup>2</sup>, M. Omelchenko<sup>2</sup>

<sup>1</sup> Scientific research institute of urgent children's surgery and trauma, radiology, Moscow, Russia; <sup>2</sup> Mental health research center of Russian academy of medical sciences, laboratory of neuroimaging and multimodal analysis, Moscow, Russia

\* Corresponding author.

Some previous findings that revealed loss of grey matter, and reduced numbers of synaptic structures could indicate participation of neurotransmitters in pathogenesis of schizophrenia. Also, abnormalities in diffusion parameters of anterior thalamic radiation (ATR) were previously reported in UHR patients. Main idea of this study was simultaneous measurement of GABA (major inhibitory neurotransmitter) concentration and ATR diffusion parameters in both brain hemispheres.

30 male right-handed patients with UHR (mean age –  $20.4 \pm 2.6$  years) and 27 healthy volunteers (mean age –  $21.1 \pm 2.7$  years) were participated in this study. Research protocol contains (1) Diffusion-weighted MRI images obtained by echo-planar pulse sequence ( $b$ -factors = 800 and  $0 \text{ mm}^2/\text{s}$ ) MR spectra registered with MEGA-PRESS pulse sequence (TE = 68 ms, TR = 2000 ms) from left (Lfl) and right frontal lobes (Fig. 1).

This study revealed significant intergroup differences in: (1) GABA/Cr ratios in Lfl ( $0.137 \pm 0.041$  for patients vs  $0.191 \pm 0.046$  for controls,  $P < 0.01$ ); fraction anisotropy ( $0.420 \pm 0.018$  vs  $0.435 \pm 0.026$ ;  $P = 0.016$ ) and mean diffusivity ( $0.757 \pm 0.015 \times 10^{-3} \text{ mm}^2/\text{s}$  vs.  $0.746 \pm 0.024 \times 10^{-3} \text{ mm}^2/\text{s}$ ;  $P = 0.019$ ) of ATR of the left hemisphere. GABA/Cr ratios were correlated with Axial diffusion ( $r_s = 0.60$ ;  $P = 0.012$ ) and fractional anisotropy ( $r_s = 0.53$ ;  $P = 0.027$ ) of the left ATR. No changes of diffusion parameters of ATR and GABA/Cr ratios were not found in the right hemisphere. No statistically significant correlations were observed in the control group.

UHR patients demonstrated worse structural organization of the ATR anterior, which appeared to be associated with an abnormal bioelectric activity in the region related to working memory maintenance and with lower concentration of the major inhibitory neurotransmitter.

### Thalamic contribution to pathogenesis of psychiatric disorders: Potential biomarkers for diagnosis and new targets for treatment

A. Pashkov

South Ural state university, biomedical school, Chelyabinsk, Russia

\* Corresponding author.

**Introduction.**– Thalamus as a brain hub plays an important role in human cognition. Modern studies provide convincing data on the violation of information processing at the level of thalamus in schizophrenia, depression, addictions, Parkinson's disease and others.

**Objectives.**– Our aim was threefold: (1) to classify the available data regarding the involvement thalamic nuclei in the pathogenesis of mental disorders; (2) to identify the prospects for studying thalamus on model organisms and humans (taking into account translational neuroscience perspective); (3) to emphasize the main difficulties and advantages of carrying out such studies.

**Methods.**– PubMed, Science Direct and Google Scholar databases from January 2005 to June 2017 were searched for studies, including data on human and animal thalamic lesions, and those ones, concerning the role of thalamus in psychiatric disorders (in comparison with investigation of thalamic structure and mode of its functioning in healthy human controls).

**Results.**– Ninety-two studies met the inclusion criteria. Careful analysis of these papers has shown that lesions of individual groups of thalamus nuclei, as well as their structural and functional changes in psychiatric disorders, manifest themselves in various patterns of clinical symptoms, depending on the loci of their projections to extrathalamic brain structures (both cortical and subcortical), neurotransmitter/ neuropeptide specificity, as well as lateralization of the lesion.

**Conclusions.**– We suggest that such results, presented in form of novel biomarkers and treatment targets, may contribute to developing field of precise and objective diagnostics in psychiatry based on RDoC framework.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Real-world effectiveness of clozapine for mental retardation: Results from a mirror-image and a reverse-mirror-image study

C. Rohde<sup>1\*</sup>, J. Nielsen<sup>2</sup>

<sup>1</sup> Aarhus university hospital 1, department of affective disorders, Aarhus, Denmark; <sup>2</sup> Copenhagen university hospital, mental health centre Glostrup, Copenhagen, Denmark

\* Corresponding author.

**Background.**– The most efficient pharmacological treatment of patients with mental retardation is antipsychotics, but whether clozapine is efficient remains unknown.

**Objective.**– We aimed to investigate the efficacy of clozapine on naturalistic outcomes in patients with mental retardation.

**Methods.**– By using the national health registers, all patients with mental retardation initiating clozapine between 1996–2012 were identified. First, a normal mirror-image model (self-controlled design) were used to investigate whether initiation of clozapine

was associated with reduced psychiatric admissions and inpatient days, reduced number of individuals performing intentional self-harm or overdose, and less use of concomitant psychiatric drugs. Second, a reverse mirror-image model was used to investigate whether termination of clozapine did change the number of psychiatric admissions.

**Results.**– 405 patients with mental retardation redeemed clozapine. After initiation of clozapine the number of psychiatric admission were reduced by 0.65 (95% CI: 0.31–1.00) admissions and the inpatient days were reduced by 67.2 (95% CI: 83.3–164) days. The number of individuals performing intentional self-harm or overdose and using concomitant psychiatric drugs did not change. When terminating clozapine again, the psychiatric admissions were increased by 0.57 (95% CI: 0.01–1.12) admissions.

**Conclusion.**– This study, which is the largest to date, supports that clozapine is associated with a reduction in psychiatric admissions and inpatient days in patients with mental retardation. Further studies evaluating the effect of clozapine in patients with mental retardation is warranted.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Delayed ganglion and bipolar neuroretinal processing in regular cannabis users

T. Schwitzer<sup>1\*</sup>, R. Schwan<sup>1</sup>, K. Angioi-Duprez<sup>2</sup>, A. Giersch<sup>3</sup>, L. Lalanne<sup>4</sup>, E. Albuissou<sup>5</sup>, V. Laprevote<sup>1</sup>

<sup>1</sup> Centre psychothérapique de Nancy, pôle hospitalo-universitaire de psychiatrie d'adultes du Grand Nancy, Laxou, France; <sup>2</sup> CHRU Nancy, département d'ophtalmologie, Nancy, France; <sup>3</sup> Inserm, département de psychiatrie, Strasbourg, France; <sup>4</sup> CHRU Strasbourg, département de psychiatrie, Strasbourg, France; <sup>5</sup> CHRU Nancy, département de statistiques, Nancy, France

\* Corresponding author.

**Introduction.**– Cannabis use is widespread worldwide, but its impact on brain synaptic transmission has been partially elucidated. The retina is considered as an easy means of determining dysfunction in brain synaptic transmission. The endocannabinoid system is involved in regulating retinal synaptic transmission. Previous preliminary results have shown impairments in retinal ganglion cell response in cannabis users. Here, we test the extent to which earlier retinal levels – bipolar cells and photoreceptors – are affected in cannabis users.

**Objectives.**– To verify whether early retinal stages are altered in cannabis users.

**Methods.**– We recorded pattern (PERG) and flash (fERG) ERG in 53 regular cannabis users and 29 healthy controls. Amplitude and implicit time of P50 and N95 (PERG) and of a- and b-waves (fERG) were evaluated.

**Results.**– Cannabis users showed a significant increase in PERG N95 implicit time and in fERG light-adapted 3.0 b-wave implicit time, compared with controls ( $P=0.0001$  and  $P=0.002$ , respectively; Mann-Whitney U test). No significant difference was found between the groups in terms of wave amplitude ( $P=0.525$  and  $P=0.767$  for the N95 and light-adapted 3.0 b-wave amplitude respectively; Mann-Whitney U test).

**Conclusions.**– We demonstrated lagged ganglion and bipolar cell responses in cannabis users. These results reflect a delay in the transmission of visual information from the retina to the brain. This retinal dysfunction may be explained by an effect of cannabis use on retinal synaptic transmission. The consequences of these anomalies on visual perception along with the molecular mech-

anisms underlying this retinal dysfunction should be explored in future studies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Psychotropic medication for challenging behaviour in people with intellectual disability: Results of an online survey of family carers

R. Sheehan<sup>1\*</sup>, K. Kimona<sup>1</sup>, A. Giles<sup>2</sup>, V. Cooper<sup>3</sup>, A. Hassiotis<sup>1</sup>

<sup>1</sup> University College London, division of psychiatry, London, United Kingdom; <sup>2</sup> The Challenging behaviour foundation, project management, Kent, United Kingdom; <sup>3</sup> The challenging behaviour foundation, executive office, Kent, United Kingdom

\* Corresponding author.

**Introduction.**– There is ongoing controversy concerning the appropriate use of psychotropic medication for challenging behaviour in people with intellectual disability. However, there has been relatively little formal investigation of the experiences and views of family carers of people with intellectual disability and challenging behaviour regarding psychotropic medication.

**Objectives.**– To explore the experiences and attitudes of family carers of children and adults with intellectual disability and challenging behaviour with a focus on management and the use of psychotropic medication.

**Methods.**– An internet-mediated survey was devised in conjunction with family carers and disseminated by The Challenging Behaviour Foundation, a UK charity, and publicised on social media. Quantitative and qualitative data were gathered and analysed using descriptive statistics and thematic analysis.

**Results.**– Ninety-nine family carers of people with intellectual disability and various forms of challenging behaviour completed the online survey. The majority (83%) of people with intellectual disability and challenging behaviour had been prescribed psychotropic medication as part of their management, most often antipsychotic drugs. Proactive and holistic elements of care such as physical health checks and a functional behavioural analysis were frequently not completed. Many carers perceived that psychotropic medication had been used too readily and in the absence of psychosocial interventions. Adverse medication side-effects were frequently encountered but family carers felt they lacked information and were powerless in treatment decisions.

**Conclusions.**– The multi-modal management of challenging behaviour in people with intellectual disability can be improved. Preventative and non-pharmacological strategies should be available and efforts made to involve family carers in decision-making.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Neuromorphological features of development of the human cerebral cortex in the conditions of prenatal alcoholization and hypoxia

A. Solonsky<sup>1\*</sup>, A. Kudrenko<sup>2</sup>, S. Logvinov<sup>2</sup>

<sup>1</sup> Mental health research institute, Tomsk national research medical center of RAS, laboratory of psychoneuroimmunology and neurobiology, Tomsk, Russia; <sup>2</sup> Siberian state medical university, department of histology, embryology and cytology, Tomsk, Russia

\* Corresponding author.

**Objectives.**– To ascertain nature of influence of the prenatal use of ethanol and chronic hypoxia on development of the human brain.

**Methods.**– Research material - brains of 26 embryos (7–12 weeks of development) obtained from alcoholic women and 30 children of both sexes who died in antenatal, intra- and postnatal periods within the first 2 months of life from the causes which were not connected with brain pathology. The main disease in children was asphyxia of the fetus and the newborn.

**Results.**– Neuromorphological alterations of cerebral cortex in children under hypoxia were in many respects similar to those at prenatal alcohol intoxication. In children with a delay of prenatal development and normothrophics with the term of gestation 28–37 weeks who died in the antenatal, intranatal periods, in superficial layers of cerebral cortex in the anterior central and posterior central gyri, thickening of cells at each other was noted, there was no differentiation into layers. In the posterior central gyrus of children with term of gestation 38–42 weeks who lived 8 days 2 months, the area of neurons was 2.2 times larger, than in the posterior central gyrus of children with a delay of prenatal development and normothrophics with the term of gestation 28–37 weeks who died in the antenatal and intranatal periods.

**Conclusions.**– On the basis of the studied material of the human brain the similarity of effects of prenatal alcoholization and chronic hypoxia consisting of impairments of formation of micromodules in the cerebral cortex was shown.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Eye vergence responses as an objective tool supporting ADHD diagnosis in adults**

H. Super<sup>1</sup>, J. Cañete<sup>2</sup>, S. Faraone<sup>3</sup>, R.Q. Josep Antoni<sup>4</sup>  
<sup>1</sup> Braingaze, R&D, Mataro, Spain; <sup>2</sup> CSdM, mental health, Mataro, Spain; <sup>3</sup> Suny upstate medical university, psychiatry and of neuroscience and physiology, Syracuse, NY, USA; <sup>4</sup> Hospital Vall d Hebron, mental health, Barcelona, Spain

\* Corresponding author.

**Introduction.**– It has become clear that ADHD is a chronic disease that continues into adulthood. Adult ADHD is associated with a range of clinical and psychosocial impairments and personal and societal problems, which can be prevented or reduced if patients receive timely diagnosis and treatment.

The diagnosis of ADHD is determined based upon a cluster of symptoms. Their expression however is subtle, which makes the diagnosis in adults challenging especially as several other psychiatric disorders show similar symptomology. Objective measures of ADHD symptoms to support the clinical diagnosis are therefore highly desired.

Vergence is the movement of both eyes in opposite direction and has a role in obtaining stable binocular vision. Recent evidence however suggests a novel role of eye vergence in visual attention. Such vergence responses are altered in children suffering ADHD, and vergence may be used as an objective tool supporting child ADHD diagnosis.

**Objectives.**– In this study we aim to investigate vergence as a possible marker for ADHD in adults.

**Methods.**– We assessed the modulation in the angle of vergence in adults ( $n = 88$ ) previously diagnosed with ADHD while performing an attention task and compared the results to age-matched controls ( $n = 42$ ).

**Results.**– Vergence responses were different between ADHD patients and controls. Using machine learning we classified ADHD

patients with an accuracy of  $77 \pm 2\%$ . FPR and FNR were  $26 \pm 1\%$  and  $20 \pm 1\%$ , respectively.

**Conclusions.**– In combination with an attention task vergence responses can be used as an objective marker to support clinical diagnosis of adult ADHD.

**Disclosure of interest.**– HS is co-founder and shareholder of Braingaze.

\* Corresponding author.

**Introduction.**– The latest developments in life science have enabled us to observe organic brain alterations such as inflammation, even in the brains of patients with functional psychoses of unknown organic basis. Among other factors, activation of microglia, a kind of neuroglia, is an important indicator of neuroinflammation. An increase in the number of activated microglia has been reported in the brains of mouse models of stress.

**Methods.**– In this study, we examined activated microglia in human brains from possible depressive patients (DP) who had committed suicide. After blocking, sections were stained with anti-Iba-1 antibody and fluorescent images were acquired with a confocal laser scanning microscope. We then performed a detailed morphological analysis of microglia using 3D reconstruction techniques. Control brains were obtained from subjects who had suddenly died of cardiac disease (CD).

**Results.**– Our study showed that there were some significant morphological differences in the microglia of DP and those who died of CD.

**Discussion.**– This is the first report using 3D reconstruction models of human microglia that suggests neuroinflammation in suicidal patients with possible depression, similar to reports based on animal experiments. Further studies using more appropriate methodology are needed to better understand microglial response in depression.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Topographical reorganization of functional connectivity under alexithymia**

S. Tukaiev<sup>1</sup>, M. Chernykh<sup>2</sup>, I. Zyma<sup>3</sup>, Y. Havrylets<sup>4</sup>, V. Rizun<sup>4</sup>  
<sup>1</sup> National Taras Shevchenko university of Kyiv, department of social communication, department of physiology of brain and psychophysiology, Kiev, Ukraine; <sup>2</sup> National Taras Shevchenko university of Kyiv, department of human and animal physiology, Kiev, Ukraine; <sup>3</sup> National Taras Shevchenko university of Kyiv, department of physiology of brain and psychophysiology, Kiev, Ukraine; <sup>4</sup> National Taras Shevchenko university of Kyiv, department of social communication, Kiev, Ukraine

\* Corresponding author.

The alexithymia construct is characterized by impairment of emotional processing and reduced interaction between different brain areas during various experimental conditions. Yet little known about permanent alteration of functional connectivity associated with alexithymia in resting state. The aim of current study was to investigate the resting state cortical networks of alexithymic personality type. 232 volunteers, first-third year students from the Taras Shevchenko National University of Kyiv aged 18 to 24 years participated in this study. EEG was registered during the rest state (3 min). We estimated the interhemispheric and intrahemispheric average coherence across all EEG segments in all frequencies from 0.2–45 Hz. To determine the level of alexithymia we used 26-item Toronto Alexithymia Scale (TAS-26). Alexithymic personality type was found in 43 volunteers (TAS-26 total score  $\geq 74$ , alexithymia group). A control group consisted 113 subjects with low alexithymia (TAS-26 total score  $\leq 62$ , non-alexithymia group). 85 participants formed intermediate group (TAS-26 total score  $62 >$  and  $< 74$ ). In background EEG activity during the development of the alexithymia variations in EEG spatial synchronization were observed in low- and high-frequency EEG components. Alexithymic personality type includes breaking of interhemispheric anterior frontal-frontal (alpha 1,2-subband) and formation central-temporal links (alpha1-subband) (awareness and cognitive processing of incoming information). We demonstrated left lateralization of intrahemispheric links in alpha3 (occipital-parietal area) and beta (central area) subbands (inner image formation, external attention). Inter and intrahemispheric coherence in low-frequency EEG components (theta2-subband) indicates the influence of alexithymia on attention focusing, working memory, and emotional processes. Topographical reorganization of functional connectivity under alexithymia had specific features reflecting information and emotion-activating processes.

### **Bainbridge-ropers syndrome and epilepsy at older age in a male patient with a novel mutation in ASXL3**

W.M.A. Verhoeven<sup>1</sup>, J. Egger<sup>1</sup>, E. Räkens<sup>2</sup>, A. van Erkelens<sup>3</sup>, R. Pfundt<sup>3</sup>, M. Willemsen<sup>3</sup>

<sup>1</sup> Vincent Van Gogh institute for psychiatry, centre of excellence for neuropsychiatry, Venray, The Netherlands; <sup>2</sup> ASVZ, centre for people with intellectual disabilities, Leerdam/Sledrecht, The Netherlands;

<sup>3</sup> Radboud university medical centre, departement of human genetics, Nijmegen, The Netherlands

\* Corresponding author.

*Introduction.*– A mutation in the *additional sex combs like 3* (*ASXL3*) gene (18q12.1) causes Bainbridge-Ropers syndrome (BRPS) [OMIM:615485]. The phenotype typically includes severe intellectual disability, nearly absent speech and language, hypotonia as well as distinct craniofacial features such as prominent forehead, arched eyebrows, and hypertelorism. Apart from a small number of children and adolescents, no adult BRPS-patients have been described yet. As to behaviour, in addition to aggressive and autistic traits, periodic agitation and sleep disturbances are frequently described. In a minority, tonic-clonic seizures or absences occur in childhood.

*Objectives.*– In order to elucidate the clinical picture of BRPS over time, the phenotype at older age is extensively investigated.

*Methods.*– A male patient with a novel pathogenic heterozygous frameshift mutation in the *ASXL3* gene is described. Somatic, neuropsychiatric, neuropsychological and neurological investigation

was performed, including EEG registration and MRI scanning of the brain.

*Results.*– It concerns a 47-years-old male without any dysmorphisms but with severe intellectual disability and a long lasting history of challenging behaviours best typified by autistic-like repetitive and compulsive behaviours, not responding to psychotropics. In his fourth decade tonic-clonic seizures developed for which treatment with anti-epileptics was given effectively although absences persisted. MRI brain disclosed no abnormalities.

*Conclusion.*– Extensive genetic analysis including whole exome sequencing is mandatory in patients with unexplained developmental delay and intellectual disability, also in adulthood and older age. The latter not only to detect the genetic etiology of syndromic ID, but especially also to further elucidate course and prognosis of newly discovered disorders.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Successful treatment with lithium in an adult patient with phelan-McDermid syndrome caused by a heterozygous truncating mutation in the SHANK3 gene**

J. Egger<sup>1</sup>, W. Verhoeven<sup>1</sup>, R. Groenendijk-Reijenga<sup>2</sup>, S. Kant<sup>3</sup>

<sup>1</sup> Vincent van Gogh institute for psychiatry, centre of excellence for neuropsychiatry, Venray, The Netherlands; <sup>2</sup> Ipse De Bruggen, institute for people with intellectual disabilities, Zwammerdam, The Netherlands; <sup>3</sup> Leiden university medical centre, department of clinical genetics, Leiden, The Netherlands

\* Corresponding author.

*Introduction.*– Phelan-McDermid syndrome (PMS) is caused by loss-of-function of the *SHANK3* gene and is characterized by neonatal hypotonia, developmental delay, impaired speech, sleep disturbances, hyperreactivity to sensory stimuli, and higher risk of developing seizures. Its psychopathological phenotype comprises symptoms from the bipolar spectrum for which treatment with a mood stabilizing anticonvulsant in combination with an atypical antipsychotic is mostly effective. Brain imaging shows specific white matter changes and sometimes hypoplasia of the cerebellar vermis.

*Objectives.*– PMS may be accompanied by language, motor and behavioural regression. Then, psychotropic medications may be ineffective, whereas Lithium therapy seems to have beneficial effects on mood and behaviour.

*Methods.*– A 43-years-old adult male patient with a *SHANK3* mutation, intellectual disability, bipolar-like-symptoms, and regressive features is described. Extensive diagnostic assessments were performed.

*Results.*– A pathogenic heterozygous truncating mutation in the *SHANK3* gene was demonstrated. From adolescence on, marked behavioural instability accompanied by sleep disturbances, severe anxieties and attention deficits became apparent, for which over many years psychotropics were prescribed without, however, any beneficial effect. Because of intermittent aggressive and apathetic episodes and given the patient's history with serious side-effects on psychotropics, Lithium was started. MRI of the brain showed discrete loss of cerebral tissue without abnormalities of cerebellar vermis. Ultimately, Lithium addition (0.5 mmol/l) to existing olanzapine (10 mg) led to enduring stabilization of mood and behaviour.

*Conclusions.*– Pharmacological treatment of first choice in patients with PMS has to be a mood stabilizing agent in combination with a low dose of an atypical antipsychotic and, in case of *SHANK3* mutation, perhaps primarily with Lithium.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0434

### **Does time speed up when thoughts race? The experience of time in adult attention deficit/hyperactivity disorder and bipolar disorder**

L. Weiner\*, A. Giersch, G. Bertschy, S. Weibel

INSERM, 1114, university hospital of Strasbourg, Strasbourg, France

\* Corresponding author.

*Introduction.*– Overestimation of durations has been reported in individuals with Attention-Deficit Hyperactivity Disorder (ADHD), but also in bipolar disorder (BD). Inattention and racing thoughts are symptoms shared between the two disorders, and might be associated with temporal distortions. However, the relation between the speed of thoughts, attention, and working memory impairment, on the one hand, and duration perception, on the other hand, has been underexplored in both groups of patients.

*Method.*– We compared performance of 18 euthymic patients with BD, 17 unmedicated adults with ADHD, and 27 controls on verbal estimation and production tasks and judgment of the passage of time. Participants filled out a self-report measure of racing thoughts, and several neuropsychological tests.

*Results.*– The ADHD group overestimated durations compared to the BD group, although both patient groups showed significant attention and working memory difficulties. The three groups did not differ in their judgment of the passage of time. However, the ADHD group showed elevated racing thoughts relative to the other groups, and these scores were correlated with the judgment of passage of time. In the ADHD group, a relative slowing of the passage of time was associated with racing thoughts, whereas the reverse pattern was observed in healthy controls.

*Conclusion.*– Overestimation of durations in ADHD seems independent from working memory and attention dysfunction. ADHD patients seem to rely on duration estimates, and the rate of internal events, when emitting judgements on the passage of time: the more thoughts race, the slower time seems to pass.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Lithium use in depression resistant to electroconvulsive therapy**

F. Almeida\*, J. Andrade, D. Mota, S. Ferreira

Centro Hospitalar da Universidade de Coimbra, psychiatry, COIMBRA, Portugal

\* Corresponding author.

*Introduction.*– Treatment resistant depression (TRD) remains a significant challenge in clinical practice. Multiples strategies have been proposed for the management of TRD. Electroconvulsive therapy (ECT) seems to be particularly effective in severe TRD. However, unsatisfactory responses are not uncommon and no clear orientations exist for this eventuality.

*Objectives.*– To present a literature review and a clinical case report on the management of depression resistant to ECT.

*Methods.*– Description of a clinical case. Literature search on PubMed with the terms “ECT-resistant depression” OR “ECT-resistant major depressive disorder”.

*Results.*– Lithium was rapidly effective in achieving full remission after unsatisfactory response to ECT, in a case of psychotic depression. The Hamilton Depression Rating Scale (HAM-D), the Bush-Francis Catatonia Rating Scale (BFCRS) and the Montreal Cognitive Assessment (MoCA) were administered. The scores were the following (pre-ECT, post-ECT, discharge): HAM-D (46, 27, 5), BFCRS (15, 1, 1), MoCA (15, 23, 27). To date, there has been no subsequent relapse with maintenance treatment with lithium, venlafaxine and mirtazapine.

We found 3 papers on the management of ECT-resistant depression: 2 small case series from 1988 and 1995, and a more recent case-control study from 2011.

*Conclusions.*– Lithium was effective in achieving a full sustained remission in a case of ECT-resistant depression. Other cases have been reported and there may be a role for ECT in altering subsequent sensitivity to medication. Considering the renewed interest and use of ECT in TRD, further evidence on the use of appropriate specific strategies for ECT-resistance is needed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0436

### **Comparing cortical inhibition in depression and health: A transcranial magnetic stimulation study**

J. Jakhar\*, U. Mehta, B.N. Gangadhar  
NIMHANS, psychiatry, Bengaluru, India

\* Corresponding author.

*Background and aims.*– Inhibitory deficits in depression have been described using neuroimaging studies and animal models. Transcranial Magnetic Stimulation (TMS) provides a unique opportunity to non-invasively determine cortical inhibitory and excitatory interneuron functions in humans in a cost-effective manner. In this study, we aim to examine TMS single- and paired-pulse derived cortical inhibitory functions in patients ( $n=46$ ) with moderate to severe unipolar depression (ICD-10) and a group of healthy comparison subjects ( $n=30$ ).

*Materials and methods.*– After determining the resting motor threshold, twenty recordings were obtained in a random sequence for each of the following cortical inhibition/excitation parameters: test pulse derived motor evoked potential (MEP), short interval intra-cortical inhibition (SICI), long interval intra-cortical inhibition (LICI), intra-cortical facilitation (ICF) and cortical silent period (CSP). Patients were also rated on severity of their depressive symptoms using the Hamilton Depression Rating Scale (HDRS).

*Results.*– The two groups were comparable in terms of sex, resting motor threshold, LICI and ICF. However, there were significant differences on age, CSP and SICI. After controlling for age differences, patients with depression continued to have shorter duration of CSP (ANCOVA:  $F=35.79$ ,  $P<0.001$ ) and reduced SICI ( $F=5.23$ ,  $P=0.025$ ). There were no significant correlations between measures of cortical inhibition and severity of depression (HDRS).

*Conclusions.*– Patients with depression have deficits in both GABA<sub>A</sub> (SICI) and GABA<sub>B</sub> (CSP) mediated neurotransmission as measured using TMS. These cortical inhibitory deficits do not show significant associations with symptom severity and may be studied as trait markers of depression in future studies.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

Catatonia is a neuropsychiatric syndrome characterized by an onset of dysfunction in psychomotor activity and/or muscle tone, which may be associated with changes in consciousness, affect, and thinking. It is characterized by negativism, wax flexibility, catalepsy, mutism, echolalia, ecopraxia, stupor (...). It was first described in 1874 by Kahlbaum, who characterized it as specific motor disorder associated with different psychiatric disorders. Kraepelin and Bleuler restricted catatonia to a specific subtype of schizophrenia. However, the association between catatonia and other disorders, notably mood disorders, has been reinstated, including Bipolar Disorder. Its etiology is multiple and there are two severe forms: Neuroleptic Malignant Syndrome (NMS) and Malignant Catatonia (MC). These are syndromes that present high mortality, and the health professional should be aware of its etiology, signs, symptoms, evaluation and treatment. The aim of this study is to present a clinical case of MC, who was successfully treated by electroconvulsivotherapy. The case report was sustained by literature included on scientific platforms. It is essential to recognize the different clinical presentations of catatonia, taking into account that these are psychiatric alterations in which urgent intervention is justified. In the presented case, the use of antipsychotic medication aggravated the motor function and its suspension, associated with the introduction of lorazepam, resulted in a slight improvement. The electroconvulsivotherapy was the last resort, fully succeeded. The relationship between SMN and Catatonia/CM remains unclear from a psychopathological and pathophysiological point of view. Nevertheless, there is general agreement that catatonia represents a very significant risk factor for NMS.

\* Corresponding author.

*Objective.*– To study action of risperidone in anti-relapse therapy on the parameters of schizophrenic patients' immunity in presence or absence of the medication-induced hyperprolactinemia (MIH).

*Methods.*– 46 schizophrenic inpatients being under maintenance therapy with risperidone for 6 months before hospitalization were divided into two groups: group 1 – patients with MIH ( $n = 36$ ; level of prolactin higher than 25 ng/ml in women and 20 ng/ml in men), group 2 – without MIH ( $n = 10$ ; normal level of prolactin in the

blood). Methods used: PANSS, identification of surface receptors of immunocompetent cells, levels of IgM, IgG, IgA and prolactin' level with immune-enzyme analysis sets; in female part of sample of reproductive age blood sampling in the first phase of the menstrual cycle.

*Results.*– Lower degree of severity of general psychopathological symptoms ( $P = 0.015$ ) and lower total score according to PANSS ( $P = 0.008$ ) in patients of group 1 in comparison with patients of group 2 were noted.

Lower values of CD3<sup>+</sup> CD19<sup>-</sup> ( $P = 0.028$ ), CD3<sup>-</sup> CD19<sup>+</sup> ( $P = 0.014$ ) and CD3<sup>+</sup> CD4<sup>+</sup>-lymphocytes ( $P = 0.048$ ) as well as higher number of HLADR<sup>+</sup> ( $P = 0.049$ ) and CD95-lymphocytes ( $P = 0.058$ ) were found in comparison with patients without MIH.

Higher values of CD3<sup>+</sup> CD4<sup>+</sup>- ( $P = 0.040$ ), HLADR<sup>+</sup>-lymphocytes ( $P = 0.040$ ) and lower IgM ( $P = 0.018$ ) in male patients in comparison with female persons were noted.

*Conclusion.*– Thus, features of risperidone action on the main parameters of the patients' immunity with MIH were revealed. The analysis of PANSS indices in schizophrenic patients under long-term anti-relapse therapy with risperidone demonstrated that in patients with MIH, disease proceeded in a milder, less intensive form.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

Treatment-resistant depressions represent a serious public health problem considered as one of the major issue for early XXI century in psychiatry. Five to 18% of general population will experience a major depressive episode during their lifetime, 20–30% of which will relapse with the subsequent occurrence of multiple recurrences in spite of well-conducted antidepressant treatments. New treatment strategies aiming at achieving significant clinical improvement of patients with such are thus needed. For this purpose, the effectiveness of both invasive (deep brain stimulation, vague nerve stimulation) and non-invasive (repetitive transcranial magnetic stimulation, transcranial direct current stimulation) brain neuromodulation techniques has extensively been investigated for the management of treatment-resistant depression. In this symposium, we propose to make a state-of-the-art review of the clinical research on four brain neuromodulation technics and discuss in the light of recent experimental evidence, the therapeutic effects and tolerability, the use among therapeutic alternatives according to the standard algorithms, and the targeted depressed patient subpopulations. The present symposium will be proposed under the combined sponsorship of the Fondation FondaMental and the French Association of Biological Psychiatry and Neuropsychopharmacology.

### **Psychoneuroimmunomodulating effect of immune cells treated with psychoactive drug in depressive – Like animals**

E. Markova<sup>1\*</sup>, M. Knyazheva<sup>1</sup>, I. Savkin<sup>1</sup>, T. Amstislavskaya<sup>2</sup>

<sup>1</sup> Federal State Budgetary scientific institution “Research Institute of Fundamenta, neuroimmunology laboratory, Novosibirsk, Russia;

<sup>2</sup> Research institute of physiology and fundamental medicine, laboratory of experimental models of neurodegenerative processes, Novosibirsk, Russia

\* Corresponding author.

**Introduction.–** We first demonstrated the possibility of animal's behavior directed regulation by the transplantation of immune cells with definite functional characteristics. It was shown also the ability of immunocytes with in vitro caffeine modulated functional activity to stimulate passive behavior in animals in a dose-dependent manner.

**Objectives.–** We investigated the influence of caffeine modulated immune cells on the functional activity of the immune and nervous systems in depressive-like animals.

**Methods.–** (CBAXC57Bl/6) F1 male mice with depressive-like behavior, developed under long-term social stress, were undergoing the transplantation of immune cells in vitro treated with caffeine. Recipient's behavior, parameters of nervous and immune systems functional activities before and after transplantation were estimated.

**Results.–** It was shown that transplantation of immunocytes with caffeine modulated functional activity caused in depressive-like recipients stimulation of motor and exploratory activities in the “open field”, significant increase in mobility in the forced swimming test and anhedonia reduction. Behavioral changes were registered on the background of neurogenesis stimulation in hippocampus and modulation of regulatory cytokines synthesis in this and other (hypothalamus, striatum, prefrontal cortex) brain regions. In recipient's immune system were identified the splenocytes proliferative activity modulation, stimulation of the immune response, decrease in tryptophan catabolism in the spleen and modulation of cytokines production of its cells.

**Conclusions.–** Results demonstrated that immunocytes treated in vitro with caffeine after the transplantation caused positive psychoneuroimmunomodulating effect in depressive-like recipients by acting on the pathogenetic mechanisms of depression. So, it may be considered as a promising method in the immunotherapy of depression.

### **Repetitive transcranial magnetic stimulation (rTMS) in schizophrenia: Effects on depression, negative symptoms and cognition**

N. Maslenikov<sup>\*</sup>, E. Tsukarzi, S. Mosolov

Moscow research institute of psychiatry, department for treatment of mental disorders, Moscow, Russia

\* Corresponding author.

**Introduction.–** Brain stimulation is promising strategy for augmentation of pharmacotherapy in schizophrenia patients with depression.

**Objectives.–** Estimation of rTMS efficacy for depressive, negative and cognitive symptoms in schizophrenia.

**Methods.–** 66 patients were included in the study in accordance with criteria: schizophrenia (F20, ICD-10), CDSS  $\geq 6$ , PANSS composite index  $< 0$ , effective antipsychotic therapy in stable dose regimen, no antidepressants in 2 weeks prior to inclusion. Patients were randomized in 2 add-on treatment groups: 15-Hz rTMS on the left dorsolateral prefrontal cortex (100% intensity, 6-second trains, 60-second intervals, 20-train session, 5 sessions per week for 3 weeks) in the 1<sup>st</sup> group and antidepressant treatment in the 2<sup>nd</sup> one (active control). Patients were assessed weekly with CDSS, PANSS, cognitive tests. 50% CDSS score reduction after 3 weeks was criterion of efficacy.

**Results.–** Responders rate was 62.5% in rTMS and 52.9% in active control group with CDSS score reduction of 50.6% ( $P < 0.05$ ) and 47.4% ( $P < 0.05$ ) correspondingly. PANSS negative subscale reduction was 15.5% ( $P < 0.05$ ) for rTMS and 5.8% ( $P < 0.05$ ) for active control group. Cognitive test results have inverse correlation with PANSS negative subscale, the strongest Spearman's correlation was  $-0.45$  ( $P < 0.05$ ) for symbol coding task. The mean score improvement in this test was 20.3% ( $P < 0.05$ ) in rTMS and 11.4% ( $P < 0.05$ ) in active control group. Fast cognitive response was more likely to correspond with the positive outcome of the treatment.

**Conclusions.–** Fast antidepressive effect with significant reduction of negative symptoms and improvement of cognition were the prominent features of rTMS action in schizophrenia.

### **Immunological criteria of prognosis of protracted course of organic disorders**

V. Nikitina<sup>1\*</sup>, T. Vetlugina<sup>1</sup>, V. Rudnitsky<sup>2</sup>, O. Lobacheva<sup>1</sup>, O. Perchatkina<sup>2</sup>, M. Axenov<sup>2</sup>

<sup>1</sup> Mental health research institute, Tomsk national research medical center, Russia, laboratory of psychoneuroimmunology and neurobiology, Tomsk, Russia; <sup>2</sup> Mental health research institute, Tomsk national research medical center, Russia, borderline states department, Tomsk, Russia

\* Corresponding author.

**Introduction.–** In organic asthenic disorders beyond mental dysfunction of the organism, imbalance of immunity system is often revealed that leads to weakening of mechanisms of the immune protection. During further progression of organic asthenic disorder, gradual formation of organic personality disorder occurs.

**Materials and methods.–** Clinical-immunological examination of 232 patients (group 1) with organic emotional-labile (asthenic) disorder (F 06.6) and 93 patients (group 2) with organic personality disorder (F 07.0) has been conducted. Laboratory investigation included phenotyping of immunocompetent cells by flow cytometry. The level of brain-specific protein S-100 was determined by ELISA-test.

**Results.**– Significant differences between parameters of the immunity in examined groups have been identified. Immune status of patients with organic personality development as compared with patients of group 1 was characterized by lower values of number of T-lymphocytes – CD3<sup>+</sup> phenotype ( $P=0.0001$ ), higher values of number of lymphocytes with Fas-receptors of readiness to apoptosis (CD95) ( $P=0.0001$ ) and level of protein S-100 ( $P=0.0012$ ).

**Conclusion.**– Immune deficiency and disturbance of neuroimmune mechanisms of regulation should be considered as peculiar characteristics of united psychobiological process in organic pathology. Disturbances of immune protection are adverse factors promoting formation of organic mental disorders, their protracted course and polymorphism of clinical symptoms. Totality of factors such as decrease of number of T-lymphocytes, heightening of number of lymphocytes with Fas-receptors of readiness to apoptosis and heightening of level of protein S-100 allows considering them as predictors of formation of protracted course of organic mental disorders at early stages of disease.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Efficiency of multi-channel electrical stimulation of neck nervous structures in patients with panic disorder**

T. Petrenko<sup>1\*</sup>, K. Retjanskiy<sup>2</sup>, V. Kublanov<sup>3</sup>

<sup>1</sup> Ural federal university, research medical and biological engineering centre of high technologies, Ekaterinburg, Russia; <sup>2</sup> Ural state medical university, the department of psychiatry, Ekaterinburg, Russia; <sup>3</sup> Ural federal university, research medical and biological engineering center of high technologies, Ekaterinburg, Russia

\* Corresponding author.

**Introduction.**– Anxiety disorders are the most common among all mental disorders. The effectiveness of medication approach remains low.

**Objectives.**– In the current study, we have investigated the effectiveness of the method of dynamic correction of activity of the sympathetic nerves system (DCASNS) in comparison of standard medications approach in patients with panic disorder. The DCASNS method is realized by the medical device 'SYMPATHOCOR-01' that creates spatial-distributed field of current pulses to impact on neck nervous structures by means two multi-element electrodes, which are located on opposite sides of the neck.

**Methods.**– The study included 40 patients from clinical base of the Department of Psychiatry of Ural State Medical University with diagnosed 'panic disorder'. All patients were randomly divided into two equal group. Patients from the first group received antidepressant – escitalopram 10 mg once daily. Patients from the second received a course of ten procedures of DCASNS by the 'SYMPATHOCOR-01' device. The period of therapy and dynamic follow-up was six weeks. The Hamilton (HAM-A) and Sheehan (SPRAS) anxiety scales were used to determine changes in state of patients.

**Results.**– For patients from the first group were follow changes by scales for the six-weeks period: HAM-A (from  $26.35 \pm 7.53$  to  $15.35 \pm 4.20$ ), SPRAS (from  $72.83 \pm 21.41$  to  $39.27 \pm 8.13$ ). For patients from the second group (DCASNS): HAM-A (from  $27.49 \pm 7.32$  to  $7.30 \pm 2.05$ ), SPRAS (from  $74.33 \pm 23.42$  to  $24.22 \pm 5.29$ ).

**Conclusion.**– The neurostimulation therapy in comparison antidepressant was a faster onset of the therapeutic effect, a faster reduction quantity and severity of panic attacks during the whole period of observation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Maintenance electroconvulsive therapy: 6-year experience at 12 De Octubre Hospital in Madrid**

D. Rentero Martín<sup>\*</sup>, M. Caballero, I. Torio, E.M. Sanchez-Morla, M. Dompablo, R. Rodriguez-Jimenez, G. Rubio  
Hospital Universitario 12 de Octubre, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Acute Electroconvulsive Therapy (aECT) is an effective treatment, and the response rates can be as high as 70–90% depending on the diagnosis. Nevertheless, up to 40–50% of patients relapse after successful acute treatment. Thus, it is necessary to establish maintenance ECT (mECT) programs for a given profile of patients.

**Objectives.**– We present sociodemographic and clinical data for 30 patients included in the mECT program of the 12 de Octubre Hospital in Madrid since its development in november 2011. An analysis of their clinical course is performed pre- and post-inclusion in the mECT program, with the aim of verifying its clinical usefulness and cost effectiveness.

**Methods.**– For each patient, a comparison of several clinical variables pre- and post-inclusion in the program is performed. Attendance to emergency department, number of admissions and length of stay pre- and post-initiation of the mECT is compared. Moreover, an analysis of the costs associated to these variables is conducted.

**Results.**– Our results show that following the inclusion in the mECT program, patients decreased their attendance to the emergency department, and reduced the number and length of hospital admissions. There was also a reduction in the associated costs.

**Conclusions.**– The mECT Program at 12 De Octubre Hospital has demonstrated clinical utility and a positive cost-effectiveness balance.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Physical activity impacts positively on depression and objective sleep in patients with multiple sclerosis**

D. Sadeghi Bahmani<sup>1\*</sup>, M. Papadimitriou<sup>2</sup>, J. Bansi<sup>2</sup>, J. Kesselring<sup>2</sup>, U. Lang<sup>1</sup>, E. Holsboer-Trachsler<sup>1</sup>, S. Brand<sup>1</sup>

<sup>1</sup> University of Basel psychiatric hospital, center for affective, stress and sleep disorders ZASS, Basel, Switzerland; <sup>2</sup> Kliniken Valens, rehabilitation center, Valens, Switzerland

\* Corresponding author.

**Background.**– There is growing evidence that regular physical activity has a favorable effect on psychological functioning and sleep. However, as regards patients with MS, evidence is still scarce. The aim of the present study was therefore to investigate the impact of a regular physical activity program on psychological functioning and subjective and objective sleep in patients with MS.

**Methods.**– A total of 14 patients (mean age about 40 years; EDSS: 2–5) took part in this longitudinal and four weeks lasting intervention study. At baseline and 4 weeks later, patients completed self-rating scores covering depression, mental toughness and subjective sleep. Further, sleep was assessed via sleep-EEG-recordings at both time points. Patients had physical activity programs every weekday for 1 to 4 hours.

**Results.**– Compared to baseline, at the end of the study symptoms of depression and sleep complaints decreased. Objective sleep onset latency decreased, slow wave sleep increased and the number of awakenings decreased, resulting in a more stable objective sleep.

**Conclusions.**– In patients with MS, regular physical activity has the potential to impact positively on psychological functioning and both subjective and objective sleep.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cytokine profile in patients with epilepsy with associated depression**

N. Sivakova<sup>1\*</sup>, L. Lipatova<sup>1</sup>, N. Serebryanaya<sup>2</sup>

<sup>1</sup> Saint Petersburg V.M. Bekhterev psychoneurological research institute, department of epilepsy, Saint Petersburg, Russia;

<sup>2</sup> North-Western state medical university named after I.I. Mechnikov, department of clinical laboratory diagnostics, Saint Petersburg, Russia

\* Corresponding author.

At present time, there are many experimental and clinical study on the inflammatory theory of epileptogenesis and depressive disorders (De Simoni M.G. et al., 2000; Lehtimäki K.A. et al., 2004). Cytokines influence on neuronal transmission of mediators and contribute the development of hyperexcitability of neurons (Zou J.Y., Crews F.T., 2005). The cell-mediated immune activation and the process of inflammation induce the dysregulation of a brain-derived neurotrophic factor (BDNF) and decrease in the hippocampal neurogenesis and neurodegeneration associated with epileptogenesis and the development of depression.

The aim is to investigate the cytokine status and concentration of BDNF in blood plasma in patients with epilepsy (PE) with associated depression.

**Materials and methods.**– Cytokines and BDNF were analyzed in blood samples of 60 PE and 31 healthy donors (HD) using method of enzyme linked immunosorbent assay.

**Results.**– The study showed a significant disbalance of cytokines in the blood of PE: the increased levels of pro-inflammatory cytokines (IL-1 $\beta$  (316.5  $\pm$  14.0 pg/ml), IL-8 (157.1  $\pm$  99.4 pg/ml) and TNF- $\alpha$  (14  $\pm$  3 pg/ml)), decrease of the concentration of the receptor antagonist and significantly reduced the content of BDNF (4448 pg/l). The direct correlation established between immune disbalance and the presence of depressive disorders in patients with epilepsy ( $r = 0.67$ ;  $P < 0.01$ ) ( $r = 0.71$ ;  $P < 0.01$ ) ( $r = -0.83$ ;  $P < 0.01$ ) (img. 1).

**Conclusion.**– The results confirm the data on the inflammatory genesis of epilepsy and depressive disorders. The immune disbalance is more expressed in PE with severe depressive disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0447

### **The recombinant human interleukin IL-2 as agent for the adjuvant treatment of patients with epilepsy and associated depression**

N. Sivakova<sup>1\*</sup>, L. Lipatova<sup>1</sup>, N. Serebryanaya<sup>2</sup>, T. Kapustina<sup>1</sup>

<sup>1</sup> Saint Petersburg V.M. Bekhterev psychoneurological research institute, department of epilepsy, Saint Petersburg, Russia;

<sup>2</sup> North-Western state medical university named after I.I. Mechnikov, department of clinical laboratory diagnostics, Saint Petersburg, Russia

\* Corresponding author.

Currently, there are many experimental and clinical evidence of the inflammatory theory of epileptogenesis and depression, and also, to dysregulation of neurotrophins.

The aim was study the cytokines and BDNF of patients with epilepsy (PE) and PE with associated depression (PED) before and after treatment with recombinant human interleukin IL-2 (rIL-2).

**Materials and methods.**– We investigated cytokines and BDNF in plasma blood of 38 PED and 60 PE before and after treatment with rIL-2h. The control group is 32 PE only treated AED and 31 healthy donors (HD).

**Results.**– Levels of IL-1 $\beta$ , IL-8 and TNF $\alpha$  increased, the concentration of rIL-1 $\beta$  and BDNF were reduced in both groups (PED and PE). The concentration level of IL-1 $\beta$  in PED is 2.5 times higher than in PE and HD ( $P < 0.01$ ). The initial BDNF was 4448 pg/l, its concentration is increased to 7023 pg/l ( $P < 0.01$ ) in PE, after treatment with rIL-2h. The concentration of BDNF tended to decrease in the control group PE. The average concentration of BDNF has not changed after treatment of rIL-2 in PED, however, within this group was observed two opposite trends of changes in BDNF: in the first subgroup BDNF increase 2.6 times, in the second – reducing 3.5 times, after treatment with rIL-2h.

**Conclusions.**– Our results support the “cytokine theory” of epilepsy and depressive disorders. Changes in the expression of BDNF in patients with associated depression after the treatment of rIL-2h should be considered from the standpoint of neuroplasticity as a predictor of therapeutic response in patients with associated depression.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0448

### **Brain markers of clinical response to rTMS for auditory hallucinations in schizophrenia**

F. Thomas<sup>1\*</sup>, C. Gallea<sup>2</sup>, A. Valero-Cabr e<sup>3</sup>, D. Januel<sup>1</sup>

<sup>1</sup> EPS Ville Evrard, unit e de recherche clinique, Neuilly-sur-Marne, France; <sup>2</sup> Brain and spine institute, Cenir, Paris, France; <sup>3</sup> Brain and spine institute, UMR 7225 FrontLAB, Paris, France

\* Corresponding author.

In schizophrenia, rTMS is proposed as a therapeutic treatment for HA resistant to antipsychotic drugs. Several reviews and meta-analyses show that magnetic stimulation of the left temporoparietal junction (ITPJ) resulted in a significant improvement in hallucinations in patients with schizophrenia (Freitas et al., 2009, Poulet et al., 2010). However, some patients do not appear to show significant improvement in their hallucinatory symptoms following brain stimulation treatment (Demeulemeester et al., 2012). Studies are needed to better understand this treatment and the variability of the clinical response after rTMS to increase its effectiveness. Recent findings generally suggest that interindividual differences in patterns of anatomical connectivity between a TMS-targeted region and its brain connections are likely to influence behavioral impact (Quentin et al., 2013) and also, most likely, the therapeutic impact induced by neurostimulation. The study of brain connectivity thus appears as a possible way of research for a better understanding and optimization of the effectiveness of the treatment of schizophrenia by rTMS. The main objective of this project is to determine if there are differences in structural and / or functional connectivity before the application of rTMS treatment between responder and non-responder patients to this treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0449

### Acute multisession bifrontal transcranial direct current stimulation for treatment of intractable tinnitus: A double blinded randomized controlled trial

A. Yadollahpour<sup>1,2\*</sup>, N. Saki<sup>3</sup>, A. Bayat<sup>3</sup>, S. Rashidi<sup>1</sup><sup>1</sup> Bioelectromagnetic clinic, Imam Khomeini hospital, Ahvaz Jundishapur university of medical sciences, Ahvaz, Iran;<sup>2</sup> Department of medical physics, school of medicine, Ahvaz Jundishapur university of medical sciences, Ahvaz, Iran;<sup>3</sup> Department of psychiatry, school of medicine, Ahvaz Jundishapur university of medical sciences, Ahvaz, Iran

\* Corresponding author.

**Introduction.**– Transcranial direct current stimulation (tDCS) has shown promising but heterogeneous therapeutic efficacy on tinnitus.

**Objectives.**– To investigate therapeutic effects of acute multi-session tDCS (anodal/cathodal over the right/left dorsolateral prefrontal cortex (DLPFC)) on tinnitus symptoms.

**Methods.**– This was a double blinded randomized controlled trial on patients ( $n=42$ ) with chronic intractable tinnitus who were randomly divided into real or sham tDCS. The tDCS protocol consisted of twice daily sessions (intersession: 6 hours) of 2 mA current for 20 min for 5 consecutive days through 35 cm<sup>2</sup> electrodes. The anode was placed over F4, and the cathode over F3. The tinnitus handicap inventory (THI) was assessed pre- and post-intervention, and at one month follow-up. Tinnitus loudness and distress were assessed prior to intervention, and at immediately, one hour, one week, and at one month after the last tDCS session.

**Results.**– Real tDCS significantly reduced THI score at immediately post-treatment ( $P=0.001$ ) that lasted up to one month post-treatment (average reduction:  $20.042 \pm 10.2697$ ,  $P<0.001$ ). In the real tDCS, 72% patients showed significant clinical improvement, whereas 35.29% patients in sham tDCS improved indicating a significant different effect ( $P<0.05$ ). Real tDCS significantly reduced the distress immediately post-treatment ( $P<0.001$ ) and lasted one week ( $P=0.062$ ). Real tDCS reduced distress more than the sham condition, but the differences were not significant. The real tDCS significantly reduced loudness at “immediately post-stimulation” ( $P=0.045$ ) and persisted 1 hour ( $P=0.021$ ).

**Conclusions.**– Acute repeated sessions of tDCS may be promising treatment for intractable tinnitus with persisting effects.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0450

### Comparison of 20 Hz rTMS in acute and standard protocols in intractable major depression: A randomized controlled trial

R. Rostami<sup>1,2</sup>, R. Kazemi<sup>2</sup>, A. Shakeri<sup>3</sup>, A. Yadollahpour<sup>3\*</sup><sup>1</sup> Psychology department, faculty of psychology and educational science, Tehran university, Tehran, Iran; <sup>2</sup> Atieh clinical neuroscience center, Tehran, Iran; <sup>3</sup> Department of medical physics, school of medicine, Ahvaz Jundishapur university of medical sciences, Ahvaz, Iran

\* Corresponding author.

**Introduction.**– Studies on developing more efficient treatment protocols of rTMS for treatment of intractable depression are ongoing. **Objectives.**– To comparatively evaluate the therapeutic efficacy of an acute and the standard 20 Hz rTMS in drug resistant major depression in an open label single blinded clinical trial.

**Methods.**– The patients ( $n=24$ ) were randomly divided into standard or acute rTMS groups who received 20 Hz rTMS over left dorsolateral prefrontal cortex. The two groups received the same protocol consisted of ten sessions each session of 60 trains (2.5 s, inter-train of 17.5 s) at 120% MT, except that the standard group received daily one session for 2 consecutive weeks and the acute group twice daily with intersession interval of 2 hours. The 17-item Hamilton depression rating scale (HDRS-17) was used to determine treatment response (50% reduction in HDRS-17 score) and remission (score lower than 8). The response and remission rates were compared between two groups.

**Results.**– Ten patients completed the standard treatment where the response and remission rate was respectively 50% and 40%. The average HDRS-17 score significantly reduced posttreatment, compared with the baseline ( $P=0.006$ ). Both the response and remission rate in the acute rTMS was 33%. Moreover, the average HDRS-17 score was significantly reduced posttreatment compared with the baseline ( $P=0.042$ ). The two groups showed no significant difference in response and remission rate ( $P=0.05$ ).

**Conclusions.**– To reduce the total treatment period, we can use acute rTMS, while keeping the total number of pulses constant as standard protocol.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0451

### Spectral powers of prefrontal and sensorimotor regions of brain predict response to repetitive transcranial magnetic stimulation

A. Yadollahpour<sup>1\*</sup>, R. Rostami<sup>2,3</sup>, R. Kazemi<sup>3</sup>, A. Shakeri<sup>4</sup><sup>1</sup> Ahvaz Jundishapur university of medical sciences, medical physics, Ahvaz, Iran; <sup>2</sup> University of Tehran, psychology department, faculty of psychology and educational science, Tehran, Iran; <sup>3</sup> Atieh clinical neuroscience center, psychiatry department, Tehran, Iran; <sup>4</sup> Ahvaz Jundishapur university of medical sciences, medical physics department, Ahvaz, Iran

\* Corresponding author.

**Introduction.**– Quantitative assessments of repetitive transcranial magnetic stimulation (rTMS) effects are crucial to develop more efficient and personalized treatments.

**Objectives.**– To determine the spectral powers of different sub-bands of EEG correlated with treatment response to rTMS.

**Methods.**– In an open label study 10 patients with intractable major depression received a ten session 20 Hz rTMS over left dorsolateral prefrontal cortex. The EEGs were recorded in all subjects prior and post intervention using a 19-channel EEG system. Hamilton depression rating scale (HAM-D) was also used to determine treatment response. The rTMS protocol consisted of daily one session of 60 trains (2.5 s, inter-train of 17.5 s) at 120% MT for 5 consecutive days per week and 2 weeks. Absolute and relative powers in all electrodes for delta (0–4 Hz), theta (4–8 Hz), alpha (8–12 Hz), sensorimotor rhythm (SMR)(12–15 Hz), beta (15–20 Hz), and high beta (20–28 Hz) were compared prior and post-intervention in the responders.

**Results.**– In the responders ( $n=5$ ), absolute powers of alpha in F3, F4, C3, and C4 electrodes, absolute power of theta and alpha sub-bands in C4 electrode significantly changed ( $P<0.05$ ). In the SMR band, absolute powers in the Fp1, Fp2, F3, F4, F7, FZ, C3, and C4 significantly changed ( $P<0.05$ ). In beta sub-band, relative power in C4 and absolute power in Fp1, Fp2, F4, CZ, and C4 significantly changed ( $P<0.05$ ) (Table 1).

**Conclusions.**– The spectral powers of particular sub-bands in pre-frontal cortex and sensorimotor area can predict response to rTMS treatment.

### Immunotypes of the Asthenic Symptom-Complex in patients with paranoid schizophrenia

S. Zozulya<sup>1\*</sup>, A. Yakimets<sup>2</sup>, I. Oleichik<sup>2</sup>, T. Klyushnik<sup>1</sup>

<sup>1</sup> Mental health research center of the Russian academy of medical sciences, laboratory of neuroimmunology, Moscow, Russia; <sup>2</sup> Mental health research center of the Russian academy of medical sciences, department for the study of endogenous mental disorders, Moscow, Russia

\* Corresponding author.

The new approach in psychiatry is an attempt to analyze the immune mechanisms of the development of the asthenic disorders in the endogenous process using immunological (inflammation) parameters to specify the diagnosis of these disorders.

The aim was the differentiation of immunological features (the immunotypes) of the asthenic symptom-complex in patients with paranoid schizophrenia (PS).

The study included 43 patients aged 20–55 years with PS in the stage of therapeutic remission. Clinical evaluation was assessed by PANSS and MFI-20. The activity leukocyte elastase (LE) and a1-proteinase inhibitor (a1-PI) was detected in serum.

The asthenic disorders in total group with PS were associated with an increase in the activity of acute-phase proteins (by the activity of a1-PI) and deficiency in the functional activity of neutrophils (according to LE activity). These data are in contrast to those in patients with schizophrenia in the acute stage of the disease as previously was shown.

Two immunotypes depending on the activity of LE were revealed. The 1st one (42%) demonstrated moderate increase both LE and a1-PI activity as compared to normal values ( $P < 0.001$ ). The asthenic symptoms in these patients were transient and accompanied by the depression. The 2nd one (58%) showed an increase in a1-PI

( $P < 0.001$ ) but not LE activity ( $P > 0.05$ ). The asthenic symptoms in these patients were irreversible and formed at the stage of remission.

Thus, the investigated inflammation parameters allow evaluating the activity of the pathological process in the brain and can be used as markers of the asthenic symptom-complex in PS.

### Favorable impact of aerobic exercise training (AET) on disease symptoms, depression and cardiovascular fitness in children and adolescents with inflammatory bowel disease (IBD)

L. Mählmann<sup>1</sup>, M. Gerber<sup>2</sup>, R. Furlano<sup>3</sup>, C. Legeret<sup>3</sup>, N. Kalak<sup>1</sup>, E. Holsboer-Trachsler<sup>1</sup>, S. Brand<sup>4\*</sup><sup>1</sup> University of Basel, psychiatric clinics, Basel, Switzerland;

<sup>2</sup> University of Basel, department of sport, exercise and health, Basel, Switzerland; <sup>3</sup> University of Basel, children's hospital, Basel, Switzerland; <sup>4</sup> Psychiatric university hospital, center for affective, stress and sleep disorders, Basel, Switzerland

\* Corresponding author.

**Background.**– Acute and chronic exercise has the potential to impact on the physiological system related to cardiovascular fitness, inflammatory indices and depression in pediatric patients with Inflammatory Bowel Disease (IBD). The aim of the present intervention study was to investigate the influence of acute and chronic exercise on IBD-related inflammatory indices, exercise capacity and depression, among children and adolescents with IBD and healthy controls.

**Method.**– Twenty-one children and adolescents with IBD were compared to 23 gender- and age-matched healthy controls (HC). At baseline and after 8 weeks, exercise capacity, physical activity, fitness, IBD-related inflammatory indices (erythrocyte sedimentation rate (ESR), albumin, C-reactive protein (CRP), cortisol, hemoglobin, hematocrit, thrombocytes and leukocytes) were assessed. Depression was self-rated.

**Results.**– Patients with IBD were less subjectively and objectively active, and reported higher scores of depression. After a single exercise bout (6 MWT) albumin, haemoglobin, erythrocytes, haematocrit and leukocytes increased in all participants.

After a long-term AET intervention, ESR, CRP and thrombocytes significantly decreased in all participants. Depression decreased over time.

**Conclusion.**– The pattern of results suggests that moderate regular PA may be recommended as an adjuvant anti-inflammatory therapy in pediatric IBD. Further, regular PA had a favourable impact on depression.

### The effects of psychosociological factors associated with male circumcision on child mental health in Turkey: A preliminary report

F.H. Çetin<sup>1</sup>, T. Sekmenli<sup>2</sup>, H.A. Güler<sup>1</sup>, S.A. Ersoy<sup>1</sup>, K. Durmuş<sup>1</sup>, S. Türkoğlu<sup>1</sup>, I. Çiftçi<sup>2</sup>

<sup>1</sup> Selcuk university medical faculty, child and adolescent psychiatry, Konya, Turkey; <sup>2</sup> Selcuk university medical faculty, child surgery, Konya, Turkey

\* Corresponding author.

**Introduction/Objective.**– In this preliminary study; it was aimed to determine sociodemographic and psychometric variables on the child's anxiety level before the circumcision and to shed light on the development of preventive measures in this context.

**Method.**– Thirty-four children aged 8–12 years were analyzed. All cases were assessed with Revised Child Anxiety and Depression Scale (RCADS) child form and Piers-Harris Children's Self-concept Scale (PHCSS); children's parents were assessed with RCADS - parent form, Eysenck Personality Inventory (EPI), Beck Depression Inventory (BDI), and Beck Anxiety Inventory (BAI). All cases were assessed with Schedule for Affective Disorders and Schizophrenia for School-age Children (K-SADS) and clinical evaluation. Sociodemographic data form was filled in for each case.

**Results.**– There was a negative correlation between PHCSS-anxiety and popularity subscale scores with the RCADS-child form anxiety and depression subscale scores ( $\rho = -0.357$ ,  $P < 0.05$ ;  $\rho = -0.528$ ,  $P = 0.001$ ;  $\rho = -0.354$ ,  $P < 0.05$ ;  $\rho = -0.423$ ,  $P < 0.05$ ). A positive correlation was found between total anxiety and total anxiety-depression subscale scores of the RCADS child form with BDI score of the parents ( $\rho = 0.425$ ,  $P < 0.05$ ;  $\rho = 0.422$ ,  $P < 0.05$ ). In the group who were not informed about operation before circumcision, the scores of RCADS-child form total anxiety-depression subscale were higher ( $36.00 \pm 20.98$  v.s.  $23.86 \pm 17.90$ ,  $P < 0.05$ ). Interestingly, the post-circumcision ceremony plan increased the total anxiety-depression subscale score of RCADS-child form ( $30.07 \pm 19.93$  v.s.  $19.16 \pm 16.73$ ;  $P < 0.05$ ).

**Conclusions.**– This study showed that; adequate information should be given before circumcision, the anxiety levels of children with low self-esteem may be higher and the depressive mood of the parents may lead to anxiety in child.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Longitudinal association between childhood conduct problems and first line mental health service reception

M. Déry<sup>1</sup>\*, C.E. Temcheff<sup>2</sup>, R. St-Pierre<sup>2</sup>, A. Storey-Martin<sup>1</sup>, J. Toupin<sup>1</sup>, P. Hanan<sup>2</sup>

<sup>1</sup> Université de Sherbrooke, psychoeducation, Sherbrooke, Canada;

<sup>2</sup> McGill university, educational and counselling psychology, Montreal, Canada

\* Corresponding author.

**Introduction.**– While elevated levels of mental health service use are associated with conduct problems (CP) in children, little is known about the reciprocal relationships between the severity of CP and first line mental health service usage over time. **Objective.** To explore the transactional relationships between the severity of CP and first line mental health service utilization over two years.

**Method.**– The participants were 340 elementary school children who were rated above the threshold for elevated risk on DSM-

oriented scales for CP and oppositional defiant problems. The longitudinal relationships between CP severity and service use were tested using autoregressive cross-lagged model (three measurement points), with CP severity scores being provided by teachers and information on service use being provided by parents. **Results.**– The fit of the autoregressive cross-lagged model was satisfactory ( $\chi^2(18) = 26.16$ ,  $P = 0.10$ ; CFI = 0.97; TLI = 0.96; RMSEA = 0.04). The stability coefficients were moderate to strong for severity of CP and for service reception. A negative relationship between service reception at T1 and CP at T2 was observed, suggesting that CP were rated as less severe one year later when children received first line services compared to children who did not receive services.

**Conclusion.**– Despite the strong continuity of CP, the fact that first line mental health services for CP were linked to subsequent lower CP severity one year later is encouraging. Understanding this dynamic relationship represents a first step in the amelioration of services in first line clinics for children with CP.

### Coping in teenagers and their parents urgently received in child and adolescent psychiatry

S.H. Ghezaiel<sup>1</sup>\*, S. Halayem<sup>1</sup>, Y. Zgueb<sup>2</sup>, A. Bouden<sup>1</sup>

<sup>1</sup> Razi hospital, child and adolescent psychiatry, Tunis, Tunisia; <sup>2</sup> Razi hospital, avicenne adult psychiatry, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– The number of teenagers urgently received in Child and Adolescent Psychiatry is increasing. In fact, adolescence is a transition period during which youths and their families have to face multiple stressors.

**Objectives.**– Determine the profile of teenagers and highlights coping strategies used by them and their parents.

**Method.**– It is a transverse and descriptive study including 75 adolescents who were received urgently in Child and Adolescent Psychiatry department at hospital Razi. Following data were collected: socio-demographic, clinical, personal and family characteristics. A-cope questionnaire was assessed for measuring coping strategies in adolescents and Brief-cope questionnaire for parents. **Results.**– The sample of the study was formed of 75 adolescents from 10 to 17 years (73.3% girls). Mean age was 13.7 years. 48% were consulting for a suicidal behavior. About 50% of parents were primary scholar level. The most retained diagnosis according to DSM-V was adjustment disorder with depressive mood. 27.3% of adolescents had a history of maltreatment, 26.7% had a psychiatric family history. The mean score of diversity of strategies in our population was 36.57, the most coping strategies used by adolescents were seeking diversion (mean score = 22.47), developing social support (mean score = 19.84), engagement (mean score = 16.40), ventilating feelings (mean score = 15.41) and solving family problems (mean score = 15.28) and the most strategies used by parents were planning (mean score = 7), religion (mean score = 6.8) and acceptance (mean score = 6.7).

**Conclusion.**– Studying coping in this population is very important in a way to improve it.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Anaclitism/autocriticism in female adolescents with borderline personality disorder: Associations with non-suicidal self-injuring

F. Guénolé<sup>1</sup>\*, S. Spiers<sup>1</sup>, L. Gicquel<sup>2</sup>, M. Corcos<sup>3</sup>, A. Pham-Scottez<sup>4</sup>, M. Speranza<sup>5</sup>

<sup>1</sup> Centre hospitalier universitaire de Caen, service de psychiatrie de l'enfant et de l'adolescent, Caen, France; <sup>2</sup> Centre hospitalier universitaire de Poitiers, service de psychiatrie de l'enfant et de l'adolescent, Poitiers, France; <sup>3</sup> Institut Mutualiste Montsouris, service de psychiatrie de l'adolescent et du jeune adulte, Paris, France; <sup>4</sup> Hôpital Sainte-Anne, clinique des maladies mentales et de l'encéphale, Paris, France; <sup>5</sup> Centre hospitalier de Versailles, service universitaire de psychiatrie de l'enfant et de l'adolescent, Le Chesnay, France

\* Corresponding author.

**Introduction.**– Psychodynamic models of adolescent borderline functioning suggest that non-suicidal self-injury (NSSI) – a particularly frequent symptom in borderline girls – may constitute a way of coping with distress resulting from anaclitic interpersonal-relatedness difficulties they typically experience (Clarkin et al., 2015).

**Objectives.**– To investigate the relationship in borderline female adolescents between NSSI and the two dimensions of Blatt's developmental model of lifelong depressive experience (Blatt, 2008): anaclitism and autocriticism; we hypothesized that NSSI would be more strongly associated with anaclitism than with autocriticism. **Methods.**– The study was conducted within the European Research Network on Borderline Personality Disorder in Adolescence (Corcos et al., 2013). Participants were administered the Ottawa Self-Injury Inventory (OSI; Cloutier and Nixon, 2003) and the Depressive Experience Questionnaire (DEQ; Blatt et al., 1992).

**Results.**– Borderline patients ( $n = 57$ ; mean age =  $16.5 \pm 1.2$ ) had significantly higher scores than healthy controls on both Anaclitism and Autocriticism DEQ dimensions (0.97 vs 0.22 and 0.93 vs 0.01, respectively;  $P < 0.001$ ). Patients with NSSI on the OSI ( $n = 40$ ) had significantly higher Anaclitism scores than patients without NSSI (1.17 vs 0.48;  $P < 0.01$ ); Autocriticism scores did not significantly differ between subgroups (1.00 vs 0.76).

**Conclusions.**– The study corroborates the hypothesis that NSSI in adolescents with borderline functioning is linked to high anaclitism, which should be taken into consideration in clinical practice with these patients. More studies are necessary to better understand the relationships between NSSI and developmental psychopathology in borderline patients.

**Disclosure of interest.**– This research was supported by a grant from the WYETH Foundation for Child and Adolescent Health & by a grant from the LILLY Foundation. This work was conducted in a European collaborative research project on borderline personality disorder (European Research Network on Borderline Personality Disorders EURNET-BPD).

### Gene environment interaction of SLC6A4 and maternal negative affectivity predicting behavior problems in Korean preschoolers

J. Ha<sup>\*</sup>, E. Kim

Yonsei university severance hospital, department of psychiatry and institute of behavioral science in medicine, Seodaemun-Gu, Republic of Korea

\* Corresponding author.

Individuals with short variants of SLC6A4 are more vulnerable to internalizing and externalizing problems than those with long variants. These problems in preschoolers are associated with poor emotional regulation. This study assumes that maternal negative emotions will increase the risk of child's internalizing and externalizing problem by reducing the chances of developing emotional regulation. We investigated whether maternal negative affectivity moderates the effect of genetic polymorphism of SLC6A4 on children's behavior problems.

Participants included 143 preschoolers and their mothers in South Korea. CBCL and EAS Adult Scale were used to measure child behavior and maternal affectivity. DNA from saliva was genotyped for serotonin transporter polymorphism.

Maternal negative affectivity showed main effects in externalizing ( $b = 5.78, P < .001$ ) and internalizing problems ( $b = 6.09, P < .001$ ). The interaction of SLC6A4 polymorphism with maternal negative affectivity showed main effects on externalizing ( $b = -7.62, P < .01$ ) and internalizing problem ( $b = -9.77, P < .01$ ) Children with two short alleles showed considerable changes in both externalizing and internalizing problems according to maternal negativity; however, children with one short allele or none show relatively few change in behavior problems due to maternal affectivity.

In conclusion, the effect of SLC6A4 polymorphism on child behavior was moderated by maternal negative affectivity. In addition, the impacts of maternal negative affectivity vary on the child's genetic risk. High maternal negative affectivity triggered risk allele while low maternal negative affectivity allows risk allele shows less behavior problems. Children with two short variants of SLC6A4 genotype may benefit from intervention that modulates maternal negative affectivity.

### Prevalence of attention deficit hyperactivity disorder (ADHD) in a pediatric endocrine clinic in Saudi Arabia

S. Habis<sup>1</sup>\*, F. Alhaidar<sup>2</sup>, A. Alharbi<sup>1</sup>, L. Alanazi<sup>1</sup>, A. Babiker<sup>3</sup>

<sup>1</sup> King Saud university, King Khalid university hospital, college of medicine, Riyadh, Saudi Arabia; <sup>2</sup> King Saud university, King Khalid university hospital, psychiatry department, Riyadh, Saudi Arabia; <sup>3</sup> King Abdullah specialized children's hospital and King Saud Bin Abdulaziz for health sciences, pediatric endocrine, Riyadh, Saudi Arabia

\* Corresponding author.

**Background.**– Attention-deficit hyperactivity disorder (ADHD) is a chronic neurobehavioral disorder with a substantial lifelong impact on personal and social functioning, academic performance, and the health system in general. It is one of the most frequent childhood-onset psychiatric conditions, with an estimated worldwide-pooled prevalence exceeding 5% in school-age children, and a prevalence of 1.3–16% in Arab countries. It was previously hypothesized that ADHD may be associated with hormonal changes. We aimed to address this association in the study group.

**Methods.**– This is a quantitative cross-sectional study to estimate the prevalence of ADHD among children with Endocrine disorders who attended the Pediatric Endocrine clinic at King Khalid University Hospital, Riyadh, Saudi Arabia (November 2015–March 2016). The data was gathered by an interview answering questions about social demographics, basic medical profile including the endocrine diagnosis, and a valid screening tool for ADHD (ADHD Rating Scale). **Results.**– The study showed that ADHD was associated with low socioeconomic status and other social demographic characteris-

tics in our study group. Analysis revealed that the prevalence of ADHD was 14.9% ( $n = 46/309$  children). Of these, 67.39% ( $n = 31/309$ ) were males. There was no statistical evidence suggesting association between ADHD and obesity, thyroid dysfunction, and growth deficit. However, there might be an association with diabetes (Tables 1–3).

**Conclusion.**– According to our findings, ADHD may not be associated with other endocrine disorders; diabetic children are probably less likely to develop ADHD. Further larger studies are required to confirm and possibly explore potential protective mechanisms of diabetes against ADHD.

## The relationship between the number of internet game genre usage and adolescent internet game addiction

H. Hyunho<sup>1</sup>, Y. HyeonWoo<sup>1</sup>, J. Sun-jin<sup>1</sup>, J. Hyunsuk<sup>1</sup>, S. Hye jung<sup>1</sup>, L. Seung-Yup<sup>2</sup>

<sup>1</sup> Catholic medical center/Catholic university of Korea, department of preventive medicine, Seoul, Republic of Korea; <sup>2</sup> Uijeongbu St. Mary's hospital, college of medicine, The Catholic university of Korea, department of psychiatry, Seoul, Republic of Korea

\* Corresponding author.

**Introduction.**– In the modern age, a variety of internet game genres are emerging, and youths who use Internet games will be exposed to more diverse genres in the future. Therefore, it is necessary to study game genre variety and internet game addiction. Studies that have explored the relationship between the number of used game genres and internet game addiction is rare.

**Objectives.**– This study is to examine whether there is a difference in the prevalence of Internet game addiction according to the number of internet game genres used by adolescents.

**Methods.**– This study analyzed the data of 1103 middle school students at the baseline of the Internet user Cohort for Unbiased Recognition of gaming disorder in Early Adolescence (iCURE) study. The number of Internet game genres used by subjects as independent variables was calculated. The number of game genre was divided into 1–2 types, 3–5 types. Internet game addiction was surveyed using Internet Gaming Use-Elicited Symptom Screen (IGUESS). IGUESS scale was consists of 9 question and total score was 0–27. Score of 10 over were classified as Internet game addicts.

**Results.**– Adolescents using 3–5 types of Internet game genre are 1.9 times higher possibility to take an Internet game addiction than adolescents using 1–2 types of Internet game genre (95% CI: 1.136–3.051).

**Conclusions.**– Adolescents with various game genre usage patterns are more likely to be addicted to internet games. We need to look through prospective observational studies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## The negative effects of media exposure on behavioral problems in toddlers and young children

S.J. Kim<sup>1</sup>, Y. Shin<sup>1</sup>, S. Cho<sup>1</sup>, L. Kiyoung<sup>1</sup>, M. Jang<sup>2</sup>, D. Kim<sup>3</sup>

<sup>1</sup> Ajou university hospital, psychiatry, Suwon, Republic of Korea; <sup>2</sup>National center for mental health, psychiatry, Seoul, Republic of Korea; <sup>3</sup> Korean development institute, health economics, Sejong, Republic of Korea

\* Corresponding author.

**Introduction.**– Previous studies on television-use shows the negative associations between excessive TV-viewing in early childhood and behavioral problems. Recently, the increasing amount of time children are spending on smart-devices has raised concerns on the impact of these behaviors on their psychological development. The use of smart devices by very young children has not been studied comprehensively.

**Objectives.**– This study examines the association between the use of smartphone and television and behavior problems among toddlers and young children (2–5 years old) in Korea.

**Methods.**– This research is based on the first wave of the I-CURE (Internet-Cohort for Understanding of internet addiction Risk factors/Rescue in Early livelihood) study where 400 caregivers were

invited to enroll. We analyze 326 children whose primary caregiver is the biological mother. Time for each media use of a child is reported by their mother, and child behavior reported by their mother is assessed with a Korean version of Child Behavior Checklist (K-CBCL)1.5–5.

**Results.**– Among 326 toddlers, 12.3% used smartphone daily (Fig. 1). Total TV viewing time (10.2 h/week) is longer than Smartphone using time (4.1 h/week), but smartphone exposure time is more associated with children’s behavior problems than TV exposure time. The smartphone excessive use is highly associated with both internalizing and externalizing symptoms, while TV use is mainly associated with externalizing symptoms (Table 1).

**Conclusions.**– Early smartphone use may lead to internalizing and externalizing behaviors among young children, especially to sleep disorder and somatic symptoms. These results imply that smartphone use among young children should be carefully monitored and controlled by mothers.

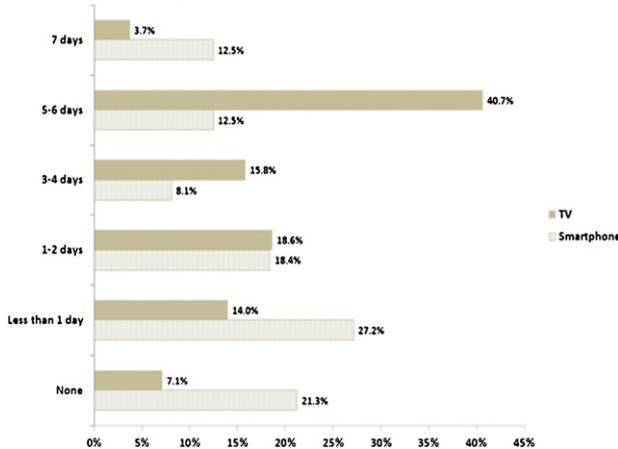

Fig. 1 Frequency of Usage of TV and Smartphone Per Week.

### The neurocognitive development of premature male infants at 10 months of age

S. Kiselev\*, E. Suleimanova, M. Lavrova, I. Tuktareva  
Ural federal university, clinical psychology, Ekaterinburg, Russia  
\* Corresponding author.

**Background.**– It was shown that prematurity is a risk for neurodevelopmental disorders, particularly for ADHD and autism [Anderson & Doyle, 2008]. However, the impact of prematurity on

neurocognitive functions in the early stages of development is not investigated thoroughly. We have revealed that prematurity has specific (not global) negative effect on neurocognitive development in premature male infants at 5 months age (Kiselev et al., 2017). The aim of this research was to reveal the differences in neurocognitive development in premature and mature full-term male infants at 10 months of age.

**Method and participants.**– The participants were 13 premature male infants at 10 months of corrected age and 13 age-matched healthy full-term male infants. The gestational age of preterm infants was between 29 and 35 weeks. The Bayley Scales of Infant and Toddler Development (3rd Edition) were used to evaluate the neurocognitive abilities in infants.

**Results.**– The results were evaluated by one-way ANOVA, with level of performance in five Bayley scales as dependent variable, with group as between-subjects factors. Premature infants performed significantly ( $P \leq 0.05$ ) more poorly than the full-term infants on cognitive scale, receptive language, gross and fine motor. No significant ( $P \leq 0.05$ ) differences were found between preterm and full-term infants on expressive language.

In view of the obtained results it can be assumed that the prematurity has specific (not global) negative effect on neurocognitive development in premature male infants at 10 months age.

**Funding.**– The research was supported by grant of the Russian Science Foundation no. 16-18-10371.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Effect of body-oriented therapy on executive abilities in preschool children with ADHD

S. Kiselev<sup>1</sup>\*, A. Parshakova<sup>2</sup>

<sup>1</sup> Ural federal university, clinical psychology, Ekaterinburg, Russia;

<sup>2</sup> Child hospital, neuropsychological department, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– It is known that children with ADHD have deficit in executive abilities. The goal of this study was to reveal the effect of body-oriented therapy on executive abilities in preschool children with ADHD. We compared the efficacy of two methods of treatment (body-oriented therapy for children vs. conventional motor exercises) in a randomized controlled pilot study.

**Methods and participants.**– 12 children with ADHD between 5 to 6 years of age were included and randomly assigned to treatment conditions according to a 2 × 2 cross-over design. The body-oriented therapy included yogas’ exercises and breathing techniques.

To assess the executive functions and attention in children we used 5 subtests from NEPSY (Tower, Auditory Attention and Response Set, Visual Attention, Statue, Design Fluency). Effects of treatment were analyzed by means of an ANOVA for repeated measurements. **Results.**– The ANOVA has revealed ( $P < .05$ ) that for all 5 subtests on executive functions and attention the body-oriented therapy was superior to the conventional motor training, with effect sizes in the medium-to-high range (0.51–0.87).

**Conclusions.**– The findings from this pilot study suggest that body-oriented therapy can effectively influence the executive abilities in preschool children with ADHD. However, it is necessary to further research the impact of body-oriented therapies on the prevention and treatment of ADHD in children.

**Funding.**– The research was supported by Russian Foundation for Basic Research, grant no. 15-06-06491A.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Sub-threshold depression in different groups of adolescents

I. Kupriyanova<sup>1</sup>, I. Karaush, B. Dashieva

Mental health research institute, Tomsk national research medical center, borderline states department, Tomsk, Russia

\* Corresponding author.

**Introduction.**– The detection of sub-threshold depression is discussed by researchers of adolescent mental health. The prevalence of sub-threshold depression varies from 5 to 29%, it is regarded as a predictor of the actual development of depression, accompanied by a disruption of functioning and increase of suicidal risk.

**Objective.**– To study the prevalence of sub-threshold depression in adolescents.

**Material.**– 659 adolescents 12–17 years, of which 139 students in urban comprehensive schools, 297 pupils of rural schools, 223 pupils of the correctional boarding schools for children with hearing and vision impairments.

**Methods.**– The Children's Depression Inventory (M. Covaks., 1992), clinical and statistical methods were used.

**Results.**– The level of risk for depressive symptoms “above average” was 26.6% (22.3% – boys, 28% – girls), high in 7.9% (1.7% and 14.5%, respectively).

The adjustment disorders were diagnosed in 29 adolescents, 68 pupils had some signs of affective disorders, affecting the quality of functioning. The predominant symptoms were periodic low mood, irritability, negative self-esteem, pessimistic attitude towards the future, reduction of academic performance, problems of interpersonal interaction, and elements of risk behavior.

**Conclusion.**– Sub-threshold depression was detected in 10.3% of adolescents, of which 15.8% were urban, 10.8% – rural and 6.3% – adolescents with disabilities. This group needs monitoring and preventive measures with the involvement of the social environment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Design of a website for helping people with the Down syndrome to develop a life plan

A. Landuran<sup>1\*</sup>, C. Conseil<sup>1</sup>, B. N'Kaoua<sup>2</sup><sup>1</sup> INRIA Bordeaux Sud-Ouest, Gironde, Talence cedex, France;<sup>2</sup> University of Bordeaux, Gironde, Bordeaux, France

\* Corresponding author.

**Introduction.**– Self-determination means to make decisions about one's own fate or life without undue external influences. In France, this notion is expressed through the law on equal rights and opportunities, participation, and citizenship of people with disabilities. This law places the life plan at the center of the compensation process. The life plan is a projection into the future and constitutes a guide for pursuing personal objectives in many spheres of daily life. However, the self-determination and prospective memory difficulties experienced by people with intellectual disability (ID) considerably limit their ability to develop a life plan. Today, the use of digital tools has shown relevant results in terms of improving social inclusion in people with ID.

**Objective.**– In this context, the objective of our work is to design and develop a digital tool for helping people with ID to develop a life plan.

**Method.**– To do so, a user-oriented process with more than one hundred interviews has been conducted with adults with Down's Syndrome (DS) and their caregivers.

**Results.**– Results show that scores of usability, effectiveness, efficiency, and satisfaction increased at each stage of the design. Moreover, the first evaluation of this tool (after one month of use by 2 people with DS) shows positive results with regard to the development of a life plan and generally on psychological well-being, worries and perceived self-determination.

**Conclusion.**– This research confirms the importance to develop tools to help people with intellectual disability make plans for the future to improve their well-being.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Multiple comorbidities in a fidgety child: Sotos syndrome type I with ADHD, hypothyroidism, anemia, vitamin D deficiency, abnormal EEG and borderline intelligence quotient

D.K. Mohinder Singh<sup>1\*</sup>, P. Jha<sup>2</sup>, V. Ghildiyal<sup>2</sup>, S. Ganpatrao Patil<sup>3</sup>, R. Ghildiyal<sup>2</sup>

<sup>1</sup> Mahatma Gandhi missions medical college, Navi Mumbai, India, department of psychiatry, Mumbai, India; <sup>2</sup> Mahatma Gandhi missions medical college, Navi Mumbai, India, department of psychiatry, Navi Mumbai, India; <sup>3</sup> Mahatma Gandhi missions medical college, Navi Mumbai, India, pediatric neurology, Navi Mumbai, India

\* Corresponding author.

**Introduction.**– There is sparse data on Sotos syndrome in the contextual interplay of neuropsychiatric and medical comorbidities.

**Objectives.**– To report a rare case report of multiple comorbidities in a 7-year-old fidgety boy.

**Methods.**– Case report. Master Y, a 7-year-old boy presented to the child psychiatry clinic brought by his parents with chief complaints of problems in his studies, hyperactivity, inattentiveness, behavioral problems since past few years. No features of autism were reported. Mild Facial dysmorphism was noted in physical examination. The child was not cooperative for formal mental status examination and was very restless, inattentive, hyperactive and fidgety.

**Results.**– Patient was diagnosed with ADHD (combined type). His blood report revealed iron deficiency anaemia (Hemoglobin 9g) and severe vitamin D deficiency and an elevated TSH (8.61). His EEG profile revealed sharp waves over frontal region and generalized epileptiform activity. He was started on Thyroid Hormone, Vitamin D and Iron Supplements from Pediatrics. He was diagnosed with Sotos Syndrome type I from Pediatric Neurology after clinical evaluation and appropriate genetic testing and was given clearance for Methyl Phenidate for ADHD and no antiepileptics were advised. IQ testing according to WISC testing came to 82. Tablet Methyl Phenidate 10 mg od and behavior therapy and OT was advised. His subsequent EEG and blood tests were normal and is doing clinically well.

**Conclusions.**– Sotos syndrome Type I can have ADHD and interplay of thyroid dysfunction, iron deficiency anemia, EEG abnormalities and Vitamin D deficiency as seen in our case.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparative efficacy and tolerability of lurasidone versus other atypical antipsychotics for the treatment of adolescent schizophrenia: A systematic literature review and network meta-analysis

D. Ng-Mak<sup>1</sup>, C. Arango<sup>2</sup>, E. Finn<sup>3</sup>, A. Byrne<sup>3</sup>, K. Rajagopalan<sup>4</sup>, A. Loebel<sup>5</sup>

<sup>1</sup> Sunovion pharmaceuticals Inc., health economics and outcomes research, Marlborough, USA; <sup>2</sup> Hospital General Universitario Gregorio Marañón, department of child and adolescent psychiatry, Madrid, Spain; <sup>3</sup> QuintilesIMS, n/a, London, United Kingdom; <sup>4</sup> Sunovion pharmaceuticals, health economics and outcomes research, Marlborough, USA; <sup>5</sup> Sunovion Pharmaceuticals, health economics and outcomes research, Fort Lee, USA

\* Corresponding author.

**Introduction.**– This comparative analysis assessed the relative efficacy and tolerability of lurasidone versus other atypical antipsychotics in the treatment of adolescent schizophrenia.

**Methods.**– A systematic literature review identified 13 randomized-controlled trials in adolescent schizophrenia-spectrum disorders. The Bayesian network meta-analysis compared lurasidone to other atypical antipsychotics on Positive and Negative Syndrome Scale (PANSS), Clinical Global Impressions-Severity (CGI-S), all-cause discontinuation, discontinuation due to adverse events, weight gain, somnolence, and extrapyramidal symptoms. Results from the fixed effects models were reported as mean differences for continuous outcomes and odds ratios for binary outcomes; each with a 95% credible interval.

**Results.**– Lurasidone had numerically greater improvement for PANSS and CGI-S compared with ziprasidone, asenapine, paliperidone ER, aripiprazole, and quetiapine, but not with olanzapine, risperidone, or clozapine. The odds ratios for all-cause discontinuation were significantly lower for lurasidone than aripiprazole (0.28 [0.10, 0.76]) and paliperidone ER (0.25 [0.08, 0.81]) as were discontinuations due to adverse events for lurasidone compared with asenapine (0.16 [0.03, 0.80]), aripiprazole (0.17 [0.02, 0.90]), olanzapine (0.06 [0.00, 0.47]), paliperidone ER (0.02 [0.00, 0.23]) and quetiapine (0.13 [0.02, 0.70]). Lurasidone was also associated with significantly lower weight gain than olanzapine (–3.62 kg [–4.84, –2.41]), quetiapine (–2.13 kg [–3.20, –1.08]), risperidone (–1.16 kg [–2.14, –0.17]), asenapine (–0.98 kg [–1.71, –0.24]), and paliperidone ER (–0.85 kg [–1.57, –0.14]). Rates of somnolence and extrapyramidal symptoms were similar for lurasidone and comparators.

**Conclusions.**– This network meta-analysis showed lurasidone was associated with comparable efficacy, lower weight gain and fewer discontinuations due to adverse events than other atypical antipsychotics for the treatment of adolescent schizophrenia.

**Disclosure of interest.**– Daisy Ng-Mak, Krithika Rajagopalan, and Antony Loebel are employees of Sunovion Pharmaceuticals Inc. Elaine Finn and Aidan Byrne are employees of QuintilesIMS, which received funding from Sunovion Pharmaceuticals Inc. This study was sponsored by Sunovion Pharmaceuticals Inc.

### Knowledge, practices and needs of french general practitioners regarding psychotic symptoms in adolescents and young adults

F. Perquier<sup>1</sup>, V. Kovess-Masféty<sup>2</sup>, M. Ferrua<sup>3</sup>, G. Gozlan<sup>4,5</sup>, M.O. Krebs<sup>5,6,7,8</sup>

<sup>1</sup> GHT Paris, psychiatrie & neurosciences, centre hospitalier Sainte-Anne, département d'épidémiologie, Paris, France; <sup>2</sup> EHESP Sorbonne Paris Cité, EA 4057 université Paris Descartes, Paris, France; <sup>3</sup> Gustave Roussy, équipe management des organisations de santé, Villejuif, France; <sup>4</sup> SAMSAH, PrépSy, Paris, France; <sup>5</sup> Faculté de médecine Paris Descartes, centre hospitalier Sainte-Anne, service hospitalo-universitaire, Paris, France; <sup>6</sup> Université Paris Descartes, université Paris Sorbonne Paris Cité, centre de psychiatrie et neurosciences UMR S 894, Paris, France; <sup>7</sup> CNRS, GDR3557 institut de psychiatrie, Paris, France; <sup>8</sup> Inserm, laboratoire de psychopathologie des maladies psychiatriques, centre de psychiatrie et neurosciences UMRS 894, Paris, France

\* Corresponding author.

**Introduction.**– General practitioners (GPs) play a significant role in detecting emerging psychiatric disorders in young adults aged 15 to 25, including psychosis. The way they screen and refer these patients has rarely been investigated in France.

**Objectives.**– To estimate the proportion of GPs who had ever seen young patients with symptoms of psychosis or schizophrenia and to assess GPs' knowledge, practices and needs in treating these patients.

**Methods.**– A web-based survey was completed by 300 GPs aimed to be representative of the French GP population according to age, sex, region and size of GPs' municipality of practice.

**Results.**– Approximately 69% of French GPs have ever seen a young person with obvious symptoms of psychosis or schizophrenia. They mostly refer them to specialized emergency services (57%). Among symptoms suggestive of early psychosis, GPs mostly identify school withdrawal (72%), aggressive behaviors (71%) and deterioration in personal hygiene (55%). 42% of them systematically refer young patients with suggestive signs to a specialized facility or to a mental health professional. However, GPs still report fear of stigma or of scaring the patient (50%), inadequate mental-health structures (19%) and/or insufficient information regarding existing structures (18%). 97% of GPs would be willing to refer these patients to mental-health services dedicated to young adults, 94% to receive information about early intervention and 87% would agree to use self-administered screening questionnaires.

**Conclusion.**– Implementation of rapid screening tools, information repositories and services dedicated to early intervention may improve GPs' management of early psychosis in young patients.

**Disclosure of interest.**– The study was supported by the Pierre Deniker Foundation.

The survey among GPs was financially supported by Otsuka Lundbeck that had no role in the construction of the questionnaire or in data analyses.

### Enhancement motives as a mediator of alcohol use among adolescents in Sfax, Tunisia

N. Smaoui<sup>\*</sup>, N. Charfi, M. Turki, M. Maalej Bouali, S. Omri, L. Zouari, N. Zouari, J. Ben Thabet, M. Maalej

Hedi Chaker university hospital, department of psychiatry "C" Hedi Chaker university hospital, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– The implication of sensations and pleasure seeking in alcohol use, among adolescents, is emphasized by various occidental studies. Therefore, data related to Tunisian adolescents are not available.

**Objectives.**– Our aims were to assess the prevalence of alcohol use among a sample of students from the city of Sfax and to determine the link between alcohol use and different dimensions of sensations seeking.

**Methods.**– This was a cross-sectional study enrolling 317 middle and high school students in Sfax (Tunisia). The alcohol dependence was evaluated by Alcohol Use Disorders Identification Test (AUDIT). The Sensation Seeking Scale (SSS-V) was used to assess the level of sensation seeking.

**Results.**– The average age of students was  $15.79 \pm 1.5$  years with a sex ratio of 1.07. The prevalence of current alcohol use was 8.8%. According to the AUDIT, alcohol dependence was identified among 42.8% of the alcohol users. The two main motives for alcohol consumption, reported by students, were the search for new experiences (57.8%) and the sensation of pleasure (60.7%). According to SSS-V, the average total score was more important among the alcohol users (23.9 versus 18.2;  $P < 0.001$ ). Alcohol use was correlated to the sensations seeking in particular on the dimensions of disinhibition ( $P < 0.001$ ), experience seeking ( $P = 0.002$ ) and boredom susceptibility ( $P = 0.001$ ). The average score of the thrill and adventure seeking was higher among the alcohol users, but without significant relationship (7.3 versus 6.9,  $P = 0.2$ ).

**Conclusion.**– Our study shows that sensations seeking, observed through enhancement motives, are related to alcohol use in Tunisian adolescents.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Non-syndromic orofacial clefts and increased risk for psychiatric disorders**

K. Tillman<sup>1</sup>, M. Hakelius<sup>2</sup>, M. Ramklint<sup>1</sup>, J. Höjjer<sup>3</sup>, L. Ekselius<sup>1</sup>, F. Papadopoulos<sup>1</sup>

<sup>1</sup> Akademiska university hospital, department of neuroscience, psychiatry, Uppsala, Sweden; <sup>2</sup> Akademiska university hospital, department of surgical sciences, maxillofacial surgery, and the department of surgical sciences, plastic surgery, Uppsala university hospital, Uppsala, Sweden; <sup>3</sup> Karolinska Institutet, Biostat Core, unit of biostatistics, IMM, Stockholm, Sweden

\* Corresponding author.

**Introduction.**– Being born with an orofacial cleft (OFC) can increase the risk of poor academic achievements and psychological health later in life.

**Objectives.**– To investigate the risk of psychiatric diagnoses in individuals with OFC, stratified by cleft type, compared with individuals without OFC and healthy siblings.

**Methods.**– A nationwide register-based cohort of all individuals born in Sweden with OFC between 1973 and 2013 ( $n = 7842$ ) was compared to a comparison cohort of healthy individuals ( $n = 78,409$ ) as well as to their healthy siblings. By linking to Swedish registers, we examined the risk of psychiatric diagnoses, suicide attempts and suicides by using Cox regression. The analyses were adjusted for perinatal factors, genetic syndromes and associated anomalies, parental socioeconomic factors as well as parental psychiatric morbidity and history of suicide attempts.

**Results.**– Children with non-syndromic OFC had a significantly higher risk of intellectual disability, language disorders, ADHD, ASD, psychosis and behavioral and emotional disorders with onset in childhood, compared with individuals without OFC. Children with

cleft palate only (CPO) had the highest risks and those with cleft lip (CL) the lowest. No increased risks were found regarding suicide or suicidal attempts. The healthy siblings of patients with OFC were less likely to be diagnosed with a psychiatric disorder.

**Conclusions.**– Children with non-syndromic OFC have increased risk for several neurodevelopmental disorders. The sibling analyses suggest that the higher risk cannot fully be explained by shared environmental or genetic factors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0471

### **Childhood maltreatment as a predictor of later psychological distress: A Tunisian study**

M. Turki<sup>\*</sup>, N. Charfi, N. Smaoui, S. Omri, M. Maalej-Bouali, L. Zouari, N. Zouari, J. Ben Thabet, M. Maalej

Hedi Chaker university hospital, psychiatry "C" department, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Maltreatment during childhood or adolescence is still widespread and often unrecognized. It has been linked to later physical and psychosocial disturbances.

**Aim.**– The aim of this study was to investigate the relationship between history of maltreatment and psychological distress as well as alcohol use among adolescents.

**Methods.**– It was a cross-sectional study involving 315 pupils from 4 middle and high schools in Sfax (Tunisia). We used the Alcohol Use Disorders Identification Test (AUDIT) to recognize risky alcohol-consumption.

**Results.**– The mean age was 16 years with a sex-ratio of 1.08. The participants have suffered in the past from physical abuse (16.2%), moral harassment (35.5%) or sexual abuse (1.6%). Among them, 7.3% had a psychiatric problem, 7.3% have already attempted suicide and 19.7% have drunk alcohol at least once in their lifetime.

Adolescents with history of physical abuse were more likely to attempt suicide ( $P = 0.002$ ). Those having suffered from moral harassment or sexual abuse were more likely to have a psychiatric problem later ( $P = 0.002$  and  $P = 0.045$  respectively) and to attempt suicide ( $P = 0.008$  and  $P = 0.045$  respectively).

Alcohol users were more likely to have histories of physical abuse ( $P = 0.002$ ), moral harassment ( $P = 0.003$ ) and suicide attempt ( $P = 0.015$ ). AUDIT score was significantly higher in alcohol users having suffered from sexual abuse ( $P = 0.011$ ).

**Conclusion.**– Our study highlighted the link between histories of maltreatment and later alcohol consumption and psychological disturbances. Thus, alcohol use management in adolescents with histories of maltreatment must include underlying issues of abuse and related psychological distress to reduce co-occurring health risk behaviors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Attention deficit and hyperactivity disorder in children with penetrating eye injury**

H. Yilmaz<sup>1</sup>, B.N. Özbaran<sup>1</sup>, E. Demirkılınc Biler<sup>2</sup>, M. Palamar Onay<sup>2</sup>

<sup>1</sup> Ege university, child and adolescence psychiatry, Izmir, Turkey;

<sup>2</sup> Ege university, ophthalmology, Izmir, Turkey

\* Corresponding author.

**Introduction.**– ADHD is significantly related to increased risk of injuries. One of the most important factors leading to non-congenital unilateral blindness in pediatric population is eye injury.

**Objectives.**– To assess both ADHD and other possible psychiatric disorders in children with penetrating eye injuries.

**Methods.**– 37 children with penetrating eye injury (PEI) aged between 4–13 years old as a patient group and 24 children with accommodative refractive esotropia (ARE) aged between 4–13 years old as a control group were recruited to study. All patients underwent a complete ophthalmic examination. History of penetrating eye injury and socio-demographic data were recorded. After clinical stabilization we assessed each group with Schedule for Affective Disorders and Schizophrenia for School Aged Children, Present and Lifetime Version. Turgay DSM-IV-Based Child and Adolescent Behavior Disorders Screening and Rating Scale was fulfilled by parents in order to evaluate ADHD symptoms.

**Results.**– 72.2% ( $n=26$ ) of children with PEI and 45.5% ( $n=10$ ) of children with ARE had a mental disorder ( $P=.178$ ). ADHD was the most frequent and anxiety disorder was the second leading psychiatric disorder in both groups. Prevalence of ADHD was found 48.7% in the PEI group versus 22.7% in the control group, respectively ( $P=.046$ ).

**Conclusion.**– ADHD was more common in children with PEI. In addition, prevalence of ADHD between PEI and ARE groups was statistically significant. ADHD is treatable psychiatric disorders, if it is diagnosed properly. Therefore, a suitable diagnosis and treatment of ADHD may prevent vision loss due to penetrating eye injuries in children.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Early onset of Gilles de la Tourette syndrome. Treatment results

I. Zaytsev<sup>1\*</sup>, D. Zaysev<sup>1</sup>, N. Titov<sup>2</sup>

<sup>1</sup> D.E. Zaytsev's psychoneurological center, psychiatry, Saint-Petersburg, Russia; <sup>2</sup> D.E. Zaytsev's psychoneurological center, neurology, Saint-Petersburg, Russia

\* Corresponding author.

**Introduction.**– Gilles de la Tourette syndrome (GTS) is a neurodevelopmental condition with onset in childhood and characterized by multiple motor tics and at least one phonic tic. Associated clinical features determine the severity of outcome and social disability (social impact).

**Objectives.**– To determine treatment results depending on the age of onset GTS and severity of coexistent psychopathology.

**Methods.**– Were included 46 children (31 boys, 15 girls) with onset of GTS in age from 3 to 10 years old. According to the age of onset GTS all children were divided into 3 groups: group I – age of onset GTS up to 3 years old (10 boys, 2 girls); group II – age of onset GTS from 3 to 6 years old (18 boys, 5 girls); group III – age of onset after 6 years old. All children were treated with Metaklopromid 0.01 as initial therapy in total dosage till 0.5 mg/kg/day. They got plus second drug – Tiaprid 0.1 in total dosage till 400 mg/day.

**Results.**– Despite the fact that children in group I had almost always ADHD, impulsiveness, aggression showed the fastest and more persistent reduction of tics and coexistent psychopathologies. Most children in group II with OCD and ADHD couldn't be totally reduced with tics and coexistent psychopathologies. Children in group III were reduced with OCD and ADHD, but not totally with their tics.

**Conclusion.**– Children with early onset of GTS (up to 3 years old) are compensated better with adequacy antipsychotic therapy compared to children with onset after 3 years old.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The prevalence of depression among the elderly in the Municipality of Igoumenitsa, Greece

N. Lamprou<sup>1</sup>, K. Argyropoulos<sup>1</sup>, D. Avramidis<sup>2\*</sup>, P. Gourzis<sup>3</sup>, E. Jelastopulu<sup>1</sup>

<sup>1</sup> University of Patras, Greece, public health, Patras, Greece;

<sup>2</sup> University of Patras, Greece, medical school, Patras, Greece;

<sup>3</sup> University hospital of Patras, Greece, psychiatry, Patras, Greece

\* Corresponding author.

**Introduction.**– Depression is the commonest psychiatric disorder in the elderly; it is often misdiagnosed and under-treated.

**Objective.**– To estimate the prevalence of depression among the elderly of a rural area in Greece and to identify its associated factors.

**Method.**– A cross-sectional study was conducted among 263 elderly residents aged 60 years old and above, all members of day care centers or home care recipients. Data was collected using the Geriatric Depression Scale (GDS-15) questionnaire. Furthermore, socio-demographic data and three questions from the European Health Interview Survey (EHIS), regarding self-reported or by a physician diagnosed depression, was included. A third questionnaire part consisted of the Athens Insomnia Scale (AIS), a self-assessment psychometric instrument to evaluate the quality of sleep.

**Results.**– Based on the GDS scores, 41.2% of the respondents screened positive for depressive symptoms. In 153 (58%) participants reported never have been affected by depression, depressive symptoms were found in 43 (27.8%). Depression was more common among the respondents who were aged 80 years old and above (59%) compared to those aged 60 to 79 years old (33.1%). Depression was also more frequent among females (45.4%) compared to males (27.9%), the elderly who lived alone (52%) compared to those living with family (41.2%), and among home recipients (57.7%) compared to members of day care centers for elderly (29%).

**Conclusions.**– High prevalence of depression in elderly is evident but rarely recognised. Primary Care providers need to be vigilant when treating elderly patients as depression is commonly found in this age group.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction.**– Tools to identify unsafe older drivers are wanted. Dobbs and Shopflocher (2010) proposed the Screen for the Identification of Cognitively Impaired Medically At-Risk Drivers, A Modification of the DemTect (SIMARD-MD). The DemTect is a cog-

nitive screening test (Kalbe et al., 2004) but was not developed to identify unsafe drivers.

**Objectives.**– To examine: (a) associations between scores on the SIMARD-MD and DemTect and other measures of cognition (e.g., Standardized Mini-Mental State Examination [SMMSE]), and (b) the association between SIMARD-MD and DemTect and on-road tests results.

**Methods.**– Thirty healthy older drivers (17 men, 13 women; aged 70 to 87) completed cognitive tests and a standardized on-road driving test.

**Results.**– The SIMARD-MD and DemTect were inter-correlated ( $r = .85, P < .001$ ) and with other tests (e.g., SMMSE,  $r = .59, P = .001$  and  $r = .47, P = .009$ ). Neither SIMARD-MD nor DemTect scores were associated with on-road scores ( $r = .17, P = .364$  and  $r = .19, P = .313$  respectively). Using proposed SIMARD-MD cut-points, 21 participants (70%) were predicted to pass the on-road test, eight participants (26.7%) were “indeterminate”, and one participant (3.3%) was predicted to fail. The driving instructor’s determination was that all participants passed.

**Conclusions.**– The SIMARD-MD was not associated with on-road results. Furthermore, when a test developed with a high prevalence of a condition (both the SIMARD-MD and DemTect were) is used in a low prevalence situation (as the SIMARD-MD was applied here and as suggested by its proponents) a positive result is likely a “false positive”. This study demonstrates the pitfalls of administering the SIMARD-MD to healthy older drivers.

### Risperidone-associated sexual dysfunction in women

I. Berrahal<sup>1</sup>, Y. Abid<sup>1</sup>, H. Maatallah<sup>1</sup>, R. Triki<sup>2</sup>, M. Cheour<sup>1</sup>, R. Ghachem<sup>2</sup>

<sup>1</sup> Razi Hospital, Psychiatry Ward “Ibn Omrane”, Mannouba, Tunisia;

<sup>2</sup> Razi hospital, psychiatry Ward “Pinel”, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Sexual dysfunction is the most bothersome symptom and adverse drug effect of antipsychotics and Risperidone seems to be the antipsychotic treatment causing the most sexual dysfunction.

**Objective.**– The aim of this study was to describe sexual dysfunctions occurred in a population of women treated with risperidone.

**Methods.**– It was a retrospective and descriptive study about 60 Tunisian women treated with risperidone during 1 year at least, consulting in the Adult Outpatient “Pinel” of Razi hospital from 2014 to 2015.

**Results.**– Sixty female patients were included in this study. The mean age was 28 years (SD: 3.4). They were treated for schizophrenia (50%), Bipolar disorder (25%), schizoaffective disorder (16.6%) and personality disorder (8.4%). Risperidone was prescribed in monotherapy in 53.3% of cases. The other associations were with a Benzodiazepine (33.3%), a mood stabilizer (41.6%) and antiparkinsonism drug (18.3%).

The most common sexual ADEs was a decreased sexual desire in 46.6% of the cases. The others sexual ADEs were amenorrhoea (27%), vaginal dryness (18%) and Galactorrhea in (10%). However, we found one case of increased sexual desire.

**Conclusion.**– An attention to the associated sexual and reproductive functions side effects of risperidone in women is necessary in order to improve the adherence to the treatment of our patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Evaluation of a decision-making algorithm for hospitalization of elderly affected by Diogenes syndrome or related disorders

B. Calvet<sup>1,2\*</sup>, M. Boulesteix<sup>1</sup>, J.P. Clément<sup>1,2</sup>

<sup>1</sup> Esquirol hospital center, geriatric psychiatry, Limoges, France;

<sup>2</sup> INSERM, UMR1094, Limoges, France

\* Corresponding author.

Diogenes syndromes and related disorders (DS) are rare psychiatric conditions still not sufficiently studied scientifically. However, they present major problems of care for practitioners at home faced with the difficult decision of hospitalization, specifically regarding potential suicidal risk for the person torn away from his house.

The objective of this retrospective analytical observational study was to evaluate the concordant validity of a decision-making algorithm for DS hospitalization. It was realized by comparing the care strategies obtained with this scale and those led in practice by a Mobile Psychiatric Team of Evaluation and Follow-up for the Elderly (EMESPA) in Limoges.

Elderly with DS and assessed by EMESPA at home between 2013 and 2016 were selected on 905 outpatients. After several preliminary works, a scale baptized Ethical and Clinical Score of Diogenes Hospitalization (SECHD) was created to help in the decision of hospitalization of these subjects. Statistical analyses assessing its psychometric qualities were carried out.

Thirty two older people were recruited. The total SECHD score and its sub-scores concerning the environmental and the intrinsic factors predicted significantly the decision of hospitalization of these subjects. Good performances were found, with respective levels of significance:  $P = 0.005$ ,  $P = 0.017$  and  $P = 0.012$ .

The SECHD appears to be performing for the detection of the indication of hospitalization for subjects with DS, and could thus be used in practice to carry out prospective analyses. More studies would be necessary on larger samples in order to improve the relevance of this score into clinical practice.

### Body esteem as a common factor of binge eating and sexual dissatisfaction among women: The role of dissociation and stress response during sex

G. Castellini<sup>1\*</sup>, C. Lo Sauro<sup>1</sup>, V. Ricca<sup>1</sup>, A. Rellini<sup>2</sup>

<sup>1</sup> University of Florence, department of neuroscience, psychology,

drug research and child health, Florence, Italy; <sup>2</sup> University of

Vermont, department of psychology, Burlington, USA

\* Corresponding author.

**Introduction.**– The relationship between eating disorder psychopathology and sexuality is a promising field of research, as eating disorders and sexual dysfunction show several shared cognitive, emotional and biological maintaining factors.

**Objective.**– The present cross-sectional study performed in a non-clinical sample showed that a dysfunctional body image esteem and binge eating behaviors are associated with less sexual satisfaction in women.

**Methods.**– In the present cross-sectional study we evaluated a non-clinical sample of 60 heterosexual women (ages 25–35 years), in terms of dissociation during sex with a partner, body image disturbance and pathological eating behaviors. Finally we evaluated the

stress-induced Hypothalamic-Pituitary Adrenal Axis (HPA) activation in response to a sexual stimuli and its association with both binge eating and dissociation.

**Results.**– A dysfunctional body image esteem and binge eating behaviors are associated with higher sexual distress in women. In particular, body esteem was significantly associated with greater dissociation during sex with a partner. Moreover, women who reported greater dissociation during sex with a partner and binge eating behaviors (Fig. 1) showed higher levels of cortisol in response to sexual stimuli.

**Conclusions.**– Women reporting binge eating episodes and dissociation during sexual experiences represented a subpopulation with a relevant uneasiness towards their body perception, and with higher stress response during sexual stimuli. Trans-diagnostic treatments targeted on dissociation and body image esteem may improve sexual dysfunction as well as pathological eating behaviors.

### Psychotropic drugs are associated with functional decline and more needs in nursing homes

A.R. Ferreira<sup>1</sup>, E. Moreira<sup>2</sup>, J. Guedes<sup>3</sup>, M.R. Simões<sup>4</sup>, L. Fernandes<sup>2\*</sup>  
<sup>1</sup> Faculty of medicine, university of Porto, PhD program in clinical and health services research/PDICSS, center for health technology and services research/CINTESIS, Porto, Portugal; <sup>2</sup> Faculty of medicine, university of Porto, center for health technology and services research/CINTESIS, Porto, Portugal; <sup>3</sup> Higher institute of social work, of Porto, Porto, Portugal; <sup>4</sup> Faculty of psychology and educational sciences, university of Coimbra, psychological assessment laboratory, CINEICC, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Ageing is associated with higher prevalence of chronic and mental health conditions, determining greater care demands and functional disabilities that often precipitate institutionalization in nursing homes (NH). In NH, psychotropic drugs are frequently prescribed as long-term treatment, regardless of adverse effects, which are likely to worsen functional decline.

**Objectives.**– To analyse the NH prescription of psychotropics, and examine their relation with cognition, function and needs.

**Methods.**– A cross-sectional study was conducted. All NH residents were eligible ( $\geq 60$  years). Psychotropic drugs were grouped using the Anatomical Therapeutic Classification(ATC), and participants were assessed with Mini Mental State Examination/MMSE (cognition), Camberwell Assessment of Needs for the Elderly/CANE

(needs), and Adults and Older Adults Functional Assessment Inventory/IAFAI (basic/BALD and instrumental activities of daily living/IADL).

**Results.**– Overall, 170 residents entered the study, with a mean age of 83.9 (sd = 7.1) years. Cognitive and functional decline were prevalent, with 57.6% presenting cognitive decline and IAFAI mean score of 45.1% (sd = 23.4). From the sample, 79.6% were prescribed with at least one psychotropic, and 31.8% were using  $\geq 3$ , being anxiolytics (53.3%), antidepressants (33.5%) and antipsychotics (16.2%) the most frequent. Positive associations were found between psychotropics and IAFAI total ( $r_s = 0.183$ ,  $P = 0.046$ ), IADL ( $r_s = 0.189$ ,  $P = 0.040$ ), met ( $r_s = 0.275$ ,  $P = 0.001$ ), unmet ( $r_s = 0.177$ ,  $P = 0.039$ ) and global needs ( $r_s = 0.240$ ,  $P = 0.005$ ), but not with cognition ( $r_s = -0.026$ ,  $P = 0.743$ ).

**Conclusions.**– Psychotropic drugs were frequently prescribed, and were associated with important negative outcomes. This association with worse functional capacity may increase the overall dependency and subsequently the number of needs. Non-pharmacological interventions should be encouraged.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Adherence to physical activity in elderly diabetic patients: The association with depression and anxiety

R. Mendes<sup>1,2</sup>, M. Cunha<sup>1</sup>, S. Martins<sup>2,3</sup>, L. Fernandes<sup>2,3,4\*</sup>

<sup>1</sup> São João hospital centre CHSJ, department of internal medicine, Porto, Portugal; <sup>2</sup> Center for health technology and services research CINTESIS, faculty of medicine, university of Porto, Porto, Portugal; <sup>3</sup> Faculty of medicine, university of Porto, department of clinical neurosciences and mental health, Porto, Portugal; <sup>4</sup> São João hospital centre CHSJ, clinic of psychiatry and mental health, Porto, Portugal

\* Corresponding author.

**Introduction.**– Diabetes Mellitus/DM is a chronic pandemic disease, affecting about 422 million people worldwide. Its increase has been associated with many factors, in particular physical inactivity and obesity. In this context, physical activity/PA is recommended since it can prevent and contribute to the management of the DM and the associated morbidity. Furthermore, patients with DM are less likely to engage and adhere to PA. Some barriers, such as pain, tiredness and depression have been reported as poor adherence factors.

**Objective.**– To analyze whether anxiety/depression were associated with adherence to PA in elderly patients with DM.

**Methods.**– This cross-sectional study included elderly outpatients from Internal Medicine Department in CHSJ/Porto, Portugal. Patients aged  $\geq 65$  y.o. and had been diagnosed with DM. Those unable to communicate were excluded. The Hospital Anxiety and Depression Scale/HADS was used for anxiety and depression assessment. Adherence to regular PA was dichotomized for analysis.

**Results.**– This study included 94 elderly patients, with a mean age of 75.2 y.o.(sd = 6.6), mostly female (53.2%), married (63.8%) and with low education level (61.7%). According to HADS, 16.1% presented depression and 25.8% anxiety. Most of the patients (85.1%) were non-adherent to PA. Comparing the two groups, non-adherent patients presented higher depression (median 3 vs. 1,  $P = 0.004$ ) and anxiety scores (median 4 vs. 2,  $P = 0.28$ ).

**Conclusions.**– Higher anxiety and depression has been associated with less adherence to PA, which is in accordance with previous research. Considering this data, early detection and treatment of anxiety and depression could be used in order to improve patients' engagement with exercise, contributing also to prevention and better management of this disease.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Sociodemographic profile of transsexual patients in Poland**

P. Galecki<sup>1</sup>, M. Filip<sup>1</sup>, M. Zajackowska<sup>1</sup>, A. Robacha<sup>2</sup>, A. Orzechowska<sup>1</sup>

<sup>1</sup> Medical university of Lodz, department of adult psychiatry, Lodz, Poland; <sup>2</sup> Mental health clinic and the pathology of intimacy clinic, mental health clinic and the pathology of intimacy clinic, Lodz, Poland

\* Corresponding author.

**Introduction.**– Broadening and popularizing knowledge about the determinants of transsexuality in medical and non-medical communities play an important role in shaping the positive attitudes, tolerance and respect towards persons suffering from this condition and also enables them to receive a proper medical and psychological help. Patients would also benefit from improved diagnostic, therapeutic and legal processes related to the gender change in Poland.

**Objectives.**– The aim of the study is sociodemographic characteristics of the group affected by transsexuality in Poland.

**Methods.**– Study includes a retrospective analysis of medical record of patients (in the period from 2009–2015) aged 18 and above, both sexes, with definitive transsexual diagnosis (ICD 10-F64), treated in the Mental Health Clinic and the Pathology of Intimacy Clinic in Lodz. One group of approximately 136 participants and no control group was created. The obtained data was analyzed statistically.

**Results.**– Of the 136 participants in the study, 30 were diagnosed with transgender type – MtF (22.05%) and 106 – FtM (77.94%). The age range in the study was wide. The oldest person was 53 years old, the youngest was 17 years old (M = 25.57, SD = 7.89). The study also included the number of years of treatment (attendance at the clinic) – maximum 24 years, minimum less than 1 year (M = 5.34, SD = 4.58).

**Conclusions.**– Gathering and analysis of sociodemographic data is important for elucidating the transsexual patient's profile. It facilitates better understanding, timely recognition and choice of appropriate treatment for these patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Evaluation of the psychosocial profile of elderly with fall-related hip fracture: Preliminary results from 6-month follow-up descriptive study**

M. Gardea Resendez<sup>1</sup>, A. Lopez-Rangel<sup>1</sup>, O. Kawas-Valle<sup>1</sup>, V. Peña-Martinez<sup>2</sup>, R. Eguia-Rodriguez<sup>1</sup>, A. Barragan-Rodriguez<sup>1</sup>

<sup>1</sup> Universidad Autonoma de Nuevo Leon, psychiatry, Monterrey, Mexico; <sup>2</sup> Universidad Autonoma de Nuevo Leon, orthopaedics & traumatology, Monterrey, Mexico

\* Corresponding author.

Fall-related hip fractures (FRHP) in the elderly represent a major public health concern of increasing incidence. Studying the

psychosocial profile of these patients can contribute to the development of preventive and rehabilitation strategies.

The objective was to determine the sociodemographic and psychological characteristics of elderly hospitalized for FRHP in the department of orthopedics of a northeastern Mexican university hospital.

A cross-sectional study was conducted, including all patients over 65 years hospitalized for FHRP. A questionnaire assessing sociodemographic characteristics and comorbidities, the Barthel Index of Activities of Daily Living, Downton Fall Risk Index and the Ryff's Psychological Well-Being Scale were applied during the first 6 months of the year-long evaluation.

A total of 37 cases were identified, 30 of which met the criterion of inclusion. 76.66% of patients were females and 86.66% had none or elementary education. Analysis of work status, monthly income and main income source showed that most patients lived in extreme poverty. 83.33% were engaged to at least one social, religious or physical activity on a regular basis. Prior to the fracture, 60% of the patients were at high risk of falls and 40% had moderate to full dependence for daily-life activities. Analphabetism and cognitive or sensorial impairment impeded the application of Ryff's Scale in 86.66% of patients.

Preliminary findings showed that female gender, low education, extreme poverty, inadequate support system, lack of engagement in social and productive activities, as well as elevated risk for falls and diminished functional independence, are common denominators among elderly with FHRP.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– Behavioral symptoms are common in Alzheimer's disease (AD). Few data are available concerning the prevalence of these in low- and middle-income countries.

**Objective.**– To estimate the prevalence of behavioral symptoms among the older people with AD in the Central African Republic (CAR) and the Republic of Congo (ROC).

**Methods.**– The EPIDEMCA (Epidemiology of Dementia in Central Africa) is multicentre population-based study carried out in rural and urban areas of the CAR and the ROC between 2011 and 2012 in people aged 65 and over, following a Two-phase design. The first phase was a cognitive screening using the Community Screening Interview for? Dementia. In the second phase, participants suspected of dementia underwent clinical assessment. Diagnosis of dementia was established through the DSM-IV criteria and the clinical criteria proposed by the NINCDS-ADRDA for AD. Behavioral disorders were evaluated through the neuropsychiatric inventory.

**Results.**– The study population consisted of 98 AD patients. At least one behavioral disorder was reported in 91.7% (CI<sub>95%</sub>: 84.3–96.3), 38.1% of them reporting one or two behavioral disorders and 53.6%

reporting three or more. The most frequent symptoms were depression (62.2%), anxiety (41.8%), irritability (36.7%), apathy (33.6%) and delusions (31.6%).

**Conclusion.**– The prevalence of behavioural disorders is high in our study. However, further studies will be needed to better characterize behavioral disorders in others African countries.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Apolipoproteine E and neuropsychiatric symptoms in Central Africa**

Y. Ines<sup>1\*</sup>, P. Nubukpo<sup>1</sup>, P. Mbelesso<sup>2</sup>, B. Ndamba-Bandzouzi<sup>3</sup>, J.F. Dartigues<sup>4</sup>, P.M. Preux<sup>1</sup>, M. Guerchet<sup>5</sup>

<sup>1</sup> INSERM, U1094, tropical neuroepidemiology, Haute Vienne, Limoges, France; <sup>2</sup> Department of neurology, Amitié hospital, Bangui, Central African Republic; <sup>3</sup> Department of neurology, Brazzaville university hospital, Brazzaville, Congo; <sup>4</sup> Center of recherche Inserm U1219 “Bordeaux Population Health”, Bordeaux, France; <sup>5</sup> King’s College London, centre for global mental health, health service and population research department, London, United Kingdom

\* Corresponding author.

**Introduction.**– Genetic determinants of behavioral disorders in dementia have been proposed from family studies, especially the  $\epsilon 4$  allele of the apolipoprotein E (APOE  $\epsilon 4$ ) gene which increases the risk of dementia in Caucasian populations.

**Objective.**– To evaluate the association between behavioral symptoms and APOE among the older people in the Central African Republic (CAR) and the Republic of Congo (ROC).

**Methods.**– The EPIDEMCA (Epidemiology of Dementia in Central Africa) is multicentre population-based study carried out in rural and urban areas of the CAR and the ROC between 2011 and 2012 in people aged 65 and over, following a two-phase design. After a cognitive screening using the Community Screening Interview for Dementia, participants suspected of dementia underwent clinical assessment. Diagnosis of dementia was established through the DSM-IV criteria and the clinical criteria proposed by the NINCDS-ADRDA for AD. Behavioral disorders were evaluated through the neuropsychiatric inventory during the clinical assessment. Blood sample was taken from all consenting participants and the APOE gene was genotyped.

**Results.**– The study population consisted of 322 older people. The median age was 75.5 years [65–99]. There was a female predominance. Behavioral disorders were reported by 192 participants (59.8%). The APOE  $\epsilon 4$  gene was present in 135 (41.9%) older people. This allele was protective for behavioral disorders after univariate analysis (OR = 0.7, 95% CI: 0.6–0.9,  $P = 0.031$ ).

**Conclusion.**– In this study, APOE  $\epsilon 4$  is protective of the behavioral disorders. However, complementary analyzes are necessary to better characterize this link.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0485

### **Testosterone and luteinizing hormone levels in hypersexual men and healthy controls; Associations with methylation status of HPA and HPG axis genes**

J. Jokinen

Umeå university, clinical sciences, Umeå, Sweden

Hypersexual disorder as suggested to be included in the DSM-5 integrates aspects of sexual desire deregulation, impulsivity and compulsivity. However, it is unknown how it affects gonadal activity and the function of HPG axis.

**Objective.**– To investigate testosterone and luteinizing hormone (LH) levels in 67 men with hypersexual disorder compared to 39 age matched healthy controls and epigenetic modifications in HPA and HPG-axis coupled CpG-sites (5'-Cytosine-phosphate-Guanine-3' regions in DNA).

**Methods.**– Basal morning plasma levels of testosterone, Sex Hormone-Binding Globulin (SHBG), and LH were assessed. The genome-wide methylation pattern of over 850K CpG-sites was measured in whole blood using the Illumina Infinium Methylation EPIC BeadChip adjusted for white blood cell type heterogeneity. CpG-sites located within 2000 bp of the transcriptional start site of HPA and HPG axis coupled genes were included. We performed multiple linear regression models of methylation  $M$ -values to plasma testosterone levels as well as methylation  $M$ -values to plasma LH levels respectively.

**Results.**– LH plasma levels were significantly higher in hypersexual patients compared to healthy volunteers. Plasma testosterone and SHBG levels did not differ between the groups. 221 individual CpG-sites were tested. For testosterone plasma levels, twelve were nominally significant ( $P < 0.05$ ), and twenty for LH plasma levels. No individual CpG site was significant after multiple testing corrections.

**Conclusions.**– Our results show evidence of dysregulation of the HPG axis with increased LH plasma levels but no significant epigenetic changes of HPA and HPG axis coupled genes were related to LH and testosterone levels in hypersexual men.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

PW0486

### **Relationship between forgiveness elderly and prosperous aging in primary health care**

M. Karvela<sup>1\*</sup>, E. Kotrsotsiou<sup>2</sup>, C. Hatzoglou<sup>3</sup>, M. Gouva<sup>1</sup>

<sup>1</sup> TEI of Epirus, research laboratory psychology of patients families and health professionals, Ioannina, Greece; <sup>2</sup> TEI of Thessaly, research laboratory of care, T.E.I. of Thessaly, Larisa, Greece, Ioannina, Greece;

<sup>3</sup> Postgraduate Program “Primary Health Care”, university of Thessaly, Larisa, Greece, medical school, university of Thessaly, Larisa, Greece

\* Corresponding author.

**Background.**– The elderly persons continue to invest substantially in emotional relationships and the forgiveness has been linked to conditions that reduce the symptoms of psychopathology and high levels of quality of life.

**Objectives.**– The overall objective of this research study was to investigate the relation of the forgiveness of the elderly with their quality of life and psychopathology, in the context of primary health care.

**Method.**– The total sample included 192 older people with a mean age 74.80 (SD = 6.80). The elderly people completed: (a) The

Heartland Forgiveness Scale (HFS), (b) The SCL-90-R: Symptom Checklist-90-R, (c) Quality of Life (SF-36) and (d) questionnaire concerning socio-demographic information.

**Results.**– Univariate and multivariate analysis was applied for the statistical analysis of the data, which showed that: the forgiveness of the older people is positively related to all subscales of quality of life and negatively to the sub-scales of psychopathology. More specifically, observed statistically significant correlation between the scale Heartland Forgiveness Scale (HFS) and mental health (SF36) ( $P=0.000$ ), social role functioning (SF36) ( $P=0.000$ ), general health perceptions (SF36) ( $P=0.004$ ).

**Conclusions.**– The results from this study highlight the important role of forgiveness in the high quality of life in older people.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0487

### **Clinical features in Libido disorders (nonpsychotic mental diseases in men)**

N. Kibrik\*, M. Yagubov, I. Kan

Moscow research institute of psychiatry, sexopathology, Moscow, Russia

\* Corresponding author.

A comprehensive study of 150 men aged 20 to 50 years with complaints of sexual desire disorder, helped distribute them into 4 groups, depending on the nature of their mental disorders. The first group consisted of patients with endogenous depression – 45 (30%) of people in the second – patients with neurotic depression – 48 (32%) people in the third – patients with neurasthenia – 35 (23.3%) people, in the fourth – patients with residual-organic brain damage – 22 (14.7%) patients. In violation of endogenous depression libido is a total character, having a specific daily and seasonal rhythms. In patients with neurotic depression, disorders of sexual desire may occur against a background of fairly pronounced compensatory capacities of the individual, moderate (functional) behavioral and somatic-vegetative disorders. As part of neurasthenia sexual desire disorder observed in 2–4 months after the onset of the patients expressed neurotic symptoms For disorders of libido in organic mental disorders characterized by a certain dynamics resistant decreased libido, less dependent on external conditions. At light loads, patients do not find the strength and the desire to enter into intimate contact. Treatment in patients with a decrease in libido included antidepressants, trazodone (50–150 mg per day) was chosen because it does not negatively affect sexual function and multimodal mechanism of action.

**Conclusion.**– The study of disorders of sexual desire with the definition of clinical features is an important diagnostic criterion for qualification of mental disorders and to develop adequate therapeutic and rehabilitative programs.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0488

### **The effects of short-term psychosocial support and hormone therapy on quality of life in individuals with gender dysphoria**

E. Mutlu<sup>1</sup>, G. Öz<sup>2</sup>, K. Başar<sup>1</sup>

<sup>1</sup> Hacettepe university, faculty of medicine, psychiatry, Ankara, Turkey; <sup>2</sup> Ceylanpinar state hospital, psychiatry, Şanlıurfa, Turkey

\* Corresponding author.

**Introduction.**– In people with gender dysphoria (GD), transition involves psychiatric evaluation and follow-up, hormone therapy (HT) and surgical interventions. Quality of life (QoL) has been reported to be worse in people with gender dysphoria. Cross-sectional studies support that hormone therapy reduces mental and social distress and improves QoL.

**Objectives.**– To investigate the effects of psychosocial support and hormone therapy on mental health indices including QoL, and perceived discrimination in people with GD by naturalistic follow-up design.

**Methods.**– Individuals presenting to the psychiatry clinic for sex-reassignment and diagnosed as GD were evaluated twice: initially at the first interview and finally before the decision was made for genital surgery. Turkish version of the WHO QoL-BREF, Perceived Discrimination Scale (personal and group subscales), Multidimensional Scale of Perceived Social Support, Beck Depression Inventory, and a form on sociodemographic and transition-related features were filled by the participants.

**Results.**– Participants' ( $n=33$ , all assigned female at birth) mean age at first assessment was  $26.6 \pm 4$ . Mean follow-up duration was  $25.9 \pm 11$  months, mean HT duration was  $13.8 \pm 5$  months. Improvement in the psychological and social domain QoL scores ( $t=-3.581$ ,  $P=.001$ ,  $t=2.609$ ,  $P=.014$  respectively) and family support scores ( $z=-2.671$ ,  $P=.008$ ), reduction in the scores of perceived discrimination against the individual ( $z=3.487$ ,  $P \leq .001$ ) and depressive symptoms' severity ( $z=-3.650$ ,  $P \leq .001$ ) were significant.

**Conclusions.**– To our knowledge, this is the first follow-up study that shows that short-term psychosocial support and hormone therapy is associated with better QoL and lower personal perceived discrimination, however this study only involved transmen.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0489

### **The role of neuropsychiatric symptoms in predicting course and progression in major neurocognitive disorders**

J.M. Santacruz Escudero, C. Chimbí, D. Chavarro, M. Borda, R. Samper, H. Santamaría García<sup>1</sup>

Pontificia Universidad Javeriana, Psiquiatría, Bogotá, Colombia

\* Corresponding author.

Neuropsychiatric symptoms are crucial for determining course in neurocognitive disorders. However, little is known regarding to what extent presence of neuropsychiatric symptoms predicts disease progression, cognitive and functional impairments in behavioral variant frontotemporal dementia (bvFTD) and in alzheimer dementia.

**Methods.**– We performed two different evaluations (Time 1 (T1) and Time 2 (T2)) with 3 years of difference in a group of bvFTD ( $n=49$ ), AD ( $n=50$ ). Neuropsychological, clinical and cognitive correlates were measured in each time T1 and T2. By using different multiple regression models, we explored if behavioral symptoms (measured by Columbia, Yesavage at T1) predict disease progression as measured by changes over T1 and T2 in cognitive (MoCA, IFS, and clock figure) and functional dependency (Lawton scale).

**Results.**– Behavioral symptoms, in particular depression, psychosis, apathy and disinhibition were factors able to predict cognitive and functional progression in bvFTD. By contrast, regression model revealed that depression and insomnia were behavioral factors able to predict progression in AD.

**Conclusion.**– Neuropsychiatric symptoms are crucial to predict disease progression in bvFTD and AD patients in differentiated ways.

Our results suggest that tracking early behavioral symptoms in neurocognitive disorders playing an important role in the early detection, disease tracking, and neuroanatomical specification of bvFTD, as well as in future research on potential disease-modifying treatments.

*Introduction.*– Our hypothesis has been that we might utilize the Internet to identify and study digital communities of people with paraphilias.

*Methods.*– In three longitudinal studies investigating zoophilia, pedophilia, and gay BDSM, we applied mixed methods qualitative and quantitative solutions. In the first part, we selectively searched entire internet with modified version of DEVONagen Pro, using combination of keywords [“zoophilia” AND/OR “pedophilia” AND/OR “bdsm” AND/OR “kind” AND/OR “help”]. Through these efforts, we identified several thousand “hits” where people exchanged conversations about paraphilias. Over the course of two years, we carefully archived and qualitatively studied these materials. Subsequently, we advertised and collected survey responses from about a third of individuals whose posts were analyzed qualitatively.

*Results.*– We identified a number of methodological and ethical challenges concerning investigations of paraphilias using digital spaces. First, using selective search approach, our research minimized selection bias of digital materials for qualitative analysis as we looked for data across entire English-language Internet. Second, we show that using the Internet, and digital discussion spaces in particular, is an effective way of investigating paraphilias. Third, we show that retrospective qualitative analysis of discussions happening online effectively captured self-described lives of people living with paraphilias. Fourth, we show that surveys might be administered to capture data such as demographics and other information not available through qualitative analysis. Fifth, we devised an ethical system for collecting data on paraphilias.

*Conclusions.*– These findings ensure appropriate investigation of paraphilias on digital spaces, while exercising the highest ethical and methodological standards.

\* Corresponding author.

*Background.*– The quality of oral health in older people has been linked to conditions that increased psychological and social symptoms.

*Objectives.*– This study examined the relationship between oral health in older people and internal and external shame.

*Method.*– The total sample included 204 older people with a mean age 74.17 (SD=7.06). The elderly people completed (a) The Geriatric Oral Health Assessment Index (GOHAI), (b) The Other As Shamer Scale- OAS, (c) Experience of Shame Scale, ESS and (d) questionnaire concerning socio-demographic information.

*Results.*– One way ANOVA and MANCOVA was used for statistical analysis. Results did not show significant differences in oral health of elderly people in educational level, place of residence, friends in the past and marital status. Chronic disease was found to directly contribute in the in reducing the quality of oral health ( $F=5.063$ ,  $P=.025$ ). Thus GLM analysis found strong associations between quality of oral health and feeling of emptiness (OAS) ( $P=.000$ ), feeling of inferiority (OAS) ( $P=.009$ ), mistakes (OAS) ( $P=.012$ ), total external shame (OAS) ( $P=.002$ ), characterological shame (ESS) ( $P=.008$ ), bodily shame (ESS) ( $P=.000$ ) and total internal shame (ESS) ( $P=.005$ ).

*Conclusions.*– Our findings provide more detailed information on the negative effects of oral health on external and internal shame in elderly people.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

*Introduction.*– Although the etiology of gender dysphoria (GD) is not completely known, it has been said that prenatal exposure to testosterone could be an important factor in development of it. The ratio of the 2nd to the 4th (2D:4D) digit lengths has been suggested to represent prenatal testosterone levels. The data on 2D:4D digit ratios in subjects with GD are inconclusive and contradictory.

*Objectives.*– The present study aims to investigate the difference in 2D:4D digit ratios between subjects with female-to-male (FTM) GD, their sisters and, female controls.

**Methods.**– Thirty-five subjects with FtM GD (according to DSM-5 criteria), 35 their sisters and, 38 female controls were included in the study. Photocopies of the palms and digits of the hands of the participants were taken of all subjects and 2D:4D digit ratios were measured.

**Results.**– Comparisons between the groups revealed that the right-hand 2D:4D ratios in female controls are significantly higher than in subjects with FtM GD ( $P=0.02$ ). While there was no significant difference between subjects with FtM GD and their sisters in right-hand 2D:4D ratios, subjects with FtM GD had lower left-hand 2D:4D digit ratios compared to their sisters ( $P=0.047$ ).

**Conclusions.**– Our results support a biological etiology of subjects with FtM GD, pointing increased prenatal testosterone exposure in FtM GD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.
