\* Corresponding author.

**Introduction.**– Very little is known about experiencing stigma in dementia and factors which may influence it. The study was conducted within the JPND-funded MEETINGDEM project (2014–2017) which aimed to adapt and implement the Meeting Centre Support Programme (MCSP) for people with dementia and their carers in Italy, Poland and the United Kingdom.

**Objectives.**– To study if the experience of stigma is influenced by participation in the MCSP as compared to care as usual.

**Methods.**– People living with dementia recruited to participate in the study were assessed regarding the stigma experience (SIS), their depressive symptoms (CSDD), quality of life (DQoL, AOL-AD), obtained social support (DSSI) before and after 7 months of using MCSP ( $n=65$ ) or usual care ( $n=49$ ) available in Italy, Poland and the UK. Obtained data were statistically analysed using e.g. Kruskal-Wallis test or ANCOVAs.

**Results.**– People with dementia in all countries experienced stigma, although there were differences between countries and between MCSP and UC users. Statistically significant changes among MCSP users compared to the UC, after 7 months, were noticed for Social Isolation in Poland ( $P=0.000$ ) and for Social Rejection in the UK ( $P=0.03$ ). There were no significant changes in stigma experiences among people in Italy or among the whole group.

**Conclusions.**– People with dementia, living in Italy, Poland and the UK, experience stigmatisation. This study results shows that there may be a possibility of influencing the experience of stigmatisation via delivering adjusted support as MCSP. But there is still a need for further research in this field.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

Farina<sup>4</sup>, A. d'Arma<sup>4</sup>, F. Saibene<sup>4</sup>, I. Hendriks<sup>5</sup>, F. Meiland<sup>5</sup>, R.M. Dröes<sup>5</sup>

<sup>1</sup> Wroclaw medical university, department of psychiatry, Wroclaw, Poland; <sup>2</sup> University of Worcester, association for dementia studies, Worcester, United Kingdom; <sup>3</sup> University of Bologna, department of psychology, Bologna, Italy; <sup>4</sup> Don Gnocchi, foundation, Milan, Italy; <sup>5</sup> VU university medical center, department of psychiatry, Amsterdam, The Netherlands

\* Corresponding author.

**Introduction.**– The Meeting Centre Support Programme (MCSP) for people with dementia and carers was adapted and implemented in Italy, Poland and the United Kingdom within the JPND-funded MEETINGDEM project (2014–2017).

**Objectives.**– To study the effectiveness of MCSP compared to care as usual on various outcome measures.

**Methods.**– A pretest-post test multicentre controlled study was conducted. 9 Meeting Centres (MCs) participated (Italy-5, Poland-2, UK-2). Outcomes measures assessed after 7 months were: behaviour (NPI), depression (CSDD) and quality of life (DQoL, QoL-AD). Data were analysed by ANCOVAs. Additionally, a mixed methods explanatory design was used to measure satisfaction of MCSP participation.

**Results.**– 85 people with dementia and 93 carers using MCSP as well as 74 dyads getting UC were included in this study. QoL aspects of people with dementia in MCSP, compared to UC, raised (DQoL: Self-esteem;  $F=4.80$ ,  $P=0.03$ ; Positive Affect;  $F=14.93$ ,  $P<0.00$ ; Feelings of Belonging;  $F=7.77$ ,  $P=0.01$ ). Number of neuropsychiatric symptoms decreased more in MCSP compared to UC. Higher attendance levels correlated with a neuropsychiatric symptom reduction ( $\rho=0.24$ ,  $P=0.03$ ) and an increase of obtained social support ( $\rho=0.36$ ,  $P=0.001$ ). Moreover, the percentage of satisfied users increased significantly over time ( $P=0.05$ ) and the majority of carers (91%) reported a decrease in burden after 7 months. Focus group analysis showed that people with dementia and carers improved their ability to maintain an emotional balance in all countries.

**Conclusions.**– The MCSP successful implementation and its effectiveness observed in all countries encourages to disseminate this type of support world-wide.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– Reduction in neuronal activity, oxidative stress and inflammatory processes are supposed to impact the cognitive processes. Whole-body cryotherapy (WBC), used mostly in rehabilitation, is a biological intervention by exposure to extremely low temperatures. There are some research showing its anti-inflammatory and anti-oxidative effects which suggests that it may be used in other medical fields.

**Aim.**– The assessment of whole-body cryotherapy effect on cognitive functions, mood and blood parameters measures among people with mild cognitive impairment (MCI).

**Materials and methods.**– 21 people with MCI ( $21 \leq \text{MoCA test} \leq 26$ ) recruited to participate in the study underwent 10 WBC sessions ( $-110^\circ\text{C}$  do  $-160^\circ\text{C}$ ). They were assessed before (T1), after the last WBC session (T2) and at follow-up after two weeks using DemTect, SLUMS, TYM, FAS, GDS. Additionally, BDNF, NO, interleukins (IL-6, IL-8, IL-10) were measured in T1 and T2. Obtained data were statistically analysed.

**Results.**– The memory processes, measured by DemTect and TYM, improved significantly ( $P=0.000$  i  $P=0.0001$ , respectively). Moreover, participants declared the increase of their activity level (GDS, item 13) in T2 and T3 ( $P=0.009$ ). The NO level in plasma raised significantly ( $P=0.014$ ) and IL-6 level decreased ( $p=0.023$ ) with the increase of BDNF concentration ( $P=0.031$ ).

**Conclusions.**– Short, repetitive exposure on extreme low temperatures may be a possible additional form of therapy in mild cognitive impairment. The possible explanations are immunostimulative and immunomodulative role of WBC.

### Quality of life of the elderly – Assessing physical and mental comorbidities

V. Voros<sup>1\*</sup>, P. Osvath<sup>1</sup>, A. Kovacs<sup>1</sup>, A. Boda-Jorg<sup>1</sup>, M. Popa<sup>2</sup>, T. Tenyi<sup>1</sup>, S. Fekete<sup>1</sup>, C. ICT4Life<sup>3</sup>

<sup>1</sup> University of Pecs, department of psychiatry and psychotherapy, Pecs, Hungary; <sup>2</sup> University of Maastricht, department of data science and knowledge engineering, Maastricht, The Netherlands; <sup>3</sup> ICT4Life, Consortium, Madrid, Spain

\* Corresponding author.

**Introduction.**– ICT4Life project is aimed to improve quality of life and independence of patients with Alzheimer's disease and their caregivers while using the developed ICT platform and integrated care system.

**Objectives.**– To assess cognitive functioning of elderly and to investigate whether cognitive decline is associated with quality of life and physical and mental comorbidities. Our hypothesis was that patients with cognitive decline have poorer quality of life and have more co-morbid illnesses.

**Methods.**– In the framework of the ICT4Life project, 60 elderlies completed a structured interview and self-administered questionnaires assessing cognitive functions (MMSE, CDT), quality of life (OPQOL, QoL-AD), depression (BDI-SF), and associated physical and mental disorders. Sample correlation and sample variances were performed on two populations (elderly with and without dementia).

**Results.**– The MMSE and the CDT were well correlated in measuring cognitive levels, representing an efficient way of tracking cognitive functioning in elderly. Dementia was associated with higher mean age (78 years vs. 73 years), lower educational level and poorer

quality of life (28% vs. 72% have moderate or better QoL). Subjects with cognitive decline were more likely to have other physical and mental illnesses, especially cardiovascular disorders and depression (78% vs. 10%).

**Conclusions.**– Clinically significant cognitive decline was found in the majority of elderly people. These subjects have poorer quality of life and have more physical and mental comorbidities. Different ICT technologies with an integrated care platform providing continuous monitoring may help patients with Alzheimer's disease to improve their quality of life and reduce burden of caregivers, medical staff, and society.

### Lithium's impact on the sexual function of bipolar patients

O. Zerriaa<sup>\*</sup>, F. Fekih-Romdhane, J. Jendoubi, B. Oueslati, I. Ghazali, R. Ridha

Razi hospital, forensic psychiatry department, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Lithium is the gold standard mood stabilizer. Yet there are only few studies examining the effect of this drug on sexual function in patients with bipolar disorder.

**Objectives and methods.**– The aim of our study was to evaluate the impact of lithium on the sexual function of bipolar patients.

We conducted a systematic review of the literature. Search has been made in Medline using the following keywords: "sexual dysfunction", "lithium" and "bipolar disorder". No time restrictions have been applied.

**Results.**– Biological studies suggest that lithium could decrease testosterone levels in males and increase oestradiol levels in females resulting in a menstrual disturbances and sexual dysfunction.

Clinical studies results were heterogeneous. Some studies showed that one third of bipolar patients treated with lithium experienced difficulties in sexual functions. In fact, lithium may reduce sexual thoughts and desire, worsen erectile function and reduce sexual satisfaction.

Other studies found that using only lithium did not have remarkable effect on sexual function among bipolar patients. However, patients on concomitant benzodiazepines prescription with lithium, reported negative effects on their sexual function. Thus, sexual dysfunction among bipolar patients treated with lithium seemed to be a result of its association with other drugs such as antipsychotics, antidepressants and benzodiazepines.

**Conclusion.**– The combination of lithium with other drugs appeared to be associated with sexual dysfunction. Sexual dysfunction during lithium treatment among bipolar patients is thought to be an important cause of non compliance resulting in frequent relapses. Psychiatrists should systematically search for sexual difficulties when treating bipolar patients with lithium to reduce the risk of non compliance.

### **Sexual dysfunction during pregnancy: Prevalence and relationship with depression among the women of Azad Jammu Kashmir**

U. Zubair<sup>1\*</sup>, A. Ali<sup>2</sup><sup>1</sup> PIMS-SZAMBU, psychiatry, Islamabad, Pakistan; <sup>2</sup> Poonch medical college Rawalkot AJK, psychiatry, Rawalakot, Pakistan

\* Corresponding author.

**Introduction.**– Sexual dysfunction is defined as the inability of a person to experience the sexual arousal or to achieve sexual satisfaction under appropriate circumstances as a result of either physical or psychological problems. Female sexual dysfunction (FSD) affects ≈ 40–50% of the women. FSD occurs as a part of various medical conditions like pregnancy, Diabetes Mellitus, psoriasis, depression and anxiety, etc.

**Objective.**– To determine the sexual function and its relationship with depression among the pregnant women.

**Methods.**– The sample population comprised of 161 pregnant women reporting for the ante natal checkup at a tertiary care hospital in AJK. Sexual function was assessed using the Female sexual function index (FSFI). Depression was assessed by using the Patient Health Questionnaire-2 (PHQ-2). Relationship of depression and other socio-demographic factors was assessed with the sexual dysfunction.

**Results.**– Out of 161 pregnant women screened through FSFI, 19.9% had normal sexual function while 80.1% had sexual dysfunction. After applying the logistic regression we found that parity, tobacco smoking, worry about future, previous loss or complication, duration of marriage and depression had significant association with the sexual dysfunction.

**Conclusion.**– This study showed a high prevalence of sexual dysfunction among pregnant women in AJK. Special attention should be paid to the primiparous women or those with longer duration of marriage and previous pregnancy loss or complications. Worry about future and presence of depressive symptoms also emerged as an independent factors responsible for the sexual dysfunction in our target population.

## **Psychotherapy**

PW0499

### **Psychotherapy and technology. A new support to treatment and psychotherapeutic assessment**

A. Acerra

University of Naples SUN, Psichiatria, Naples, Italy

**Introduction and objectives.**–Research in psychotherapy imposes, among other things, a challenge with objectivity. In addition to that, the research data are limited partially due to the scarcity of standardized and reliable tools. In particular, until now, researchers have been lacking of an effective and shared monitoring tool able to assess psychopathological disorders and their development in a given time-frame, for a given case and considering the relational and non-verbal aspects of the therapeutic process.

**Methods.**– Telepress Doctor Notes is a method that combines clinical interpretative models with the monitoring of the interactions and transactions via a technology originally intended for audiovisual classification and analysis. Introduced by Telpress International BV this technology, which is based on a software architecture, has been newly applied in psychological assessment and in individual.

This methodology is useful in clinical assessment, for example in the analysis of Adult Attachment Interview (AAI) and in the study of implicit mentalization, based on non-verbal and procedural elements. Psychotherapists can compare data useful for research and clinical ends and, when permitted, extract visual clues of data provided by other clinicians; keeping track of the evolution of their own research and treatment becomes a possible and simple task.

**Conclusions.**– Fundamental goals:

- annotate on the basis of verbal and non-verbal communication;
  - indexing and quick data retrieval of audio elements;
  - (selective) sharing of the information with the scientific community;
- for research, training and therapeutic ends.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Grief in a mental health center: A brief psychotherapy evaluation**

P. Marqués Cabezas<sup>1</sup>, J.A. Espina Barrio<sup>1</sup>, A. Alvarez Astorga<sup>1\*</sup>, P. García Vazquez<sup>1</sup>, I. Sevillano Benito<sup>2</sup>, R. Hernandez Anton<sup>1</sup><sup>1</sup> HCU Valladolid, psychiatry, Valladolid, Spain; <sup>2</sup> Hospital Provincial de Avila, Psychiatry, Avila, Spain

\* Corresponding author.

**Introduction.**– The Complicated Grief diagnostic criteria are included in the Diagnostic and Statistical Manual of Mental Disorders (DSM-5). The prevalence is around 20%. Over 5–15% of bereaved people develop severe long term reactions to their loss.

**Methods.**– Patients from a Health Center were evaluated. They were treated from August 2014 to August 2015 with psychotherapy and drugs. The Grief Coping Program (Espina Barrio, 1995) based on The Grief Counselling and Therapy (Worden, J. W., 1997) was used. Retrospective evaluation was made by telephone or interview. We collected socio demographic data, Inventory of Complicated Grief (ICG) and some questions about Grief Recovery.

**Results.**– 45 patients were included, 11 of them did not complete the study (2 did not meet criteria, 5 did not complete enough sessions, 3 abandoned and 1 declined). 34 concluded the therapy, 3 did not answer, 10 were not located. 21 completed the psychotherapy and the evaluation. The results are similar other work made 10 years ago in other sector by the same therapist.

**Conclusion.**– This kind of psychotherapy decrease symptoms, and a change of attitude towards the lost. Patients have a better perception of their present state and expectations for improvement.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**System version of short-term polymodal psychotherapy based on self-regulation methods (Practice “OCEAN” for patients with alcohol dependence syndrome)**

D. Belyakov

Moscow research and practical centre for narcology of the department of public health, Moscow, rehabilitation department filial no. 9, Moscow, Russia

The author describes a special method based on a multi-modal psychotherapy for patients with alcohol dependence syndrome. There are a lot of psychotherapeutic methods for chemical-abused patients. Among them, there are traditional relaxation practices, such as autogenic training that includes direct interaction of physician and patient. A therapeutic effect exists due to alliance that takes place between doctor and patient. Nowadays, autogenic training is the basic method for self-regulation of alcohol addicts in Russia. During last years, the popularity of autogenic training came down. The Practice “Ocean”<sup>®</sup>, proposed by author, helps patients to achieve self-psychological recovery through the use of self-regulation breathing techniques, psychotherapy meditation and auto-hypnotic impact, that are more modern. The method is designed to work in group or individual format, including remission period. Also, the e-poster describes the duration of remission with various types of treatment: Practice “Ocean”<sup>®</sup>, autogenic training and medication.

**A complementary qualitative analysis in a clinical trial with a new technique for severe mental disorder based on fictional films**

A. Fernández Alonso\*, A. Rodríguez Rodríguez, M. Magariños López, I. García del Castillo, L. Caballero Martínez  
Hospital Universitario Puerta de Hierro Majadahonda, psychiatry, Majadahonda Madrid, Spain

\* Corresponding author.

The authors designed a technique inspired on film analysis to help mitigate the distortions and deficiencies in film perception and understanding, caused by severe mental disease (Caballero et al., 2010; Caballero et al., 2016). This technique was tested in a randomized and controlled clinical trial with 48 patients suffering schizophrenia. Measured with the PANSS the effect size turned out in favour of the new technique for positive factor (0.82;  $P < 0.01$ ) negative factor (0.89.  $P < 0.005$ ) and disorganized factor (0.49; 0.05) (Magariños, 2016; García; 2016).

An additional qualitative study was made focusing on the acceptability, perceived utility, and gender biases in this technique between the Experimental Group and Control Group, with the results and comparisons between both groups showed in the attached tables. Patients in the Experimental Group reported greater improvement in memory, concentration and recognition of the characters emotions. However, patients in the Control Group enjoyed more the cinematic experience and perceived greater subjective improvement in their “general mental capacities”. Qualitative analysis can complement and better define the quantitative results obtained in controlled clinical trials regarding psychotherapy on serious mental illnesses and contribute, in this way, to the correct application of their results.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

**Psychological correction of psychoemotional state in women with pregnancy hypertensive complications**

A. Gardanov<sup>1\*</sup>, Z. Gardanova<sup>2</sup>, K. Anisimova<sup>2</sup>, V. Esaylov<sup>2</sup>, D. Khritinin<sup>3</sup>

<sup>1</sup> Student, Moscow state university of medicine and dentistry, Moscow, Russia; <sup>2</sup> Russian national research medical university NI Pirogov, psychotherapy, Moscow, Russia; <sup>3</sup> I.M. Sechenov First Moscow state medical, psychiatry, Moscow, Russia

\* Corresponding author.

*Introduction.*– Psychoemotional disorders in pregnant women represent a significant medical and social problem, as the consequences caused by this pathology have a strong effect on infants born to such mothers, and their mothers during and after pregnancy. The purpose of psychological correction of emotional States in pregnant women with hypertensive syndrome Ericksonian method of hypnosis.

*Objectives.*– The study was conducted on the basis of fsbi “research center for obstetrics, gynecology and Perinatology named after academician V.I. Kulakov” Ministry of healthcare of the Russian Federation. The study involved 150 pregnant women with hypertensive syndrome. 75 pregnant women with hypertensive syndrome received psychological correction method of Ericksonian hypnosis in the amount of 15 sessions.

*Methods.*– To assess the psycho-emotional state the techniques used: depression scale Beck and the scale of anxiety Spielberg-Hanina (State Anxiety Inventory – STAI). The study was carried out 4 times in the first, second, third trimester and three months postpartum.

*Results.*– When comparing psycho-emotional state of pregnant women with hypertensive syndrome on the background of psychological correction method Ericksonian hypnosis and pregnant women with hypertensive syndrome who did not receive psychological correction revealed statistically significant differences. In pregnant women with hypertensive syndrome, receiving psychological correction method Ericksonian hypnosis, revealed a lower level of depression and situational anxiety than women who did not receive psychological correction.

*Conclusions.*– Thus, our study has proved the necessity of psychological correction method Ericksonian hypnosis and its effectiveness for stabilization of psychoemotional state of pregnant women with hypertensive syndrome and prevention of preeclampsia.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

**EMDR training’s in Bosnia and Herzegovina resulted with the first national EMDR conference**

M. Hasanovic<sup>1\*</sup>, S. Morgan<sup>2</sup>, S. Richman<sup>2</sup>, S. Oakley<sup>2</sup>, Š. Šabanović<sup>3</sup>, I. Pajević<sup>1</sup>

<sup>1</sup> University clinical center Tuzla, department of psychiatry, Tuzla, Bosnia, Herzegovina; <sup>2</sup> Trauma aid UK, humanitarian assistance programmes, Hove, United Kingdom; <sup>3</sup> Islamic relief world wide, department of Sarajevo, Sarajevo, Bosnia, Herzegovina

\* Corresponding author.

The needs for EMDR (eye movement desensitisation and reprocessing) treatment of Bosnia-Herzegovina (BH) citizens, affected by 1992–1995 war, increased. The Trauma Aid UK (former Humanitarian Assistance Programmes UK & Ireland) works in partnership with mental health professionals in BH.

**Objectives.**– We aim to build an environment in which qualified and experienced professionals trained in EMDR may establish and sustain complete EMDR education and to keep international standards of EMDR practice.

**Method.**– Authors described the history of idea and its realization of EMDR education considering all needed phases that were provided from the Trauma Aid UK with non profit, humanitarian approach in sharing skills of EMDR to mental health therapists in BH.

**Results.**– The trainers from Trauma Aid UK completed five EMDR trainings in Bosnia-Herzegovina for recruited trainees from different cities and entities in BH. For continual professional development (CPD) all of these mental health professionals need to be active participants in professional and scientific meetings. Though, Association of Bosnia and Herzegovina EMDR Therapists, member of EMDR Europe, organized the First EMDR conference in Bosnia-Herzegovina sponsored by Trauma Aid UK under the patronage of EMDR Association of UK & Ireland.

**Conclusion.**– Five training of Bosnia-Herzegovina mental health workers to effectively use EMDR with enthusiastic help of EMDR trainers from Trauma Aid UK resulted with European accredited EMDR practitioners, one European accredited EMDR consultant and the first EMDR conference in BH. This will keep national development of psychotherapy capacities in post-war BH.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The Effect of (MCT), (MBCT) on couple communication patterns with the mediating of perceived stress, perceived social support and emotion regulation in patients with (CHD)**

S. Hashemi<sup>1\*</sup>, M. Mohammadebrahim<sup>2</sup>, N. Akbar<sup>3</sup>  
<sup>1</sup> Islamic Azad university, psychology, Tehran, Iran; <sup>2</sup> Shahed university, psychology, Tehran, Iran; <sup>3</sup> Iran university of medical sciences, Rajaei cardiovascular medical and research center, Tehran, Iran

\* Corresponding author.

**Background.**– Psychosocial risk factors have been associated with coronary heart disease (CHD). Social support within couples' relationships has been shown to be important for patient health outcomes and adjustment to the psychological and physical conditions in patients with(CHD). Constructive interactions with family, especially within couples can reduce the level of perceived stress and increase perceived social support and effect on experienced emotions.

**Methods.**– This research was an experimental (pretest, posttest with two experimental groups and one control group) design of the CHD patients of Rajaei hospital, a sample of 45 subjects were chosen through random sampling and considering the available conditions and then were put into two experimental and control group. Measurement tools of the study included Cohen's perceived stress scale, perceived social support questionnaire (MSPSS), emotion regulation questionnaire (Gross & John) and communication pattern questionnaire (CPQ). Data was analyzed through of multivariate analysis of covariance (MANCOVA) and stepwise regression analysis.

**Results.**– Findings of the study indicated that MCT and MBCT had an effect on the reduction of perceived stress and on the increase of

perceived social support and improvement of emotion regulation and couple communication patterns among CHD patients.

**Conclusions.**– The present study can be helpful in achieving an effective solution to the decrease of stress, increase of social support, improvement of emotion regulation and couple communication pattern and to the improvement of mental condition in general.

**Keywords:** Meta cognitive therapy; Mindfulness; Couple communication pattern; Perceived stress; Perceived social support; Emotion regulation; Coronary heart disease

### **The effectiveness of cognitive-behavioral group therapy on quality of life in Iranian patients with rheumatoid arthritis**

H. Jamilian<sup>\*</sup>, M. Nokani, M. Ghasemi, N. Tavakoli  
 School of medicine, Arak university of medical sciences, psychiatry, Arak, Iran

\* Corresponding author.

**Introduction.**– Rheumatoid arthritis (RA) has many deleterious consequences. The main management aim is to reduce the impact of the disease on patients' lives by improving quality of life and reducing disability.

**Objectives.**– The aim of the present study is to investigate the effectiveness of cognitive-behavioral group therapy (CBT) on quality of life in patients with RA.

**Methods.**– Two-arm, parallel randomized controlled trial was employed in which the participants were selected from an academic rheumatology clinic in Arak, Iran. Female adults with RA of at least one but no more than eight years duration with mild to moderate disease activity (Disease Activity Score (DAS28)  $\leq 5.1$ ) defined as eligible. All participants received standard medical care from a rheumatologist and the intervention group received additional twelve weekly sessions of CBT for pain management. The primary outcomes were the post treatment physical and mental components of quality of life assessed by 36-Item Short Form Survey.

**Results.**– Analysis of covariance revealed no significant difference between CBT and control group regarding post treatment physical component (adjusted mean 51.8 vs 50.2 respectively) and mental component (adjusted mean 54.2 vs 51.5 respectively) of quality of life questionnaire. However, significant differences were found in terms of depression ( $P=0.003$ ) anxiety ( $P=0.031$ ), fatigue ( $P=0.033$ ), and visual analog scale for pain ( $P=0.046$ ) in favor of CBT. There were no significant differences regarding disability and pain rating index between two groups.

**Conclusion.**– Our findings indicate that CBT can be used as an adjunct to standard clinical management of RA.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0507

### **Influence of mindfulness training on stress reduction during pregnancy**

S. Kiselev<sup>\*</sup>, I. Volik  
 Ural federal university, clinical psychology, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– It is known that women who experience high stress during pregnancy are more likely to deliver preterm infants. The

goal of this study was to evaluate the influence of mindfulness training on stress reduction during pregnancy.

**Method.**– In the current study we included 27 women who participated in the mindfulness training during pregnancy. The control group included 27 women who were in the reading control condition during pregnancy. Women were eligible to participate if they were experiencing elevated levels of perceived stress or pregnancy-specific anxiety (PSA), as indicated by responses to the Perceived Stress Scale and the PSA scale on a screening questionnaire. Women enrolled between 12 and 26 weeks gestation were randomly assigned to either the mindfulness training or to the reading control condition. Effects of training were analyzed by means of an ANOVA with repeated measurements.

**Results.**– ANOVA has revealed that women in the mindfulness intervention experienced larger decreases from pre- to postintervention in pregnancy-specific anxiety and pregnancy-related anxiety than participants in the reading control condition.

**Conclusion.**– This study suggests that mindfulness training during pregnancy may effectively reduce pregnancy-related anxiety. However, it is necessary to do further research on the impact of mindfulness training on stress reduction during pregnancy.

**Funding.**– The research was supported by Act 211 Government of the Russian Federation, agreement 02.A03.21.0006.

### **System of integrative psychotherapy of somatoform and psychosomatic disorders patients**

O. Kudinova\*, T. Chorna

Kharkiv medical academy of postgraduate education, psychotherapy, Kharkiv, Ukraine

\* Corresponding author.

The main goal of the investigation was the integrative psychotherapy system established. On the basis of the examined 350 patients with somatoform disorders and 250 patients with chronic psychosomatic diseases we have elaborated a test that allows to evaluate quantitatively the influents of the disease on patients' social functions. We created the integrative psychotherapy system with cognitive-oriented, suggestive and autosuggestive implementations. Elucidation of peculiarity of personal perception of the disease served as basis of elaboration of purposeful system of psychotherapy, consulting, psychological support for psychosomatic patients with high-effectiveness 1.5–3 years catamnesis in 85% patients. Psychotherapy should be used first of all as a target-oriented. Our experience showed the necessity of the use the integrative models of psychotherapy, parted on stages. On the first stage the receptions of cognitive and suggestive psychotherapy are used. There is group therapy on second stage. On the third stage elements of the autogenic training mastered. The system examination high efficacy was shown.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Feasibility of a new interactive group implementation on an acute inpatient psychiatric floor during the critical period of shift changes**

L. Leontieva<sup>1</sup>, S. Safadi<sup>2</sup>, N. Javaid<sup>1</sup>, S. Tabi<sup>1</sup>, C. Leddy<sup>1</sup>, D. Tylee<sup>1</sup>, C. Roe<sup>3</sup>

<sup>1</sup> SUNY upstate medical university, psychiatry, Syracuse, USA;

<sup>2</sup> Neurons Away LLC, n/a, Syracuse, USA; <sup>3</sup> SUNY upstate medical university, research, Syracuse, USA

\* Corresponding author.

Agitation on inpatient psychiatric units is one of the major challenges in psychiatry. Most studies done so far have focused on pharmacological treatments for agitation, few have initiated investigations focusing on non-pharmacological interventions. Art therapy is a new modality that is being researched and explored. Studies on inpatient psychiatric units incorporating art therapy have shown improvement in the emotional and psychological well-being of patients. This project examines the effects of implementing a group focused on creative expression as a means to decrease incidences of agitation on the inpatient unit during the critical period of staff shift change.

This observational study was conducted for 3-month on the acute, 23 beds inpatient psychiatric unit. Group sessions were designed to target inpatients' ineffective coping strategies and encourage new cognitive and emotional brain pathways. Each 1-hour group session was conducted on the unit in an open area where the maximum number of patients could join. We tracked group attendance, incidents of agitation during the 5 hour period starting from the beginning of the group session, and as-needed medications administration during the same time frame.

The average daily census was 17. Average group attendance was 41%. Average agitation incidences were 2%, as-needed medications was 10% of daily census. Patients indicated an increase in happy feelings, a decrease in sad feelings, and decrease in anger.

Group proved to be feasible and well received by the patients and staff. It helped to decrease agitation and extra-medication administration. The patients felt happier, less sad, and less angry.

### **Potential of a homogeneous group in psychotherapy of schizophrenics**

S. Manojlovic<sup>1</sup>, J. Nikolic-Popovic<sup>2</sup>

<sup>1</sup> Clinical center Nis, psychiatric clinic, Nis, Serbia; <sup>2</sup> Faculty of medicine, university of Nis, psychiatry, Nis, Serbia

\* Corresponding author.

Insurmountable loneliness and isolation of schizophrenics is difficult to overcome in a dyadic relationship. Intensity specific to such a relationship, experienced in e-contrastrs of acceptance and rejection, does not enable a stable adaption to reality. Group psychotherapy undermines the intensity of developing and transference tensions connected to the original dyadic situation, allowing progress. Therapeutic capacities of the group ensure the group as a whole is able to take on functions resembling the functions of the ego on an individual level. The group for schizophrenics determines reality with its formal and content determinants. The schizophrenic patient has an opportunity to, in a tolerant atmosphere constantly built by the therapist, approach others within his comfort zone. Transference relationships are diluted by multiplying. Homogeneous groups of schizophrenics are based on underlying levels of functioning or disorders. Seeing how the group possesses its setting and a topic of

conversation, allows the actual referential frame to be related to the fluid conceptualisation, therefore making its effects visible to members. Development of cohesion of the group diminishes the sense of fear and loneliness. Similar cognitive deficit implies a more specific determination of work techniques, enabling setting a test of reality and working through content and acquiring insight. Norm of understandable communication in the group is a formal frame for establishing contact. For the schizophrenic, the homogeneous group intensifies therapeutic effects, whereas the presence of the former in a heterogenous group contributes more to the group dynamic than the patient himself.

### Psychotherapy within psychiatric training: Are we improving?

L. Matutyte<sup>1</sup>\*, E. Sönmez<sup>2</sup>, T. Gargot<sup>3</sup>

<sup>1</sup> Vilnius university, faculty of medicine, clinic of psychiatry, Vilnius, Lithuania; <sup>2</sup> Caycuma state hospital, psychiatry department, Zonguldak, Turkey; <sup>3</sup> Hôpital Pitié-Salpêtrière, service de psychiatrie de l'enfant et de l'adolescent, Paris, France

\* Corresponding author.

*Introduction.*– The European Federation of Psychiatric Trainees (EFPT) states that practice of “psychotherapy is an integral part of being a psychiatrist”. To evaluate the extent of psychotherapy training, EFPT Psychotherapy Working Group led a study between 2013–2015 in 23 European countries among psychiatric trainees. The study showed the discordance between the interest of psychotherapy and the real training situation (Gargot et al., 2017).

*Objective.*– To evaluate the changes in conditions regarding psychotherapy training throughout the years.

*Methods.*– Each year, EFPT collects information about the actual situation of psychiatric training in member countries. Delegates from 34 National Trainees Associations fill an online survey and share updates on various aspects of psychiatric training in their country. In this study, we compared member countries' responses about psychotherapy training from 2011 to 2017.

*Results.*– Findings have shown a shift of trainees' preferences in psychotherapy training. According to the most recent survey, psychotherapy training was the most important issue of postgraduate psychiatric training, leaving behind the salary and working conditions. Despite the importance of psychotherapy training, financial support for trainees has decreased (from 27% in 2015 to 11.90% in 2017). Even with less financial support, in recent years, more trainees got practical skills of psychotherapy, but less than one half of respondents received appropriate supervision, thus psychotherapy training remains mostly based on theoretical knowledge and at the trainees' own expense.

*Conclusion.*– Greater institutional funding and more time for supervision are highly demanded, since for trainees psychotherapy was one of the most important factors of improvement.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The psychotherapy competention in somatic medicine

B. Mykhaylov<sup>1</sup>, B. Fedak<sup>2</sup>, O. Kudina<sup>3</sup>, V. Zabashta<sup>2</sup>

<sup>1</sup> Kharkov medical academy of postgraduate education, psychotherapy, Kharkov, Ukraine; <sup>2</sup> Healthcare utility “regional clinical hospital, centre of urgent medical care and accident medicine”, psychotherapy, Kharkiv, Ukraine; <sup>3</sup> Kharkiv medical academy of postgraduate education, psychotherapy, Kharkiv, Ukraine

\* Corresponding author.

Over the last years there is a worldwide steady growth of somatic diseases, in aetiopathogenesis of which a psychogenic factor plays a significant role. The same trend is representative to Ukraine. Provided that in the clinical pattern of somatic diseases are observed states posing a vital threat, such as Coronary Heart Disease (CHD), Myocardial infarction (MI), Transient Ischaemic Attacks (TIA), Cerebral Stroke (CS) patients. The main goal of our research were observed the psychosomatic relationships in these patients and established the psychotherapy oriented support system. Thus the 480 patients, were investigated 165 CHD, 90 TIA, 105 CS, 110 MI. A formation of inadequate internal disease pattern, fear of oneself future promote generation and progression of maladaptive psychological responses that are unfavourable for disease prognosis and decrease a level of patients' social function and life quality the all groups patients.

In most cases, an efficiency of treatment products depends on both adequacy of therapeutic methods choice and numerous psychological factors. A formation of motivation, greater patient's involvement in treatment process is the philosophy of our psychotherapy system, multimodal based. All patients were separated on randomized intervened and control groups. The more high efficacy were observed in intervened groups ( $P < 0.05$ ).

It also requires an introduction of new organizational forms of medical and psychological and psychotherapeutic activity's implementation on all levels of health care system. Provided of importance is a development of new programs for medical and psychological follow-up of such patients on different treatment stages.

### Multiple sclerosis patient: Identifying targets for psychotherapy

E. Nikolaev<sup>1</sup>\*, N. Vasil'eva<sup>2</sup>, T. Karavaeva<sup>3</sup>, E. Chekhaty<sup>3</sup>

<sup>1</sup> Chuvash state university, department of social and clinical psychology, Cheboksary, Russia; <sup>2</sup> Chuvash republic clinical hospital, neurology unit, Cheboksary, Russia; <sup>3</sup> Bekhterev national center for psychiatry and neurology, department of neuroses and psychotherapy, Saint-Petersburg, Russia

\* Corresponding author.

*Introduction.*– According to Saint-Petersburg school of psychotherapy “targets” for psychotherapy is a clinical and psychological phenomenon the change of which is the goal of psychotherapy at a particular stage of treatment. This phenomenon has not been studied enough in multiple sclerosis (MS) patients.

*Objectives.*– To determine the characteristics of the clinical and psychological state of MS patients, whose change in the process of targeted psychological intervention could become the goal of ongoing psychotherapy.

**Methods.**– The study involved 104 MS patients aged 19 to 64 during in-patient treatment in Chuvash Center for MS, Cheboksary. Clinical interviews, psychological diagnostics of personal traits were used in the sample of MS patients. The interrelations of different clinical and psychological parameters were found by factor analysis.

**Results.**– A set of psychotherapy targets were specified while studying the sample: targets related to the specificity of MS (asthenic disorders, depression and anxiety spectrum disorders, cognitive impairment), targets related to a patient's personality (psychopathological traits, dissatisfaction with social support, perfectionist self-control, suppression of emotions, characteristic time perspective); targets related to psychotherapy contact (expectation of high results from treatment, magic defenses, suicide tolerance), targets related to patient's social situation (reduced professional activity, dissatisfaction with the economic standing, instability of the family relations); targets related to psychotherapy methods (lack of understanding of the disease progression mechanisms in case of psychoeducation, and cognitive impairment in case of supportive psychotherapy). No sex-related differences were revealed.

**Conclusions.**– The construct of targets for psychotherapy may provide a more definite rationale for personalized programs of psychological interventions for MS patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0514

### **Psychological and psychotherapeutic approaches to verbal hallucinations**

C. Noël

*Queen Fabiola Children's university hospital, adolescent unit, Brussels, Belgium*

**Introduction.**– Verbal hallucinations are experienced by a considerable proportion of the general population, with, in particular, a significant prevalence among adolescents and children.

**Objective and method.**– Lines of approach to work with the patient on his hallucinatory experience are provided through a literature review about verbal hallucinations.

**Results.**– This review shows first that, among adolescents and children, most hallucinations are transient and occur in a context of anxiety or are associated with trauma. Their persistence and one's reaction to them are more significant than their presence. Psychologically, verbal hallucinations can be seen as a dissociative response to trauma, by which the emotional and experiential content is dissociated. From a psychoanalytic point of view, they come from an “unthinkable” that is rejected out of the mind and considered as a perception.

Psychotherapeutic approaches nowadays have the advantage of giving to the patient the place of an expert. The psychoanalytic outlook aims at transforming the hallucination into a thought, as the intolerable experience is symbolized within the clinical relationship. CBT offers protocols such as role plays, avatar therapy or reality testing, as well as attentional training or acceptance and commitment therapy, which aim at promoting psychological flexibility. Hallucination Focused Integrative Treatment helps among others to develop one's own coping strategies.

**Conclusion.**– Every one of these outlooks implies listening to the patient's experience, addressing it openly and focusing on its singularity and on the appropriation process which can be based on the hallucinatory experience.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cognitive-behavioural therapy, a new treatment for delusional disorder?**

J. Pemán-Rodríguez<sup>\*</sup>, F.J. Gómez-Beteta, J.E. Ibáñez-Vizoso,

M. Villanueva-Gallego, M. Pérez-Lombardo,

G. Montero-Hernández, I. Alberdi-Páramo

*Hospital Clínico San Carlos, Instituto de Psiquiatría y Salud Mental, Madrid, Spain*

<sup>\*</sup> Corresponding author.

**Introduction.**– Delusional disorder is characterized by a difficult evolution, with little response to antipsychotic drugs. For years there have been theories that suggest that delusions arise from alterations in the ways of processing and evaluating information. Faced with this situation, the idea of treatment through cognitive-behavioral therapy (CBT) of delusions arises by modifying the processing pathways and producing changes at the cognitive level that allow an adequate evaluation of the information.

**Objectives.**– To review the existing literature on the efficacy of CBT in the treatment of delusional disorders, as well as the usefulness of CBT in the study of the pathways of delusional disorder.

**Methods.**– PUBMED's website is searched for articles under the following terms: “Delusional disorder and cognitive-behavioural therapy”.

**Results.**– It seems to be a relationship between self-esteem with the degree of conviction in the delusional belief.

The main mechanism of CBT is the reduction in the conviction of the delusions.

It has been objectified significant reductions in preoccupation and emotional level; as well as significant improvements in social/working level and functioning.

Efficacy is independent of the content of the delusion.

**Conclusions.**– CBT is a valid method in the treatment of delusional disorder, and may be considered as a first option.

More research is needed on the efficacy of CBT as a single or concomitant treatment with drug therapy.

CBT appears to be a suitable method for the study of etiopathogenic mechanisms in the delusional disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Therapeutic beliefs and practices of Jewish-Israeli and Palestinian-Israeli social workers**

E. Tartakovsky

*Tel-Aviv university, social work, Tel-Aviv, Israel*

<sup>\*</sup> Corresponding author.

**Introduction.**– The present study investigates social workers' preferences regarding four therapeutic orientations: psychodynamic therapy (PDT), cognitive-behavioral therapy (CBT), client-centered therapy (CCT), and eco-systemic therapy (EST).

**Objectives.**– To reveal similarities and incongruence when comparing the social workers' beliefs in the efficacy of the different therapeutic orientations and the frequency of their use in practice.

**Methods.**– 679 social workers (528 Jewish and 151 Palestinian) reported their beliefs regarding the efficacy of the four therapeutic orientations, and 343 additional social workers (193 Jewish and 150 Palestinian) reported how often they apply the therapeutic orientations in their practice.

**Results.**– CCT was the most preferred and PDT was the least preferable therapeutic orientations among social workers in Israel. Social workers with a private practice reported greater use of PDT (both Jewish and Palestinian social workers) and less use of CBT and EST

(Jewish social workers). Finally, a larger number of clients was associated with greater use of CBT (among both Jewish and Palestinian social workers) and EST (among Jewish social workers). Among Jewish social workers, a higher proportion of Palestinian clients was associated with greater use of CBT, EST, and CCT. Palestinian social workers used CCT more frequently with their Palestinian clients, while they used it less with their clients belonging to all the other ethnic groups.

**Conclusions.**– The results obtained demonstrate that an incongruence exists between social workers' therapeutic beliefs and their practices. In addition, social workers tend to use different therapeutic interventions when working with clients belonging to different ethnic groups.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Suicidology and Suicide Prevention - Part I

PW0517

### The link between aggression and suicidality among adolescents

L. Pechnikova, M. Iosifyan, G. Arina\*

Lomonosov Moscow state university, department of neuro-and pathopsychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– The relation between personality traits and susceptibility to suicidality is excessively studied during the last decades. The role of such personality traits as hopelessness, neuroticism, and extroversion has been already established (Brezo, Paris & Tureck, 2016). However, more research is needed to investigate the role of aggression and anger in susceptibility to suicidality, especially among adolescents.

**Objective.**– The aim of present study is to investigate the extent of aggression among adolescents with suicidal behaviors.

**Methods.**– 23 girls (age range 13–17,  $M_{age} = 14.5$ ), which performed suicidal attempts in the past and were diagnosed with conduct disorder, participated in the study. 20 healthy girls (age range 13–17,  $M_{age} = 14.9$ ) also participated in the study. All adolescents completed the 29-item Buss–Perry Aggression Questionnaire (Buss & Perry, 1992).

**Results.**– Mann-Whitney *U*-test showed that girls with suicidal attempts had higher scores in Physical Aggression ( $U = 142$ ,  $P = .033$ ,  $r = .325$ ), Anger ( $U = 129$ ,  $P = .014$ ,  $r = .375$ ) and Hostility ( $U = 88$ ,  $P = .001$ ,  $r = .526$ ), compared to their healthy peers.

**Conclusion.**– The study revealed a link between aggression, more characteristically hostility, and suicidality among female adolescents. These results are in line with previous research on positive links between aggression and suicidal behavior, as well as depression (also related to suicide), among adolescents (Benarous et al., 2014; Zhang et al., 2012). Thus, the severity of aggression traits should be taken into account in diagnostics and treatment of adolescents with susceptibility to suicidality.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Investigating the role of childhood victimization in suicidal and self-injurious behavior among a sample of male inmates: A cross-sectional study

E. Capuzzi\*, C. Cappellini, M. Clerici

University of Milano-Bicocca, department of medicine and surgery, Monza MB, Italy

\* Corresponding author.

**Introduction.**– Suicide and non suicidal self-injury (NSSI) are common among prisoners. The prevalence of mental illness and substance use disorder is higher in prison than in the community<sup>1</sup> and the risk of death by suicide inside the prison is about 3–6 times that of the general population<sup>2</sup>. In addition prisoners have greater experiences of childhood trauma (CT), an exposition associated with suicidal behaviors<sup>3</sup>.

**Objectives.**– To examine associations among CT and life-time suicide attempt or NSSI.

**Methods.**– We enrolled 88 male inmates. The sample was divided, according to presence of life-time suicide attempts or NSSI, into two groups, compared for sociodemographic and clinic characteristics. History of CT was assessed with the Childhood Trauma Questionnaire Short Form (CTQ-SF)<sup>4</sup>. The presence of specific trauma (emotional, physical and sexual abuse; emotional and physical neglect) was determined by meeting a threshold of moderate maltreatment severity<sup>5</sup>.

**Results.**– Subjects with ( $n = 25$ ) and without a history of suicide attempt or NSSI ( $n = 63$ ) show a statistically significant association in the scores of all five subscales of CTQ-SF. After controlling for potentially confounders, dual diagnosis (OR:2.6, 95% CI: 1.1–3.9) and childhood physical abuse (OR:2.9, 95% CI: 1.2–4.6) was related to an increasing likelihood of suicide attempt or NSSI. The likelihood was higher among subjects with two or more CT (OR:6.2, 95% CI: 3.3–9.2) (Table 1).

**Conclusions.**– The findings could indicate the importance of considering the impact of co-occurring CT in terms of intervention on suicidal behaviors and NSSI mostly in prisoners with dual diagnosis.

Table 1 Factors associated with Life-time suicide attempt or NSSI: multiple logistic regression analyses.

Variable	Model 1		Model 2	
	OR (95% CI)	P	OR (95% CI)	P
Age	.0 (-.0 - .0)	0.901	-.0 (-.1 - .1)	0.691
Foreigner (yes/not)	0.4 (-1.1 - 1.9)	0.628	.1 (-1.8 - 1.9)	0.946
Incarceration (years)	-.0 (-.2 - .1)	0.651	-.0 (-.2 - .1)	0.718
Parental mental illness (yes/not)	.50 (-.9 - 2.0)	0.491	-.2 (-2.2 - 1.8)	0.831
Parental substance use (yes/not)	.4 (-1.2 - 2.1)	0.612	-.5 (-2.6 - 1.5)	0.612
Physical Abuse (yes/not)	2.9 (1.2 - 4.6)	0.001	-	-
Dual Diagnosis (yes/not)	2.6 (1.1 - 3.9)	<0.001	2.2 (.5 - 4.0)	0.012
One CT	-	-	2.6 (.6 - 4.5)	0.009

**Ketamine and its anti-suicidal effects:****A systematic review**L. Castanheira<sup>1</sup>, E. Fernandes<sup>1</sup>, C. Ferreira<sup>1</sup>, L. Ferreira<sup>2</sup>, J. Jerónimo<sup>1</sup>, J.M. Pereira<sup>1</sup><sup>1</sup> Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, psychiatry, Lisboa, Portugal; <sup>2</sup> Hospital Distrital de Santarém, psychiatry, Santarém, Portugal

\* Corresponding author.

**Introduction.**– About 90% of individuals who die by suicide have a history of mental illnesses. Pharmacological approaches to the treatment and prevention of suicide depend mostly on the treatment of the primary psychiatric disorders. Lithium and clozapine are two pharmacological interventions reported to reduce suicide risk. Early evidence suggests that ketamine may be an effective intervention for preventing suicide.

**Objectives.**– To discuss the efficacy of ketamine as an anti-suicidal agent.

**Methods.**– The PubMed and Cochrane databases were searched up to June 2017, using key-words “ketamine” and “suicidal ideation” (SI).

**Results.**– There were selected twelve significant articles published on the topic. A total of 316 patients with SI have been reported in the literature as undergoing ketamine therapeutic. Nine studies administered a dose of 0.5 mg/Kg intravenously (i.v.) over 40 minutes, while two studies delivered a 0.2 mg/kg i.v. over 1–2 minutes and another study administered an oral suspension. The first effects were observed after 40 minutes and the last effects were seen up to 10 days post-infusion.

**Conclusion.**– The evidence to date supporting the clinical use of ketamine as a treatment for patients with SI is preliminary. Larger controlled studies that compared the risks with the potential benefits of ketamine as a treatment strategy in the clinical setting are needed. All studies reviewed examined the effects of ketamine on SI. Future studies are necessary to evaluate the effectiveness of ketamine for long-term prevention of suicidal behavior and to determine if ketamine induced effects on SI and behavior will be generalizable to patients who do not suffer primarily from a mood disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0520

**Outcomes of a case managed community based treatment in the prevention of suicide among people with severe schizophrenia**S. Diaz-Fernandez\*, J.J. Fernandez-Miranda, J. Diaz-Leiguarda  
AGC SM-V-HUCAB-SESP Asturian mental health service, Centro tratamiento integral, Gijón, Spain

\* Corresponding author.

**Introduction.**– Case management approach for people with schizophrenia improves treatment compliance and should help to prevent suicidal behaviour.

**Objectives.**– To know retention in treatment of people with severe schizophrenia and suicide rates among them in a case managed community based program.

**Methods.**– 8-year prospective, observational, open-label study of patients with severe schizophrenia (GCI-S  $\geq 5$ ) undergoing community based, case managed treatment in Spain ( $n = 200$ ). Assessment included at the beginning and after 3, 12, 24, 36 and 96 months: the Clinical Global Impression severity scale, the Camberwell Assessment of Needs (CAN) and the WHO Disability Assessment Schedule

(WHO-DAS). Reasons for discharge, including deaths by suicide, were recorded.

**Results.**– CGI-S at baseline was 5.9 (0.7). After eight years 42% of patients continued under treatment (CGI-S = 4.1 (0.9);  $P < 0.01$ ); 37% were medical discharged (CGI = 3.4 (1.5);  $P < 0.001$ ) and continued standard treatment in mental health units; DAS decreased in the four areas ( $P < 0.005$ ) in both groups, and also CAN ( $P < 0.01$ ); 10% were voluntary discharges. Twelve patients died during the follow up, four of them by suicide (2%), while suicide rates among people with schizophrenia in standard treatment in Spain are between 5–10%. All patients had their own case manager, mainly a nurse (89%).

**Conclusions.**– Retention of patients with schizophrenia with severe symptoms and impairment in a community based, case managed programme, was really high and seemed to be useful to decrease suicides among them. This kind of intensive treatment showed better rates of treatment compliance and suicide behaviour than standard one.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Time series analysis of successful suicides in Iran (2006–2016)**S.S. Hashemi Nazari<sup>1</sup>, H. Nazari<sup>2</sup>, A. Shojaei<sup>3</sup><sup>1</sup> Shahid Beheshti university of medical sciences, school of public health, epidemiology, Tehran, Iran; <sup>2</sup> School of public health, Shahid Beheshti university of medical sciences, Tehran I.R. Iran, department of epidemiology, Tehran, Iran; <sup>3</sup> Iranian legal medicine organization, Tehran, Iran, legal medicine research center, Tehran, Iran

\* Corresponding author.

**Introduction.**– Forecasting is a complex set. Rates of suicide shows a small increasing trend in Iran. It is quite important to explore suicide trends in the previous data and recognize its pattern via time series analysis.

**Objectives.**– To determine future successful suicides in Iran using past trends.

**Methods.**– The total monthly suicide data (April 2006–March 2016) were gathered from Iranian Legal Medicine organization. Time series analysis was done on the data using forecast, fit.AR, tseries and fpp packages in R software. Cross-validation procedure was used to evaluate the three forecast methods (Time series linear model, autoregressive integrated moving average and exponential smoothing) to distinguish which of these methods is more proper and the best model according to mean absolute error index was chosen for forecasting.

**Results.**– A number of 35,635 successful suicides occurred within 10 years. An increase in the monthly suicide rates were observed. The ETS (A, N, A) model was selected as the best model with additive error and seasonality component. A total of 4091 suicides were predicted for 12 future months (Fig. 1).

**Conclusion.**– This was the first attempt to forecast suicide in Iran. Considering that suicide rate has increased in recent years, if we'd like to succeed in preventing and controlling suicide, more extensive studies should be done on the factors influencing it. Close evaluation of current intervention programs and implementation of new ones might contribute to its prevention.

### Ten year suicide rate trends by gender and age in Iran

S.S. Hashemi Nazari<sup>1\*</sup>, N.K. Hajar<sup>2</sup>, A. Shojaei<sup>3</sup>

<sup>1</sup> Shahid Beheshti university of medical sciences, school of public health, epidemiology, Tehran, Iran; <sup>2</sup> School of public health, Shahid Beheshti university of medical sciences, Tehran I.R. Iran, department of epidemiology, Tehran, Iran; <sup>3</sup> Iranian legal medicine organization, legal medicine research center, Tehran, Iran

\* Corresponding author.

**Introduction.**– Suicide is an important public health problem which is attracting widespread interest due to its worldwide increase<sup>1</sup>.

**Objectives.**– To compare the successful suicide rates by sex and age in Iran from March 2006 to February 2016.

**Methods.**– The data on 10-year suicide and population were gathered from Iranian legal medicine organization and statistical center, respectively. The trend of annual suicide rates by sex and age (among 4-age groups) were assessed.

**Results.**– Totally 35,635 suicidal deaths have been investigated countrywide over a 10-year period consisting of 25,106 (70.45%) men and 10,529 (29.50%) women. The suicide rate between 2014 and 2016 was almost constant and around 5.3 (per 100,000 population) but 23% higher than the rate in 2006. The suicide rate in men was 2.38 times higher than that in women. The 15–29 and 5–14 year age group had the highest and lowest frequency with 18,339 (51.46%) and 753 (2.11%) cases, respectively. The suicide trends in the two age groups (15–29 and 30–49) were quite similar to that of the whole country but a completely different trend was observed in suicide incidence in the two age groups of 69–50 and ≥ 70 years old (Fig. 1).

**Conclusion.**– One of the goals of the national health system is to prevent suicide in the society and due to the high suicide rate in the youth and men, the authorities are required to pay special attention to these groups in social planning.

### Cracked not broken

K. Hines

The Kevin & Margaret Hines foundation, brain health & wellness, Alpharetta, USA

Kevin Hines is a suicide attempt survivor who survived a jump from the Golden Gate Bridge in San Francisco. He is one of only thirty-four (less than 1%) to survive the fall and he is the only Golden Gate Bridge jump survivor who is actively spreading the message of living mentally healthy around the globe.

Now, he is a mental health advocate, global speaker, best-selling author, documentary filmmaker and social entrepreneur who reaches audiences all over the world with his story of an unlikely survival and his strong will to live. Kevin shares his story of hope and celebration of life. He discusses his evidence informed recovery 10-step toolkit which plays a crucial role in his recovery.

He travels the globe sharing his inspiring story of hope and recovery. In addition to saving thousands of lives, his storytelling normalizes the conversation around brain health and suicide prevention, thus eradicating stigma.

The first time Hines shared his story in public, it was to a group of seventh and eighth graders at the middle school. He received 120 letters, one from each of the students who had listened to him. Among those were six from children who were suicidal. Because the letters were screened, those students received help. That was the beginning of his mission. Hines has spoken to millions of people since then, always with the same basic message: You are not alone. Recovery is possible.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Relationship between suicide attempt and cognitive functions in schizophrenia patients

H.M. Öztürk<sup>1\*</sup>, N. Yüksel<sup>2</sup>

<sup>1</sup> Ufuk university, faculty of medicine Dr. Rıdvan Ege hospital, psychiatry, Ankara, Turkey; <sup>2</sup> Gazi university, faculty of medicine, psychiatry, Ankara, Turkey

\* Corresponding author.

**Introduction.**– Suicide is known as a major cause of premature death in schizophrenia patients. An association has been reported

between suicidal behavior and both lower and higher cognitive functions and greater insight in schizophrenia.

**Objectives.**– The aim of this study was to compare cognitive functions, hopelessness and insight in schizophrenia patients with and without suicide attempt and determine the predictive factors for suicide attempt.

**Method.**– 50 patients diagnosis of schizophrenia were enrolled prospectively to the study, were categorized based on patient and interviewers as suicide attempters and non-suicide attempters. These groups were compared about depression, positive/negative symptoms, insight, hopelessness and cognitive functions.

**Results.**– In group of suicide attempters hopelessness, insight and depression were higher than non-suicide attempters. Neuropsychological performance was better in patients with suicide attempt. Stroop test times were better, WCST perseverative responses, errors were better in patients with suicide attempt.

**Conclusion.**– According to our results patients with suicide attempt executive functions are better than patients without suicide attempt.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Profile of suicide victims in non-psychiatric units of general hospitals

A. Paraschakis, K. Goulas

Department of general adult psychiatry, psychiatric hospital of Attica "Dafni", Athens, Greece

\* Corresponding author.

**Introduction.**– Patients hospitalized for physical illness(es) have an increased suicide risk. Psychiatrists apart, other medical specialties are generally unfamiliar with identifying and managing suicidal patients.

**Methods.**– Literature review (PubMed, articles in English, adult victims, years 1997–2017).

**Results.**– Victims are usually men, >50 years of age, 50% married, with economic difficulties, weak supportive system and/or family conflicts, without history of psychiatric disorders or prior attempts. Main somatic problems: malignant neoplasms (~30%), cardiovascular and neurologic diseases, chronic obstructive pulmonary disease, brain injuries. Commonest psychiatric diagnoses: depression, delirium, drug/alcohol (ab)use. Uncontrolled pain, dyspnea, visual hallucinations, excessive anxiety and psychomotor agitation may act as precipitating factors. The medications apremilast, varenicline, isoretrinoïn and mefloquine appear to increase suicide risk. Particularly risky are the periods of the announcement of the diagnosis/grave prognosis and of frequent/severe recurrences. Such individuals were usually "silent", withdrawn, indifferent for treatment or prognosis, unwilling to be visited by relatives and may have asked for an early discharge. Very rarely had they expressed suicidal intentions. They usually die by jumping from a height. Suicide usually takes place within the first 1–2 weeks of hospitalization, mostly at night (probably due to reduced supervision). Suicide victims in psychiatric units are younger, 2/3 single, with positive psychiatric history, have usually communicated their intentions, die mostly by hanging and act later during their hospitalization.

**Conclusion.**– Suicidal patients in medical-surgical wards apparently have distinct characteristics from the respective in the psychiatric ones. The primary physician should be vigilant for such cases, promptly identify them and swiftly involve the consultation-liason psychiatry team.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Organizational conditions associated with suicidal ideation in resident physicians

K. Pereira-Llma\*, J.A. Crippa, S.R. Loureiro

Ribeirão Preto medical school, university of São Paulo, department of neuroscience and behavior, Ribeirão Preto, Brazil

\* Corresponding author.

**Introduction.**– Despite the marked increase in suicidal ideation with the start of residency training, few studies have investigated organizational variables associated with this problem in resident physicians. **Objectives.**– To investigate the associations of measures of organizational structure and culture with suicidal ideation in resident physicians.

**Methods.**– A total of 288 (72.0%) resident physicians from 30 residency programs completed a survey including demographic (age, sex, marital status) and residency (specialty, year, duty hours) information, and the following standardized measures: Patient Health Questionnaire-9 (PHQ-9); Positive and Negative Organizational Conditions Scale of the Burnout Syndrome Inventory. Suicidal ideation was defined as endorsement of item 9 in the PHQ-9. Univariable and multivariable logistic regression analyses were performed to identify organizational factors associated with suicidal ideation in the overall sample of resident physicians, as well as within the subgroup of residents with depressive symptoms (PHQ-9 ≥ 10).

**Results.**– A total of 127 (44.1%) resident physicians screened positive for depression and 26 (9.0%) for suicidal ideation. Multivariable analysis of the overall cohort identified feeling of belonging to a team (OR 0.395, 95% CI 0.226–0.693,  $P = .001$ ) and safety culture (OR 0.415, 95% CI 0.234–0.737,  $P = .003$ ) with reduced risk for suicidal ideation. Multivariable modeling within the subgroup with depressive symptoms also demonstrated a negative association between suicidal ideation and feeling of belonging to a team (OR 0.273, 95% CI 0.154–0.485,  $P < .001$ ).

**Conclusions.**– Promoting feelings of belonging to a team and safety culture are potential targets for organizational interventions to prevent suicidal ideation in resident physicians.

**Support.**– FAPESP (grant 2014/06972-7).

### Different impact of childhood adversities on suicide behavior in borderline personality disorder and postpartum major depression

A. Plaza Estradé<sup>1</sup>, V. Esther<sup>2</sup>, G. Estel<sup>3</sup>, R. Alba<sup>4</sup>, B. Judith<sup>5</sup>, T. Anna<sup>4</sup>, R. M. Jesus<sup>5</sup>, G.E. Lluïsa<sup>4</sup>, D.A. Luis<sup>6</sup>, V. Joan<sup>7</sup>

<sup>1</sup> CPB mental health services, crisis intervention and suicide prevention unit, Barcelona, Spain; <sup>2</sup> CPB mental health services, BPD program day hospital, Barcelona, Spain; <sup>3</sup> Universidad Autónoma de Barcelona, psychology department, Barcelona, Spain; <sup>4</sup> Hospital clinic, perinatal psychiatry program, Barcelona, Spain; <sup>5</sup> CPB mental health services, BPD program day hospital, Barcelona, Spain; <sup>6</sup> CPB mental health services, CPB mental health center, Barcelona, Spain; <sup>7</sup> CPB mental health services, BPD program day hospital, crisis intervention and prevention suicide unit, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Childhood abuse has been associated with the presence of suicide attempts in both, borderline personality disorders (BPD) and postpartum major depression (PMD), although there is little literature regarding the impact of childhood adver-

sities and its characteristics in the presence of ideation suicidal, in both diagnoses.

**Objective.**– The study aim was to compare the influence of childhood adversities and its characteristics (age, perpetrator, frequency) in suicidal ideation (SI) and suicide attempt (SA), between PMD and BPD women.

**Method.**– One hundred women diagnosed of PMD (DSM-IV; SCID) and sixty eight women with BPD DSM-IV-TR diagnostic criteria participate in the study. Socio-demographic and clinical variables were collected through a clinical interview. Childhood adversities (CAs), including physic (CPA), emotional (CEA) and sexual (CSA) abuses, were evaluated using the Early Trauma Inventory Self Report (Bremner et al., 2007).

**Results.**– The BPD sample has the most elevated presence of previous SA and SI. BPD women showed also a significantly greater number of CAs, including abuses compared with PMD and HC women, except in parental death, and presence of CSA with penetration. There is a significant increase of SI in PMD women in presence of Total CAs ( $P = .009$ ), Global CAs ( $P = .009$ ), CPA ( $P = .045$ ), CEA ( $P = .015$ ), and CEA by intra-familial perpetrator ( $P = 0.032$ ). Only the presence of CEA with start between 12–18 years old in BPD women had a significant association ( $P = .049$ ) with SA.

**Conclusions.**– The presence of abuse in childhood has a different impact on women with BPD and women with PMD, regarding the presence of suicide ideation, showing no differences in its impact on the suicide attempt.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Correlates of suicidal behavior among alcohol-dependent men**

Y. Razvodovsky

Grodno state medical university, pathological physiology, Grodno, Belarus

**Introduction.**– Alcohol dependence (alcoholism) is associated with a considerable risk of suicidal behavior. Accumulated evidence suggests that a lifetime diagnosis of alcohol dependence is a major risk factor for attempted or completed suicide. In relation to this, it is crucial to investigate the risk factors of suicidal behavior among alcoholics in order to prevent suicide attempts and completions among this subgroup.

**Objectives.**– This study seeks to identify risk factors of suicidal behavior among alcohol-dependent men. The present study also aims to determine the differences between alcohol-dependent suicide attempters and completers.

**Methods.**– The sociodemographic and mental health characteristics of 117 male alcohol-dependent suicide attempters and 99 male alcoholics who commit suicide were investigated.

**Results.**– Alcohol-dependent men, who attempt or complete suicide are characterized by poor social support, living alone, interpersonal conflicts, unemployment, psychiatric comorbidity. Results show that, compared with suicide attempters, suicide completers were older (40 vs. 32.1), unmarried (43.4% vs. 33.3%), unemployed (63.6% vs. 46.2%). Consumption of alcohol at the time of suicidal behavior was reported more commonly by suicide completers (84.8% vs. 70.1%). Positive blood alcohol cases were found more frequently in suicide attempters age 18–29 (91.9%) and suicide completers age 30–39 (93.3%).

**Conclusions.**– Suicide attempters and completers were similar on most sociodemographic variables. However, suicide completers were more likely to use alcohol before suicidal act. The acute alcohol intoxication is a proximal risk factor for suicidal behavior among alcohol-dependent men.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The spatial pattern of suicides in Europe**

S. Kandrychyn<sup>1\*</sup>, Y. Razvodovsky<sup>2</sup><sup>1</sup> Minsk regional hospital, cardiology, Minsk, Belarus; <sup>2</sup> Grodno state medical university, pathological physiology, Grodno, Belarus

\* Corresponding author.

**Introduction.**– The regularity in suicide rates in Europe was one of the essential challenges facing social scholars at the end of XIXth century.

**Objectives.**– The present study aims to assess the continuation of this phenomenon in XXIth century.

**Methods.**– To explore this phenomenon suicide rates were obtained from WHO official publications for 1990, 2000, 2010 and 2012 across 41 European nations. In order to examine the regularity of spatial suicide pattern the data sets were subjected to Spearman's rank order correlation analysis.

**Results.**– The suicide rates rank order distribution between European nations in 1990 was associated with suicide rates in 2000, 2010 and 2012 ( $r_s = .91, .81, \text{ and } .80$ , respectively,  $P < .001$ ). The national suicide death indices show the significant positive correlation over the studied period, what means the definite regularity of suicide mortality pattern and absence of essential changes or fluctuations between the regions. The highest indices have the countries situated on the Northern and Eastern part of the European continent (Lithuania, Russia, Belarus and Hungary). On the opposite pole are the nations settled the Mediterranean and British islands. Thus the fixed gradient in suicide distribution with the growing to the north and north-east of European continent is visible. The same stable vector in suicide spatial distribution is duplicated on the vast territories on the east part of Europe.

**Conclusions.**– The data presented support the idea that spatial regularity in suicide distribution in Europe is not generally connected with social and cultural changes occurred during the centuries.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Psychological manipulation as a predictor of parasuicidal behavior in persons with reaction to severe stress and adjustment disorders**

E.T. Sokolova, K.O. Andreyuk, A. Ryzhov<sup>\*</sup>

Lomonosov MSU, faculty of psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Psychological manipulation deteriorates cooperation, compliance and psychotherapeutic change.

**Objectives.**– To study the correlation of repeated suicidal attempts with the inclination to employ manipulation as an available means of control for own and others behavior and emotional states in situations of distress. Additionally, it is assumed that the high-levels of the manipulateness have a negative effect on the mentalization functions and can be regarded as suicide predictors.

**Methods.**– 41 patients with ICD-10 F43.2 and F43.8 diagnoses and repeated suicidal attempts and 41 controls were administered (1) MACH-IV modified machiavellism scale (Christie, 1970, Znakov, 2002), (2) a modification of Rosenzweig Picture-Frustration Study with the additional task to describe thoughts and feelings of

depicted personages. Expert ratings, quantitative and qualitative analyses of data were employed.

**Results.**– Suicide attempters scored significantly higher on manipulative attitudes than controls. Within suicide attempters the high level of machiavellism was associated with multiple, and low level with singular attempts ( $P < .01$ ). This points to the link between machiavellism and the choice of parasuicide as a persistent method of manipulative communication and self-regulation. The parasuicidal group demonstrates combination of two opposite types of mentalization distortion: over-concreteness and over-abstraction (with predominance of the latter), coupled with intolerance to ambiguity, lack of cooperation in conflictual situations, excessive demands on self and others ( $P < .05$ ).

**Conclusions.**– The tendency to manipulate other people in conjunction with weak capacity to symbolize and differentiate one's own and others experiences, deteriorates a tolerance of interpersonal ambiguity, are regarded as predictors and maintaining factors of suicidal behavior.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Future clinicians' attitudes towards suicidal patients: A survey on temperamental predictors of medical students**

P. Solano<sup>1\*</sup>, A. Aguglia<sup>1</sup>, N. Di Tullio<sup>2</sup>, M.P. Sormani<sup>2</sup>, G. Serafini<sup>1</sup>, M. Amore<sup>1</sup>

<sup>1</sup> Clinica Psichiatrica, neurosciences, section of psychiatry, university of Genova, Genoa, Italy; <sup>2</sup> Biostatistics, biostatistics department of health sciences, university of Genova, Genova, Italy

\* Corresponding author.

**Introduction.**– Temperament deeply influences man's attitude towards life, death and the world he lives in. Clinicians' attitude towards suicidal patients impacts on their possibility of treating them effectively.

**Objectives.**– To investigate the impact of temperament in predicting certain attitudes towards auto and etero-suicidality in medical students.

**Methods.**– 366 medical students of the first–fourth year who have never studied psychiatry were enrolled. Subjects completed a socio-demographic form, TEMPS-A and SOQ. Bivariate Pearson Correlation (SPSS, v.20; IBM Corp) tested the relationship between temperaments and attitudes toward suicide. Associations were corrected for positive responses to SOQ items 105, 106, 108.

**Results.**– Previous experience with suicidality determined more positive attitudes towards it. Depressive temperament: positive association with “social disinterest” ( $P = 0.001$ ;  $r = 0.199$ ); negative with “acceptability” ( $P = 0.001$ ;  $r = -0.198$ ), “perceived factual knowledge” ( $P = 0.000$ ;  $r = -0.213$ ), “emotional perturbation” for suicide ( $P = 0.044$ ;  $r = -0.124$ ). Irritable and anxious temperaments: negative opinions towards auto- and etero-suicidality. Cyclothymic temperament: negative association with “acceptability” ( $P = 0.000$ ;  $r = -0.273$ ). Hyperthymic temperament: positive associated with “perceived factual knowledge” ( $P = 0.02$ ;  $r = 0.190$ ); negatively with “emotional perturbation” ( $P = 0.006$ ;  $r = -0.169$ ). Irritable temperament: negatively associated with “acceptability” ( $P = 0.000$ ;  $r = -0.287$ ); “perceived factual knowledge” ( $P = 0.000$ ;  $r = -0.227$ ), “emotional perturbation” ( $P = 0.041$ ;  $r = -0.125$ ), “personal defense” ( $P = 0.022$ ;  $r = -0.194$ ). Anxious temperament: inversely associated with “acceptability” ( $P = 0.000$ ;  $r = -0.280$ ); “perceived factual knowledge” ( $P = 0.000$ ;  $r = -0.402$ ), “personal defense” ( $P = 0.012$ ;  $r = -0.157$ ).

**Conclusions.**– Depressive temperaments show the highest social disinterest whereas irritable and anxious temperaments the most negative opinions of suicidality.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The blue-whale phenomenon: A Google-based investigation in Italy**

P. Solano<sup>1\*</sup>, F. Bovis<sup>2</sup>, E. Pizzorno<sup>3</sup>, G. Giacomini<sup>1</sup>, A. Aguglia<sup>1</sup>, G. Serafini<sup>1</sup>, M. Amore<sup>1</sup>

<sup>1</sup> Clinica Psichiatrica, neurosciences, section of psychiatry, university of Genova, Genoa, Italy; <sup>2</sup> Biostatistics, department of health sciences, Genova, Italy; <sup>3</sup> Forensic and legal medicine, health sciences, university of Genova, Genova, Italy

\* Corresponding author.

**Introduction.**– The Blue Whale Game is a social network phenomenon that has become popular worldwide in the last months. Although its existence in real life is much debated, it has become a well-known mediatic character. Evidence shows associations between online suicide-related search volumes and national suicide-rates worldwide [1].

**Objectives.**– To analyze the phenomenon and its association with online suicidal dimensions evaluated through online search-volumes of suicide-related words.

**Methods.**– Google Trends provided Italian data of online search-volumes of “Blue Whale”, “commit suicide”, “suicide”, “how to commit suicide”, “sadness”, “loneliness” in Google Search and Google News (2013–2017). STATA was used to perform Pearson correlation coefficient ( $\alpha = 0.05$ ).

**Results.**– No online searches for “Blue Whale” in Google Search and Google News resulted before March 2017. The number of Google Search online queries peaked from the 7th May–25th July 2017. Than it decreased constantly. There is no association between monthly and weekly suicide-related queries and Blue Whale search volumes in Google News. “To commit suicide” ( $P = 0.0061$ ) and “how to commit suicide” monthly queries (0.0582) were significantly associated with “Blue Whale” monthly search volumes in Google Search. Weekly search volumes of “Blue Whale” were associated with “suicide” ( $P = 0.0011$ ) and “to commit suicide” ( $P < 0.0001$ ) search volumes in Google Search.

**Conclusions.**– Blue Whale online searches were associated with suicide-related Google Search online queries pertaining to active suicidality.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Associations among history of suicidal attempt and gonadal axis hormones in hospitalised patients with high suicidal risk**

A. Marčiulionienė\*, B. Berentaite, V. Adomaitiene, V. Steibliene  
Lithuanian university of health sciences, psychiatry clinic, Kaunas, Lithuania

\* Corresponding author.

**Introduction.**– There were an estimated 788,000 suicide deaths worldwide in 2015 (WHO). It is known that suicidal behavior is associated

with higher scores in personality domains with self-directed aggression [1]. There is the hypothesis about the role of gonadal hormones in the pathophysiology of suicidal behavior [2,3].

**Objectives.**– To evaluate the associations between suicidal attempt, personality type, prolactin and free-testosterone concentrations in hospitalized patients with high suicidal risk.

**Methods.**– All non-psychotic patients, without organic brain disorders, with high suicidal risk, hospitalized during 9 month period in Psychiatry Clinic were invited to participate in this prospective study: 56 patients (males – 33.9%) signed an informed consent form. Serum concentrations of total testosterone, sex hormone binding globuline and prolactin were collected on the day of admission; Columbia suicide severity rating scale and Big Five Inventory were used.

**Results.**– All patients were divided into 2 groups according to suicidal risk: suicidal attempt before hospitalisation ( $n=47$ , 84%) and no suicidal attempt ( $n=9$ , 16%). No significant associations were found between age, gender, personality type and suicidal risk. The history of suicidal attempt in male patients group associated with significantly lower serum prolactin concentration, in comparison to males without suicidal attempt ( $676.2 \pm 492.6$  nmol/l vs.  $2031.04 \pm 1549.9$  nmol/l;  $P=0.007$ ). In female patients group, the history of suicidal attempt associated with significantly lower free-testosterone concentration, in comparison to females without suicidal attempt ( $0.0197 \pm 0.0142$  nmol/l vs.  $0.0395 \pm 0.0247$  nmol/l;  $P=0.013$ ).

**Conclusions.**– History of suicidal attempt was associated with lower prolactin concentration in male and with lower free-testosterone concentration in female patients group.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Schizophrenia and Other Psychotic Disorders - Part II

PW0534

### Is there a stigma towards schizophrenia in mass media outlets?

M. Alvarez de Mon Gonzalez<sup>1\*</sup>, V. Pereira<sup>1</sup>, T. Dot<sup>1</sup>, H. Saiz<sup>2</sup>, I. Alberdi<sup>3</sup>, G. Lahera<sup>4</sup>, F. Ortuño<sup>1</sup>

<sup>1</sup> Clínica Universidad de Navarra, psychiatry, Pamplona, Spain;

<sup>2</sup> Complejo Hospitalario de Navarra, psychiatry, Pamplona, Spain;

<sup>3</sup> Hospital Clínico San Carlos, psychiatry, Madrid, Spain; <sup>4</sup> Hospital Príncipe de Asturias, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Schizophrenia has been portrayed in many movies, tv shows, and such. However, in some occasions, the disorder has not been given a proper representation.

**Objective.**– To conduct a qualitative analysis on the Tweets that refer to schizophrenia, from the Twitter accounts of prominent US mass media outlets.

**Methods.**– 15 US news media outlets were selected and analyzed. These outlets were chosen based on the number of followers on their Twitter accounts and were narrowed down to those with the most followers. Some major news outlets (ex. Wall Street Journal) were excluded for not having a section on health. The Tweets were selected if they made any reference to schizophrenia (ex. schizophrenia from @washingtonpost). This study focused on the Tweets from 2007–2016.

**Results.**– 174 Tweets were selected and divided into four categories. 50% focused on general interest (“Man accused of faking sign interpretation at #MandelaMemorial hallucinated angels, suffers from

schizophrenia”), 29.31% were testimonies from patients (“A young man writes about living with schizophrenia and the struggle to connect”), 16% revolved around scientific advancements (“Talk therapy is found to ease schizophrenia”) and 5% had a condescending tone towards these disorders (“1/3 of Americans believe that prayer is sufficient to cure severe mental illness like schizophrenia”).

**Conclusions.**– Although the mass media outlets have been very respectful when dealing with patients and their families, these platforms have not been utilized to their full potential. Social media can be a great intermediary that bridges the gap between science and the general public.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Improvement of schizophrenia social amotivation and expressive deficits over time after cariprazine and risperidone treatment: Post hoc analysis of a phase-3 trial

I. Laszlovszky, A. Barabassy\*, B. Sztatmári, J. Harsányi, E. Szalai, G. Németh

Gedeon Richter Plc., clinical development unit, Budapest, Hungary

\* Corresponding author.

**Introduction.**– In recent years, primary and secondary negative symptoms and sub-domains such as social amotivation and expressive deficit referred to as Liemburg factors have been recognized. Cariprazine is a potent dopamine D<sub>3</sub> receptor preferring partial agonist approved by EMA for the treatment of schizophrenia and by FDA for the treatment of schizophrenia and bipolar mania.

**Objectives.**– To utilize the Liemburg factors to conduct a post-hoc analysis of social amotivation and expressive deficit over time in patients with predominant negative symptoms of schizophrenia.

**Methods.**– Subjects with schizophrenia and a PANSS factor score for negative symptoms (PANSS-FSNS)  $\geq 24$  with minimal EPS, positive and depressive symptoms were randomized to a target dose of cariprazine 4.5 mg/d or risperidone 4 mg/d for 26 weeks of double-blind treatment. Post hoc analyses evaluated the change from baseline (CfB) and the time course of the PANSS-derived Liemburg factors (social amotivation and expressive deficit).

**Results.**– A total of 461 patients were randomized (1:1) to double-blind treatment. Statistically significant improvement in favor of cariprazine versus risperidone was seen on core negative symptoms ( $P=.004$ ) and expressive deficit ( $P=.004$ ) at Week 26. The mean CfB always favored cariprazine with statistically significant differences for expressive deficit from Week 14 and for social amotivation from Week 18 onwards.

**Conclusion.**– By targeting negative symptoms of schizophrenia, including social amotivation and expressive deficits, cariprazine can be a solution for patients who are attempting to gain back their lost initiative and their ability to interact with the community.

**Disclosure of interest.**– I am a co-worker of Gedeon Richter PLC.

### The method of improving compliance in patients with schizophrenia

I. Belokrylov\*, V. Sokolov, A. Bryukhin

Peoples' friendship university of Russia, RUDN university, department of psychiatry and medical psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Low compliance significantly reduces the effectiveness of treatment of patients with schizophrenia. To improve it,

various psychotherapeutic technologies are offered. However, in Russia, many of them are poorly reproduced due to the weak development of appropriate methods.

**Objectives.**– Development of psychotherapeutic technology to improve compliance with patients with schizophrenia based on the most reproducible methods; efficiency mark.

**Methods.**– A group of patients with a paranoid form of schizophrenia (F20.0, ICD-10);  $n=50$ , 29 men, 21 women, mean age  $32 \pm 6.4$  years, randomized to 2 groups (25/25); the main group received psychotherapy to improve compliance, developed in the study (3 sessions per week for 30 minutes each for 1 month). In the control of patients psychological and educational conversations were conducted, which were completely identical in time and frequency. The results were analyzed using testing.

**Results.**– The factor analysis of clinical-pathopsychological parameters, correlating with low adherence to treatment, divided them into 3 groups: (1) cognitive – associated with a distorted awareness of the disease; (2) communicative – associated with dysfunctional family relationships; (3) irrational – associated with the unconscious benefit of the disease. Based on these data, compliance therapy is built on 3 methods: cognitive-behavioral; family and psychodynamic. The analysis shows significantly better results in the main group both in terms of increasing compliance and reducing the symptoms of the disease ( $P < 0.05$ ).

**Conclusions.**– The developed method of corrective therapy can be recommended for systematic use.

**Disclosure of interest.**– The publication was prepared with the support of the “RUDN University Program 5-100.

### Retinal ganglion cells dysfunction in schizophrenia patients with visual hallucinations

F. Bernardin<sup>\*</sup>, R. Schwan, T. Schwitzer, V. Laprevote  
Centre psychothérapique de Nancy, pôle hospitalo-universitaire de psychiatrie d'adultes du Grand Nancy, Laxou, France

\* Corresponding author.

Structural abnormalities of the retinal ganglion cells are documented in schizophrenia and have been associated to visual hallucinations (VH) in neurological disorders. We aim to study functional abnormalities of retinal ganglion cells in schizophrenia patients with VH.

We compared the amplitude and implicit time of the P50 and the N95 waves of the pattern electroretinogram in schizophrenia patients with VH (VH group,  $n=7$ ), Auditory Hallucinations or no hallucination (AH/NH group,  $n=8$ ) and controls ( $n=30$ ). Preliminary findings showed a significant increase of the N95 implicit time in the HV group compared with controls ( $P=.05$ ). No difference was found between the HV and HA/NH groups but a gradient appeared to emerge between the 3 groups.

Functional impairment of the retinal ganglion cells appears to be more pronounced in schizophrenia patients with HV. These preliminary results need to be confirmed with a larger sample.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Global functioning and quality of life in primary versus secondary negative symptoms in schizophrenia

O.O. Capatina<sup>\*</sup>, A. Campean, A. Toma  
Iuliu Hatieganu university of medicine and pharmacy, neuroscience, Cluj-Napoca, Romania

\* Corresponding author.

**Background.**– Negative symptoms in schizophrenia are considered to be a core feature of the disease and may be classified as primary or secondary. Primary negative symptoms are considered to be an intrinsic feature of schizophrenia while secondary symptoms are considered to be caused by depression, medication side-effects, positive symptoms, social deprivation.

**Aims.**– The aim of this study was to determine the impact of primary versus secondary negative symptoms on the quality of life and functional outcomes in patients diagnosed with schizophrenia.

**Methods.**– Patients were assessed using the Positive and Negative Symptoms Scale (PANSS), Negative Symptoms Assessment Scale (NSA-16), Calgary Depression in Schizophrenia Scale (CDSS), Simpson Angus Scale (SAS), Lehman Quality of Life Scale (QoL), Global Assessment of Functioning Scale (GAF). The patients were divided in two groups a first group with primary negative symptoms and a second group with secondary one.

**Results.**– In this ongoing study our preliminary results show primary negative symptoms have a greater impact on global functioning and patients have greater social and vocational impairments than patients with secondary negative symptoms.

**Conclusions.**– Negative symptoms have a strong contribution to poor functioning and reduced quality of life, but an important distinction should be made between primary and secondary negative symptoms. Even though these symptoms often appear to have similar phenomenology at a clinical level, and that they are not easily distinguished, secondary negative symptoms have often clearly defined causes and are easier to treat than primary ones.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Working memory and visual binding in schizophrenia

V. Cestari<sup>1\*</sup>, A. Sciarretta<sup>2</sup>, P. Spataro<sup>1</sup>, D. Sarauili<sup>3</sup>,  
V. R.S. Marques<sup>1</sup>, C. Rossi-Arnaud<sup>1</sup>

<sup>1</sup> Sapienza university of Rome, department of psychology, Rome, Italy; <sup>2</sup> San Giovanni Evangelista hospital, acute psychiatric care unit, department of mental health RM-G, Tivoli, Italy; <sup>3</sup> CNR, cell biology and neurobiology institute, Rome, Italy

\* Corresponding author.

**Introduction.**– Working memory (WM) is a limited capacity system which temporarily stores and manipulates information. More recently, a component allowing WM to be linked to perception and long-term memory, the episodic buffer, was added to the model (Baddeley, 2000) and its role has been investigated using paradigms in which features had to be bound together and remembered. A few studies have begun to assess whether individuals with schizophrenia show a specific deficit in these WM binding processes.

**Objectives.**– To investigate the capacity of individuals with schizophrenia to form and maintain bound representations of visual features.

**Methods.**– The performance of schizophrenic patients and healthy controls was examined in simultaneous (Experiment 1) and sequential (Experiment 2) visual WM tasks used by Allen et al.

(2012) to investigate the attentional requirements of colour-shape binding processes.

**Results.**– Patients with schizophrenia did not show a disproportionate deficit in the encoding and maintenance of integrated representations (here, coloured shapes). However, with sequential presentation, their memory performance was worse than that of healthy controls in the first three serial positions, but not in the last (most recent) position.

**Conclusion.**– Individuals with schizophrenia are not specifically impaired in feature binding processes. Rather, findings suggest that their visual representations are more fragile and susceptible to interference from upcoming items compared to healthy controls. These data provide important clinical evidence in support of the two-component view of visual WM advanced by Allen et al. (2014).  
**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Differences in intensity of cognitive impairment in patients with schizotypal disorder**

O. Dorofeeva<sup>1\*</sup>, M. Vinogradova<sup>2</sup>, A. Chepeliuk<sup>2</sup>

<sup>1</sup> FSBI “Zakusov institute of pharmacology”, laboratory of clinical psychopharmacology, Moscow, Russia; <sup>2</sup> Lomosov Moscow state university, department of neuro- and pathopsychology, faculty of psychology, Moscow, Russia

\* Corresponding author.

**Introduction.**– The research of cognitive functions in patients with schizotypal disorder (SD) is important to elucidate their contribution in clinical pattern, severity of disease and prognosis following treatment. The commonalities and differences in results of investigations of cognitive impairment in SD suggest the heterogeneity of this group. It's important to study the similarities and differences in cognitive profiles of schizotypy and schizophrenia spectrum disorders.

**Objectives.**– To research differences in intensity of cognitive impairment of schizotypy and schizophrenia spectrum disorders.

**Methods.**– Wechsler Adult Intelligence Scale, a revised form (WAIS-R). 32 schizotypal personality disorder (SPD) patients and 30 schizophrenic patients (pseudoneurotic type) were enrolled to the study. Patients had an equivalent age and educational level. ANOVA one-way test was used.

**Results.**– SPD subjects had better performance in the Similarities ( $F(1;58)=5.227, P=0.026$ ), the Digit Symbol ( $F(1;57)=4.759, P=0.033$ ) and the Picture Arrangement ( $F(1;56)=4.091, P=0.048$ ) subtests in comparison with schizophrenia. They also demonstrated a tendency to increase in Picture Completion subtest ( $F(1;56)=3.966, P=0.051$ ) and had a higher level of nonverbal intelligence ( $F(1;56)=4.860, P=0.032$ ). SPD and schizophrenic patients had similarities in peculiar answers, subjective association with stimuli. SPD patients could switch from subjective manner of performance to a standard one, use compensatory strategies. Schizophrenic patients had limitations in changing of the performance manner and applying of compensatory strategies.

**Conclusions.**– These findings suggest commonalities in some of verbal tests in SPD and schizophrenia. The main differences in cognitive profiles in schizophrenia and SPD primarily laid in higher intensity of impairments in performance of visual-perceptual tasks in schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Treating psychosis in Italian outpatient setting: Long acting injectable antipsychotics, team work and compliance**

F. Facchini<sup>1</sup>, P. Vaschetto, M. Petrizzelli, G. Gallino  
*Asl Città di torino, Dipartimento di Salute Mentale, Turin, Italy*

\* Corresponding author.

**Introduction.**– Poor compliance to treatment is a major challenge in therapy of psychoses. Increasing the effectiveness of interventions on adherence may have an impact not only in improving medical treatment but also in overall patient health. Interventions combining elements from pharmacotherapy and different approaches (cognitive-behavioral therapy, family and community-based engagement) have shown better outcomes.

**Objectives.**– To assess the effect on compliance of different therapeutic approaches in psychotic patients taking long acting injectable antipsychotics (LAI), treated in a public health service, following outpatient setting.

**Methods.**– We recruited 115 psychotic patients (schizophrenia, bipolar disorders, other psychosis) upon LAI treatment: 42.7% following medical treatment as usual (TAU), 57.3% pharmacotherapy combined with other professional interventions (educators, paramedics, psychologists) in a team work management (TWM). We assessed socio-demographic data, global functioning and compliance.

**Results.**– No statistical differences ( $P<0.05$ ) were found in demographic variables between TWM and TAU group. Both groups were homogenous for global functioning (GAF score  $50 \pm 5$ ). TWM group showed better compliance intended as not skipping any administration (87.4% in TWM vs 77% in TAU).

**Conclusions.**– Our study suggests that treating psychoses with the use of long acting injectable antipsychotics results in good adherence with the possibility of easy monitoring of global functioning, nevertheless to improve compliance a “tailored on patient” therapeutic team approach seems determinant for continuity even in long acting injectable pharmacotherapy. Further research needed to evaluate differences in global functioning and compliance among diverse diagnosis: psychosis but also off-label LAI therapies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Resilience, burden of care, and quality of life in Egyptian family caregivers of patients with schizophrenia**

S. Harfush

*Tanta university, psychiatric and mental health nursing, Tanta, Egypt*

Caring for mentally ill patients affects the family caregivers' physical and mental health which leads to a lot of burden. Consequently, family caregivers need resilience to help in relieve this burden and to regain their quality of life.

**Objective.**– The present study was designed to assess the levels of resilience, burden and quality of life among family caregivers of patients with schizophrenia and their relationships.

**Setting.**– The study was conducted at the psychiatric outpatient clinic of Mental Health Hospital in Tanta City and Psychiatric Outpatient Clinic.

**Subjects.**– A descriptive correlational design was utilized in the study, using a convenient sample of family caregivers of patients with schizophrenia ( $n=109$ ). Tools: Connor Davidson Resilience Scale (CD-RISC), Burden of Care Inventory, and the World Health Organization Quality of Life Scale.

**Results.**– The present study indicated a significant positive correlation between resilience level and quality of life. On the other hand, caregiving burden was negatively correlated with each of resilience and quality of life. Moreover, family caregivers have moderate level of resilience, and around two thirds of them have poor overall quality of life and experiencing moderate to severe burden.

**Conclusion.**– The present study concluded that, decreasing family caregivers' burden and enhancing their quality of life is imperative, this can be done by emphasizing the significant role of resilience.

**Recommendations.**– A rehabilitation program and ongoing interventions for family caregivers should be established to enhance their resilience and consequently to decrease their burden and improve their quality of life.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Aripiprazole-induced hypersexuality:**

#### **A case report and literature review**

M. Kaji<sup>1</sup>, M. Onaya<sup>2</sup>, K. Akihiro<sup>2</sup>, S. Hisaomi<sup>2</sup>

<sup>1</sup> Keio university hospital, neuropsychiatry department, Shinjuku, Japan; <sup>2</sup> National hospital organization Shimofusa psychiatric medical center, neuropsychiatry, Chiba, Japan

\* Corresponding author.

Hypersexuality is a pathological sexual behaviour. It has been reported as a side effect of antipsychotics, as well as a symptom of neuropsychiatric illnesses. However, the mechanism is still unclear. We present a case of a 34-year-old female patient with schizophrenia who was diagnosed at the age of 25 years. At the age of 31 years, she reported auditory hallucinations and persecutory delusions, and was admitted to our hospital. Aripiprazole 12 mg was started and was increased to 24 mg, after which her positive symptoms decreased. However, the patient developed hypersexuality, and exhibited behaviour such as approaching a male patient's crotch with her face. Aripiprazole was decreased to 12 mg and olanzapine 10 mg was started, which resulted in a decrease in her hypersexuality. Olanzapine treatment was discontinued after the patient's discharge, but she did not report hypersexuality or any positive symptoms.

One year later, aripiprazole was discontinued because of the patient's pregnancy. Two months after delivery, her auditory hallucinations worsened, and she entered our hospital. As aripiprazole 12 mg did not improve her symptoms, the dosage was increased to 24 mg. Subsequently, she reported increased libido and kissed a male patient in public. Aripiprazole was decreased to 12 mg and olanzapine 10 mg was started, which resulted in a decline in hypersexuality.

In this case, hypersexuality was observed twice after increases in aripiprazole dosage. Neither the patient's positive symptoms nor prolactin accounted for this behaviour. Considering the mechanism of action of aripiprazole and past reports, dopamine stimulation could lead to hypersexuality.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Emotional stroop performance in psychotic disorders; Preliminary results**

B. Keřková

Charles university and general university hospital in Prague, department of psychiatry, first faculty of medicine, Prague, Czech Republic

**Introduction.**– Abnormal emotional reactivity plays a key role in the development and maintenance of psychotic disorders. Ineffective management of general or disorder-specific stress relates to a poor prognosis. The emotional Stroop task (EST), in which participants respond to the color of a series of emotional words, can quantify emotional reactivity and compare the effect of general and disorder-specific threat. The task has not been thoroughly utilized in research on psychotic disorders.

**Objectives.**– This study aimed to adapt the EST for persons with a psychotic disorder and to examine their performance.

**Methods.**– Patients diagnosed with a psychotic disorder (F20, F23 and F25 by the ICD-10 criteria) and matched controls completed a control questionnaire (CAPE-42) and a digital version of the EST. The EST included 360 experimental trials comprised of length and frequency-matched words belonging to one valence category (neutral, negative) and one semantic category (neutral, positive-symptom-related, negative-symptom-related). Words occurred on screen in a random order for a fixed response period of 1000 ms, preceded by a variable 1000–2000 ms inter-trial-interval.

**Results.**– Mean participant RTs were calculated for each word category, with errors and trials in which the RT fell more than 2 SDs from the participant's mean removed. The means were submitted to a 2 × 2 × 3 (group, valence, semantics) repeated-measures ANOVA. Group differences in reactivity to general and disorder-specific threat are reported.

**Conclusions.**– This study describes a novel EST paradigm designed for persons with a psychotic disorder. Preliminary results trace trends in emotional reactivity in this subgroup.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Alterations of regional cerebral blood flow and emotional recognition in patients with first episode psychosis**

P. Makarić<sup>1</sup>, D. Bosnjak<sup>2</sup>, M. Živković<sup>3</sup>, A. Savić<sup>4</sup>, P. Brečić<sup>5</sup>, V. Jukić<sup>6</sup>, Z. Mađžarac<sup>7</sup>, R. Petrović<sup>8</sup>, M. Rojnić Kuzman<sup>7</sup>

<sup>1</sup> University psychiatric hospital Vrapče, the addictions department, Zagreb, Croatia; <sup>2</sup> University psychiatric hospital Vrapče, general psychiatry, Zagreb, Croatia; <sup>3</sup> University psychiatric hospital Vrapče, department for psychotic disorders, Zagreb, Croatia; <sup>4</sup> University psychiatric hospital Vrapče, urgent psychiatry, Zagreb, Croatia; <sup>5</sup> University psychiatric hospital Vrapče, department for affective disorders, Zagreb, Croatia; <sup>6</sup> University psychiatric hospital Vrapče, forensic psychiatry, Zagreb, Croatia; <sup>7</sup> University clinical hospital center Zagreb, psychotic disorders, Zagreb, Croatia; <sup>8</sup> University clinical hospital center Zagreb, department for nuclear medicine, Zagreb, Croatia

\* Corresponding author.

**Introduction.**– Alterations of regional cerebral blood flow (rCBF) have been observed in patients with schizophrenia, even in the first episode of psychosis (FEP). However, these alterations have been associated with psychopathology inconsistently.

**Objectives.**– To analyse the relationship of the rCBF alterations, psychopathology status and emotional recognition in FEP during acute phase.

**Methods.**– We conducted a cross-sectional study on 40 patients with FEP at the acute phase of illness during their hospitalization at Zagreb University Hospital Centre. Assessment included Single-photon emission computed tomography (SPECT), Penn emotion recognition task and Positive and Negative Syndrome Scale (PANSS).

**Results.**– While our results showed hypoperfusion of rCBF in various brain regions, there was no statistically significant correlation of

(± 4.05)60.79 (± 4.37)63.08 (± 5.77)Treatment compliance 100%100%77.7%66.6%BMI26.39 (± 4.73)25.78 (± 3.76)Prolactin477.2 (± 336.2)299.94 (± 41.88)190.34 (± 49.7)\*\*\*\*  $P < 0.001$ ; \*\*  $P < 0.01$ ; \*  $P < 0.05$ .

There is an indirect correlation between age and changes in the score on:

- BPRS-N, BNSS and ICG-SI scales ( $p < 0.05$ ).
- PSP scale.

The greatest score reductions were observed in subjects aged < 35 years.

**Conclusions.**– ALAI is effective in improving psychopathological symptoms, especially negative symptoms and functionality. ALAI does not cause weight gain and achieving a reduction in prolactin levels.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Impact of sociodemographic variables and vulnerability to stress in the onset of first episode psychosis

L. Rossini Gajsak<sup>1</sup>, M. Celic Ruzic<sup>2</sup>, A. Koricancic Makar<sup>3</sup>, M. Rojnic Kuzman<sup>3</sup>

<sup>1</sup> *Neuropsychiatric hospital Dr. Ivan Barbot, department of biological psychiatry, Popovaca, Croatia*; <sup>2</sup> *Psychiatric hospital Sv. Ivan, department of integrative psychiatry, Zagreb, Croatia*;

<sup>3</sup> *University clinical hospital center Zagreb, department of psychiatry, Zagreb, Croatia*

\* Corresponding author.

**Introduction.**– Recent findings in patients with first episode psychosis (FEP) indicate that they are associated with elevated baseline and challenge-induced hypothalamic pituitary adrenal (HPA) activity.

**Objectives.**– To assess the difference in response to psychosocial stress and connections with sociodemographic variables in FEP patients and healthy controls.

**Methods.**– We have assessed clinical status through clinical psychiatric interviews, standardized psychiatric scales and validated psychological scales, (LEQ, WHOQOL-BREF, PBI, Rosenberg) in 48 subjects with FEP and 50 age and gender matched controls. All participants were then exposed to the Trier Social Stress Test (TSST). We have analyzed distribution of frequencies between the groups for categorical variables through chi square test.

**Results.**– Our findings indicate a differences between patients and controls in salivatory cortisol measured in 5 time points during the TSST, ANOVA repeated measures  $F = 5.09$ ,  $P = 0.03$ , post-hoc test, 1-cortisol i 3-cortisol,  $P < 0.05$ . We have also found statistically significant results in elevated cortisol levels between the participants with serious childhood illnesses, ANOVA repeated measures,  $df = 1.0$ ,  $F = 6.3$ ,  $P = 0.01$ , post-hoc, 2-cortisol,  $P < 0.05$ , as well as between the participants regarding cigarette smoking, ANOVA repeated measures  $df = 1.0$ ,  $F = 4.4$ ,  $P = 0.04$ , post-hoc, 1-cortisol i 2-cortisol,  $P < 0.05$ .

**Conclusions.**– Our findings support the alterations of stress response, indicating vulnerability to stress in participants with FEP and possibly proneness to psychotic state in correlation to sociodemographic variables.

**Funding.**– This work was funded by the grant of the Croatian Science Foundation No. UIP-2014-09-1245 Biomarkers in schizophre-

nia – integration of complementary methods in longitudinal follow up of first episode psychosis patients.

### Perception of contradictions in schizophrenia: Primary approbation of questionnaire

G. Rupchev<sup>1</sup>, A. Alekseev<sup>1</sup>, A. Tkhostov<sup>2</sup>, M. Vinogradova<sup>2</sup>, A. Ryzhov<sup>2</sup>, A. Spivakovskaya<sup>2</sup>, O. Tikhomandritskaya<sup>2</sup>

<sup>1</sup> *Federal state budgetary scientific institution “mental health research center”, laboratory of psychopharmacology, Moscow, Russia*; <sup>2</sup> *Lomonosov Moscow state university, faculty of psychology, department of neuro- and pathopsychology, Moscow, Russia*

\* Corresponding author.

**Introduction.**– Incoherence is a new concept in psychology. It characterizes the inconsistency in person’s representations of the world, himself and other people. The development of psychodiagnostic tools for assessing incoherence is an actual problem.

**Objectives.**– The purpose of this study is to approbate the questionnaire for the assessment of the perception of contradictions.

**Method.**– The study involved 26 schizophrenia patients and 15 healthy subjects. Experimental questionnaire “Study of contradictions” includes 39 pairs of opposing or not opposing characteristics of the person (both physical and psychological and social). The subject is asked to answer “YES” or “NO” to questions whether a person can be characterized simultaneously by both characteristics of the pair. The results are processed on 4 scales: physical antonyms (tall and short); physical non-antonyms (tall and lightweight); social and psychological antonyms (kind and evil); social and psychological non-antonyms (happy and evil).

**Results.**– Most subjects of both groups had no difficulty completing the questionnaire which indicates the possibility of its use in clinical settings. There were no significant differences between groups on the scale “physical antonyms”. However, it was found that patients with schizophrenia significantly less likely to coexist in a person’s opposite psychological and social characteristics. Also, patients with schizophrenia significantly more often than healthy subjects rejected the possibility of coexistence in humans not opposite characteristics, both physical and psychological and social.

**Conclusions.**– The results allow to consider that tolerance of some inconsistency in the perception of themselves and others is a normative phenomenon.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0551

### The gender factor in the value orientations of patients with schizophrenia

E. Leontieva<sup>1</sup>, A. Tkhostov<sup>1</sup>, G. Rupchev<sup>2</sup>\*

<sup>1</sup> *Lomonosov Moscow state university, faculty of psychology, department of neuro- and pathopsychology, Moscow, Russia*;

<sup>2</sup> *Federal state budgetary scientific institution “mental health research center”, laboratory of psychopharmacology, Moscow, Russia*

\* Corresponding author.

**Introduction.**– The rehabilitation success of patients with schizophrenia depends on the necessity of reassessment that should be done during the rehabilitation period. Gender plays a significant role within differentiated approach for schizophrenia patients.

**Objectives.**– Gender specific factors in the value orientations of schizophrenia patients.

**Method.**– 111 patients diagnosed with F20XX according to ICD-10, 53 men and 68 women, aged  $35 \pm 9$  with disease duration of  $5.4 \pm 4.5$ , underwent a formalized clinical interview where they chose close and rejected values (direct naming), compared the values among themselves (the hierarchy analysis method) and reported values that had changed after the illness. Chosen values were then divided into clusters: abstract, interpersonal communication, social strength and self-realization values.

**Results.**– Significant differences among men and women with schizophrenia were found in close value choices such as family ( $P < 0.01$ ), friendship ( $P < 0.01$ ), faith ( $P < 0.01$ ), freedom ( $P < 0.1$ ) categories.

**Conclusion.**– Men and women with schizophrenia are different in their value choices what can be considered/concluded/claimed as they have different goals for rehabilitation and social adaptation. Women with schizophrenia mostly focused on interpersonal communication, thus, they showed significantly higher score in “family values score” than men, who denied or did not support those clusters of values. Men were orientated towards abstract and religious values. Hence, it should be taken into consideration while setting the rehabilitation goals.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Assessment of quality of life changes among first episode psychosis patients in Singapore

P. Satghare\*, E. Abidin, S. Shahwan, B.Y. Chua, S. Verma, M. Subramaniam

*Institute of mental health, research, Singapore, Singapore*

\* Corresponding author.

**Introduction.**– Quality of Life (QOL) is a vital and valid outcome measure in first episode psychosis (FEP).

**Objectives.**– To determine the prevalence of change in QOL among FEP patients who indicated minimal clinically important difference (MCID) scores using World Health Organisation Quality of life- BREF (WHOQOL- BREF) and to identify its socio-demographic and clinical correlates over 1 year.

**Methods.**– The change in QOL scores between two study visits were determined by MCID scores by distribution-based methods, namely standard error of measurement ( $1 \text{ SEM} = \sqrt{2 \times \text{SD}_1 \times \sqrt{1 - r_{xx}}}$ ) for the four domains of WHOQOL-BREF and using logistic regression to determine the significant correlates of improvement.

**Results.**– 89 participants who completed both baseline and 1 year follow-up were included in the study. Based on 1 SEM approach, MCID cut-offs derived were – 1.65 (Physical health), 1.76 (Psychological health), 2.27 (Social relationship) and 1.42 (Environment). Improvement in QOL of FEP patients across the four domains: 69.66% (Physical health), 67.42% (Psychological health), 76.4% (Social relationships) and 57.3% (Environment). For Physical health ( $P = 0.0172$ ) and social relationships ( $P = 0.049$ ), patients belonging to Malay ethnicity (versus Chinese) and for Psychological health ( $P = 0.0484$ ), brief psychotic disorders patients showed positive MCID scores in QOL (versus schizophrenia) at the end of 1 year.

**Conclusion.**– The current study provides MCID scores on WHOQOL-BREF instrument among patients with FEP. Clinical cut-offs enable researchers and clinicians to better interpret the impact of disease on QOL of patients over time as well as to improve the efficacy of the interventions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Is smoking cannabis protective effect against metabolic alterations in psychosis? Results From a 3-years longitudinal study on patients with a first-episode of psychosis

J. Vázquez Bourgon<sup>1</sup>, R. Romero Jiménez<sup>1</sup>, M. Gomez Revuelta<sup>1</sup>, F. Pilar Cuéllar<sup>2</sup>, E. Castro Fernández<sup>2</sup>, B. Crespo-Facorro<sup>1</sup>

<sup>1</sup> *University hospital Marqués de Valdecilla-IDIVAL, CIBERSAM, psychiatry, Santander, Spain;* <sup>2</sup> *Instituto de Biomedicina y Biotecnología de Cantabria IBBTEC, CIBERSAM, Santander, Spain, pharmacology, Santander, Spain*

\* Corresponding author.

**Background.**– Cannabis smoking is highly prevalent among patients with a psychotic disorder. Its use has been found related to clinical characteristics of the disorder including age of onset, symptoms' severity and cognitive impairment. However, recent studies, both in healthy subjects and patients with psychosis, propose a possible protective effect of cannabis on weight gain and related metabolic alterations. Even so, there are no previous studies on the long-term longitudinal effect of cannabis on first-episode drug-naïve patients, thus not avoiding confounding effects of chronicity and previous treatment exposure. We aimed to explore the effect of cannabis smoking on weight and lipid/glycemic metabolic measures in a sample of first-episode non-affective psychosis patients.

**Material and methods.**– Anthropometric measurements and glycemic and lipid parameters were obtained at baseline and after 3 years of having initiated treatment. Patients were divided into two groups depending on self-reported cannabis use (cannabis users and non-users).

**Results.**– Cannabis users presented at baseline lower weight ( $F = 14.85$ ,  $P < 0.001$ ), BMI ( $F = 13.14$ ,  $P < 0.001$ ), total cholesterol ( $F = 4.85$ ,  $P = 0.028$ ) and LDL-cholesterol ( $F = 6.26$ ,  $P = 0.013$ ), than non-users. These differences were also observed at 3 years: weight ( $F = 8.07$ ,  $P = 0.005$ ), BMI ( $F = 4.66$ ,  $P = 0.032$ ) and LDL-cholesterol ( $F = 3.91$ ,  $P = 0.049$ ).

**Conclusions.**– Our results support the hypothesis that cannabis has a protective effect against weight gain and related metabolic alterations that are frequently observed in psychotic patients. However, this positive effect does not overcome the well known negative impact of cannabis on psychosis prognosis. Thus, clinicians should continue recommending cannabis use cessation, although being aware of a probable occurrence of a deterioration in metabolic parameters.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>1</sup> *Faculty of medicine and dentistry, Palacky university and university hospital, department of psychiatry, Olomouc, Czech Republic;*

<sup>2</sup> *Faculty of social science and health care, Constantine the*

*Philosopher university, department of psychology sciences, Nitra,*

*Slovak Republic*

\* Corresponding author.

**Introduction.**– Both positive and negative symptoms of schizophrenia are related to other clinical variables.

**Objectives.**– The purpose of the investigation was to explore the relationship between positive or negative symptoms, social anxiety, hope, personality, and self-stigma in schizophrenia spectrum disorders.

**Methods.**– 57 outpatients took part in this cross-sectional study. All patients completed the Liebowitz Social Anxiety Scale, Internalized Stigma of Mental Illness Scale, Beck Depression Inventory-II, Beck Anxiety Inventory, Adult Dispositional Hope Scale, and Temperament and Character Inventory – Revised. The disorder severity was evaluated by Clinical Global Impression – Severity scale, and Positive and Negative Syndrome Scale. The patients were in a stabilized state.

**Results.**– Both positive and negative symptoms of schizophrenia positively correlated with global severity of the disorder, the severity of the general and social anxiety symptoms, the severity of self-stigma, and negatively with personality traits Self-directedness and Cooperativeness. Only negative symptoms significantly positively correlated with the severity of depressive symptoms and personality trait Harm-avoidance and negatively with the hope and personality trait Persistence. Comorbidity with social phobia is associated with statistically significantly higher mean scores on the total score of schizophrenic symptomatology, negative subscale average rating, and general psychopathological items. Patient with comorbid depression would experience a higher level of negative symptomatology than patients without such comorbidity.

**Conclusions.**– Both positive and negative symptoms highly correlated with the severity of anxiety symptoms including social anxiety, self-stigma and negatively with the character traits Self-directedness and Cooperativeness. The negative symptoms only correlated negatively with hope, depression, Harm-avoidance, and Persistence.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0555

### **Comorbidity of schizophrenia and social phobia – impact on quality of life, hope, and personality traits: A cross-sectional study**

K. Vrbova<sup>1</sup>, J. Prasko, M. Ociskova, M. Holubova  
Faculty of medicine and dentistry, Palacky university and university hospital, department of psychiatry, Olomouc, Czech Republic

\* Corresponding author.

**Introduction.**– The most common comorbid disorder in schizophrenic patients is a social phobia. It is usually an unrecognized problem that may be associated with a high distortion in managing claims of life.

**Objectives.**– The purpose of the study was to explore whether the comorbidity of social phobia affects symptoms severity, positive and negative symptoms, self-stigma, hope, and quality of life in patients with schizophrenia spectrum disorders.

**Methods.**– This is a cross-sectional study in which all participants completed the Internalized Stigma of Mental Illness scale, Adult Dispositional Hope Scale, Liebowitz Social Anxiety Scale, Beck Anxiety Inventory, Beck Depression Inventory-II, Positive and Negative Syndrome Scale, Quality of Life Enjoyment and Satisfaction Questionnaire, Temperament and Character Inventory – Revised, and the demographic questionnaire. The disorder severity was assessed both by a psychiatrist and by the patients.

**Results.**– The study included 61 patients of both genders. Clinically, the patients with comorbid social phobia had the earlier onset of the illness, more severe current psychopathology, more intense anxiety, and higher severity of depressive symptoms. The patients with comorbid social phobia had the significantly lower quality of life, lower mean level of hope and experienced a higher rate of the self-stigma compared to the patients without this comorbidity. They also exhibited higher average scores of personality trait harm avoidance and a lower score of personality trait self-directedness.

**Conclusions.**– The study demonstrated differences in demographic factors, the severity of the disorder, self-stigma, hope, and personality traits between patients with schizophrenia spectrum disorders with and without comorbid social phobia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Motor function and psychotic symptoms in patients with schizophrenia**

S.M. Wang<sup>1</sup>, L.C. Kuo<sup>2</sup>

<sup>1</sup> The Hong Kong Polytechnic University, Department of Rehabilitation Sciences, Kowloon, Hong Kong S.A.R.; <sup>2</sup> National Cheng Kung University, Department of Occupational Therapy, Tainan, Taiwan R.O.C.

\* Corresponding author.

**Introduction.**– Emerging evidence indicates that motor abnormalities are associated with progression of psychotic symptoms in individuals at the prodromal stage and can predict onset of full-blown psychosis. It is proposed that because of shared neurological malfunction in basal ganglia, motor abnormalities and psychotic symptoms are connected. To date little is known about whether the association between different types of motor function and psychotic symptoms exists in patients with full-blown schizophrenia.

**Objectives.**– This study was to examine the association of fine motor, muscle strength, and balance to psychotic symptoms in schizophrenia patients only treated with second-generation antipsychotics.

**Methods.**– Seventy schizophrenia patients (42 men and 28 women) were recruited. The McCarron Assessment of Neuromuscular Development was used to evaluate fine motor, muscle strength, and balance. The Positive and Negative Syndrome Scale was used to assess severity of psychotic symptoms. Considering gender differences, correlations between muscle strength and psychotic symptoms were analyzed separately by gender.

**Results.**– Poorer fine motor and balance were correlated to more severe negative symptoms ( $r = -.46, P < .001$ ) and positive symptoms ( $r = -.28, P = .02$ ), respectively. Weaker muscle strength was correlated to more severe negative symptoms ( $r = -.53, P < .001$ ), but increased muscle strength was correlated to more severe positive symptoms ( $r = .42, P = .006$ ) in men.

**Conclusions.**– Motor function keeps association with psychosis in patients with full-blown schizophrenia, supporting the hypothesis of shared basal ganglia dysfunction. Future research to examine whether compensatory mechanisms in cortical regions affect muscle strength is warranted.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### How are we using mass media in the combat against drug addiction?

M. Alvarez de Mon Gonzalez<sup>1\*</sup>, V. Pereira<sup>1</sup>, H. Saiz<sup>2</sup>, T. Dot<sup>1</sup>, I. Alberdi<sup>3</sup>, G. Lahera<sup>4</sup>

<sup>1</sup> Clinica Universidad de Navarra, psychiatry, Pamplona, Spain;

<sup>2</sup> Complejo Hospitalario de Navarra, psychiatry, Pamplona, Spain;

<sup>3</sup> Hospital Clinico San Carlos, Madrid, Spain; <sup>4</sup> Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– The harmful use of alcohol ranks third among the main risk factors for premature death and disability in the world, after smoking and hypertension. Problems with illegal drug use are increasing worldwide.

**Objective.**– To conduct a qualitative analysis on the Tweets that refer to drug addiction or alcoholism, from the Twitter accounts of prominent US mass media outlets.

**Methods.**– 15 US news media outlets were selected and analyzed. These outlets were chosen based on the number of followers on their Twitter accounts and were narrowed down to those with the most followers. The Tweets were selected if they made any reference to drug or alcohol addiction (ex. “alcoholism or alcohol abuse” from: @HuffingtonPost). This study focused on the Tweets from 2007–2016.

**Results.**– 277 Tweets were selected and divided into four categories. 25% focused on general interest (“How an epidemic of heroin and prescription drug addiction has left its mark on the 2016 presidential race”), 58.33% were testimonies from patients (“My bottom was gonna be death” – Eminem opens up about drug addiction, “Retired soccer star Abby Wambach opens up about her drug and alcohol abuse”), 10% had a condescending tone towards these disorders and the rest revolved around scientific advancements.

**Conclusions.**– Twitter is a platform that is frequently used to express personal experiences, in the hopes of inspiring people to avoid the use of drugs. However, Twitter is not being sufficiently utilized to spread awareness about the devastating psychological, neurological, and general health effects these addictions may cause.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Sexual Addiction in HIV-infected men

Y. Ashenbrenner<sup>1,2\*</sup>, E. Chumakov<sup>1,2</sup>, N. Petrova<sup>1</sup>

<sup>1</sup> Saint Petersburg state university, department of psychiatry and addictions, St. Petersburg, Russia; <sup>2</sup> Saint Petersburg psychiatric hospital no. 1 named after P.P. Kaschenko, outpatient department no. 2, St. Petersburg, Russia

\* Corresponding author.

**Introduction.**– Sexual addiction (SA) is associated with risky sexual behavior and an increased risk of HIV.

**Objective.**– To estimate the frequency of SA in HIV-infected men.

**Methods.**– 63 HIV-infected men were examined. The R. Irons and J. Schneider criteria (1997) were used for diagnosis of SA.

**Results.**– The sample was divided into two groups: men who have sex with men (51%; MSM; average age  $30.4 \pm 8.9$ ) and men who have sex with women (49%; MSW;  $34.2 \pm 7.9$ ). SA was established in 19 MSM and 6 MSW (59.4 and 19.4%, respectively,  $P < 0.001$ ). Men with SA were characterized by the desire for simultaneous or repeated subsequent sexual contacts (46.9 for MSM and 16.1% for MSW,  $P = 0.009$ ), an increasing amounts of unfamiliar sexual

partners (71.9 and 19.4%;  $P < 0.001$ ), perception of a partner only as a sexual object (59.4% and 22.6%,  $P = 0.003$ ), use of commercial sex services (9.4% and 54.8%,  $P < 0.001$ ), neglect of safe sex (100% men). The drug dependence was more common among MSW (18.8 and 61.3%,  $P < 0.001$ ). The comorbidity of chemical and non-chemical addictive behavior reached 25.0% for MSM and 19.4% for MSW. MSM took drugs before sexual intercourse to raise mood, reduce anxiety and increase sexuality. Chemical addictive behavior in MSW was not associated with sexual intercourse.

**Conclusions.**– We revealed a high incidence of sexual addiction in HIV-infected men especially in MSM (59%). Sexual addictive behavior is one of the main factors that forms the conditions for HIV infection in MSM, while chemical addictive behavior was dominated in MSW.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Low serum level of epidermal growth factor in chronic ketamine users

N. Fan<sup>1\*</sup>, M. Zhang<sup>1</sup>, H. He<sup>1</sup>, Y. Ning<sup>1</sup>, Y. Ding<sup>1</sup>, X. Ke<sup>2</sup>, D. Wang<sup>1</sup>, X. Deng<sup>3</sup>

<sup>1</sup> Guangzhou psychiatric hospital, biological psychiatry laboratory,

Guangzhou, China; <sup>2</sup> Shenzhen Kangning hospital, psychiatry,

Shenzhen, China; <sup>3</sup> Guangzhou Baiyun voluntary drug rehabilitation hospital, psychiatry, Guangzhou, China

\* Corresponding author.

**Background.**– Growth factors play an important role in brain developing and mature. Whether Epidermal growth factor (EGF) plays a role in the pathophysiology of ketamine related disorders is unexplored. In this study, we examined the serum levels of EGF in chronic ketamine users as compared to healthy controls. The possible relationship between serum EGF levels with the demographic, ketamine use characteristics and psychopathological symptoms were also analyzed.

**Methods.**– 67 chronic ketamine users and 40 healthy subjects were recruited. Serum EGF levels were measured by enzyme-linked immunosorbent assay (ELISA). The psychopathological symptoms were assessed using Positive and Negative Syndrome Scale (PANSS), Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI).

**Results.**– The serum level of EGF in the chronic ketamine users were significantly lower than that of healthy subjects ( $22.34 \pm 4.81$  pg/ml vs.  $87.10 \pm 2.96$  pg/ml,  $F = 15.169$ ,  $P < 0.01$ ). The serum EGF level was negatively correlated with the current average dose of ketamine consumption per day of use ( $P = 0.015$ ), and positive association with the PANSS positive symptom score ( $P = 0.022$ ).

**Conclusions.**– Serum level of EGF decreased in chronic ketamine users compared to healthy subjects, which may play a role in the pathophysiology of chronic ketamine use.

### Do cannabis and cannabinoids have anxiolytic therapeutic effect?

M. Hasanovic<sup>\*</sup>, I. Pajević

University clinical center Tuzla, department of psychiatry, Tuzla, Bosnia, Herzegovina

\* Corresponding author.

**Introduction.**– Written historical evidence reveals that Cannabis sativa has been used medically, recreationally and spiritually for more than five centuries in many cultures.

**Objectives.**– To review what the studies, conducted over the past two decades, indicate about anxiolytic effects of the cannabis and cannabinoids.

**Methods.**– We selected literature review using PubMed resources, to summarize the findings of the existing publications on cannabis and cannabinoids and their possible anxiolytic therapeutic effects only.

**Results.**– The use of simple ‘smoked cannabis’ remains dangerous because of the effects on inducing psychosis which the article itself refers to, and needs to remain illegal. Overall, based on available research, it does appear that marijuana can cause anxiety, and isn’t a great treatment for anxiety. Research supports cannabis’ clear acute effect on neurocognition, while non-acute effects for prolonged use of marijuana are unclear and still insufficiently explored. Due to cannabidiol’s (CBD) safety and tolerability, the absence of psychoactive or cognitive effects, the existence of clinical trials with positive results and its broad pharmacological spectrum, CBD is a cannabinoid whose initial results will likely lead to implementation into clinical practice.

**Conclusion.**– There is more evidence that cannabis causes anxiety than its ability to successfully treat anxiety, so use of marijuana is not recommended. Further controlled studies are essential to determine the precise mechanisms of action of cannabinoids on various neuropsychiatric disorders like anxiety and depression as well as the safety of their use are needed. Never just the use of ‘smoking cannabis in an unlicensed way’.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Binge drinking, mood and psychological well being in university students**

T. Heffernan\*, M. Michell

Northumbria university, psychology, Newcastle upon Tyne, United Kingdom

\* Corresponding author.

**Introduction.**– Low to moderate alcohol use in university students is associated with a range of positive outcomes, including improved academic performance, cognitive performance, and psychological well-being; whereas heavy episodic drinking or ‘binge drinking’ is associated with lower ratings on these indices. However, a recent survey of students’ drinking habits reported at the 2012 Annual American Sociological Association Meeting found that students who binged felt ‘happier’ and more socially satisfied than non-bingers; although the ‘happiness’ measure used was not a standardised tool.

**Objectives.**– The current study explored this further by comparing bingeing and non-bingeing university students on mood and psychological well-being.

**Methods.**– An existing-groups design was used to compare 35 binge-drinkers (drinking 8 units/more for females and 10 units/more for males in one/more sessions across the week; mean age = 20.0) and 35 non-binge drinkers (mean age = 21.2). Each completed a Recreational Drug Use Questionnaire; the Hospital Anxiety and Depression Scale measuring mood; and the Oxford Happiness Questionnaire which measures psychological well-being.

**Results.**– The two groups did not differ significantly in terms of gender, age, mood, cigarette use, years spent drinking alcohol and last drink in hours ( $P > .05$  in all cases); none reported using any illicit drug. However, binge drinkers scored significantly lower in terms of psychological well-being compared with non-binge drinkers ( $F(1, 68) = 9.57, P < .005$ ).

**Conclusions.**– The findings of this study suggest that binge-drinking students report significantly lower levels of psychological well-being than non-binge drinkers. The implications of this will be discussed at conference.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **What impact does alcohol hangover have upon event based prospective memory?**

T. Heffernan

Northumbria university, psychology, Newcastle upon Tyne, United Kingdom

**Introduction.**– The alcohol hangover (AH) state is characterized by range of symptoms that remain after one’s blood-alcohol level returns to zero following a previous bout of excessive drinking. These symptoms include drowsiness, fatigue, gastro-intestinal problems, dry mouth, nausea, sweating, and tremulousness. Research on what impact a state of AH has upon cognitive performance is sparse, with some evidence of reduced alertness, problems in concentration, as well as deficits in executive function.

**Objectives.**– The present study aims to extend this focus to explore what impact a state of AH has upon everyday memory in the form of prospective memory (PM: memory for future plans/actions).

**Methods.**– 20 participants in a state of AH were compared with 24 controls that did not have a hangover. The Prospective Remembering Video Procedure (PRVP) was used as an objective test of objective PM – within which each participant was required to recall previously assigned actions in response to location cues as they appeared during a short 10-minute video focusing on shop fronts/passers-by in an unfamiliar shopping area.

**Results.**– The results found that, after observing no between-group differences on gender, age alcohol use (weekly units and years spent drinking), cigarette use, depression and anxiety, the AH group recalled significantly fewer action-location combinations than the non-AH group ( $P < .05$ ).

**Conclusions.**– It appears that the alcohol hangover state impairs event based everyday prospective memory. The wider implications are considered further at the conference itself.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Four-itemed problematic internet game screener: Usefulness of the brief version of internet game use elicited symptom screen (IGUESS-4)**

S.J. Jo<sup>1</sup>, H.K. Lee<sup>2</sup>, Y. Hyeon Woo<sup>3</sup>, J. Hyunsuk<sup>4</sup>, S. Hye Jung<sup>4</sup>, H. Hyunho<sup>3</sup>

<sup>1</sup> College of medicine, The Catholic university of Korea, Seoul, Korea, department of preventive medicine, Seoul, Republic of Korea; <sup>2</sup> The Catholic university Uijeongby St. Mary’s hospital, department of psychiatry, Uijeongbu, Republic of Korea; <sup>3</sup> The Catholic university of Korea, department of preventive medicine, Seoul, Republic of Korea; <sup>4</sup> The Catholic university of Korea, department of preventive medicine, Seoul, Republic of Korea

\* Corresponding author.

**Introduction.**– The Internet Game Use Elicited Symptom Screen (IGUESS) was an Internet gaming disorder (IGD) screener based on the IGD’s nine diagnostic criteria of DSM-5. Recently

ICD-11 beta draft included three diagnostic criteria for gaming disorder, which has prompted academic debate.

**Objectives.**– This study performed to develop a brief, core symptom-focused, and diagnostically valid screener for IGD.

**Methods.**– We conducted the IGD screening test among 121 child and adolescent using the IGUESS. A clinicians conducted diagnostic interviews for all, which generated a gold-standard of IGD diagnosis. Among nine items of IGUESS, four items with the highest diagnostic accuracy were identified for the IGUESS-4. Convergent validity was assessed via correlation of Young's Internet addiction test (IAT) and IGUESS-4. ROC curve analysis was used to assess criterion-related validity and optimal cut-off score was estimated. Reliability of the iguess-4 was assessed using Cronbach's alpha and Cohen's Kappa statistic.

**Results.**– Salience, getting longer time spent, try and failure on control, and continuation despite problems were selected as the items of IGUESS-4. Correlation coefficient of IAT and IGUESS-4 was  $r=0.870$  ( $P<0.001$ ). As a result of ROC analysis, the area under the curve(AUC) was 0.919. With the cut-off score of 5, sensitivity and specificity was 0.868 and 0.868 respectively. Cronbach's alpha of the IGUESS-4 is 0.909, and Cohen's Kappa between screening results of the IGUESS-4 and the full-version was 0.916.

**Conclusions.**– The IGUESS-4 is suggested as a brief, valid and reliable screening tool for IGD, and could be used in the community resources and primary care settings with lower burden.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **What are you waiting for? Drug addicted individuals wait for money but not for drugs**

A. Just<sup>\*</sup>, C. Meng, T. Robbins, K. Ersche  
*Behavioural and clinical neuroscience institute, department of psychiatry, Cambridge, United Kingdom*

\* Corresponding author.

**Introduction.**– Impulsivity is a hallmark of addiction. The inability to stop an initiated response is one aspect of impulsivity shown to be both a determinant and consequence of drug use, but the same has not yet been shown for premature responding – another aspect of impulsivity. Furthermore, as impulsivity has only been examined in non-drug contexts, the degree to which context influences impulsivity remains unknown.

**Objectives.**– We aim to determine whether premature responding is a predisposing trait, and the degree to which context plays a role in this form of impulsivity. We hypothesized that premature responding is a predisposing trait, which is influenced by context. Therefore, we predict that both addicted individuals and their unaffected siblings will demonstrate increased premature responses, and that this behaviour will be particularly pronounced when anticipating drug rewards.

**Methods.**– Using the monetary incentive delay task – a measure of reward anticipation – we investigated responses made before the target (i.e. premature), when anticipating monetary or drug rewards, in four distinct populations: stimulant-dependent individuals ( $n=50$ ), their unaffected siblings ( $n=50$ ), unrelated non-dependent stimulant users ( $n=29$ ), and unrelated control participants ( $n=50$ ). We analysed the data using non-parametric tests.

**Results.**– Groups did not differ in premature responses when anticipating monetary reward ( $P=0.604$ ), but did significantly differ when anticipating drug reward ( $P=0.006$ ). This effect was due to increased premature responses in stimulant-dependent individuals when compared with the other groups ( $P<0.05$ ).

**Conclusion.**– These findings indicate that premature responding in itself may not be predisposing, but that this form of impulsivity is dependent on context.

**Disclosure of interest.**– This research was funded by a Medical Research Council (MRC) grant (G0701497), and conducted within the Behavioural and Clinical Neuroscience Institute (BCNI), which is jointly funded by the MRC and Wellcome Trust. ### **Goal commitment predicts outcome of adolescent cannabis use disorder**

Y. Kaminer  
*University of Connecticut health center, psychiatry, Farmington, USA*

**Objective.**– Commitment to change is an innovative potential mediator in adolescents with cannabis use disorders (CUD). The Adolescent Substance Abuse Goal Commitment (ASAGC) questionnaire is a new reliable and valid 2-scale measure developed to assess the adolescent's commitment to either abstinence (i.e., recovery model) or harm reduction (HR) model, that in addition to decrease in negative consequences, includes consumption reduction as a stated treatment goal. The objective of this paper is to examine the ASAGC's ability to predict treatment outcome of adolescents with CUD.

**Method.**– During sessions three and nine of a 10-week treatment program, therapists completed the ASAGC for 170 adolescents 13–18 years of age with alcohol use disorder (AUD), the majority of whom (82%) were diagnosed with co-occurring CUD. Cannabis use was confirmed by drug urinalysis and self-reports.

**Results.**– Logistic regression analyses assessing goal commitment (GC) at Session 3 indicated that both HR and recovery predicted cannabis use at Session 3. However, only recovery assessed predicted later cannabis use. When GC at Session 9 was examined, only recovery predicted cannabis use, concurrently and longitudinally during aftercare. These results indicated that adolescents who had higher scores for recovery were less likely to use cannabis. HR was not a significant predictor for outcome.

**Conclusions.**– Study findings demonstrate that GC consistently predicts CUD treatment outcome. Only GC to abstinence is a salient predictor for cannabis use.

### **Spine density in the nucleus accumbens is differentially changed after rat gambling task with different housing condition**

J.H. Kim  
*Yonsei university college of medicine, physiology, Seoul, Republic of Korea*

**Introduction and aims.**– Poor decision-making is closely related to symptoms of various psychiatric disorders. Rat gambling task (rGT) adopts the basic principle of Iowa Gambling Task. Dendritic spine is a key structure for structural plasticity in the brain, and its morphology dynamically changes through the learning process. Here we

examined how housing condition and choice preference appeared in rGT contributes to morphological change of dendritic spines in the nucleus accumbens (NAc).

**Methods.**– Rats were housed as isolated or paired, and trained in a touch screen chamber to learn the relationships between 4 different light signals on the screen and accompanied reward outcomes or punishments set up with different schedules. Once they show a stabilized pattern of preference upon free choice, rats were separated as risk-averse or risk-seeking group according to their preference of choice. Then, NAc tissues were immunostained with antibodies against GFP proteins and confocal imaging was conducted. With Neuronstudio Software, spine density was counted and its morphological differences were identified.

**Results.**– We observed that rGT alone with pair-housing, whether it turned out to be risk-averse or risk-seeking, did not contribute to show any difference in spine density compared to control group. However, when combined with isolation-housing, rGT showed increased number of total and thin spine density only in risk-seeking compared to control groups.

**Conclusions.**– These results indicate that trait (risky choice preference) and environment (isolated housing) inter-influence to contribute to morphological changes of dendritic spines in the NAc, and may suggest that these changes might underlie maladaptive decision making.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Wide difference in symptoms distribution among the DSM-5 internet gaming disorder criteria**

Y.S. Kweon<sup>1\*</sup>, S.Y. Lee<sup>1</sup>, H.K. Lee<sup>1</sup>, H. Jeong<sup>2</sup>, H.W. Yim<sup>2</sup>, S.J. Jo<sup>2</sup>, S.Y. Bang<sup>3</sup>, J.S. Choi<sup>4</sup>

<sup>1</sup> Uijeongbu St. Mary's hospital, psychiatry, Uijeongbu-si, Republic of Korea; <sup>2</sup> The Catholic university of Korea, department of preventive medicine, Seoul, Republic of Korea; <sup>3</sup> College of Medicine- Eulji university, department of psychiatry, Seoul, Republic of Korea; <sup>4</sup> SMG-SNU Boramae medical center, department of psychiatry, Seoul, Republic of Korea

\* Corresponding author.

**Introduction.**– Although diagnostic criteria were proposed for internet gaming disorder (IGD) in the DSM-5, exploration of the prevalence of each criterion relied extensively on self-measurement.

**Objectives.**– To explore the relative prevalence of IGD criteria.

**Methods.**– We interviewed 766 students, who participated after informed consents. The subjects were grouped as normal (0–2), at-risk group (3–4) and IGD group ( $\geq 5$ ) according to the number of positive criteria and were compared using Wilcoxon rank sum test or Kruskal-Wallis test with a two-sided  $P$ -value of 0.05.

**Results.**– The most common DSM-5 criterion displayed by the IGD group was 'loss of control' (90.5%). Compared to the control, the at-risk group and the IGD group demonstrated significantly higher 'loss of control' in the post hoc. However, the at-risk group and the IGD group displayed no statistical difference for 'loss of control' ( $P=0.196$ ).

'Continued gaming despite negative consequences' (78.6%) and 'Preoccupation' (73.8%) were the second and the third common IGD symptom. Unlike 'loss of control', these two criteria showed significant differences between the at-risk group and the IGD group ( $P<0.001$  and  $P=0.001$ , respectively).

'Tolerance', 'escapism', 'withdrawal', 'loss of interest other than gaming' and 'jeopardizing opportunities' followed in descending

order. The most infrequently displayed IGD criteria among the IGD group was 'Deceiving' (31.0%).

**Conclusions.**– The prevalence of the proposed IGD criteria of DSM-5 varied widely in the IGD group. Each criterion may have a different level of clinical implication in the diagnosis and such difference should be considered when making potential refinement in the diagnostic criteria.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Is exercise addiction in fitness centers a socially accepted behavior?**

M. Lichtenstein<sup>1\*</sup>, B. Emborg<sup>2</sup>, S. Hemmingsen<sup>3</sup>, N.B. Hansen<sup>4</sup>

<sup>1</sup> Department of psychology, university of Southern Denmark, Odense C, Denmark; <sup>2</sup> Aarhus university, department of public health, Aarhus, Denmark; <sup>3</sup> Odense university hospital, department of clinical research, Odense, Denmark; <sup>4</sup> University of Southern Denmark, department of psychology, Odense, Denmark

\* Corresponding author.

**Introduction.**– Fitness exercise is popular and associated with improved health and social status. Taken to extremes, however, exercise can become an addiction. One suggested symptom of exercise addiction is "conflicts" with family and friends. However, it may be difficult to recognize excessive exercise patterns if they are accepted and encouraged by relatives.

**Objectives.**– The aim of this study was to explore if fitness exercisers with a high risk of addiction experienced the same level of exercise support as exercisers with a low risk of addiction. Furthermore, we wanted to examine if social support affected the subjective reporting of "conflicts".

**Methods.**– The Exercise Addiction Inventory was completed by 577 fitness members. They further rated their "exercise support from family and friends" and "present eating disorder".

**Results.**– Exercisers at high risk of exercise addiction reported the same level of support from relatives as those at low risk. Exercisers with high levels of exercise support reported significantly fewer conflicts, even if they were at high risk of addiction. If an eating disorder was present, the level of exercise support was significantly reduced.

**Conclusions.**– Exercise addiction might be difficult to identify with the general behavioral addiction symptom "conflict", since exercise is socially accepted even in subjects with high risk of exercise addiction. If an eating disorder is present, the exercise routines seem to be interpreted as socially undesirable. Screening for exercise addiction with the EAI should take into account that fitness exercisers rarely report conflicts, which could result in false negative cases.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Results of a clinical trial of a new antagonist of opioid receptors**

E. Mukhametshina<sup>1\*</sup>, M. Samsonov<sup>2</sup>, E. Krupitsky<sup>3</sup>

<sup>1</sup> R-Pharm, Medical, Moscow, Russia; <sup>2</sup> R-Pharm, Medical, Moscow, Russia; <sup>3</sup> Bekhterev Research Psychoneurological Institute, Department of Addictions, St. Petersburg, Russia

\* Corresponding author.

Odelepran is a new pan opioid receptor antagonist for the treatment of alcohol dependence.

To reach the goal a multinational, multicenter, randomized, double-blind, placebo-controlled phase III trial of the efficacy and safety of the 125 mg Odelepran tablets in patients with alcohol addic-

tion was conducted ( $n=644$  patients). Over three months course of treatment, Odelepran had the highest effect in decreasing the rates of alcohol consumption, where the difference in comparison with placebo was statistically significant. The contribution of the individual consultation of the patients, which was more frequent during the first three months of the treatment, should not be ignored in achieving those results. Decrease in the rates of daily alcohol consumption was higher during the first three months of the treatment, and the statistically significant differences with Odelepran superiority were observed during the second and third months of the treatment. Analysis of percentage of days abstinent in a month shows that the difference with placebo group was statistically significant at the three months period with Odelepran superiority.

Differences in alcohol craving, which was measured by the Obsessive-Compulsive Drinking scale (objectively), and by the Visual Analogue Scale (subjectively), show Odelepran superiority during the course of the treatment, and at the end of the treatment. Clinical significance of the treatment efficacy was proved by the indications that were not directly related to the alcohol consumption, such as CGI-I scale and effectiveness index. Both of these indications were higher at the Odelepran group versus placebo at the three months treatment period.

### Evaluating readiness-to-change drinking behavior in treatment naive alcoholic out-patients

P. Ponizovskiy, A. Gofman

Moscow research institute of psychiatry, department of mental disorders complicated by substance abuse, Moscow, Russia

\* Corresponding author.

*Background.*– Assessing readiness to alter drinking behavior in alcoholic patients is important in choosing individual-focused treatment strategies.

*Aims.*– The study identifies the level of readiness-to-change drinking behavior in treatment naive alcoholic patients seeking medical advice at early stages of the disease.

*Method.*– 34 treatment naive alcoholic patients were investigated regarding the level of their motivation for treatment. The level of motivation for treatment was defined by summing up the overall quantitative ratings of awareness of alcohol addiction and its harmful effects.

*Results.*– A high level of motivation for treatment was identified in 30% of patients ( $n=10$ ) who reported negative effects of alcohol consumption on their health and social relations. 38% of patients ( $n=13$ ) demonstrated middle level of motivation reporting the presence of alcohol related problems in their life but demonstrated tendencies to self-justification and positively described the euphoric, relaxing, and tranquilizing effects of alcohol. 32% of patients ( $n=11$ ) had low level or no motivation for treatment correlating with high levels of addiction denial and strong craving for alcohol. Patients reported their alcohol consumption as “natural”. Their motivations to enter treatment were related to current external threats to employment, driving license, or spouse.

*Conclusion.*– The study provides evidence of patients seeking treatment at the early stages of alcohol dependence. In spite of displaying similar clinical features they have different motivation profiles. A high proportion (70%) of patients with low and middle level of motivation for treatment support adopting graded therapeutic interventions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0571

### Markers of the oxidative stress in blood plasma of alcoholic patients in the process of the therapy

V. Prokopieva<sup>1</sup>, E. Yarygina<sup>1</sup>, A. Mandel<sup>2</sup>

<sup>1</sup> Mental health research institute, Tomsk national research medical center of RAS, laboratory of psychoneuroimmunology and neurobiology, Tomsk, Russia; <sup>2</sup> Mental health research institute, Tomsk national research medical center of RAS, addictive states department, Tomsk, Russia

\* Corresponding author.

*Objective.*– Dynamic of carbonylated proteins (CP) and products of lipid peroxidation (PLP) in alcoholics' blood plasma at baseline and after therapy in group of patients with different initial oxidative status was studied.

*Methods.*– Blood sampling from 46 male alcoholic patients occurred twice: at baseline and by week 2 of standard antialcohol medication. In blood plasma CP were identified with 2,4-dinitrophenylhydrazine, PLP with thiobarbituric acid. Blood of 34 healthy men was used as control. Control indices were as follows: for CP 0.37 (0.29–0.44) nmol/mg, for PLP 2.50 (2.10–2.90) nmol/ml, taken for 100%. If in an alcoholic patient PLP and/or CP exceeded control values by more than 20%, presence of oxidative stress (OS) was regarded. OS reduction/activation after therapy was regarded according to CP and PLP decrease/increase.

*Results.*– At baseline in 14 patients CP and PLP did not exceed control values by more than 20% (group “without OS”). In the rest 32 patients OS was revealed (group “with OS”). After the therapy in “without OS” group PLP did not change (at baseline: 3.10 (2.50–4.23), after: 3.15 (2.40–4.63) nmol/ml;  $P=0.38$ ), and indicator CP increased (at baseline: 0.31 (0.28–0.38), after: 0.35 (0.33–0.43) nmol/mg;  $P=0.03$ ). Different dynamics was in the group “with OS” – after therapy decrease occurred both in CP (at baseline: 0.41 (0.34–0.49), after: 0.38 (0.30–0.47);  $P<0.001$ ) and PLP (at baseline: 3.12 (2.50–4.37), after: 2.80 (2.30–3.37);  $P<0.001$ ).

*Conclusion.*– In groups of alcoholics characterized by different initial oxidative status the differently directed dynamics of markers of OS in the process of therapy were found.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### From goals to habits in alcohol dependence: Association with treatment outcome and cognitive bias modification training

M. Sebold<sup>1</sup>, M. Garbusow<sup>1</sup>, S. Nebe<sup>2</sup>, L. Sundmacher<sup>1</sup>, S. Kuitunen-Paul<sup>2</sup>, H.U. Wittchen<sup>2</sup>, M. Smolka<sup>2</sup>, U. Zimmermann<sup>2</sup>, M. Rapp<sup>3</sup>, Q. Huys<sup>4</sup>, F. Schlagenhauf<sup>1</sup>, A. Heinz<sup>1</sup>

<sup>1</sup> Charité, Universitätsmedizin Berlin, department of psychiatry and psychotherapy, Berlin, Germany; <sup>2</sup> Technische Universität Dresden, Technische Universität Dresden, Dresden, Germany; <sup>3</sup> University of Potsdam, Potsdam, Germany; <sup>4</sup> University of Zürich, Zürich, Switzerland

\* Corresponding author.

*Introduction.*– The dominance of the habitual, model-free over the goal-directed, model-based decision system might contribute to high relapse rates in individuals suffering from addictive disorders. In alcohol dependence (AD), however, results for this shift is mixed

presumably because decision-making in AD depends on alcohol-associated expectations. Moreover, associations with prospective relapse and the effectiveness of therapeutic interventions have not yet been examined.

**Objectives.**– To investigate the shift from model-based to model-free decision-making in AD and its association with relapse, alcohol expectancies and a cognitive bias modification (CBM) training.

**Methods.**– We performed two studies including detoxified AD patients and controls. All subjects performed a Markov-decision task to assess model-free and model-based decision-making. In study 1, we assessed neural correlates via fMRI, alcohol expectancies via questionnaire and followed up all patients for one year to assess relapses. In study 2, AD patients performed the task prior to a CBM training.

**Results.**– In study 1, patients who relapsed had reduced medial prefrontal cortex (mPFC) activation during model-based decision-making. High alcohol expectancies were associated with low model-based control in relapsers, while the opposite was observed in abstainers and control subjects. In study 2, AD patients with a shift towards model-free decision-making at baseline showed stronger benefit from a cognitive bias modification training.

**Conclusions.**– Study 1 suggests that therapeutic interventions in AD patients could target subjective alcohol expectancies and that increased mPFC activation might be an important neural correlate of relapse risk. Study 2 further suggests that patients with predominantly model-free decision-making might specifically benefit from a CBM training.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The relationship between adolescents' internet game addiction and suicidality**

H.J. Son<sup>1\*</sup>, H.W. Yim<sup>1</sup>, S.J. Jo<sup>1</sup>, H. Jeong<sup>1</sup>, H. Han<sup>1</sup>, Y.S. Kwon<sup>2</sup>

<sup>1</sup> Catholic University of Korea, Preventive Medicine, Seoul, Republic of Korea; <sup>2</sup> Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Psychiatry, Uijeongbu, Republic of Korea

\* Corresponding author.

**Introduction.**– Various social, physical and mental problems cause suicide ideation, suicide plan and suicide attempt.

Particularly, it is an important issue because the first leading of death among adolescents in Korea is suicide. Also, Internet game addiction has been mentioned to increase suicidality.

**Objectives.**– The purpose of this study was to examine the relationship between adolescents' internet game addiction and suicidality.

**Methods.**– This study was targeting 2319 subjects enrolled in iCURE, a prospective cohort study that was conducted for the purpose of identify internet game addiction and risk factors. And data were collected from 2198 people, excluding 121 people with depressive symptoms.

The internet game addiction, which is an independent variable, used the Internet Game Use-Elicited Symptom Screen (I GUESS). If the total score is above 10 points, it is internet game addiction.

The suicidality, a dependent variable, was considered to be a suicidality in the last 12 months using one of the three items of suicide ideation, suicide plan and suicide attempt.

To determine the association between adolescents' internet game addiction and suicidality, multiple logistic regression analysis were conducted to adjust effect of confounding variables.

**Results.**– Internet game addiction was not significantly associated while controlling suicidality with sex, school level, time to use internet game, anxiety, friend support and sleep time.

**Conclusions.**– It is difficult to suggest that internet game addiction plays an important direct significant factor in suicidality of adolescents. It is needed to examine how Internet game addiction plays a role in adolescents' suicidality by prospective observation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Sexual hormones mediate the behavioral response to D-amphetamine in healthy female subjects**

A. Weidenauer<sup>1\*</sup>, U. Sauerzopf<sup>1</sup>, M. Bauer<sup>2</sup>, L. Bartova<sup>1</sup>, N. Praschak-Rieder<sup>1</sup>, S. Kasper<sup>1</sup>, M. Willeit<sup>1</sup>

<sup>1</sup> Medical university of Vienna, department of psychiatry and psychotherapy, Vienna, Austria; <sup>2</sup> Medical university of Vienna, department of clinical pharmacology, Vienna, Austria

\* Corresponding author.

**Introduction.**– Several studies in animals and humans show a modulating role of sexual hormones not only on neuronal development but also on dopamine release and the behavioral response to dopamine-releasing agents. Studies in humans and rodents suggest that estrogen might facilitate while progesterone might inhibit the stimulating effects of d-amphetamine. Effects of hormonal contraceptives are unknown.

**Objectives.**– To assess the impact of sexual hormones and hormonal contraception on the behavioral response to d-amphetamine in healthy female subjects.

**Methods.**– Thirteen female stimulant-naïve healthy subjects underwent one oral administrations of d-amphetamine 0.4 mg/kg bodyweight (8 subjects on hormonal estrogen/progesterone combination contraceptives). Behavioral effects were assessed using the drug effects questionnaire (DEQ) and the subjective states questionnaire (SSQ). Blood serum levels of follicle stimulating hormone (FSH), luteinizing hormone (LH), estrogen, progesterone, and testosterone were measured before amphetamine administration.

**Results.**– There was a significant positive relationship between the behavioral response to d-amphetamine and serum concentration of LH, FSH and estrogen, with estrogen explaining up to 65% of the behavioral response. No negative relationship with progesterone was observed. Regarding hormonal contraception a significant “blunting” influence on the action of d-amphetamine was observed. **Conclusions.**– Our preliminary data suggest that sexual hormones exert a significant impact on the stimulating effects of d-amphetamine and, for the first time to our knowledge, show a “blunting” effect of hormonal contraceptives on the behavioral response of d-amphetamine in healthy female subjects.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Pharming or self-medication? A case report of three patients addicted to fentanyl treated in a care center for drug addicts**

I. Zabaleta Andreu<sup>1\*</sup>, S. Arias Rubio<sup>1</sup>, C. Sanahuja Muñoz<sup>1</sup>, C. Aguilar Romero<sup>1</sup>, I. García Hoyos<sup>1</sup>, J. Klotz<sup>2</sup>

<sup>1</sup> Hospital Universitario de Fuenlabrada, psychiatry, Fuenlabrada, Spain; <sup>2</sup> N.Y. State psychiatric institute, Columbia university, division of child and adolescent psychiatry, New York, USA

\* Corresponding author.

**Introduction.**– Fentanyl is an opioid agonist utilized in medicine as an analgesic and anesthetic. It is characterized by having a potency 80 to 100 times stronger than morphine and a brief latency period.

**Objectives.**– To describe the recreational use of Fentanyl among population groups other than “traditional” consumers of opiates.

**Methods.**– Clinical cases of three youths with similar consumption patterns are presented.

**Results.**– Case 1, R.L, a 22-year-old male who goes to the CAID in November 2015 for smoking fentanyl for 1 year. He consumes fentanyl both socially and solitarily. He has had depressive symptoms since childhood and consumption of drugs since adolescence.

Case 2, R.V, a 22-year-old male who came to CAID in November 2015 for consumption of sublingual fentanyl patches for 1 year. He uses the substance with two friends in a social context. He has experienced anxious symptoms since childhood and consumption of various types of drugs since the age of 15.

Case 3, A.S., a 22-year-old male attending the CAID in June 2016 for fentanyl addiction. He makes a claim for treatment because his two fentanyl-user friends come to the center and refers to “wanting to understand what is happening to him” and refuses medication. Consumption of fentanyl occurs in the context of “experiencing sensations”. There was no mention of psychiatric antecedents.

**Conclusions.**– The rise in consumption of fentanyl and other synthetic opioids by certain groups of users, can become a serious public health problem. It is urgent that measures are implemented to study and control this phenomenon.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Depression - Part II

### The prevalence and correlates of depression, anxiety and stress among undergraduate private medical students in Dhaka, Bangladesh

F. Ashher<sup>1\*</sup>, S. Islam<sup>2</sup>, K. Kamrun<sup>2</sup>

<sup>1</sup> ICDDR-B, infectious diseases division, Dhaka, Bangladesh;

<sup>2</sup> ICDDR-B, noncommunicable diseases division, Dhaka, Bangladesh

\* Corresponding author.

**Introduction.**– Depression is projected to become the cause for 2nd highest DALY by 2020, while anxiety disorders currently afflict 264 million people worldwide. Medical students reportedly exhibit a higher rate of psychological morbidity. The burden and the correlates of these afflictions among undergraduate private medical students in Bangladesh remain largely unexplored.

**Objective.**– The study aimed to estimate the prevalence of depression, anxiety & stress and their correlates among undergraduate private medical students in Dhaka, Bangladesh.

**Methods.**– A multi-center, cross-sectional study was carried out in three private medical colleges from March to August, 2017. Final sample consisted of randomly recruited 310 students (response rate 86.11%) who completed a self-administered, semi-structured questionnaire including DASS-21. Scores for each of the subscales (Depression, Anxiety and Stress) were calculated as per the severity-rating index. Adjusted multiple logistic regression was used to detect the significant correlates.

**Result:** Majority of the respondents were male (162, 52.26%) and the average age was 21 years. The prevalence of depression, anxiety and stress were 43.0%, 51.3% and 27.1% respectively. The proportion was significantly higher among female students (49.4%, 52% and 38.5% respectively) than the male (37%, 50.6% and 18% respectively).

Other factors such as ‘1st/2nd year student’, ‘taking tea/coffee > 2 times/day’, ‘staying at hostel’ and ‘sleep < 8 hours/day’ showed significant ( $P < 0.05$ ) associations.

**Conclusion.**– Significant proportions of undergraduate private medical students were found to be depressed, anxious and stressed, highlighting a pervasive negligence towards mental health. Comprehensive systematic measures such as counseling service and friendlier environment for females are direly needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### A combination of Rhodiola Rosea and Crocus Sativus extracts for depression: A prospective observational study

M. Bangratz<sup>1\*</sup>, S. Ait Abdellah<sup>2</sup>, A. Guilbot<sup>1</sup>, M. Dubourdeaux<sup>3</sup>, P. Lemoine<sup>4</sup>

<sup>1</sup> PiLeJe laboratory, research and development R&D, Paris, France;

<sup>2</sup> PiLeJe laboratory, clinical research, Paris, France; <sup>3</sup> PiLeJe Industrie, research and development, Saint Bonnet de Rochefort, France;

<sup>4</sup> Clinique Lyon Lumière, Meyzieu, France

\* Corresponding author.

Conventional antidepressants have substantial side effects and often result in premature treatment discontinuation. In addition, their efficacy in non-severe major depression is questionable. The search for alternative treatments has therefore become a high priority. Many natural products and medicinal plants have been shown to produce interesting results for the treatment of depression, among them, Rhodiola rosea and Crocus sativus (saffron). In this study conducted with general practitioners, 45 adults aged 18 to 85 years who were suffering from mild or moderate depression (CIM-10 definition) and had a score on the Hamilton rating scale for depression (HAM-D) between 8 and 18 received two tablets containing 308 mg of an extract of rhodiola and 30 mg of an extract of saffron per day for 6 weeks. After 6 weeks of supplementation (D42), the HAM-D score (primary outcome) significantly decreased from  $13.5 \pm 2.5$  at D0 to  $5.5 \pm 3.8$  at D42 ( $P < 0.0001$ ). At D42, score improvement was reported in 83.3% of the patients. Both the HADS-Anxiety and HADS-Depression scores significantly decreased between D0 and D42, the decrease being significant from two weeks of supplementation. At the end of the study, both the general practitioners and patients rated a significant improvement in the depressive state. Supplementation was well tolerated. The results of this observational study performed in primary care suggest that the proprietary supplement containing rhodiola and saffron tested could be of interest for mild and moderate depression. Further double-blind placebo-controlled study are needed to confirm these results.

**Disclosure of interest.**– employee of PiLeJe Laboratory.

### A positive correlation between self-ratings for aggression and severity of major depression

B. Batinic<sup>1\*</sup>, J. Nesvanulica<sup>2</sup>, I. Stankovic<sup>2</sup>

<sup>1</sup> Clinic of psychiatry clinical centre of Serbia, faculty of philosophy, department of psychology, Belgrade, Serbia; <sup>2</sup> Faculty of philosophy, department of psychology, Belgrade, Serbia

\* Corresponding author.

**Introduction.**– Studies of depressive individuals show a relationship between, on the one hand, the severity of depression and,

on the other, aggression directed towards their environment and themselves.

**Objectives.**– The aim of the study was to ascertain the correlation between self-ratings for aggression and severity of major depression (MDD), as well as gender differences in the expression of aggression in the context of depressive disorder.

**Methods.**– The study sample consisted of 82 patients (51 female, 31 male) diagnosed with MDD, aged between 18 and 65 years old ( $M = 46.21$ ). Assessment instruments included The Beck Depression Inventory-II (BDI-II) and The Buss-Perry Aggression Questionnaire (BPAQ) consisting of 4 sub-scales: Physical Aggression, Verbal Aggression, Hostility and Anger.

**Results.**– The average BPAQ and BDI-II scores were 80.98 ( $SD = 17.74$ ) and 27.21 ( $SD = 11.53$ ), respectively. The total score of the BPAQ and its sub-scales of Physical Aggression, Hostility and Anger showed a significant positive correlation with the BDI-II score ( $P < 0.01$ ). Verbal aggression did not significantly correlate with BDI-II score ( $P = 0.289$ ). In addition, there was a significant difference between depressed males and depressed females in terms of physical aggressiveness (males were more physically aggressive), but not in terms of total aggressiveness, verbal aggression, anger, or hostility.

**Conclusions.**– The study results show that the greater the general aggression and its correlates – physical aggression, anger and hostility – the greater the depression. Interventions focusing on identifying and targeting aggression should be considered in the successful treatment of patients diagnosed with MDD.

**Keywords:** Self-ratings for aggression; Intensity of depression

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Diurnal salivary alpha-amylase and cortisol in out-patients with major depressive disorder

S. Bauduin\*, M. van Noorden, S. van der Werff, B. van Hemert, N. van der Wee, E. Giltay

Leiden university medical center, psychiatry, Leiden, The Netherlands

\* Corresponding author.

**Introduction.**– Previous research has shown that the stress hormone cortisol in saliva differentiates between patients with psychiatric disorders and healthy controls on a group level. The enzyme alpha amylase in saliva (sAA), released under the influence of the autonomic nervous system (ANS), may be a more specific biomarker, differentiating between MDD and other psychiatric disorders.

**Methods.**– sAA and salivary cortisol levels were determined in 7 saliva samples collected during the day from participants that partook in a Routine Outcome Monitoring (De Beurs et al., 2011) measurement (97 MDD patients, 142 patients with other psychiatric problems (OPP), and 594 controls). Clinical diagnoses were assessed using the Mini International Neuropsychiatric Interview (MINI; Van Vliet & De Beurs, 2007).

**Results.**– On average, MDD patients had higher sAA levels upon awakening (day 1:  $P = 0.05$ ; day 2:  $P = 0.03$ ) and the area under the curve with respect to the increase ( $AUC_i$ ;  $P = 0.05$ ), in comparison to both controls and the OPP group. Evening cortisol levels were higher in MDD patients compared to healthy controls. Cortisol levels did not differentiate between MDD and other psychiatric disorders at any time point.

**Conclusion.**– MDD patients showed increased morning levels of sAA and increased levels of evening cortisol, indicating enhanced stress systems of the ANS and hypothalamus-pituitary-adrenal axis. Moreover, sAA levels were also able to differentiate between

the MDD and OPP groups. Although these biomarkers are useful on a group level, they show too much variability to be beneficial for the individual patient within the clinical care setting.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Biomarkers of antidepressant pharmacological treatment response: A systematic review and meta-analysis of the last 15 years

P. Gorwood<sup>1\*</sup>, G. Voegeli<sup>1</sup>, N. Ramoz<sup>2</sup>, M.L. Cléry-Melin-Galichon<sup>1</sup>

<sup>1</sup> Hopital Sainte-Anne, Paris Descartes university, cmme, Paris, France; <sup>2</sup> Inserm U894, centre of psychiatry and neuroscience, Paris, France

\* Corresponding author.

**Background.**– Antidepressant drugs are widely prescribed, but response rates after 3 months are only around one-third, explaining the importance of the search of objectively measurable markers predicting positive treatment response. These markers are being developed in different fields, with different techniques, sample sizes, costs, and efficiency. It is therefore difficult to know which ones are the most promising.

**Objective.**– Our purpose was, for the first time, to compute comparable (i.e., standardized) effect sizes, at study level but also at marker level, in order to conclude on the efficacy of each technique used and all analyzed markers.

**Methods.**– We conducted the first systematic search on the PubMed database to gather all articles published since 2000 using objectively measurable markers to predict antidepressant response from five domains, namely cognition, electrophysiology, imaging, genetics, and transcriptomics/proteomics/ epigenetics. A manual screening of the abstracts and the reference lists of these articles completed the search process.

**Results.**– Executive functioning, theta activity in the rostral Anterior Cingulate Cortex (rACC), and polysomnographic sleep measures could be considered as belonging to the best objectively measured markers, with a combined  $d$  around 1 and at least four positive studies. For inter-category comparisons, the approaches that showed the highest effect sizes are, in descending order, imaging (combined  $d$  between 0.703 and 1.353), electrophysiology (0.294–1.138), cognition (0.929–1.022), proteins/nucleotides (0.520–1.18), and genetics (0.021–0.515).

**Conclusion.**– Markers of antidepressant treatment outcome are numerous, but with a discrepant level of accuracy. Many biomarkers and cognitions have sufficient predictive value ( $d \geq 1$ ) to be potentially useful for clinicians to predict outcome and personalize antidepressant treatment.

**Disclosure of interest.**– Philip Gorwood received during the last 5 years, research grants from Eli Lilly, Ethypharm and Servier, and fees for presentations at congresses or participation in scientific boards from Alcediag-Alcen, AstraZeneca, Biocodex, Bristol-Myers-Squibb, Ethypharm, Janssen, Lilly, Lundbeck, Naurex, Otsuka, Roche, Sanofi Pasteur MSD, Servier.

### Ketamine metabolite rescues chronic stress-induced depression in rats

D. Chou<sup>1</sup>, Y.C. Ho<sup>2\*</sup>

<sup>1</sup> Taipei medical university, department of physiology, Taipei, Taiwan R.O.C.; <sup>2</sup> Mackay medical college, department of medicine, New Taipei City, Taiwan R.O.C.

\* Corresponding author.

**Introduction.**– Major depressive disorder affecting more than 100 million people worldwide every year is a heterogeneous illness. To date, current pharmacotherapies require prolonged administration from several weeks to months for an appreciable response.

**Objectives.**– It is still unclear that whether ketamine metabolite rescues chronic stress-elicited depression-like behavior.

**Methods.**– Depression-like behavior in the rats were induced by learned helplessness (LH) procedure. Forced swim test (FST) and sucrose preference test (SPT) were used to study the depression-like behavior.

**Results.**– Rats receiving learned helplessness procedure exhibited high failure rate in the escapable footshock test compared to control group. LH rats exhibited an increase in immobile time during the FST and a reduction in sucrose consumption. Intraperitoneal ketamine metabolite injection decreased immobile time during the FST and increased sucrose consumption in LH rats.

**Conclusions.**– Ketamine metabolite rescues LH-induced depression-like behavior including despair behavior and anhedonia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Depression in women but not men is associated with a very high risk of cardiovascular mortality in primary care population in Latvia**

R. Ivanovs<sup>1</sup>, A. Kivite<sup>2</sup>, I. Mintale<sup>3</sup>, J. Vrublevska<sup>4</sup>, R. Logins<sup>1</sup>, L. Berze<sup>1</sup>, E. Rancans<sup>1</sup>

<sup>1</sup> Riga Stradins university, department of psychiatry and narcology, Riga, Latvia; <sup>2</sup> Riga Stradins university, department of public health and epidemiology, Riga, Latvia; <sup>3</sup> University Clinic of Paul Stradins, department of cardiology, Riga, Latvia; <sup>4</sup> Riga Stradins university, department of psychiatry and narcology, Riga, Latvia

\* Corresponding author.

**Introduction.**– Depression has been recognized as independent risk factor for development and prognosis of cardiovascular diseases (CVD). Recent evidence suggests that women with depression have a poorer CVD prognosis than men. The Systematic Coronary Risk Evaluation (SCORE) system estimates the 10-year risk of a first fatal atherosclerotic event.

**Objectives.**– To examine association of depression and the 10-year risk of a first fatal atherosclerotic event in primary care population in Latvia.

**Methods.**– This cross-sectional study was carried out within the framework of the National Research Program BIOMEDICINE at 24 primary care facilities. During one week period in 2015 all consecutive adult patients attending General practitioner (GP) for medical reasons were invited to complete the Patient Health Questionnaire (PHQ-9) followed by physical measurements. The Mini International Neuropsychiatric Interview (MINI) was conducted over the telephone within 2 weeks after the visit to GP. A hierarchical multivariate analysis was carried out.

**Results.**– The study population consisted of 1569 subjects, 31.0% men and 69.0% women. Of the interviewed participants 23.4% showed a very high 10-year CV mortality risk according to the SCORE ( $\geq 10\%$ ). Depression symptoms (PHQ-9  $\geq 10$ ) were present in 15.0% of individuals. According to the MINI 10.2% had current and 28.1% had a lifetime depression. Subjects with depression symptoms had 1.57 times higher odds of very high CV risk. When analysis was stratified by gender, depression (PHQ-9) remained statistically significant only for women (odds ratio = 2.16).

**Conclusions.**– We found a statistically significant association between depression and a very high CV mortality risk in women but not men.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Efficacy and tolerability of patients' treatment with moderate to severe depression with trazodone in comparison to SSRI/SNRI**

O. Khaustova

Bogomolets National Medical university, psychosomatic medicine and psychotherapy, Kiev, Ukraine

**Introduction.**– Antidepressants' effective treatment is limited by delay in onset of therapeutic effects, poly-symptoms' and intolerable side-effects' presence. New rationale strategy for greater treatment efficacy is multi-targets drugs with combining multiple pharmacological actions.

**Objective.**– We studied the efficacy and tolerability of patients' treatment with moderate to severe depression with trazodone in comparison to SSRI/SNRI.

**Methods.**– 100 patients with MDD was randomly assigned to two treatment groups for 8 weeks. Study group (SG) was treated with trazodone average dose 255 mg; control group (CG) – SSRI/SNRI (average doses: paroxetine 23.75 mg; sertraline 63.6 mg; escitalopram 12.5 mg; venlafaxine 170 mg). The evaluation was by scales HAM-D17, HAM-A.

**Results.**– Therapeutic effect was faster in SG compared with CG (SG W1 HAM-D17 decreased on  $6.2 \pm 4.3$ , W2 – on  $9.3 \pm 4.6$ ; CG, respectively  $5.3 \pm 3.9$  and  $8.1 \pm 4.1$ ). Therapeutic response in SG was 67.2%, in CG – 65.8%. Significant reduction HAM-D17 score was in insomnia and somatic symptoms of anxiety items in SG. Overall decline HAM-A score was  $11.3 \pm 5.9$  in SG,  $10.8 \pm 5.3$  in CG. More rapid onset of anxiolytic trazodone action was compared to SSRI/SNRI (SG W1 HAM-A decreased on  $5.4 \pm 2.9$ , CG –  $3.5 \pm 2.5$ ,  $P=0.04$ ). The overall proportion of adverse events was 1.87 times lower in the study group compared with the control.

**Conclusions.**– Was confirmed trazodone superiority in efficacy and safety compared to SSRI/SNRI in more rapid onset of action, anxiolytic effect, reducing insomnia and minimize side effects.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Psychosocial intervention for paternal depression in Karachi, Pakistan**

N. Husain<sup>1</sup>, N. Mehmood<sup>2</sup>, T. Kiran<sup>3</sup>, A. Qureshi<sup>3</sup>, F. Lunat<sup>1</sup>, A. Bux<sup>3</sup>, S. Farooque<sup>3</sup>, I. B Chaudhry<sup>1</sup>

<sup>1</sup> University of Manchester, division of psychology and mental health, Manchester, United Kingdom; <sup>2</sup> Karwan e Hayat, research, Karachi, Pakistan; <sup>3</sup> Pakistan institute of living and learning, research, Karachi, Pakistan

\* Corresponding author.

**Background.**– Rates of paternal depression are high and it is associated with internalizing and externalizing difficulties in the offspring and also with father-child conflicts. There are some reports of parenting interventions with fathers in the developed world but such programs are rare in low and middle income countries.

**Objectives.**– To explore whether fathers with depression will engage with proposed intervention (Learning through Play Plus)

and whether LTP Plus will lead to reduction in symptoms of depression.

**Methods.**– This was a pre-post experiment design. Fathers with children aged 0–30 months were screened with Edinburgh Postnatal Depression Scale (EPDS) and diagnosis was confirmed through Clinical Interview Schedule Revised (CISR). A total 23 fathers completed baseline assessment which included Hamilton Depression Rating Scale (HDRS), Multidimensional Scale of Perceived Social Support (MSPSS), Euro-Qol quality of life scale (EQ-5D) and Parenting Stress Index (PSI). Twelve sessions of LTP Plus were offered during the period of three months.

**Results.**– The LTP Plus was acceptable to depressed fathers and all participants attended at least 7 of the total 10 sessions. Results also indicated reduction in mean scores from baseline to 3-month on HDRS (MD = 4.20,  $P < 0.00$ ) and PSI (MD = 20.07,  $P < 0.01$ ). Mean scores improved significantly on MSPSS (MD = 22.10,  $P < 0.00$ ) and EQ-5D (MD = 19.50,  $P < 0.00$ ).

**Conclusions.**– The results show that it is possible to engage with dads in a psychosocial intervention which has a potential to improve not only paternal depression and stress but possibly child outcomes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Relationships between major depression symptoms and circadian rhythm**

Y.M. Li<sup>1</sup>, R. Möttus

*The University of Edinburgh, department of psychology, Edinburgh, United Kingdom*

\* Corresponding author.

**Introduction.**– Physiological changes based on 24-hour day-night cycle are widely observed in nature. In humans, sleep-wake cycle, body temperature, feeding, and mood also exhibit circadian rhythm.

**Objectives.**– The goal is to investigate the relationships between Major Depression (MD) symptoms and circadian rhythm in healthy volunteers.

**Methods.**– Experience sampling methodology and on-line questionnaires were used in two studies. Mobile phone apps were used to collect momentary ratings of MD symptoms 4–6 times per day over 14–15 days. On-line questionnaires were employed to collect retrospective ratings of MD symptoms using the Patient Health Quality-9. The relationships between the momentary ratings of each MD symptom and circadian rhythm were analysed using three linear mixed-effect models. The fixed factors included MD severity as represented by the total score of the PHQ-9, age, gender, educational attainment, marital status, employment status, and the times of measurement (mornings, afternoons, or evenings). The random factors were participant or both participant and the time of measurement.

**Results.**– In the two studies, significant differences between momentary MD symptom ratings and the times of measurement were observed in the items in the mobile questionnaire including – “I enjoy what I am doing”, “I don’t care about anything”, and “I am restless”. The replicability of the associations across the studies was tested by correlating the standardised betas of the linear mixed-effect models: there was evidence for the effect of evenings on the depression symptoms.

**Conclusions.**– Circadian rhythm could be observed in some MD symptoms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Fears of compassion: Magnifiers of the impact of shame on depressive symptomatology**

J. Marta-Simões<sup>1</sup>, C. Ferreira

*CINEICC - Cognitive-behavioural research centre university of Coimbra, clinical psychology, Coimbra, Portugal*

\* Corresponding author.

Compassion, a warm and understanding attitude toward oneself or others in situations of suffering or failure, associates with several good mental health indicators. Nonetheless, some individuals find receiving or expressing affiliative and compassionate emotions, from self or others, to be difficult, discomfiting or frightening.

Three path analyses were conducted to test whether fears of self-compassion, of expressing compassion to others, and of receiving others’ compassion, moderate the association of shame with depression symptoms.

A total of 234 men and 590 women ( $n = 824$ ), aged from 18 to 65, participated in this study. Participants provided demographic data and completed self-report questionnaires (evaluating external shame, fears of compassion and depression symptoms). Moderator effects were tested via path analyses and graphical representations. Fears of self-compassion, of expressing compassion to others, and of receiving others’ compassion, appear to be moderators of the relationship between external shame and depression symptoms. Specifically, for any level of shame experienced, individuals who are more afraid of any form of compassion present higher levels of depression, comparing to those who are less afraid of compassion. The three moderation models (fears of self-compassion, of expressing compassion to others, and of receiving others’ compassion) explained 48%, 43% and 47% of depression symptoms’ variance, respectively.

Present results seem to corroborate the malignancy of fearing compassion, and add to literature by showing its exacerbator role on the impact of shame on the display of depression symptoms. Findings of this study underline the pertinence of working with fears of compassion in clinical approaches to ashamed and depressed individuals.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Big five personality characteristics and metabolic syndrome in patients with major depressive disorder**

M. Martinac<sup>1\*</sup>, D. Babić<sup>2</sup>, M. Pavlović<sup>2</sup>, R. Babić<sup>2</sup>

*<sup>1</sup> Public health centre, Mostar, Bosnia, Herzegovina; <sup>2</sup> University clinical hospital Mostar, department of psychiatry, Mostar, Bosnia, Herzegovina*

\* Corresponding author.

**Aim.**– To investigate the prevalence and correlation of different types of personalities in depressive disorder with respect to the presence of the metabolic syndrome and healthy controls.

**Methods.**– We conducted a cross-sectional study with a sample of 120 respondents of which 40 were with melancholic type of depression, 40 with nonmelancholic type of depression and 40 healthy subjects. The NEO-FFI personality questionnaire was used to identify personality types. Depression diagnosis was conducted with the MINI questionnaire and Hamilton rating scale for depression. The diagnosis of MS was made according to ATP III criteria. Blood pressure, waist circumference, and the concentrations of blood glucose, cholesterol, HDL-cholesterol, triglycerides and CRP were determined to all participants.

**Results.**– We found a high neuroticism and low extraversion, openness and conscientiousness in depressive patients. In MS group expressed personality characteristics was neuroticism. Neuroticism was an independent risk factor for MS in general, neuroticism and conscientiousness for decreased HDL-cholesterol, conscientiousness for the development of hyperglycemia, neuroticism were independent risk factor for hypertension, while openness had a protective role.

**Conclusion.**– The results of the research show a statistically significant high incidence of neuroticism in depressed patients. In patients with MS high scores on neuroticism also was found, neuroticism was an independent predictor of the occurrence of MS in general in the studied sample.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Everybody needs to feel safe: the aversive role of shame feelings and self-critical attitudes on depression symptoms**

A.L. Mendes<sup>\*</sup>, C. Ferreira

CINEICC - Cognitive and behavioural centre for research and intervention university of Coimbra, clinical psychology, Coimbra, Portugal

\* Corresponding author.

Early positive and secure experiences have been consistently linked with well-being and with feelings of connectedness, safeness and acceptance. Secure attachment is defined as the individual's perception that their caregivers function as a secure base to regulate anxiety and adverse feelings when confronted with stressful contexts, and that they attend to one's needs of emotional support, protection and proximity. A lack of a secure base is associated with several psychopathological symptoms, specifically with depression symptoms.

A path model which hypothesised that social safeness, external shame and self-criticism may act as mediators in the association between secure attachment and depression symptomatology was tested. The study's sample comprised 91 Portuguese women, aged between 18 and 47 years old.

The tested model accounted for 42% of depression symptoms and showed excellent model fit indices. Particularly, results indicated that a lack of early secure attachment seems to explain higher levels of depressive symptomatology through a poorer experience of social safeness and connectedness with others, the adoption of self-critical attitudes, and feelings of inferiority and non-acceptance.

These results seem to emphasise the impact of early experiences of security, acceptance and warmth in one's later well-being. Furthermore, these findings reinforce the relevance of promoting self-compassion abilities, which have been pointed out as particularly important in the prevention and treatment of depression symptomatology.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Depression among parents of children diagnosed with rare diseases**

M. Iorga<sup>1</sup>, C. Munteanu<sup>2\*</sup>, C. Domdas<sup>1</sup>, D. Muraru<sup>1</sup>, S. Drochioi<sup>3</sup>, D.T. Anton-Paduraru<sup>3</sup>

<sup>1</sup> University of medicine and pharmacy "Grigore T. Popa", behavioral sciences, Iasi, Romania; <sup>2</sup> "Gr. T. Popa" university of medicine and pharmacy, general medicine, Iasi, Romania; <sup>3</sup> University of medicine and pharmacy "Grigore T. Popa", mother and child, Iasi, Romania

\* Corresponding author.

**Introduction.**– Depression among parents of children with rare diseases represents an important factor that influence quality of life of pediatric patients.

**Objectives.**– The aim of the study is to identify the level of depression among parents with children diagnosed with three rare diseases: phenylketonuria, cystic fibrosis and hypothyroidism.

**Methods.**– A number of 29 parents (23 mothers and 6 fathers) were included in the research. The parents had to answer to the items of Beck Depression Inventory. Socio-demographic data and medical information about the disease of their children were also registered. Descriptive, comparative and correlational analysis were realized using the program SPSS Statistics v23.0.0 for MAC.OSX.

**Results.**– Parents are aged between 18 and 56 ( $M = 34.44 \pm 9.34$ ). The mothers are younger ( $M = 33.08 \pm 9.29$ ) than fathers ( $M = 39.66 \pm 8.18$ ). More than half of the families (51.7%) live in urban area. Mothers score higher on depression compared to fathers ( $t(27) = 2.472, P = .020$ ). Variables like type of chronic disease, parents' age or their level of education do not influence depression scores. The results showed positive significant correlations between the levels of parents' depression or child's age and the time passed from the diagnostic. We found that the older the child is or the longer the period from the diagnostic is, the more depressed the parents are.

**Conclusions.**– The results obtained are important for constructing personalized psychotherapies for children and their families in order to offer suitable support for enhanced quality of life

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Factors influencing relapse in recurrent depressive disorder**

R.S. Romosan<sup>1\*</sup>, L. Dehelean<sup>1</sup>, V.R. Enatescu<sup>1</sup>, A.C. Bredicean<sup>1</sup>, I. Papava<sup>1</sup>, C. Giurgi-Oncu<sup>1</sup>, A.M. Romosan<sup>2</sup>

<sup>1</sup> "Victor Babes" university of medicine and pharmacy, neurosciences, Timisoara, Romania; <sup>2</sup> "Victor Babes" university of medicine and pharmacy, neurosciences, PhD Candidate, Timisoara, Romania

\* Corresponding author.

**Introduction.**– Recurrent depressive disorder is presently one of the most prevalent psychopathological disorders in developed countries. Preventing relapses is essential for proper global functioning and quality of life of affected individuals.

**Objectives.**– To identify factors and possible predictors of relapse in patients with recurrent depressive disorder.

**Methods.**– We assessed 67 in-patients, diagnosed with recurrent depressive disorder according to ICD-10 criteria, admitted in the Timisoara Psychiatric Clinic during 2014 and 2017, by using the MINI Interview and the CERQ scale.

**Results.**– We found higher risks of relapse in patients with: a higher disorder duration, a higher number of episodes, a lower age at onset and a positive family history of affective disorders. We also found the following factors favoring relapse, which, with proper interventions, could prevent (or at least reduce the risk) of future relapses:

non-adherence to medication, legal and illegal substance use or abuse and the use of maladaptive emotion regulation strategies.

**Conclusions.**– Intervening on some of the identified factors in a timely and efficient manner may reduce or even prevent relapses, thus increasing the quality of life and global functioning of patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Tellenbach's orderliness in depression and anxiety disorders

A. Maraone<sup>1</sup>, V. Roselli<sup>1\*</sup>, V. Magliocchetti<sup>1</sup>, M. Pasquini<sup>1</sup>, L. Tarsitani<sup>2</sup>

<sup>1</sup> SAPIENZA university of Rome, department of neurology and psychiatry, Umberto I hospital, Rome, Italy; <sup>2</sup> SAPIENZA university of Rome, Rome, Italy

\* Corresponding author.

**Introduction.**– One of the more consistent premorbid personality vulnerable model to endogenous depression was that described by Tellenbach. Orderliness, conscientiousness, hyper/heteronomia and intolerance of ambiguity are the core features of Typus Melancholicus (TM). Several studies showed that in the 30–60% of patients a relationship between unipolar depression and TM.

**Objectives.**– To evaluate the potential association between TM, using orderliness (Factor 1) and conscientiousness (Factor 2), and mood and anxiety disorders. The second purpose is to assess the degree of empathy and stress vulnerability in TM.

**Methods.**– Population of 131 subjects, consists of 101 outpatients with mood and anxiety disorders according to DSM IV and 30 non-clinical controls, was enrolled. The two dimensions of TM were assessed with Kasahara's Inventory for the Melancholic Type Personality (KIMTP). Furthermore the sample was interviewed with Interpersonal Reactivity Index (IRI) and Stress-related Vulnerability Scale (SVS).

**Results.**– Patients with Major Depressive Disorder (DDM) ( $P < 0.008$ ) and Anxiety Disorders (AD) ( $P < 0.003$ ) have a considerably higher score only in Factor 1 of KIMTP than control sample. A significant correlation was both highlighted between the factor 1 and the dimension of perceived stress, demoralization and reduced social support of SVS (Table 1) and personal distress of IRI (Table 2). The factor 2 has a correlation with dimension Empathic Concern of IRI (Table 2).

**Conclusions.**– Just the dimension orderliness could be considered a factor of vulnerability for DDM and AD. This result could be explained through a socio-cultural challenge in the development of mood and anxiety disorders.

Table 1.

SVS subscales	KIMTP Factor 1 orderliness	KIMTP Factor 2 conscientiousness
SVS 1 tension	0,126	-0,121
SVS 2 demoralization	<b>0,418**</b>	-0,086

### Multimodal antidepressant in Major Depressive Disorder: Use of vortioxetine in depressive outpatients

O. Santamaria<sup>1\*</sup>, S.L. Romero<sup>2</sup>

<sup>1</sup> Nuestra Señora de Valme university hospital, psychiatry, Seville, Spain; <sup>2</sup> Virgen Macarena university hospital, psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– 50% of patients with Major Depressive Disorder (MDD), discontinue or do not respond to treatment. Vortioxetine is an antidepressant with a multimodal mechanism of action.

**Objectives.**– To assess efficacy, functionality and tolerability of Vortioxetine in a real setting.

**Methods.**– A prospective observational 8-week follow-up study. Patients with a diagnosis of MDD and a score on Montgomery-Åsberg Depression Rating Scale (MADRS) of  $\geq 20$  points.

The efficacy variables were changes in MADRS, in anhedonia using the Snaith Hamilton Rating Scale (SHAPS) and in functionality using the Sheehan Disability Scale (SDS). Also, the proportion of responsive and remission patients as well as continuity rate and rate of side effect reports.

**Results.**– A total of 66 patients were included in the study (44 female and 22 male).

The mean baseline score of 29.7 ( $\pm 5.3$ ) on the MADRS and 7.5 ( $\pm 1.2$ ) on the SAHPS. 7.9 ( $\pm 1.3$ ) on the SDS-Work, 8.2 ( $\pm 1.3$ ) on the SDS-Social life and 8.1 ( $\pm 1.1$ ) on the SDS-Family life.

We observed a significant decrease in the total score on:

– MADRS scale ( $\Delta = 20.5 \pm 8.7$ ;  $P < 0.01$ ), after 2 weeks.

– SHAPS scale ( $\Delta = 3.2 \pm 1.5$ ;  $P < 0.05$ ), after 4 weeks.

– SDS-work scale ( $\Delta = 4.9 \pm 1.6$ ;  $P < 0.01$ ), after 2 weeks.

– SDS-social scale ( $\Delta = 4.4 \pm 2.1$ ;  $P < 0.05$ ), after 8 weeks.

– SDS-family scale ( $\Delta = 3.9 \pm 1.7$ ;  $P < 0.05$ ), after 4 weeks.

At the study end, the mean treatment response rate was 68.18%, whereas the mean remission rate was 54.4%; with a rate of treatment adherence of 78.78%

**Conclusions.**– Vortioxetine is well-tolerated and effective in depression, and improves functionality in patients with MDD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0593

### Neurocognitive characteristics of patients with and without treatment-resistant depression

G. Serafini<sup>1\*</sup>, M. Pompili<sup>2</sup>, P. Girardi<sup>3</sup>, M. Amore<sup>1</sup>

<sup>1</sup> University of Genoa, neuroscience DINOGMI, Genoa, Italy; <sup>2</sup> Suicide prevention center, Sant'Andrea hospital, Sapienza university of Rome, Rome, Italy, neurosciences, Rome, Italy; <sup>3</sup> Sant'Andrea hospital, Sapienza university of Rome, Rome, Italy, neurosciences, Rome, Italy

\* Corresponding author.

**Introduction.**– Approximately 30% of patients with major depression do not successfully respond to available antidepressant medications (NRTD). Treatment-resistant depression (TRD) is commonly associated with relevant disability and psychosocial impairment worldwide.

**Objectives.**– We aimed to compare neurocognitive functions in TRD and NTRD subjects and identify possible neurocognitive predictors of resistance.

**Methods.**– Overall, 32 depressed outpatients with TRD according to Thase and Rush staging method and 22 with NTRD were recruited at the section of Psychiatry, University of Genoa (Italy). Participants completed the Trail Making Test (TMT-A/B), Verbal Fluency test (VFT), Rey Auditory Verbal Learning Test (RAVLT), Stroop Color Word Interference (SCWT), and Continuous Performance Test (CPT).

**Results.**– TRD patients reported a more impaired performance at SCWT ( $P \leq 0.001$ ), RAVLT ( $P = 0.001$ ), and TMT-A/B ( $P \leq 0.05$ ) relative to subjects with NTRD. In particular, TRD patients showed a more impaired visuospatial coordination ( $P \leq 0.05$ ) and altered cognitive flexibility ( $P \leq 0.05$ ) than patients with NTRD. TRD subjects also reported lower rates of correct detections at CPT ( $P = 0.001$ ) with a greater number of omission errors ( $P \leq 0.05$ ) than NTRD patients. After multivariate regression analyses, the amount of variation in TRD that was accounted for all predictors was 75% ( $R^2 = 0.75$ ) with the SCWT ( $P < 0.001$ ) and RAVLT ( $P < 0.001$ ) that resulted significant predictors of TRD. The rate of correct detections at CPT ( $P = 0.001$ ), phonemic ( $P = 0.001$ ) and semantic ( $P = 0.009$ ) verbal fluency, SCWT ( $P = 0.005$ ) e  $P = 0.001$ , and TMT-B ( $P = 0.010$ ) scores further predicted TRD.

**Conclusions.**– TRD was associated with greater neurocognitive impairments when compared with NTRD. Selective neurocognitive impairments might be used as early targets of treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0594

### Memory deficit upon ECT treatment of major depression is associated with increased levels of neurotoxic tryptophan catabolite in blood

J. Söderlund<sup>1\*</sup>, T. Kocki<sup>2</sup>, B. Owe-Larsson<sup>1</sup>, E. Urbanska<sup>2</sup>

<sup>1</sup> Karolinska Institutet, department of clinical neuroscience, Stockholm, Sweden; <sup>2</sup> Medical university of Lublin, department of experimental and clinical pharmacology, Lublin, Poland

\* Corresponding author.

**Introduction.**– Tryptophan degradation produce neuroactive substances including neurotoxic 3-hydroxy-kynurenine (3HK) and neuroprotective kynurenic acid (KYNA). Reduced levels of KYNA and increased levels of 3HK, detected in blood, has been associated with major depression. Increasing KYNA in blood prevented stress induced depression in a rodent model of depression. Electroconvulsive therapy (ECT) induce an excitotoxic state which may affect both these substances.

**Objective.**– To investigate if KYNA and 3HK is induced by ECT, and whether altered levels can explain antidepressive and cognitive side effects of this treatment.

**Methods.**– Blood samples and results from the cognitive testing were obtained from fourteen patients with major depression, before the first and the last ECT session in a serie of 5–7 sessions. Also blood samples one hour after the first and the last session was obtained. Nine healthy volunteers were recruited as controls. KYNA and 3HK were analyzed using HPLC.

**Results.**– Patients with reduced cognitive performance after a serie of ECT had a decreased level of KYNA and increased level of 3HK in blood, and patients with unaffected or improved performance show the opposite pattern. These chronic changes were unrelated to the antidepressive effects of ECT. However, also a 2–3-fold increase of KYNA of short duration was observed as early as 1 hour after ECT.

**Conclusion.**– ECT seem to induce changes in tryptophan degradation towards a neurotoxic dominance in patients with reduced cognitive performance after treatment. Acute changes in KYNA after ECT may suggest a new possible mechanism for how ECT exerts its antidepressive effect.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Latvian family physicians' experience and attitude in diagnosing and managing depression

J. Vrublevska<sup>\*</sup>, V.V. Vinogradova, R. Ivanovs, E. Rancans

Riga Stradins university, department of psychiatry and narcology, Riga, Latvia

\* Corresponding author.

**Introduction.**– Despite high prevalence rates of depression in primary care it continues to be under-diagnosed.

**Objectives.**– To identify family physicians' (FP's) experience and attitude in diagnosing and managing depression in Latvian primary care setting.

**Methods.**– FP's complete the structured questionnaire during educational seminars on diagnosing and treating depression carried out all over Latvia within the framework of National Research Program BIOMEDICINE.

**Results.**– In total 208 respondents (or 15.5% out of 1346 FP's in contract with the government) were recruited. Mean age of FP's was 53.2 (95% CI 51.9–54.5) and practical experience 26.7 years (95% CI 25.1–28.2). 76.4% ( $n = 165$ ) FP's absolutely agree that depression is serious disease and 81.9% ( $n = 177$ ) of FP's admit, they often must come across with the patients with depression. 72.2% ( $n = 156$ ) of doctors consider, that patients with depression use primary care more often, than other patients. 66.3% ( $n = 143$ ) of doctors quite often ask their patients about psycho-emotional status during the visits, however, 52.3% ( $n = 113$ ) suppose, their usual contact with depressive patients is middling or quite bad. 62.6% ( $n = 135$ ) of FP's suppose their practice is well suitable for the treatment of depressive patients but half of the respondents (50.9%;  $n = 110$ ), assess their ability to motivate patients for treatment as middling.

**Conclusions.**– Most of the FP's critically assess their ability to build trustful contact with depressive patients and motivate them for treatment. It is necessary to introduce FP's training program and the screening program for depression in Latvia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Early improvement of executive test performance during antidepressant treatment predicts treatment outcome in patients with major depressive disorder

S. Wagner<sup>1\*</sup>, I. Helmreich<sup>1</sup>, S. Kaaden<sup>2</sup>, J. Reiff<sup>2</sup>, S. Roll<sup>3</sup>, D. Braus<sup>2</sup>, A. Tadic<sup>4</sup>, K. Lieb<sup>1</sup>

<sup>1</sup> University medical center, department of psychiatry and psychotherapy, Mainz, Germany; <sup>2</sup> Helios Horst Schmidt Kliniken, psychiatry and psychotherapy, Wiesbaden, Germany; <sup>3</sup> Vitos Rheingau, psychiatry and psychotherapy, Eltville, Germany; <sup>4</sup> Agaplesion Elisabethenstift, department of psychiatry, psychosomatics and psychotherapy, Darmstadt, Germany

\* Corresponding author.

Executive dysfunctions frequently occur in patients with Major Depressive Disorder and have been shown to improve during effective antidepressant treatment. However, the time course of improvement and its relationship to treatment outcome is unknown. The aim of the study was to assess the test performance and clinical outcome by repetitive assessments of executive test procedures during antidepressant treatment. Executive test performance was assessed in 209 – patients with Major Depressive Disorder (mean age 39.3 ± 11.4 years) and 84 healthy controls five times in biweekly intervals from baseline to week 8. Patients were treated by a defined treatment algorithm within the early medication change study (EMC trial; ClinicalTrials.gov NCT00974155), controls did not receive any intervention. Executive domains included processing speed, cognitive flexibility, phonemic and semantic verbal fluency. Intelligence was assessed at baseline. Depression severity was tested once a week by the Hamilton Depression Rating Scale (HAM<sub>D17</sub>). 130 patients (62%) showed executive dysfunctions in at least one of four tests at baseline. A majority of these patients (65%) experienced a normalization of the impaired test performance in parallel to the improvement of depressive symptomatology. The early improvement of semantic verbal fluency predicted treatment outcome in patients with executive deficits at baseline ( $P \leq 0.037$ ). Executive dysfunctions occur in the majority of patients with Major Depressive Disorder and normalize in most patients with successful antidepressant treatment. The early improvement of semantic verbal fluency may be a candidate easily to apply for therapy response prediction which should be tested in further prospective studies.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0597

### A combined marker of early non-improvement and the occurrence of melancholic features improve the treatment prediction in patients with major depressive disorders

S. Wagner<sup>1\*</sup>, A. Tadic<sup>2</sup>, S. Roll<sup>3</sup>, N. Dreimüller<sup>1</sup>, J. Engelmann<sup>1</sup>, K. Lieb<sup>1</sup>

<sup>1</sup> University medical center, department of psychiatry and psychotherapy, Mainz, Germany; <sup>2</sup> Agaplesion Elisabethenstift, department of psychiatry, psychosomatics and psychotherapy, Darmstadt, Germany; <sup>3</sup> Vitos Rheingau, psychiatry and psychotherapy, Eltville, Germany

\* Corresponding author.

*Background.*– Early Improvement of depressive symptoms within two weeks of antidepressant treatment is a highly sensitive but less specific predictor of later treatment outcome. The aim of this

study was to identify clinical features at treatment initiation which are associated with early improvement and non-improvement as well as to identify variables predicting non-remission in patients showing an early improvement.

*Methods.*– 889 patients with a major depressive episode according to DSM-IV who had participated in an antidepressant treatment trial served as study sample. Clinical predictors (demographic variables, psychopathology, comorbid disorders) were analysed in 698 (79%) early improver, Hamilton Depression Rating Scale reduction > 20% after 14 days of treatment, compared to 191 (21%) non-improver. Furthermore, clinical predictors for later remission and non-remission were analysed in the 698 patients showing an early improvement.

*Results.*– Patients with more severe depression and suicidality were more likely to become non-improver, and also non-remitter after 8 weeks of treatment in case of early improvement. Early improver with melancholic, anxious or atypical depression as well as with comorbid social phobia or avoidant personality disorder had an increased risk for non-remission at study end. The combined marker of early non-improvement and the occurrence of melancholic features increased the specificity of treatment prediction from 30 to 90%.

*Limitations.*– A limitation was that comorbid disorders were only assessed at baseline.

*Conclusions.*– Patients with early non-improvement and melancholic features at treatment initiation have a particularly high risk of later non-remission. This group of patients should be considered more attention in treatment decisions.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Obsessive-Compulsive Disorder / Personality and Personality Disorders

PW0598

### Maladaptive perfectionism and obsessive-compulsive symptoms: The role of stress vulnerability, controlling negative affect

A.P. Amaral<sup>1\*</sup>, M.J. Soares<sup>2</sup>, A.T. Pereira<sup>2</sup>, A. Macedo<sup>3</sup>

<sup>1</sup> Institute Polytechnic of Coimbra and university of Coimbra, Coimbra Health School, Coimbra, Portugal; <sup>2</sup> University of Coimbra, department of psychological medicine, faculty of medicine, Coimbra, Portugal; <sup>3</sup> University of Coimbra and Coimbra hospital and university centre, department of psychological medicine, faculty of medicine, Coimbra, Portugal

\* Corresponding author.

*Introduction.*– Maladaptive perfectionism dimensions are highly prevalent in patients with Obsessive-Compulsive Disorder (OCD) and some researchers consider perfectionism as a risk factor for the development of obsessive-compulsive symptoms. Perfectionism is also viewed as a necessary, but insufficient, predisposing factor for OCD (Pinto et al., 2017). Additionally, several studies have reported that stress acts as a mediator or moderator of the link between perfectionism and psychological distress (Flett et al., 2016).

*Objectives.*– To analyze the mediation role of stress vulnerability in the association between maladaptive perfectionism and OC symptoms, controlling for negative affect.

*Methods.*– In a transversal study 217 students filled in: (1) Maudsley Obsessional-Compulsive Inventory; (2) Composite Frost and Hewitt & Flett - Multidimensional Perfectionism Scale; (3) Questionnaire of Stress Vulnerability, and (4) Profile of Mood States.

**Results.**– After mediation analysis, and controlling negative affect (depression, anxiety and hostility), it was found that maladaptive perfectionism contributes to higher levels of OC symptoms, either directly ( $c' = .056, P = .014, 95\% \text{ CI} = .012 \text{ to } .100$ ) or indirectly ( $axb = .27, 95\% \text{ CI} = .008 \text{ to } .054$ ) as a result of its impact on stress vulnerability ( $a = .220, P < .001$ ), which in turn leads to OC symptoms ( $b = .123, P = .012$ ). The total effect of maladaptive perfectionism on OC symptoms is significant ( $c = .083, 95\% \text{ CI} = .044 \text{ to } .123, P < .001$ ).

**Conclusions.**– Stress vulnerability is a mediator of the relationship between maladaptive perfectionism and obsessive-compulsive symptoms, controlling the effect of negative affect. Perfectionism and stress vulnerability should be taken into account in prevention and cognitive interventions of obsessive-compulsive symptoms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0599

### Maladaptive perfectionism, stress vulnerability and depressive symptoms in college students

A.P. Amaral<sup>1</sup>, M.J. Soares<sup>2</sup>, A.T. Pereira<sup>2</sup>, A. Macedo<sup>3</sup>

<sup>1</sup> Institute Polytechnic of Coimbra and university of Coimbra, Coimbra health school, Coimbra, Portugal; <sup>2</sup> University of Coimbra, department of psychological medicine, faculty of medicine, Coimbra, Portugal; <sup>3</sup> University of Coimbra and Coimbra hospital and university centre, department of psychological medicine, faculty of medicine, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Accumulated evidence suggests that stress acts as a mediator or moderator of the link between perfectionism and psychological distress (Flett et al., 2016), and according to Smith et al. (2016), perfectionistic concerns exacerbate effect of stress on depressive symptoms across clinical and non-clinical samples. Among university students, maladaptive perfectionism is associated with a wide range of psychological distress, including depression (Hamamura & Laird, 2014).

**Objectives.**– To analyze the mediation role of stress vulnerability in the association between maladaptive dimensions of perfectionism and depressive symptoms.

**Methods.**– In a transversal study, 217 students (82% females) filled in the Composite Frost and Hewitt & Flett – Multidimensional Perfectionism Scale, the Questionnaire of Stress Vulnerability, and the Profile of Mood States.

**Results.**– We found positive associations between maladaptive dimensions of perfectionism and stress vulnerability (from  $r = .181, P < .005$  to  $r = .661, P < .005$ ). More adaptive dimensions of perfectionism were not significantly associated with stress vulnerability. After mediation analysis, there was evidence that maladaptive dimensions of perfectionism led to more depressive symptoms, either directly ( $c' = .104, P = .046, 95\% \text{ CI} = .002 \text{ to } .205$ ) or indirectly ( $axb = .106, 95\% \text{ CI} = .097 \text{ to } .238$ ), as a result of its impact on stress vulnerability ( $a = .299, P < .001$ ), which in turn led to depressive symptoms ( $b = .532, P < .001$ ).

**Conclusions.**– Stress vulnerability mediated the relationship between the maladaptive dimensions of perfectionism and the depressive mood. Perfectionist students with higher scores of maladaptive dimensions are more vulnerable to stress and have greater propensity to develop depressive symptoms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0600

### Confirmatory factor analysis of the big three perfectionism scale in a sample of Portuguese university students

F. Lino<sup>1</sup>, C. Marques<sup>2</sup>, A.T. Pereira<sup>2</sup>, P. Sousa<sup>1</sup>, A.P. Amaral<sup>3</sup>, P. Oliveira<sup>4</sup>, A.I. Araújo<sup>5</sup>, A. Macedo<sup>5</sup><sup>1</sup> University of Coimbra, faculty of medicine, Coimbra, Portugal;<sup>2</sup> University of Coimbra, psychological medicine, faculty of medicine,Coimbra, Portugal; <sup>3</sup> Institute Polytechnic of Coimbra, university ofCoimbra, Coimbra health school, Coimbra, Portugal; <sup>4</sup> Universityhospital, department of psychiatry, Coimbra, Portugal; <sup>5</sup> University of

Coimbra, university hospital, psychological medicine, faculty of

medicine, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– The Big Three Perfectionism Scale (BTPS) is a new measure to study the perfectionism as a multidimensional personality trait. The BTPS postulates the existence of three second-order factors (rigid perfectionism, self-oriented perfectionism and narcissistic perfectionism).

**Objective.**– A confirmatory factor analysis was conducted to examine the factor structure of the BTPS in a sample of Portuguese university students.

**Method.**– A sample of 398 university students (68.5% females; M of age =  $21.47 \pm 2.19$ ; range: 17–32) answered the Portuguese preliminary version of the BTPS and other validated perfectionism measures (Multidimensional Perfectionism Scales from Frost and Hewitt & Flett). A sub-sample of 163 participants completed the BTPS again after approximately eight weeks.

**Results.**– After correlating items errors, the second order model of the Portuguese version of BTPS presented a marginal acceptable fit ( $\chi^2/df = 3.006$ ; TLI = 0.788; CFI = 0.802; GFI = 0.745; RMSEA = 0.071). The three factors of the Portuguese version of BTPS showed acceptable to good internal consistency reliability (Cronbach's alphas ranging from .79 to .88) and temporal stability ( $r > .69, P < .001$ ). In general, Pearson correlations with other perfectionism measures were significant, positive and low to moderate.

**Conclusions.**– The Portuguese version of the BTPS has an underlying three-factor model. Given the model fit indices, these findings should be interpreted with caution and it will be important to enlarge the sample size. All the dimensions present good reliability and concurrent validity. Further research is needed to confirm this factor structure in other Portuguese samples.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0601

### Confirmatory factor analysis of the HEXACO-60 in a sample of Portuguese university students

P. Sousa<sup>1</sup>, C. Marques<sup>2</sup>, A.T. Pereira<sup>2</sup>, F. Lino<sup>1</sup>, A.P. Amaral<sup>3</sup>, D. Mota<sup>4</sup>, S. Ferreira<sup>5</sup>, M. Coroa<sup>5</sup>, A. Macedo<sup>4</sup><sup>1</sup> University of Coimbra, faculty of medicine, Coimbra, Portugal;<sup>2</sup> University of Coimbra, faculty of medicine, psychological medicine,Coimbra, Portugal; <sup>3</sup> Institute Polytechnic of Coimbra, CoimbraHealth School, Coimbra, Portugal; <sup>4</sup> University of Coimbra, university

hospital, faculty of medicine, psychological medicine, Coimbra,

Portugal; <sup>5</sup> University hospital, department of psychiatry, Coimbra,

Portugal

\* Corresponding author.

**Introduction.**– The HEXACO-60 inventory assess the HEXACO model of personality structure which posits that personality traits consist of six dimensions – Honesty-Humility, Emotionality, Extraversion, Agreeableness, Conscientiousness and Openness to Experience.

**Objective.**— A confirmatory factor analysis was conducted to examine the factor structure of the HEXACO-60 in a sample of Portuguese university students.

**Methods.**— A sample of 632 university students (65.5% women), between 17 and 34 years old ( $M=21.42$ ;  $SD=2.28$ ) answered the Portuguese version of the HEXACO-60. A sub-sample of 212 participants completed the HEXACO-60 again after approximately eight weeks.

**Results.**— The initial model resulted in a poor fit ( $\chi^2/df=2.526$ ;  $TLI=0.741$ ;  $CFI=0.755$ ;  $GFI=0.803$ ;  $RMSEA=0.049$ ). After eliminating three items (6, 19 and 36) due to low loadings ( $\lambda < .30$ ) and correlating items errors, the second order model of the Portuguese version of the HEXACO-60 presented a marginal acceptable fit ( $\chi^2/df=2.317$ ;  $TLI=0.787$ ;  $CFI=0.801$ ;  $GFI=0.825$ ;  $RMSEA=0.046$ ). The six dimensions of the Portuguese version of HEXACO-60 showed acceptable to good internal consistency reliability (Cronbach's alphas ranging from .72 to .82) and temporal stability ( $r > .75$ ,  $P < .001$ ).

**Conclusions.**— The findings seem to suggest that the HEXACO-60 has an underlying six dimensions. The factorial model presented a marginal acceptable fit, thus these findings should be interpreted with caution. All the dimensions present good reliability. Further research is needed to confirm this factor structure in other Portuguese samples.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

### **A preliminary analysis of affiliation and social safeness in psychotic disorders: The role of negative symptoms and external shame**

M. Arge<sup>1</sup>, T. Cruz<sup>1</sup>, M.J. Martins<sup>1</sup>, M. Bajouco<sup>1</sup>, A.I. Araújo<sup>2\*</sup>, P. Castilho<sup>1</sup>, A. Macedo<sup>1</sup>

<sup>1</sup> Faculty of medicine of the university of Coimbra, psychological medicine department, Coimbra, Portugal; <sup>2</sup> Psychological medicine department, faculty of medicine, university of Coimbra, Macieira de Cambra, Portugal

\* Corresponding author.

**Background.**— Often psychotic-spectrum disorders are associated with significant burden in global functioning. Negative symptoms, such as amotivation and asociality, have been reported as one of the major contributors to disability. There is still a strong social stigma involved, which may lead to a sense of devaluation and problems in feeling safe in the social world. This may be influenced by the emergence of shame (an emotion with high social importance, crucial to the self-identity). This study aims to investigate the associations between negative symptoms, external shame and social safeness (perceiving social world as safe and soothing); and explore the mediator role of external shame in the relationship between negative symptoms and social safeness.

**Method.**— A sample of 33 patients diagnosed with a psychosis-spectrum disorder were recruited, assessed with the Positive and Negative Syndrome Scale and completed the Other as Shamer Scale and Social Safeness and Pleasure Scale.

**Results.**— All variables under study were significantly associated with each other. Negative symptoms were correlated with external shame and both were negatively associated with social safeness. Simple mediation revealed that external shame was a significant mediator in the relationship between negative symptoms total and social safeness.

**Discussion.**— These results appear to indicate that in people with psychosis, the thought of being held negatively in the mind of others is a pathway from which negative symptoms impact on social

interactions and safeness. Shame can be a useful therapeutic target for patients with negative symptoms of psychosis.

### **Vegetarian food behavior as a means of implementing a consistent axiological position of an individual**

G. Arina<sup>\*</sup>, A. Bykov

Lomonosov Moscow state university, department of neuro- and pathopsychology, Moscow, Russia

\* Corresponding author.

**Introduction.**— A significant number of people for various reasons choose to limit meat consumption or adhere to different types of vegetarian diets (e.g., Cunningham, 2009; Ruby, 2012; Fox, 2008).

**Objective:** A conscious change in food behavior is a phenomenon when a choice is made to modify a long-term internalized pattern of body regulation. The study aims to present a summary of the axiological basis of such a transformation and the motivational dynamics in the vegetarian food behavior.

**Methods.**— 51 vegetarians (average adherence period of 7 years) in Russia participated in a semi-structured interview, a survey and Rokeach's Value Survey (RVS) (1974).

**Results.**— The majority of respondents (85%) perceived their transition to vegetarianism as a possibility of a "new life", a personal value-driven act, which involved overcoming cultural and/or family habits. Retrospectively, initial motivation for the transition was linked to ethics (63%) and health (37%) and meaningfully coincided with key life value orientations of the individual in RVS (e.g. love, health, active life). Subsequently, vegetarians who initially stated health motivation to be the reason for the change tended to become more ethically conscious.

**Conclusions.**— Vegetarianism not only presents itself as a form of food behavior, but as a means of implementing a consistent values' position of an individual. The dominant motives of vegetarianism, i.e. ethics and health, meaningfully coincide with key value orientations of an individual. Long-term adherence to vegetarianism while preserving its primary motivation acquires a broader motivational basis.

**Disclosure of interest.**— The authors have not supplied a conflict of interest statement.

### **Behavioral flexibility in obsessive compulsive disorders: A translational study**

N. Benzina<sup>\*</sup>, K. N'Diaye, L. Mallet, E. Burguière

Institut du Cerveau et de la Moelle épinière, BEBG Team, Paris, France

\* Corresponding author.

Obsessive-Compulsive Disorder (OCD) is a mental disorder featuring obsessions (intrusive ideas) and compulsions which are repetitive behaviors performed through rigid rituals. This phenomenological observation has led to explore the idea that OCD patients have diminished behavioral flexibility. The pathophysiology of OCD supports this hypothesis with dysfunctional cortico-basal ganglia loops including structures involved in behavioral flexibility.

Thus, our objective is twofold: to verify the involvement of behavioral flexibility in the compulsive behavior and to explore the neurobiological bases underlying flexibility in patients and an animal model of OCD (SAPAP3-KO).

Behavioral flexibility may be challenged in reversal learning paradigms. This task has been implemented easily for neuropsychological studies in human. However, the adaptation of non-spatial reversal learning task in rodents is much more laborious due to the high number of trials required for the learning. To overcome this issue, we developed automated behavioral cages where animals could live and be exposed continuously to the task. We succeeded in designing a similar reversal learning task in both species and observed that both OCD patients and SAPAP3-KO mice showed impaired performance in our task with more trials needed than controls to reach the reversal criterion, a marker of their difficulty to reverse a previously learned association. These results suggest that OCD condition is associated with a diminished behavioral flexibility. The next step is to explore the neural basis of the behavioral flexibility and its link with compulsion by modulating the cortico-basal ganglia pathways both in patients (DBS) and SAPAP3-KO mice (optogenetic) during behavioral tasks. *Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Development of the Padua Inventory Short Form (PI-SF): Factor structure and psychometric properties**

A. Galhardo<sup>\*</sup>, D. Santos, I. Massano-Cardoso, M. Cunha Miguel Torga institute, psychology, Coimbra, Portugal

\* Corresponding author.

*Introduction.*– The Padua Inventory (PI) is 60-item self-report measure of obsessive-compulsive symptoms. Several studies analysed its factor structure and convergent and divergent validity. Recently, there is a research trend to develop more concise instruments.

*Objectives.*– The current study aimed the development of a short form of the PI Portuguese version (PI-SF). Dimensional structure and psychometric properties were examined.

*Method.*– PI-SF items were selected based on psychometric criteria. This preliminary study was conducted in a sample of 604 participants from the general population. In another sample of 338 subjects a 5-factor model was verified through confirmatory factor analysis (CFA). Cronbach alpha and composite reliability (CR) were estimated. Correlations with the Coimbra Obsessive Inventory (COI) and the Depression, Anxiety and Stress Scales (DASS-21) were calculated. Test-retest reliability was studied in a subsample of 23 participants.

*Results.*– The PI-SF included 21 items and 5 dimensions: doubt, magic thinking, contamination/washing, repeated checking, and need for order/symmetry. The 21-item version and 5 factor structure revealed a good fit to the data. (CFI = .939; GFI = .906; TLI = .928; RMSEA = .056; MECVI = 1.430). A strong correlation between the PI and the PI-SF was found ( $r = .97$ ). Concerning internal consistency, Cronbach alpha was .91 and the CR was .97. The PI-SF showed high correlations with the COI ( $r = .80$ ;  $r = .74$ ) and moderate correlations with the DASS-21 ( $r = .45$ ;  $r = .44$ ;  $r = .48$ ).

*Conclusion.*– Our findings provided a piece of evidence that the PI-SF is a reliable and valid measure of obsessive-compulsive symptoms keeping the same factor structure and being more practical to use in research and clinical settings.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Borderline personality disorder awareness month**

K. Gintalaite-Bieliauskiene

Avon and Wiltshire Mental Health Partnership NHS Trust, Recovery Service, Weston super Mare, United Kingdom

*Introduction.*– Many patients diagnosed with Borderline Personality Disorder (BPD) find this diagnosis challenging and stigmatising. Family members experience high level of distress and they are rarely involved in treatment. Understanding BPD helps to put in place effective compassionate treatments and develop a common language.

*Objectives.*– To raise awareness and provide accurate information about BPD, share the message of hope amongst mental health-care professionals, clinical commissioning group, patients and their families.

*Methods.*– 16 education sessions in March 2016 and 5 sessions in March 2017 were offered to multidisciplinary teams in North Somerset, United Kingdom. The following topics aimed at professionals were covered: structured clinical management, neurobiology, attachment, art therapy, mentalization based therapy, lessons learnt from serious untoward incidents, support through transitions, BPD traits in later life and research findings. The sessions were facilitated by clinicians, management and researchers. In addition, two evening sessions were provided to patients and their families and the third session was dedicated to families only. Handouts, websites and books list were provided. . .

*Results.*– All sessions were well attended, including families and patients from the neighbourhood Trust. The idea of developing local families support network and regular carers group was raised by the families and is being explored with the commissioners. The feedback for each session was provided, with excellent feedback received from families.

*Conclusion.*– Awareness about BPD was successfully raised. We gave a BBC radio talk following this event. We are aiming that BPD Awareness Month will become a tradition across the organisation.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Relationship between personality traits and mental health of coronary artery disease patients of Fatemeh Zahra Hospital in Sari**

F. Hadadian<sup>1\*</sup>, B. Bakhshpour<sup>2</sup>, M. Nabati<sup>3</sup>, S. Dadkha<sup>4</sup>

<sup>1</sup> Medical clinical psychology, faculty of humanities, Islamic Azad university, Sari, Iran, clinical psychology, Sari, Iran; <sup>2</sup> Ph.D.

Consultant, Assistant Professor, Payame Noor university, Sari, Iran, clinical psychology, Sari, Iran; <sup>3</sup> Mazandaran university of medical sciences, Sari, Iran, cardiology, Sari, Iran; <sup>4</sup> Ph.D student of psychology of health, faculty of humanities, Islamic Azad university, Najaf Abad, Iran, Health Psychology, Sari, Iran

\* Corresponding author.

*Introduction.*– Cardiovascular disease is the leading cause of death in many developing countries, especially Iran, and is one of the most serious risks to human life and health.

*Objectives.*– The purpose of this study was to investigate the relationship between personality traits and mental health of coronary artery disease patients of Fatemeh Zahra hospital in Sari.

*Method.*– This descriptive study was a correlation study. The statistical population of this study was all coronary artery disease patients referring to Fatemeh Al-Zahra heart surgery hospital in the city of Sari in the first two months of 2012, which were reported

about 1999 persons. The sample group was 297 people who were selected according to Krejcie and Morgan tables by simple random sampling. They were then evaluated by NEO-FFI personality scale and mental health SCL-90-R.

**Results.**– Findings showed that there is a significant positive correlation between personality traits and mental health of patients with coronary artery disease, so that there is a positive correlation between extraversion, adaptability, self-awareness and admission with mental health of patients with coronary artery disease. There was a significant negative correlation between neuroticism and mental health. In addition, the findings showed that personality traits do have predictive power for mental health.

**Conclusion.**– According to the above findings, it is possible to improve the prognosis of heart disease with more accurate monitoring and training, and by conducting counseling sessions to control the anxiety and stress of heart patients with high neurotic and help to control and regulate blood pressure.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Brain volume alteration and its correlation with anxiety severity in patients with obsessive-compulsive disorder and generalized anxiety disorder**

G.W. Jeong\*, G.W. Kim

Chonnam national university medical school and hospital, department of medicine, Gwangju, Republic of Korea

\* Corresponding author.

Obsessive-compulsive disorder (OCD) and generalized anxiety disorder (GAD) are associated with abnormalities in the processing and regulation of anxiety. Differences between OCD and GAD in the neurologic and symptomatic features have becoming more important in assessment and treatment of patients with OCD and GAD. The purpose of this study is to evaluate the differential gray matter (GM) and white matter (WM) volume alterations between healthy controls and patients with OCD and GAD using voxel-based morphometry (VBM). Sixteen patients with OCD, 16 patients with GAD, and 16 healthy controls participated in this study. Magnetic resonance image data were processed using SPM8 software with diffeomorphic anatomical registration through an exponentiated Lie algebra (DARTEL) algorithm. Compared with patients with OCD ( $P < 0.001$ ), patients with GAD showed decreased GM volumes in the precuneus, dlPFC, SOG and mPFC, as well as decreased WM volumes in the dlPFC, mPFC and angular gyrus ( $P < 0.001$ ). In analysis of covariance (ANCOVA) adjusting for the Hamilton Anxiety Rating Scale (HAM-A;  $P < 0.001$ ), patients with GAD showed significantly decreased GM volume in the mPFC as contrast to patients with OCD. The GM volumes of the mPFC in patients with GAD were negatively correlated with HAM-A scores. Our findings indicate that the mPFC volume abnormality may be associated with anxiety disorder in patients with GAD rather than OCD. This study would be useful to aid our knowledge to understand the differential neuropathology between OCD and GAD in terms of the regional volume alterations of GM and WM.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Clinical personality patterns and well-being at work in physicians working with life-threatening illnesses: Comparisons of clinicians and laboratory workers**

S. Khrushchev<sup>1\*</sup>, D. Vybornykh<sup>1</sup>, V. Barabanshchikova<sup>2</sup>, E. Rasskazova<sup>3</sup>, A. Tkhostov<sup>4</sup>

<sup>1</sup> National research center for hematology, laboratory of neurological and mental disorders in hematology, Moscow, Russia; <sup>2</sup> Lomonosov Moscow state university, the head of the laboratory of work psychology, Moscow, Russia; <sup>3</sup> Lomonosov Moscow state university, mental health research center, associate professor, senior researcher, Moscow, Russia; <sup>4</sup> Lomonosov Moscow state university, the head of clinical psychology department, Moscow, Russia

\* Corresponding author.

**Introduction.**– Although disruptive for functioning at work and well-being personality disorders often remain undiagnosed. Revealing risk groups is especially important in those working under stress like communicating with severe ill patients.

**Objectives.**– The aim was to reveal patterns of personality disorders related to well-being in clinicians and doctors working in laboratories.

**Methods.**– 180 doctors treating life-threatening illnesses (23.5% males, 84 clinicians and 96 lab workers) filled Millon Clinical Multiaxial Inventory III (Millon et al., 2009), Big Five Questionnaire – 2 (Caprara et al., 2007), Satisfaction With Life Scale (Diener et al., 1985), Work Engagement, Boredom at Work Scales (Schaufeli, Salanova, 2014), Maslach Burnout Inventory (Maslach et al., 1997). **Results.**– In both groups schizoid, avoidant, depressive, dependent, antisocial, aggressive, passive-aggressive and self-defeating personality patterns are related to burnout, boredom at work and dissatisfaction with life ( $r = .22-.60$ ) while dynamism, emotional and impulse control correlate to lower risk ( $r = .24-.62$ ). Histrionic and narcissistic patterns are associated with better well-being and lower burnout ( $r = -.20-.60$ ). Clinicians are more dominant, less scrupulous, demonstrate more histrionic and narcissistic and less avoidant, paranoid, schizotypal, self-defeating traits ( $F = 4.14-11.47$ ,  $P < .05$ ,  $\eta^2 = .02-.06$ ). Comparisons of correlations indicate that dynamism, perseverance, low schizoid traits are more important for well-being of lab workers while compulsive traits – in clinicians ( $P < .05$ ).

**Conclusions.**– Personality patterns predicting poor well-being are close in clinicians and lab workers but most of them are more prominent in lab workers indicating that both groups are targets for prevention programs.

**Funding.**– Research is supported by the Russian Foundation for Basic Research, project No. 17-06-00849.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Relationship between personality traits and mental health in athletes students**

S.J. MosaviAmiri<sup>1\*</sup>, R. GhaemiAmiri<sup>2</sup>, S.K. MousaviAmiri<sup>3</sup>

<sup>1</sup> Department of addiction studies, medical clinic of Dr. Mosavi, department of addiction studies, Amirkola, Iran; <sup>2</sup> Department of family studies, medical clinic of Dr. Ghaemim, Amirkola, Iran; <sup>3</sup> Department of family studies, medical clinic of Dr. Ghaemi, Amirkola, Iran

\* Corresponding author.

**Aim.**– The purpose of this study was to investigate relationship between personality traits and mental health in athletes students. This study was a descriptive and correlation design.

**Method.**– 60 athletes students were randomly selected and responded to NEO-PIR inventory and General Health Questionnaire (GHQ 28). NEO assesses five personality traits: Neuroticism (N), Extroversion (E), Agreeableness (A), Openness to new experience (O) and Conscientiousness (C), and GHQ assesses four dimensions: Somatic symptoms (A), Anxiety (B), Social withdrawal (C) and Depression (D). NEO assesses five personality traits: Neuroticism, Extroversion, Agreeableness, Conscientiousness, Openness to experience. The data were analyzed with Pearson correlation test.

**Results.**– The findings showed that there was positive significant correlation between neuroticism with somatic symptoms and depression, and negative significant correlation between extroversion, agreeableness, openness to new experience and conscientiousness with depression.

**Conclusion.**– Based on findings, it is concluded that physical exercises and sport plans have positive effects on mood and affect of students, and decrease physical and mental diseases in athletes students.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Comparison of pharmacological prescribing patterns of obsessive-compulsive disorder in Italy**

D. Marazziti<sup>1</sup>, F. Mucci<sup>1</sup>, B. Dell'Osso<sup>2</sup>, A. Tundo<sup>3</sup>, U. Albert<sup>4</sup>, A. Piccinni<sup>1</sup>

<sup>1</sup> Università di Pisa, Dipartimento di Medicina Clinica e Sperimentale, Pisa, Italy; <sup>2</sup> Università di Milano, Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, Milano, Italy; <sup>3</sup> Istituto di Psicopatologia, Roma, Istituto di Psicopatologia, Roma, Italy;

<sup>4</sup>Università di Torino, Dipartimento di Neuroscienze "Rita Levi Montalcini", Torino, Italy

\* Corresponding author.

**Introduction.**– Obsessive-compulsive disorder (OCD) is a debilitating neuropsychiatric disorder characterized by experiencing intrusive thoughts and/or carrying out repetitive and ritualized behaviors that are time consuming and invalidating. Despite its relative ease of diagnosis, OCD still remains underdiagnosed and/or not properly treated. Besides delayed therapeutic effect and treatment resistance, some therapeutic failures may be due to different prescribing practices.

**Objectives.**– The aim of the study was to investigate the psychopharmacological prescribing patterns in large sample of patients ( $n=1800$ ) recruited from four Italian centers specialized in OCD, in comparison to available national and international guidelines.

**Methods.**– The centers were asked to complete a specific data sheet questionnaire on patients' therapeutic status. Statistical analyses were carried out by SPSS.

**Results.**– Selective serotonin reuptake inhibitors were the most prescribed drugs in all centers, whereas clomipramine and other tricyclic antidepressants were mostly used in Rome and Pisa. Mood stabilizers were almost exclusively prescribed in Pisa, while atypical antipsychotics were often used in Pisa and in Milan.

**Conclusions.**– Although still following the available guidelines about pharmacological treatment of OCD, a slight but significant degree of variability emerges from the four main specialized centers in Italy possibly depending on the different educational background, the presence of comorbidities and the availability of other specific therapeutic strategies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Obsessive compulsive disorder among university students and its impact on academic achievement**

S. Ntyl<sup>1</sup>, T. Almuhaini<sup>1</sup>, M. AlAwaji<sup>1</sup>, E. Soliman<sup>2</sup>

<sup>1</sup> Fourth year medical student, CM, Princess Nourah Bint Abdelrahman University, Riyadh, KSA, College of Medicine, Riyadh, Saudi Arabia; <sup>2</sup> Assistant Professor of Psychiatry, College of Medicine, Princess Nourah Bint Abdelrahman university, Riyadh, KSA. Lecturer of Psychiatry, faculty of medicine, Zagazig university, Egypt, Psychiatry Department, Riyadh, Saudi Arabia

\* Corresponding author.

**Introduction.**– One of the overlooked psychiatric disorders in the adult is Obsessive Compulsive Disorder (OCD). The prevalence of OCD in Saudi Arabia is 1.2% and to date there are no solid figures about OCD among university students.

**Objectives.**– To estimate how frequent is OCD among university students in Saudi Arabia and to determine its effect on academic achievement.

**Materials and methods.**– Questionnaire based Cross sectional study was conducted among 771 consented university students. The questionnaire used included sociodemographic data and Florida Obsessive-Compulsive Inventory that consists of 20 questions divided in two parts. Part 1: Identifies common symptoms of OCD and was answered in the form of (yes or no) and the cutoff point was 5, part 2: measures the severity of symptoms of OCD according to Likert five response with a cutoff point of 8. A Grade Point Average (GPA) was used as objective summative assessment for students' performance.

**Results.**– The average age of participants was ( $20.9 \pm 1.63$ ) years. Most of them were females (78.9%), single (94.7%), Saudi (96.6%) and GPA was ( $4.095 \pm 0.661$ ). Students with OCD were (30%). It was found that OCD is more common in females ( $P=0.002$ ), younger age ( $P=0.01$ ). There's a significant relation between family history of some psychiatric disorder and occurrence of OCD (Anxiety,  $P=0.001$ ) and (ADHD,  $P=0.007$ ). Also, significant effect of OCD on academic achievement was reported ( $P=0.01$ ).

**Conclusion and recommendation.**– There is a high frequency of OCD among university students with different severities which impacted their academic achievement. Further confirmation by clinical interview is needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **How does perfectionism relate to psychological wellbeing? A study in Tunisian university students**

U. Ouali<sup>\*</sup>, Y. Zgueb, E. Akrimi, A. Ouertani, F. Nacef Razi Hospital, Psychiatry A, La Manouba, Tunisia

\* Corresponding author.

**Introduction.**– Perfectionism is a multidimensional construct, with some dimensions being adaptive (perfectionistic strivings) and others maladaptive (perfectionistic concerns). The majority of studies on perfectionism was conducted in Western and East Asian societies, whereas few research on this topic exists in Arab societies.

**Objectives.**– The aim of our study was to explore perfectionism and its relationship with psychological wellbeing in a Tunisian student sample.

**Methods.**– This is a cross-sectional study conducted in April 2016 on a sample of students from Tunis-El Manar University. Students filled in the Revised Almost Perfect Scale (Short form) (SAPS) and the Depression, Anxiety and Stress Scale (DASS 21), as well as a questionnaire containing socio-demographic and clinical variables. Statistical analysis was performed using SPSS 20.

**Results.**– Our sample consisted of 416 students with a mean age of 22.5 years. 23% of the sample had an adaptive perfectionism, whereas 20,1% had a maladaptive perfectionism and 30% had a mixed adaptive/maladaptive perfectionism. Students presenting with maladaptive and mixed adaptive/maladaptive perfectionism were more prone to stress, anxiety and depression than their non-perfectionistic counterparts and students with adaptive perfectionism. A history of psychiatric disorder, mostly depression and anxiety disorders, was found in 7.2% of students. However, there was no relationship between perfectionism and psychiatric disorder.

**Conclusion.**– More than half of the students had maladaptive perfectionistic traits which seem to have a negative impact on the students' psychological wellbeing. These findings underline the need for specific psychoeducational measures and psychological counseling at universities.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Theory of mind and self-injury in borderline personality disorder

B.O. Plasencia García de Diego<sup>1\*</sup>, F. Gotor Sánchez-Luengo<sup>2</sup>, S.L. Romero Guillena<sup>3</sup>, O. Santamaría Gómez<sup>2</sup>, R. Navarro Pablo<sup>2</sup>  
<sup>1</sup> De la Merced Hospital-Osuna, Department of Psychiatry, Seville, Spain; <sup>2</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Seville, Spain; <sup>3</sup> U.S.M.C "Carmona" U.G.C Salud Mental Virgen Macarena Hospital, Department of Psychiatry, Seville, Spain  
 \* Corresponding author.

**Introduction.**– Theory of mind (ToM) is an important area of social cognition. ToM impairments have been associated with difficulties in interpersonal relationships and disruptive behaviours in patients with borderline personality disorder (BPD) [1].

**Objective.**– To analyze the correlation between ToM and the number of suicide. As well as determining whether impulsivity and depersonalization are potential confounding factors.

**Methods.**– 22 patients with a diagnosis of BPD (DSM-5 criteria) were included.

ToM was assessed using the revised version of the Reading the Mind in the Eyes Test (REMET).

Impulsivity was assessed using the Barrat Impulsivity Scale (BIS) total score and depersonalization levels using the Cambridge Depersonalization Scale (CDS)

**Results.**– The mean age was 25.91 years ( $\pm 7.20$ ). The mean number of suicide attempts in the last two years was 3.09 ( $\pm 2.30$ ).

We found:

– A strong correlation ( $r = -0.701$ ;  $P < 0.001$ ) between the number of suicide attempts and REMET. Both variables are linearly related and this relationship is indirect.

– No correlation between: the number of attempts and the BIS ( $r = 0.273$ ) and the number of attempts and the CDS ( $r = 0.170$ ).

When performing the multivariate analysis, the correlation with REMET is confirmed ( $\beta_1 = -0.632$ ;  $CI = -0.88$ ;  $-0.37$ ).

**Conclusions.**– There is a strong association in our work between poorer performance in ToM and a greater number of suicide attempts, not finding impulsivity and depersonalization symptoms to be potential confounding factors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Cognitive, emotional and communicative mechanisms of mentalization impairment in schizotypal disorder

E.T. Sokolova, K.O. Andreyuk, A. Ryzhov\*  
 Lomonosov MSU, Faculty of Psychology, Moscow, Russia  
 \* Corresponding author.

**Introduction.**– The development and functioning of mentalization, defined as the ability to represent internal states and intentions broadly depends on the relationships with important others. The objective of this study was to investigate the underlying mechanisms of the influence of destructive forms of communication and manipulateness on mentalization capacity.

**Methods.**– 40 patients with schizotypal disorders (F21) were compared to 40 controls. Mentalization quality was measured on basis of TAT narratives with the use of Social Cognition and Object Relations Scales (SCOR-S, Westen 1985). Manipulative tendencies were measured by a modified MACH-IV scale (Christie, 1970, Znakov, 2002).

**Results.**– The comparative analysis of means found significant differences (Mann-Whitney) between groups in three components of mentalization: complexity of representations of people ( $U = 281,500$ ,  $P < .01$ ), emotional investment ( $U = 594,500$ ,  $P < .05$ ), and understanding of social casualty ( $U = 292,000$ ,  $P < .001$ ). This points to the predominance in schizotypal subjects of the difficulties of representation of internal reality, reflected in a low differentiation and integration of images of people, lack of emotional response to other's feelings, logical errors and inconsistencies in explanation of causal relations between observable behavior and internal states. The regression analysis indicates causal relationship between manipulative tendencies and emotional investment aspect of mentalization ( $b = -.333$ ,  $P < .01$ ), with significant negative correlation: the higher is machiavellism, the lower is the emotional responsiveness.

**Conclusions.**– Mentalization ability manifests a significantly higher degree of impairment in schizotypal group than in normal controls, and high levels of machiavellism can be regarded as a predictor of decrease of emotional investment aspects of mentalization functions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0616

### The relationship between the level of insight and cognitive functions in obsessive compulsive disorder

Y. Satan<sup>1\*</sup>, M. Sahingoz<sup>2</sup>, E. Yilmaz<sup>3</sup>, A.A. Dagistan<sup>4</sup>  
<sup>1</sup> Konya Numune State Hospital, Psychiatry, Konya, Turkey; <sup>2</sup> Necmettin Erbakan University, Department of Psychiatry-Merem Faculty of Medicine, Konya, Turkey; <sup>3</sup> Osmaniye State Hospital, Psychiatry, Osmaniye, Turkey; <sup>4</sup> Konya Konya Training and Research Hospital, Psychiatry, Konya, Turkey  
 \*Corresponding author.

**Objective.**– The aim of this study is to evaluate the relationship between the level of insight and cognitive functions in obsessive compulsive disorder.

**Materials and methods.**– In our study the Stroop Test, Cancellation Test, WAIS-R Number Sequencing subtests, Line Orientation Test, and the AVLT were used to evaluate cognitive functions like attention and memory, visual-spatial functions and executive functions like response inhibition and resistance to interference.

**Results.**– It was found that the patients with OCD performed significantly worse than the control group in all the areas except for executive functions like response inhibition and interference affect and some of the attention areas. When all the results of the neuropsychological tests given to patients with a high level of insight, patients with a low level of insight, and to the healthy control group were evaluated, it was seen that while the patients with a high level of insight performed significantly worse in the attention, visual-spatial functions, and verbal working memory areas, those with a low level of insight performed significantly worse in almost all areas than the healthy control group. Further, when the neuropsychological test results of patients with a high level of insight and patients with a low level were compared, it was found out that there was no statistically significant difference between them except for long-term memory and verbal learning areas.

**Conclusion.**– Moreover, the fact that OCD patients with a low level of insight have more severe impairment in neuropsychological performance suggests that this group presents different neurobiological characteristics than patients with no problem of insight.

**Keywords:** Cognitive functions; Insight; OCD

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Caregiver Burden and associated risk factors in relatives of patients with obsessive compulsive disorder

D. Suculluoglu Dikici<sup>1\*</sup>, E. Eser<sup>2</sup>, F.P. Çökmüş<sup>3</sup>, M.M. Demet<sup>4</sup>

<sup>1</sup> Manisa Mental Health and Disease Hospital, psychiatry, Manisa, Turkey; <sup>2</sup> Manisa Celal Bayar University Hospital, Public Health, Manisa, Turkey; <sup>3</sup> Nazilli State Hospital, Psychiatry Clinic, Aydın, Turkey; <sup>4</sup> Manisa Celal Bayar University Hospital, Psychiatry, Manisa, Turkey

\* Corresponding author.

**Introduction.**– Obsessive compulsive disorder (OCD) is chronic disease that affects family and social relationships, occupational and academic performance for both the patients and their relatives due to cognitive, emotional and behavioral aspects of the disease. There are few studies available in the literature regarding causality of burden in relatives of patients with Obsessive-Compulsive Disorder [1].

**Objective.**– We aimed to evaluate disease burden in caregivers of patients with OCD and factors that negatively affect their lives.

**Methods.**– Study population was consisted of sixty-eight patients with OCD and their caregivers. Structured Clinical Interview for DSM-IV /Clinical Version (SCID-I/CV), Yale-Brown obsessive-compulsive scale (Y-BOCS), Y-BOCS symptom checklist, Hamilton depression rating scale (HDRS) and World Health Organization quality of life questionnaire brief form (WHOQOL-BREF-TR) were completed by the patients whereas SCID-I/CV and burden assessment scale (BAS) by the caregivers. The dependent variables is “burden in caregivers”. Student's t test, MWU, ANOVA, Kruskal Wallis ANOVA and Pearson or Spearman's correlations where appropriate; multiple linear regression were run in multivariate analyses. Type 1 error was taken as 0.05 in the analyses.

**Results.**– We found that patient's gender, patient's occupational status, YBOCS obsession scores, YBOCS compulsion scores and patient's WHOQOL-Bref environmental dimension scores are significant predictor in the OCD caregiver's burden ( $P < 0.05$ ).

**Conclusion.**– Perceived burden was affected by severity of the disease and lower socioeconomic level.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Psychoeducation for bipolar affective disorder

T. Abreu<sup>\*</sup>, G. Oliveira

Centro Hospitalar do Tâmega e Sousa,

Department of Psychiatry and Mental Health, Penafiel, Portugal

\* Corresponding author.

**Introduction.**– Bipolar Affective Disorder (BD) is a chronic disease with a major impact on patients' functioning and quality of life. Psychosocial interventions have been a great investment as adjunctive treatment for BD. One of these interventions is Psychoeducation, which intends to educate people with mental disease about the disorder, its treatment and rehabilitation.

**Objective.**– The present work intends to gather information about the effectiveness of Psychoeducation for BD.

**Method.**– The authors conducted a literature review on PubMed database for publications on Psychoeducation use in BD adult population, published between January 2010 and March 2017.

**Results and discussion.**– Different approaches are found in literature, mainly, group Psychoeducation for BD patients and group Psychoeducation for BD patients' families and caregivers. Interest in online Psychoeducation programs has been clearly increasing in the last years. Combining Psychoeducation with other psychosocial interventions has also been common, namely, with Cognitive-Behavioural Therapy. Different studies and meta-analyses had different conclusions, but in general, Psychoeducation improved medication adherence, reduced manic symptoms and increased global functioning. Results are more controversial regarding the reduction of relapse rates: some studies concluded that Psychoeducation reduced both poles relapse rates; other concluded that it had no effect on depressive relapses. In addition, a quite recent meta-analysis concluded that only interventions for family members affected relapse rates.

**Conclusion.**– Overall, Psychoeducation has revealed to be a very useful tool in the treatment of BD, whether it is used alone or in combination with other interventions and techniques.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Mixed bipolar disorder: Among 173 bipolar type 1 patients

A. Ben Haouala<sup>1</sup>, B. Amamou<sup>2</sup>, A. Mhalla<sup>1</sup>, L. Gaha<sup>1</sup>  
<sup>1</sup> Fattouma Bourguiba University Hospital, psychiatry, Monastir, Tunisia; <sup>2</sup> university hospital of Monastir, research laboratory vulnerability to psychosis, faculty of medicine of Monastir, university of Monastir, Tunisia, psychiatry, Monastir, Tunisia  
 \* Corresponding author.

**Introduction.**– Mixed Bipolar Disorder is characterized by both mania and depression simultaneously or in quick sequence.

**Objective.**– To determine the prevalence and characteristics of type I bipolar patients with mixed episodes.

**Methodology.**– This is a retrospective cross-sectional descriptive study, including all patients hospitalized for bipolar disorder type I from January 2008 to December 2015 using a pre-established form.

**Results.**– Our study involved 173 bipolar type 1 patients. 32 of them presented at least one mixed episode which corresponds to 18.5% with an average number of mixed episodes equal to  $2 \pm 1.5$ , a minimum of 1 and a maximum of 7. The mean age of our group was  $46.4 \pm 12.7$  years. 65.6% was men. The average age of onset of the disease is  $27 \pm 10$  years. The 1st episode was depressive in 46.9% ( $n = 15$ ) and mixed in 9.4% ( $n = 3$ ). The recurrence frequency of manic episodes was  $5.6 \pm 4.91$  and the frequency of mixed episodes was  $2.03 \pm 1.6$  with a maximum of 7. A dominant polarity of the manic type was found in 75% compared to 25% of depressive type. Almost all of our patients were under mood-stabilizer associated with antipsychotic. Antidepressants were prescribed in 25% of patients ( $n = 8$ ). The appearance of mixed episodes was associated with the manic polarity ( $P = 0.001$ ) and the prescription of antidepressants ( $P = 0.002$ )

**Conclusion.**– Our study shows some specificity in bipolar disorder with mixed episodes which requires further replication in independent samples.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The relationship between clinical and sociodemographic factors and suicidal behaviour in bipolar disorder

C.V. Berende<sup>1</sup>, R. Paunescu<sup>2</sup>  
<sup>1</sup> Emergency County Hospital, Psychiatry, Cluj-Napoca, Romania;  
<sup>2</sup> University of Medicine and Pharmacy "Iuliu Hatieganu", Neurosciences, Cluj-Napoca, Romania  
 \* Corresponding author.

**Introduction.**– Studies have shown that bipolar disorder is associated with a higher frequency of attempted suicide and suicidal ideas than other psychiatric disorders. It has also been proven that several clinical and sociodemographic characteristics have been associated with suicide attempts in bipolar patients.

**Objective:** The aim of the following study was to assess the relationship between suicidal thoughts and attempts and clinical and sociodemographic characteristics in bipolar patients.

**Material and method.**– This is a retrospective study that included 200 bipolar patients admitted in the Psychiatry Department of the Emergency County Hospital in Cluj-Napoca, Romania from 2012–2017. Clinical and demographic data were collected from patients' files. Inclusion criteria: patients diagnosed with Bipolar Disorder, manic (group A), mixed (group B) or depressive (group C) episode.

**Results.**– Significant correlation between gender and the incidence of suicidal attempts was revealed. Female bipolar patients had 12 times more suicidal attempts compared to male patients. The prevalence of suicidal thoughts was approximately 30% for female patients and 22% for male patients. There were no significant differences between group A, B and C regarding age of admission. There was a significant difference within the 3 groups regarding the incidence of suicidal thoughts and attempts. There was a significant difference between the number of co-morbidities and suicidal attempts.

**Conclusions.**– Suicidal behaviour in bipolar disorder is associated with female gender, older age, psychotic symptoms and increased number of co-morbidities.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0621

### Efficacy and tolerability of Quetiapine-Valproate combination therapy in the treatment of bipolar depression

S. Bise<sup>1</sup>, I. Lokmic-Pekic<sup>2</sup>, G. Sulejmanpasic<sup>3</sup>, A. Hrnjica<sup>1</sup>  
<sup>1</sup> Psychiatric Hospital, women, Sarajevo, Bosnia, Herzegovina;  
<sup>2</sup> Psychiatric Hospital, intensive care, Sarajevo, Bosnia, Herzegovina;  
<sup>3</sup> Clinical center University of Sarajevo, Psychiatric clinic, intensive care, Sarjevo, Bosnia, Herzegovina  
 \* Corresponding author.

**Introduction.**– The treatment of bipolar disorder (BD) in the depressed phase is complicated by a tendency for conventional antidepressant drugs to worsen the course of the illness. Quetiapine was approved for the treatment of depressive episodes in patients diagnosed with BD. Antidepressant efficacy valproate, which is an effective treatment for the manic phase of bipolar disorder, is of considerable interest.

**Objectives.**– To investigate the efficacy and tolerability of combination therapy quetiapine and valproate in the treatment of the bipolar depression.

**Method.**– Eight patients (23 to 65 years old) participated in this study with a diagnosis of BD, depressed phase. Patients were treated with the combination of valproate (range 900–1500 mg/day) and quetiapine (range 300–450 mg/day). Outcome measures included the Hamilton Anxiety Scale (HAM-A), as the primary outcome measure, as well as the Hamilton Rating Scale for Depression-17 item (HAM-D17) and the Clinical Global Impression-Severity subscale (CGI-S). Clinical status was evaluated at baseline and at the 4 and 8 week.

**Results.**– At 8 weeks, there was a statistically significant ( $P < 0.001$ ) clinical improvement for both the depressive and anxiety symptoms for all patients. The biggest decreases on the Ham-D occurred on the subscales of agitation, somatic anxiety, psychologic anxiety. Significant improvements were noted on the CGI scores.

**Conclusion.**– Quetiapine and valproate combination is an effective in the reducing the symptoms of depression and anxiety in the treatment BD, depressed phase, provides greater improvement and it appears to be safe with a lower risk of metabolic syndrome, without increased risk of adverse effects.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Bipolar affective disorder: “Reading the mind in the eyes” and social functioning

G. Bulat<sup>1</sup>, A.C. Bredicean<sup>2</sup>, Z. Popovici<sup>1</sup>

<sup>1</sup> “Eduard Pamfil” Psychiatry Clinic of Timisoara, Romania, Psychiatry, Timisoara, Romania; <sup>2</sup> “Eduard Pamfil” Psychiatry Clinic of Timisoara, Romania, Discipline of Psychiatry, Department of Neuroscience, “Victor Babes” University of Medicine and Pharmacy, Timisoara, Romania, Psychiatry, Timisoara, Romania

\* Corresponding author.

**Introduction.**– Patients with bipolar disorder show an impaired judgment in recognizing facial emotions. This aspect is very important in interpersonal communication.

**Objectives.**– We want to check whether socio-demographic and clinic parameters influence the level of social functioning and the relationship between reading the mind in the eyes and social functioning.

**Methods.**– We selected 40 subjects with bipolar disorder in accordance with the ICD 10 criteria. Socio-demographic parameters were analyzed: gender, age, educational level, marital status, profession and the number of episodes throughout disease progression. The tests applied were “reading the mind in the eyes” and the social functioning scale (SFS).

**Results.**– Most subjects have a low ability to interpret a person’s gaze. The most recognizable emotion of subjects is ‘Dreaming’ and the most difficult to identify was ‘Rage’. The ability to recognize the emotion of ‘Joy’ and ‘Love’ correlates with the ability to communicate ( $P < 0.05$ ), to relax ( $P < 0.05$ ) and especially to perform social activities ( $P < 0.05$ ) but also the ability to live an independent life ( $P < 0.05$ ). There are statistically significant direct correlations between the schooling level and the level of social activity ( $P < 0.05$ ) and independence ( $P < 0.05$ ). In our group of patients there are statistically significant correlations of the opposite sense between the number of episodes of disease and all items of the SFS scale.

**Conclusion.**– The ability to recognize the emotions of ‘Joy’ and ‘Love’ in patients with bipolar affective disorder correlates with social functioning. The socio-demographic and clinical settings influence the level of social functioning.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0623

### Blood-brain barrier dysfunction may be predictive of neuroprogression in bipolar disorder

C. Calkin<sup>1</sup>, L. Kamintsky<sup>2</sup>, K. Cairns<sup>3</sup>, M. Ruzickova<sup>1</sup>, M. Schmidt<sup>4</sup>, C. Bowen<sup>5</sup>, A. Friedman<sup>2</sup>

<sup>1</sup> Dalhousie University, Psychiatry, Halifax, Canada; <sup>2</sup> Dalhousie University, Medical Neurosciences, Halifax, Canada; <sup>3</sup> Nova Scotia Health Authority, Psychiatry, Halifax, Canada; <sup>4</sup> Dalhousie University, Neuroradiology, Halifax, Canada; <sup>5</sup> Dalhousie University, Health Physics, Halifax, Canada

\* Corresponding author.

**Background.**– In previous studies we found that insulin resistance (IR) and type-2 diabetes (T2D) are associated with a more chronic course of bipolar disorder (BD), poor response to mood stabilizing treatment, cognitive impairment and adverse changes in brain structure and chemistry. These findings suggest that metabolic state and IR-comorbidities, such as microvascular pathology and related blood-brain barrier dysfunction (BBBD), may play a role in the “neuroprogression” of BD. Indirect evidence of BBBD (serum/CSF markers or post-mortem tissue analysis) has been

reported in both psychiatric and neurodegenerative pathologies, yet our recent advances in magnetic-resonance imaging (MRI) analysis now present a unique opportunity to characterize and quantify BBBD in living patients with BD.

**Objective.**– Test the hypothesis that neuroprogression and pharmacoresistance in bipolar patients with IR are associated with microvascular pathology in the brain.

**Methods.**– Dynamic contrast-enhanced MRI (DCE-MRI) was used to compare BBB permeability between bipolar patients with and without IR (BD+IR, BD-IR) and healthy controls ( $n = 6$  per group).

**Results.**– We found that BD+IR patients have significantly higher volumes of BBB-disrupted brain tissue, compared to both control and BD-IR groups ( $P < 0.01$ ). Interestingly, BBBD in BD+IR patients was found to involve specific brain regions, primarily left-temporal and medial-frontal cortices.

**Conclusions.**– Our novel BBB permeability imaging and analysis technique may reveal a specific brain network predictive of BD neuroprogression in a subset of patients. Moreover, the robust nature of the BBBD assessment approach allows us to re-quantify BBBD and test the efficacy of new microvascular-targeting treatments for pharmacoresistance in BD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0624

### Relationship style in major depression and bipolar types I and II

T. Cassis<sup>1</sup>, A. Do, M. Saint Laurent, P. Cervantes, N. Low  
Institute of research - McGill University Health Center, Psychiatry, Montreal, Canada

\* Corresponding author.

**Background.**– Relationship style can influence the patient-physician relationship, adherence to treatment recommendations and course of illness. Insecure attachment styles are more prevalent in individuals with mood disorders and has been associated with worse clinical outcomes, whereas a secure attachment is linked to more positive health behaviours, such as greater adherence to health plans and preventive health behaviours.

**Aim.**– To examine the prevalence of close relationship/attachment styles in patients with major depression (MDD), bipolar type I (BPI) or bipolar type II (BPII).

**Methods.**– 219 participants were recruited from the Mood Disorders Program of the McGill University Health Center in Montreal, Quebec. Mood diagnoses were determined using the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID). Relationship/attachment styles were assessed using the Experiences in Close Relationships Questionnaire, anxious and avoidant attachment styles were examined. One-way ANOVA and Tukey post-hoc tests were conducted to examine the prevalence of attachment styles within each diagnostic group.

**Results.**– The prevalence of anxious attachment differed in the MDD, BPI and BPII groups ( $F(2, 180) = 5.652, P = .004$ ). There was no difference in prevalence of avoidant attachment style between the groups. Post-testing revealed that the BPII ( $4.5 \pm 1.31$ ) scored significantly higher than the BPI group ( $3.73 \pm 1.25, P = .003$ ).

**Conclusion.**– Bipolar type I and type II groups may develop different type of relationships with their treatment team as a consequence of their attachment patterns. Modification of treatment approaches may be warranted.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Diabetes mellitus and insulin resistance affect the clinical presentation of bipolar disorder

G. D'Agostino<sup>1</sup>, L. Steardo<sup>1</sup>, M. Fabrazzo<sup>1</sup>, G. Del Buono<sup>2</sup>, G. Cascino<sup>1</sup>, L. Perna<sup>2</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy; <sup>2</sup> University of Salerno, Department of Medicine and Surgery, Section of Neurosciences, Salerno, Italy

\* Corresponding author.

**Introduction.**– Bipolar disorder (BD) is associated with significant medical comorbidity, especially type 2 diabetes mellitus (T2D). Medical comorbidity may affect the course, the prognosis and the response to pharmacological treatments of BD patients.

**Objectives.**– Our study aimed to investigate the clinical characteristics of BD patients with T2D or with insulin resistance (IR) compared to euglycemic BD patients.

**Methods.**– We recruited 90 patients with BD. According to their glycemic status, they were divided into three groups: those with T2D (glycemia > 7 mmol/L), those with IR (HOMA index  $\geq$  1.88) and those with normal glucose metabolism. Clinical characteristics and anamnestic data were recorded through ad hoc clinical interviews. The response to pharmacological treatments was assessed retrospectively by the Alda scale.

**Results.**– 19.5% of BD patients had IR, 35.6% had T2D, and 44.8% were euglycemic. Compared to euglycemic BD patients, those with T2D or IR were significantly older ( $P=0.002$ ), had an older age at onset of the illness ( $p=0.04$ ) and higher values of body mass index and triglyceridemia. Moreover, BD patients with T2D or IR were less responsive to mood stabilizer treatment than euglycemic patients. No significant differences emerged among the 3 groups in the course of the BD, number and types of affective episodes, number of previous hospitalization.

**Conclusions.**– These findings suggest that the presence of comorbid T2D or IR may impair the response to mood stabilizers in BD and is associated to specific metabolic abnormalities, which may affect the prognosis of the disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Evaluation of executive functions in bipolar disorder

G. Hamdi\*, H. Ben Ammar, N. Smari, R. Nefzi, Z. El Hechmi  
Razi Hospital, F, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– The executive functions correspond to high level functions operating in complex situations. The function of the executive system is to facilitate the adaptation of the subject to new situations. The aim of our study was to evaluate executive functions in euthymic bipolar patients.

**Subjects and methods.**– A cross-sectional study was conducted among 50 euthymic bipolar patients and 50 healthy volunteers matched for age, sex and educational level. The evaluation of the executive functions was based on validated scales: The Stroop Test, the Wisconsin Card Sorting Test (WCST), Trail Making Test A (TMT-A) and phonemic verbal fluency.

**Results.**– The assessment by the Stroop test revealed an average completion time of the boards B and C significantly prolonged in bipolar patients compared to controls. The inhibition index was 60.70 + 58.53 seconds in bipolar patients versus 38.1 + 26.54 in controls ( $P=0.01$ ). We found no significant link between average scores

at the Stroop test among bipolar patients and the different socio-demographic or clinical characteristics.

Bipolar patients took significantly more time than the controls for passing the card sorting test, with a larger number of errors ( $P=0.001$ ).

At the phonemic fluency test, the average number of correct words generated during 60 seconds was significantly higher in the controls group ( $P=0.018$ ).

**Conclusion.**– This study has shown an impairment of executive functions among stabilized bipolar patients which explains the difficulties those subjects face to adapt to new situations.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0627

### Evaluation of attention among bipolar patients

G. Hamdi\*, H. Ben Ammar, R. Nefzi, N. Smari, Z. El Hechmi  
Razi Hospital, F, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– There are several forms of attention: selective attention, which allows the extraction of relevant information from a set of stimuli, sustained attention to maintain an interest in relevant information; and divided attention responsible for the coordination between two tasks.

The objective of this work was to evaluate attention in stabilized bipolar patients by comparing them to a control group.

**Subjects and methods.**– A case-control study was led with 50 euthymic bipolar patients and 50 healthy volunteers matched for age, sex and educational level. The study of attentional abilities has been done with the ZAZZO test and Letter Digit Substitution Test (LDST).

**Results.**– The score established at the LDST was significantly higher in the controls group ( $P=0.008$ ). The LDST score was correlated with a good educational level among the bipolar group ( $P=0.044$ ).

Assessment by the double Zazzo test showed better scores in controls in both events ( $1 P<0.001$ ,  $P=0.039$  2).

We did not notice any significant association between the different Zazzo test scores and the socio-demographic or clinical factors among patients followed for bipolar disorder.

**Conclusion.**– This work showed significant impairment of attention in euthymic bipolar patients compared to healthy subjects with a negative impact on their social performance.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0628

### Creactive protein during cognitive impairments in bipolar disorder

G. Hamdi\*, H. Ben Ammar, R. Nefzi, Z. Elhechmi  
Razi Hospital, F, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– The role of the immuno-inflammatory system in triggering cognitive decline in BD patients arouses interest in immuno-psychiatric research. The aim of this work was to evaluate the association between serum levels of high-sensitivity C-reactive protein (hs-CRP), as a marker of chronic inflammation, and cognitive disorders in a cohort of bipolar patients during remission.

**Methods.**– A cross-sectional case-control study was conducted in 50 subjects with bipolar disorder, in clinical remission, and in 50 voluntary and healthy control subjects. The evaluation focused

on cognitive characteristics and the hs-CRP level determined by immunoassay.

**Results.**– Cognitive functioning was significantly more impaired in patients with BD during remission than control subjects. However, the average scores of the span of the figures evaluating the working memory did not show a significant difference between the two groups. A significant increase in mean serum hs-CRP level was observed in patients compared to controls. The analytical study of the relationship between the average hs-CRP level and the mean scores of the various neuropsychological tests in patients with BD revealed that the mean hs-CRP level was significantly associated with cognitive impairment, based on the HVLT inhibition index ( $P=0.011$ ), and with the executive functions based on the Stroop test inhibition ( $P<0.05$ ).

**Conclusions.**– Cognitive impairments in bipolar disorder seem to be associated with a state of chronic inflammation. This should make it possible to consider controlled randomized trials evaluating the interest of anti-inflammatory drugs in the management of cognitive decline associated with bipolar disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Mitochondrial respiration in patients with bipolar disorder

J. Hroudová<sup>1</sup>, Z. Fišar<sup>1</sup>, L. Kališová<sup>1</sup>, E. Kitzlerová<sup>1</sup>, A. Lambertová<sup>1</sup>, M. Zvěřová<sup>1</sup>, H. Hansíková<sup>2</sup>, J. Raboch<sup>1</sup>

<sup>1</sup> Charles University, Department of Psychiatry, Prague, Czech Republic; <sup>2</sup> Charles University, Department of Pediatrics and Adolescent Medicine, Prague, Czech Republic

\* Corresponding author.

Our research is focused on extension of knowledge related to pathophysiological processes of bipolar affective disorder (BAD). Changes in the activities of compounds of intracellular signaling pathways are studied with the aim of discovering new biological markers of mood disorders or predictors of response to pharmacotherapy, which can be easily examined in blood samples. The aim of our study is to find out association between changes in energy metabolism, different episodes of BAD and pathophysiological processes associated or provoking BAD.

Analyses were examined in patients suffering from BAD (in period of mania, depression, remission) and compared to controls. Clinical evaluation of BAD was provided by clinicians using diagnostic scales. Mitochondrial respiration was examined in blood platelets using oxygraph; enzyme activities were measured spectrophotometrically.

Results from spectrophotometric measurements correlate with respirometry measurements. Complex-I linked respiration was found increased in patients in mania and in remission compared to healthy controls. Increased complex I activity and decreased complex II activity were observed in BAD patients in episodes of mania, depression and remission. Decreased complex IV activity was observed in BAD patients suffering from depression in comparison to controls.

It can be presumed that decrease in complex II activity is caused by adaptive mechanisms as a result of increased complex I activity. Achieved results support the hypothesis that energy metabolism in blood platelets of BAD patients differs from healthy controls. Different episodes of BAD had no effect on measured mitochondrial parameters.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Acknowledgement.**– Supported by Ministry of Health of the Czech Republic, grant no. 15-28616A.

Serbsky, Therapy of mental disorders, Moscow, Russia

\* Corresponding author.

**Introduction.**– Pharmacotherapy of depressive episodes in bipolar II disorder (BD II) is a subject of discussions. There are no direct randomized comparative studies of different medications.

**Objectives.**– Comparative efficacy and safety of sertraline, agomelatine, valproate and sertraline + valproate in depression in BDII.

**Methods.**– 89 depressive patients (total score HDRS  $\geq 17$ , CGI score  $\geq 3$ ) with BD II diagnosis, 18–65 years old (average  $38 \pm 2.5$  years), disease duration  $\geq 2$  years, were randomized into 4 groups: agomelatine ( $n=28$ ); sertraline ( $n=20$ ); valproate ( $n=21$ ); valproate + sertraline ( $n=21$ ). Rating scales were assessed at the screening and every week of therapy. The main efficacy measures were the rates of response (50% score reduction in HDRS) and remission (total HDRS score  $< 7$ ).

**Results.**– 72 patients completed the study. The reasons for the premature discontinuation: mood switches to hypomania – 1 (3.6%) for agomelatine, 4 (20%) for sertraline, 1 (5%) – suicide attempt in the combination therapy group, adverse events – 1 (3.6%) for agomelatine, 3 (14.3%) for valproate, 4 (20%) for combination, lack of efficacy – 3 (10.7%) for agomelatine.

At the end of the study the number of responders was: sertraline – 65%, agomelatine – 42.9%, valproate – 57.1%, combination – 60% (N/S); number of remitters: combination – 45%, valproate – 33.3%, agomelatine – 32.1%, sertraline – 20% (N/S). The differences in adverse events frequency between groups were N/S.

**Conclusions.**– Efficacy and tolerability were comparable in all therapeutic groups with some advantage of valproate + sertraline combination, providing the lowest level of mood switches.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Neurocognitive subgroups in bipolar disorder: Association with subjective cognitive measure

F. Lima<sup>1</sup>, F. da Ponte<sup>1</sup>, D. Martins<sup>2</sup>, M. Reinares<sup>3</sup>, B. Sole<sup>3</sup>, E. Vieta<sup>3</sup>, A. Rosa<sup>4</sup>

<sup>1</sup> Universidade Federal do Rio Grande do Sul, psychiatry and behavioral sciences, Porto Alegre, Brazil; <sup>2</sup> Hospital de Clínicas de Porto Alegre, laboratory of molecular psychiatry, Porto Alegre, Brazil; <sup>3</sup> Universitat de Barcelona, bipolar disorders program, Barcelona, Spain; <sup>4</sup> Universidade Federal do Rio Grande do Sul, pharmacology, Porto Alegre, Brazil

\* Corresponding author.

**Introduction.**– Significant cognitive function heterogeneity has been found in bipolar disorder (BD), with some patients ranging from unimpaired to severely impaired.

**Objective.**– To investigate the profile of cognitive function in bipolar patients, as well as to compare subjective cognitive function, clinical and demographical characteristics between groups.

**Methods.**– Patients older than 18 years who met DSM IV-TR criteria for BD, and were euthymic (YMRS and HDRS  $\leq$  7) were included. Healthy controls (HC) without current or past psychiatric history, and no first-degree relatives with bipolar or psychosis diagnoses also were recruited.

Comprehensive neuropsychological assessment was performed. Patients' raw scores on neuropsychological tests were standardized to z-scores based on the performance of the HC.

Cognitive Complaints in Bipolar Disorder Rating Scale (COBRA) was used as a subjective cognitive measure.

Hierarchical cluster analysis was conducted to determine whether there were specific groups based on neurocognitive patterns. Subsequently, we compared subgroups on subjective cognitive measure, demographic and clinical variables.

**Results.**– Table 1 and Fig. 1 not supplied.

**Conclusion.**– The present findings, in line with previous studies, detected three neurocognitive subgroups. Interestingly, the globally impaired subgroup was characterized by lower subjective cognitive complaints than intact group. These results may indicate the lack of insight of this specific subgroup, suggesting a possible explanation for the poor correlation between subjective-objective cognitive measures in BD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0632

### **Association between family history of bipolar disorder and therapeutics characteristics of bipolar disorder in the offspring**

H. Maatallah\*, R. Dammak, F. Amdouni, I. Berrahal, A. Feki, W. Cherif, M. Cheour

Razi Hospital, F, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– The age at onset of bipolar disorder varies greatly in different countries and continents. The association between load of family history of mood disorder and clinical evolution has not been adequately explored.

**Objectives.**– To compare therapeutics characteristics of bipolar disorder (BD) in patients with and without a family history of bipolar disorder.

**Methods.**– Two-hundred DSM-V BD patients were included. They were divided between those with family history of bipolar disorder FHBD ( $n = 80$ ) and without FHBD ( $n = 120$ ). We compared these two groups on clinical and therapeutic variables.

**Results.**– BD patients with FHBD presented an early onset of the mood disorder and more psychiatric hospitalizations than BD patients without FHBD. Furthermore, BD patients reporting family history of this disorder showed a worse therapeutic profile with poor compliance, irregular follow up and polypharmacy medication.

**Conclusion.**– These findings may help to identify the offspring of BD patients as patients with risk for particular manifestations of bipolarity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0633

### **May serum uric acid levels help us distinguish between bipolar and unipolar depression? – An exploratory study**

P. Oliveira\*, M. Coroa, J. Ribeiro, N. Madeira

Coimbra hospital university centre, psychiatry department, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Recent studies have found a correlation between serum uric acid (UA) levels and the mood disorder diagnosed, with lower UA levels found in unipolar disorder and higher levels in bipolar disorder (BD).

**Objectives.**– Assess if serum UA levels in patients admitted for unipolar depression can predict later evolution to BD.

**Methods.**– We retrospectively analyzed UA levels in patients hospitalized in our Psychiatry Department with a diagnosis of depressive disorder over a 3-year period (June/2006 to June/2009), including all patients who had an UA measurement.

Patients above 40 years old, with conditions and taking medications that alter UA levels were excluded. We subsequently identified the patients who received the diagnosis of BD later on.

**Results.**– 1074 patients were hospitalized with a diagnosis of depression within the stated time interval. 72 met inclusion criteria. 60 (83.3%) had the diagnosis of unipolar depression and 12 (16.7%) the diagnosis of BD.

We found a positive correlation between UA levels and diagnosis with higher UA in patients who were later diagnosed with BD. In multivariate analysis, a positive correlation with statistical significance was also found.

**Conclusions.**– We found a positive correlation in inpatients with unipolar depression between serum uric acid levels and later diagnostic conversion, with higher levels of uric acid in patients later diagnosed with BD. Our results suggest UA as a possible risk biomarker for BD in patients with unipolar depression.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0634

### **Effect of adjunctive infliximab on general cognition in individuals with bipolar I/II depression: A phase-II double-blind placebo-controlled trial**

Z. Pan\*, M. Subramaniapillai, Y. Lee, R. Mansur, R. McIntyre

University Health Network-Toronto Western Hospital,

University of Toronto, Psychiatry, Toronto, Canada

\* Corresponding author.

**Background.**– Impairment due to decreased cognitive function is a major factor subserving suboptimal recovery in Bipolar Depression (BD). Elevated levels of TNF- $\alpha$ , a pro-inflammatory cytokine, have been consistently reported in depressed individuals and has been linked to negatively impact cognitive performance. Infliximab is a TNF-antagonist that has shown efficacy in individuals with treatment-resistant depression. Efficacy of adjunctive Infliximab on cognitive symptoms of BD is unknown. The primary purpose is to empirically evaluate the efficacy of adjunctive intravenous Infliximab in mitigating cognitive symptoms in individuals with DSM-5-defined BD I/II as compared to placebo.

**Materials and methods.**– Study is a 12-week, fixed-dose, randomized, double-blind, placebo-controlled clinical trial. Male and female outpatients age 18–65 at Toronto Western Hospital who meet DSM-5 criteria for a current depressive episode were enrolled. Infliximab was prescribed adjunctively to a conventional mood

stabilizer. Participants were randomized to receive intravenous Infiximab or saline placebo at baseline, weeks 2, 4, and 6 under clinical observation. Follow-up assessments were performed at weeks 8, 10, and 12. Cognitive and mood assessments were performance and evaluated against placebo-controls.

**Results.**– As of Sept 2017, 212 individuals have signed informed consent; 49 subjects have enrolled in the study. We hypothesize that modulation of inflammatory systems will improve a measure of cognition in individuals with BD I/II exhibiting elevated inflammation.

**Conclusions.**– Positive results would instantiate the relevance of inflammatory systems in the phenomenology and pathoetiology of mood disorders. Moreover, positive results would encourage the development of scalable treatments targeting inflammatory systems to mitigate transdiagnostic disturbances such as cognitive dysfunction.

\* Corresponding author.

**Introduction.**– Electroconvulsive therapy (ECT) is an effective treatment for severe depression, but not all patients benefit. Few studies investigated response predictors in bipolar depression.

**Objectives.**– To identify predictors of response to ECT in bipolar depression.

**Methods.**– Inpatients treated between January 2011 and December 2014 for bipolar depression were identified by the Swedish National Patient Register. The Swedish National Quality Register for ECT provided data on response. Response was defined as 1 (very much improved) or 2 (much improved) on the Clinical Global Impression-Improvement scale. National registers provided data on current social status, prior co-morbid diagnoses, and psychopharmacological treatment in the 100-days period before admission. Logistic regression was utilized to calculate odds ratios in uni- and multivariate models.

**Results.**– Among 668 patients with a mean age of 52.4 (SD 16.8) years, 530 (79.3%) were classified as responders. Psychotic symptoms and older age (51–70 versus < 31 years) were associated with response, (odds ratio, 95% confidence interval 2.2, 1.1–4.2 and 2.0, 1.0–3.9 respectively), while personality disorders were associated

with non-response in the multivariate model (0.48, 0.27–0.86). Anxiety disorders, obsessive compulsive disorder, and attention deficit hyperactivity disorder, as well as use of antipsychotics, benzodiazepines, and anxiolytics were associated with non-response in univariate models only. Socio-demographic factors (sex, education, relationship) were not associated with response.

**Conclusions.**– Most patients (79%) with bipolar depression treated with ECT responded. As previously seen in unipolar depression, psychotic symptoms and older age predicted response while presence of a personality disorder was a negative predictor.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cognitive dysfunctions in patients diagnosed with unipolar (Major Depressive Disorder) and bipolar depression**

B. Suciu<sup>\*</sup>, R. Paunescu, I. Miclutia

Iuliu Hațieganu University of Medicine and Pharmacy Cluj-Napoca, Department of Neurosciences, Cluj-Napoca, Romania

\* Corresponding author.

**Objectives.**– Studies reveal the presence of a common characteristic in many psychiatric illnesses, such as Bipolar Disorder or Major Depressive Disorder. This characteristic is represented by the cognitive impairment, which is rarely assessed, but an important issue in affective disorders.

**Methods.**– The study included 40 patients (age between 18 and 70) diagnosed with recurrent major depressive disorder and 42 patients (age between 18 and 70) diagnosed with bipolar disorder (according to ICD-10 and DSM-V) which were evaluated during an acute depressive episode. The severity of depression was quantified clinically and by using the Hamilton Depression Rating Scale – 17 items – whereas cognitive functions were evaluated with standard cognitive tests.

**Results.**– The 2 groups had similar level of education and a predominance of the feminine gender. Both groups showed significant impairment at tests assessing phonemic fluency. Bipolar patients displayed attention focusing deficits, whereas unipolar patients obtained lower results, but not statistically significant. On the assessment of psychomotor speed, the bipolar group presented notable impairment related to psychomotor coordination, whereas the unipolar group did not reveal any differences.

**Conclusions.**– These results are similar with the literature and unveil that cognitive deficits are present in both disorders during an acute depressive episode but they show slightly different patterns of impairment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

Kapodistrian University of Athens, Medical School, 1st Department of Psychiatry, Athens, Greece; <sup>3</sup> National and Kapodistrian University of Athens, Medical School, Mental Health Care Unit, Evgenidion Hospital, Athens, Greece

\* Corresponding author.

**Introduction.**– Neuropsychological deficits in Bipolar Disorder (BD) have been examined in relation to various clinical factors (such as duration of illness and number of episodes).

**Objectives.**– However, the effect of age at onset on cognition has been scarcely studied despite its clinical relevance.

**Aims.**– The aim of our study was to investigate whether age at onset affects visual memory in patients with BD.

**Methods.**– Cognitive performance of 60 bipolar-I patients and 30 healthy controls was evaluated by using CANTAB battery tasks targeting spatial memory (SRM) and paired associative learning (PAL). Multiple linear regression analyses were performed for memory function tasks based on age at onset with age, gender and education as covariates.

**Results.**– Bipolar patients showed statistically significant worse performance in PAL compared to healthy controls ( $P=0.001$ ) whereas no statistically significant difference was observed for SRM. Moreover, among patients a statistically significant association was found ( $P=0.006$ ) between age at onset and performance in PAL. Specifically, after correcting for confounders (age, gender, education) an earlier age of illness onset was correlated with more errors committed in PAL.

**Conclusions.**– The present study is one of the few studies that have examined the effect of age at onset on memory function in BD. Early onset BD has been associated with greater genetic load and poorer prognosis and our findings indicate that it may also be associated with worse memory function as assessed with PAL. Age at onset might help identify bipolar patients at a greater risk for memory/learning impairment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

<sup>3</sup> INSERM, 1114, University of Strasbourg, Strasbourg, France

\* Corresponding author.

**Introduction.**– Bipolar disorder is characterized by episodes of mania, depression, and mixed episodes whereby depressive and manic symptoms may co-occur. Although patients frequently experience mixed episodes, the clinical boundaries between mixed depression and typical depression, and mixed mania and typical mania, are still a matter of debate. Studies have shown that speech parameters could be used to obtain relevant information regarding patients' mood states. One such parameter is the fundamental frequency (F0), i.e., the lowest frequency of a periodic waveform. The aim of this work is to investigate whether F0 dynamics are able to distinguish mixed states from typical depression and mania in patients with bipolar disorder.

**Method.**– Nineteen manic patients, 8 patients with mixed mania, 17 patients with mixed depression, and 12 patients with typical depression were recruited. Speech samples were acquired via nine verbal fluency tasks whereby participants had to produce as many words as possible during 120s. Voiced segments were estimated so that single words could be highlighted. Prosodic features, derived from Taylor's tilt intonational model, were estimated on each voiced segment.

**Results.**– Findings show that leave one out classification could successfully discriminate between mixed mania and mania (accuracy 88.8%, specificity 94.4%, sensitivity 77.7%, F1 score 82%), and mixed depression and depression (accuracy 72%, specificity 70%, sensitivity 74%, F1 score 78%).

**Conclusion.**– Our results suggest that discrete prosodic modulations might be informative regarding the presence of mixed symptoms. Future analyses will focus on the relationship between these parameters and mixed clinical features, such as racing thoughts.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Reducing inpatient suicide rates: The success of a suicide management programme in a general hospital**

A. Ang

Tan Tock Seng Hospital, Psychological Medicine, Singapore, Singapore

**Introduction.**– Inpatient suicides are common hospital sentinel events. International data on rates of inpatient suicides have ranged from 1.8 to 4.0 per 100,000 general hospital admissions.

**Objective.**– This study reviews the effectiveness of a suicide management programme in reducing the inpatient suicide rates in a general hospital.

**Methods.**– All inpatient suicides were reviewed from the period of 2000 to 2015. The suicide management programme was initiated in 2005. Comparisons of suicide rates and methods were made pre and post intervention.

The study demonstrates that the suicide management programme, which followed the principles of (1) developing guidelines and policies, (2) training of healthcare staff and (3) reducing environmental hazards, has made a significant impact in reducing suicide rates.

**Results.**– Inpatient suicide rates dropped from 5.76 per 100,000 general hospital admissions to 1.17 per 100,000 general hospital admissions for pre- and post-programme respectively.

**Conclusion.**– This study supports mandatory sentinel event reporting and demonstrates that the monitoring, robust analysis as well as customizing interventions according to the hospital's and unit's context can dramatically reduce inpatient suicides.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0640

### **The role of consultation-liaison psychiatry in patients with self-inflicted burns: A five case series and a review of current literature**

S. Gunturu

Columbia University, Psychiatry, New York, USA

\* Corresponding author.

**Objectives.**– (1) To describe the collaborative role of a consultation-liaison psychiatry in managing patients with self-inflicted burns. (2) Discuss the American Burn Association Guidelines.

**Background and aims.**– Self-inflicted burns encompass a range of deliberate self-harm behaviors involving burns with the intent to self-mutilate or to end a life by attempting suicide. As per The National Burn Repository (2006–2015), suspected self-inflicted

injuries comprised a total of 1,937 cases (1%) out of 205,033 burn injuries.

**Materials and methods.**– We discuss Five cases of self-inflicted burns. Electronic data searches of PubMed, Medline, and the Cochrane Library (years 1990–2017) were performed using keywords: “burn”, “self-immolation”, “suicide”, and “self-inflicted burn”. The authors, in consensus, selected pivotal studies and conducted a narrative review of fifteen clinical studies. **Results.**– A total of Five patients were treated by the consultation-liaison psychiatry team after self-inflicted burns as a suicide attempt. Four out of five patients were male. The reported total body surface area burned involved ranged from 23 to 70 percent. The mean length of stay in the hospital was 99.18 days. All five cases met criteria for at least one psychiatric diagnoses, and all cases had a history of substance use.

**Conclusions.**– Guidelines for trauma centers caring for burn patients have been developed in partnership with the American Burn Association (ABA). An organized and coordinated team is essential to facilitate the functional recovery of burn patients, given the devastating effect on the psychological well-being, including but not limited to dealing with intentional self-harm, acute mental illness exacerbation, substance use and other consequences of the burn injury.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Evaluation of the relationship between caregiver burden, coping styles and levels of anxiety and depression in caregivers of old age patients**

S. Ay<sup>1</sup>, H. Unubol<sup>1</sup>, S. Ezer<sup>2</sup>, O. Omay<sup>3</sup>, G. Hızlı Sayar<sup>4</sup>\*

<sup>1</sup> Uskudar University, Institute of Social Sciences, Istanbul, Turkey;

<sup>2</sup> Okan University, Vocational school of Health Services, Istanbul, Turkey; <sup>3</sup> La Teppe Medical Center, Psychiatry, Tain l'Hermitage, France; <sup>4</sup> Uskudar University, Psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– At present, caregiver's health is a public health challenge in itself, as important as the health of the elderly. This study aims to investigate the relationship between caregiver burden and levels of anxiety and depression, the factors influencing them, and also to evaluate the coping strategies of the caregivers.

**Methods.**– This study is a survey-based cross-sectional study, including a total of 70 caregivers. Sociodemographic characteristics of caregivers and care receivers were collected by a survey. The functional status of the elderly was evaluated by Katz' Index of Independence in Activities of Daily Living (ADL). Burden Interview Scale, Hospital Anxiety and Depression Scale and COPE were used to examine the caregiver burden, anxiety and depression levels and coping strategies of the caregivers.

**Results.**– Anxiety and depression levels of the caregivers included in our study were higher when compared with the other studies. The anxiety levels were correlated with the non-functional coping strategies. The use of effective social support decreased the anxiety levels.

**Conclusion.**– Country specific guidelines should be prepared for the primary healthcare centers in order to evaluate and protect caregiver health. Long-term multicenter clinical studies are needed to develop culture-specific programs for the intervention of functional coping strategies and to help caregivers cope more effectively with their daily life stressors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0642

### **Depression, anxiety and health related quality of life in patients with asthma and chronic obstructive pulmonary disease (COPD) attending primary care: A cross sectional survey**

M. Husain<sup>1</sup>, N. Chaudhry<sup>2</sup>, T. Kiran<sup>3</sup>, B. Ameer<sup>3</sup>, N. Husain<sup>4</sup>

<sup>1</sup> South London and the Maudsley NHS Foundation Trust, General Adult Psychiatry, London, United Kingdom; <sup>2</sup> Pakistan Institute of Living and Learning, Adult Psychiatry, Karachi, Pakistan; <sup>3</sup> Pakistan Institute of Living and Learning, Mental Health Research, Karachi, Pakistan; <sup>4</sup> University of Manchester, Global MEntal Health, Manchester, United Kingdom

\* Corresponding author.

**Introduction.**– Depressive and anxiety symptoms in patients with respiratory conditions such as COPD and asthma are associated with poorer survival, longer hospitalisation and poorer health related quality of life. Despite these consequences depression and anxiety often remain unrecognised in such patients.

**Objective.**– In this study we aimed to study the prevalence of depression and anxiety and its association with health related quality of life in patients with COPD and asthma attending participating general practices in Karachi, Pakistan.

**Methods.**– This was a cross sectional survey with 293 COPD and asthma patients (162 non-depressed, 131 depressed). Patient Health Questionnaire (PHQ-9) was used to categorise the depressed and non-depressed patients. Generalised Anxiety Disorder (GAD-7) was used to assess the anxiety, and health related quality of life was assessed through EuroQol – 5 Dimensions (EQ-5 D).

**Results.**– The prevalence of depression in this group was high. Depressed patients were more likely to be anxious compared to non-depressed group. Depressed COPD and asthma patients reported significantly poorer health related quality of life compared to the non-depressed patients.

**Conclusion.**– High rates of depression and anxiety in COPD and asthma patients warrant further research to inform development of appropriate interventions in Pakistan.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0643

### **The screening value of the “single question in delirium” in post-operative cardiothoracic surgery patients**

A.M. Michailidou<sup>1</sup>, N. Kokras<sup>1\*</sup>, G. Stavropoulos<sup>2</sup>, A. Kouzoupis<sup>1</sup>

<sup>1</sup> Medical School, University of Athens, First Department of Psychiatry, Athens, Greece; <sup>2</sup> Ippokrateion Hospital, Second Department of Cardiac Surgery, Athens, Greece

\* Corresponding author.

**Introduction.**– Post-operative delirium is a common sequel of cardiothoracic surgery but the timely diagnosis of delirium is often missed. Several questionnaires exist for detecting post-operative delirium, but they are characterized by complexity and require appropriate training. The Single Question in Delirium (SQiD) may be a simple alternative tool, that could be used to screen for post-operative delirium.

**Objectives.**– To verify the validity and diagnostic accuracy of the SQiD in detecting possible post-operative delirium cases following cardiothoracic surgery.

**Methods.**– Two-hundred consecutive patients undergoing cardiac surgery were evaluated for post-operative delirium according to ICD-10 criteria and the SQiD. The SQiD consists of the follow-

ing question addressed to someone familiar with the patient “Do you feel that [patient’s name] has been more confused lately?”, and responses were compared to the clinical diagnosis of delirium according to ICD-10 criteria.

**Results.**– The SQiD correctly identified 31/33 patients with delirium (94% sensitivity) and recognized 133/149 patients without delirium according to ICD-10 criteria (89% specificity). It was not possible to assess post-operatively 18 patients, either with ICD criteria or the SQiD, due to various medical reasons. In overall, SQiD displayed a 66% positive predictive value and a 98% negative predictive value, given that the prevalence of delirium in this cohort of post-operative patients was 18%.

**Conclusions.**– Under-diagnosis of postoperative delirium has detrimental consequences and therefore the prompt recognition is essential. SQiD proves an easy and accurate tool, that can be used by nurses and other non-medical hospital personnel to identify patients likely to suffer from post-operative delirium.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Neuropsychiatric symptoms associated with perampanel usage in people with pharmacoresistant epilepsy: A case series of 11 patients**

I. Koychev<sup>1</sup>, D. Okai<sup>2</sup>, A. Sen<sup>3</sup>

<sup>1</sup> University of Oxford, Department of Psychiatry, London, United Kingdom; <sup>2</sup> Oxford University Hospitals NHS Foundation Trust, Psychological Medicine Service, Oxford, United Kingdom; <sup>3</sup> Oxford University Hospitals NHS Foundation Trust, Nuffield Department of Clinical Neuroscience, Oxford, United Kingdom

\* Corresponding author.

**Aims.**– Perampanel is an anti-epileptic drug (AED) licensed in the UK in 2012 for the treatment of focal epilepsy with or without secondary generalisation. Perampanel is a second/third line AED and therefore used often in those who are treatment resistant to other AEDs. Pooled analyses have shown a consistent efficacy in terms of seizure frequency reduction. Perampanel can have an adverse effect on mood and associates with significant psychiatric and behavioural change. These side effects appear to be dose-dependent: irritability is a prime example affecting 4% of patients taking perampanel at the lowest dose (2 mg per day), increasing to 12% in those taking 12 mg per day. In the current presentation we summarise a case series of patients treated with perampanel where irritability, aggression, psychosis and/or self-referential ideas were major psychiatric side effects.

**Methods.**– A case series of 11 patients treated with perampanel at the Department of Neuroscience, Oxford University Hospitals NHS Foundation Trust.

**Results.**– We illustrate the neuropsychiatric side effects with case report examples alongside the pooled characteristics of the whole case series. The most common side effect was irritability and aggression which associated with learning disability or organic personality change. Polymorphic psychosis was also reported and associated with history of low mood. We discuss the relationship between the emergence of these side effects and drug dose, time from initiation of perampanel.

**Conclusions.**– The incidence and characteristics of perampanel-associated psychiatric symptoms, requires awareness among neurologists and psychiatrists to inform risk management and appropriate treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0645

### **Liaison psychiatry in a general hospital. Analysis of the demand for seven years**

R. Navarro Pablo<sup>1</sup>\*, F. Gotor Sanchez-Luengo<sup>2</sup>, C. Casas Gómez<sup>2</sup>, O. Santamaria Gómez<sup>2</sup>, B.O. Plasencia Garcia de Diego<sup>3</sup>, S.L. Romero Guillena<sup>4</sup>

<sup>1</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Sevilla, Spain; <sup>2</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Seville, Spain; <sup>3</sup> De la Merced Osuna Hospital, Department of Psychiatry, Seville, Spain; <sup>4</sup> U.G.C Salud Mental Virgen Macarena Hospital, Department of Psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– Hospitalization is a stressful event for most people and can develop in many cases to significant psychological problems, such as emotional reactions to illness or complications of previous mental health disorders. Liaison Psychiatry has been recognized as a sub-speciality of Psychiatry that provides psychiatric care concerned with the management of general hospital inpatients (medical, surgical or obstetric units). The role of the Liaison Psychiatrist is to assist with the evaluation and treatment of psychiatric conditions related to medical illness.

**Objective.**– To evaluate the characteristic and overall utilization rates of the psychiatric consultation liaison service in a general hospital for seven years.

**Methods.**– Evaluation of clinical data obtained from the consultations attended from October 2009 to December 2016 in a general Hospital (Seville, Spain). We analysed sociodemographics and clinical factors. **Results.**– A total of 1496 psychiatric consultations were received. Most patients were women (53%). The average age was 56 years. In most cases the inpatients had not a pre-existing psychiatric diagnosis (44%). The most frequent diagnoses were adjustment disorders (30.5%), personality disorders (11.7%) and depressive episode (8.5%).

Medical Units provided 76% of requests for psychiatric consultation. The most frequent intervention were clinical evaluation (33%) and pharmacological interventions (27%).

**Conclusions.**– According to previous studies, our data corroborate the majority of the demand for medical services versus surgical ones. Specialized training medical and nursing staff may recognize psychological distress and consequently request for early intervention.

Consultation-liaison psychiatry presents an opportunity to improve health outcomes for inpatients and reduce burden on the health care system.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0646

### The consultation-liaison psychiatry and the substance use disorder in a general hospital

R. Navarro Pablo<sup>1\*</sup>, C. Casas Gómez<sup>2</sup>, F. Gotor Sanchez Luengo<sup>2</sup>, S.L. Guillena Romero<sup>3</sup>, O. Santamaría Gomez<sup>2</sup>, B.O. Plasencia García de Diego<sup>4</sup>

<sup>1</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Sevilla, Spain; <sup>2</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Sevilla, Spain; <sup>3</sup> U.G.C Salud Mental Virgen Macarena Hospital, Department of Psychiatry, Sevilla, Spain; <sup>4</sup> De la Merced Osuna Hospital, Department of Psychiatry, Sevilla, Spain

\* Corresponding author.

**Introduction.**– Psychiatry comorbidity is very common among general hospital inpatients, including substance use disorder. The combination of medical and psychiatric illness has been linked with increased functional and occupational disability, poorer quality of life and accelerated mortality compared with those with one diagnosis alone. The Consultation-Liaison Psychiatry (CLP) objectives and operating procedures have evolved in recent years from administration of psychiatric treatment to integrating therapy into the bio-psycho-social model.

**Objective.**– Describe the characteristics of liaison psychiatric patients in the general hospital with a diagnosis of substance use disorder

**Methods.**– A retrospective study of consultations between October 2009 and December 2016 were collected and analyzed. Sociodemographic data, application, and clinical results was performed.

**Results.**– During the study period 1496 consultations were attended of which 54 were substance abuse disorder. 80% were male and 20% female. The average age was 50 years. Internal Medicine (24%) and Digestive (20%) were the services who asked for more psychiatric evaluations. 53% of total had no psychiatric history. The most frequent interventions were evaluation (35%) and pharmacological treatment (24%).

**Conclusions.**– Our study is consistent with data collected in previous literature regarding the higher prevalence of men and increased demand for medical services versus surgical. Liaison psychiatry can act as a bridge between psychiatry and medicine, ranging from derivatives psychiatric disorders, other organic diseases or use /abuse of substance and co-occurring psychiatric disorders in somatic patients, working in a multidisciplinary, we offer a comprehensive approach patient.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Clinical correlates of psychopharmacotherapy and anxiety in practice of cardiology department

N. Petrova<sup>1\*</sup>, S. Zadvorev<sup>2</sup>

<sup>1</sup> St Petersburg University- Faculty of Medicine, department of psychiatry and addiction, St-Petersburg, Russia; <sup>2</sup> City multi-field hospital No. 2, department of cardiology, St Petersburg, Russia

\* Corresponding author.

**Introduction.**– The burden of mental disorders in primary care population is extremely high and underestimated. User-friendly scale for identifying non-specific correlates of mental disorders in primary care might be helpful.

**Objective.**– To analyze non-specific clinical correlates of psychopharmacotherapy in practice of in-patient cardiology department, and to develop the scale identifying a group of patients with

significant contribution of the psychogenic component to the clinical presentation.

**Methods.**– A retrospective analysis of 1095 patients (mean age 66.8 ± 13.1 years, 56.7% women) presented to cardiology department. The frequency of psychotropic drugs out-patient prescriptions was analyzed, HADS scale was used to objectify the anxiety and depression. Psychopharmacotherapy was initiated by cardiologist without consulting by psychiatrist. Association between therapy and clinical parameters was evaluated by using multiple regression.

**Results.**– 22.9% of patients received out-patient psychopharmacotherapy. Its independent correlates of drug prescription were labile arterial hypertension; number of comorbidities; female gender; onset of palpitations before 55 (or 50) years. Regression model included these parameters taken with coefficients 8, 1, 3 and 3 (or 6), respectively. The model's  $R^2$  was 0.14. The mean score was 6.9 ± 4.5 points. Out-patient drug prescription rate is 11.2% if the score is <5, whereas it was 25.2% for 5–12 points, 40.5% for 13–15 points, and 59.6% for > 15 points. The score correlates with HADS anxiety ( $r = 0.24$ ,  $P = 0.002$ ), but not with depression score ( $r = 0.12$ ,  $P = 0.12$ ).

**Conclusions.**– The proposed algorithm, including clinical data available at the primary care level, may be helpful in identifying the candidates for an elective counselling by psychiatrist.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Cognitive function and depressivity in patients with obstructive sleep apnea before and after CPAP treatment

M. Hobzova<sup>1</sup>, L. Hubackova<sup>2</sup>, J. Prasko<sup>3\*</sup>, J. Vanek<sup>4</sup>, S. Genzor<sup>1</sup>, M. Ociskova<sup>4</sup>, A. Grambal<sup>4</sup>

<sup>1</sup> University Hospital Olomouc- Faculty of Medicine and Dentistry, University Palacky Olomouc, Department of Respiratory Medicine, Olomouc, Czech Republic; <sup>2</sup> University Hospital Olomouc, Department of Clinical Psychology, Olomouc, Czech Republic;

<sup>3</sup> University Hospital Olomouc, Department of Psychiatry, Olomouc, Czech Republic; <sup>4</sup> University Hospital Olomouc, Faculty of Medicine and Dentistry, University Palacky Olomouc, Department of Psychiatry, Olomouc, Czech Republic

\* Corresponding author.

Obstructive sleep apnea (OSA) is a disordered form of sleep-disordered breathing described as repeated obstruction of the upper airways during sleeping. OSA episodes lead to recurrent hypoxia and arousals from sleep or awakening. OSA is often accompanied by depressivity and struggles in cognitions. Treatment using continuous positive airway pressure (CPAP) is efficacious in patients with OSA. The key issue is whether the treatment of sleep apnea may decrease depressivity and improve cognitive symptoms. **Objective.**– The target of the investigation was to find if there is any improvement of depressive symptoms and cognitive functioning after continuous positive airway pressure (CPAP) treatment in the severe obstructive apnea (OSA) patients.

**Method.**– The study included 59 patients treated with CPAP for OSA in the Sleep Laboratory of the Department of Respiratory Medicine. Thirty-eight patients were treated with CPAP for one month, and twenty-one patients were in a control group. We used the following methods: Test of Visual Memory (ViMe), Numeric Rectangle, d2 (test of attention), and the Beck Depression Inventory-II, respectively.

**Results.**– Among the OSA patients, there were statistically significant improvements in all parameters: attention, working memory, and depressive symptoms after the treatment with CPAP. We found

a statistically significant positive connection between the decrease in depressive symptoms and the improvement in attention. In the control group, there were no improvements in the investigated factors.

**Conclusions.**– According to our results, the patients with sleep apnoea improved their mood and cognitive functions during the treatment by the CPAP device.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Mental illness and functional gastrointestinal syndromes – Update on mediating mechanisms**

N. Trovão<sup>1</sup>, A.R. Marques<sup>2\*</sup>, A. Marques<sup>1</sup>, L. Ribeiro<sup>1</sup>

<sup>1</sup> Centro Hospitalar Vila Nova de Gaia Espinho, Psychiatry, Vila Nova de Gaia, Portugal;

<sup>2</sup> Hospital Distrital de Santarém- Santarém, Psychiatry, Santarém, Portugal

\* Corresponding author.

**Introduction.**– Functional Gastrointestinal Syndromes (FGIS) are a complex entity of disturbances of nervous processing, visceral sensitivity and intestinal mucosa and microbiome with consistently proved influence of psychiatric comorbidity.

**Objectives.**– Considering the relevant disease impact, we aimed at obtaining updated and furthered data on FGIS pathophysiology and achieve a disease model considering the interaction with psychological aspects.

**Methods.**– We conducted a selective literature review through the queries of “psych\*”, “functional”, “irritable”, “intestinal” and “bowel” in Pubmed/Medline online databases, considering relevant references based on their focus on psychological parameters and disease mechanisms.

**Results.**– Various publications are found in which authors take into account the importance of downstream effects from altered brain processes over enteric functioning, mainly relating to the neuroendocrine stress response axis. Most psychotherapeutic interventions conducted so far seem also to act on symptom mediation by stressful cognitions. However, a clear place for personality traits and complex dimensions of psychiatric illness is lacking in recent models. Organic vulnerability for the FGIS seems to rely on impaired mucosal integrity due to abnormal immune responses to environmental insults such as diet or infections. Interestingly, disturbed inflammation in mental disorders has gained mounting evidence, which reinforces the loop behaviour of the gut-brain axis.

**Conclusions.**– Awareness of FGIS complex nature involving circular brain-gut axis influences is mandatory among doctors for adequate referral to expert teams, including the gastroenterologist and the liaison psychiatrist, and for integrative, more successful treatment strategies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Prevalence of anxiety, depression and sexual dysfunction in geriatric patients before undergoing transrectal ultrasound-guided prostate biopsy**

A. Salaj<sup>1\*</sup>, R.Y. Akman<sup>2</sup>

<sup>1</sup> Baskent University Istanbul Hospital, Department of Psychiatry, Istanbul, Turkey; <sup>2</sup> Hizmet Memorial Hospital,

Department of Urology, Istanbul, Turkey

\* Corresponding author.

**Objective.**– Being an interventional procedure, prostate biopsy may increase the level of anxiety in patients preparing to undergo it. In our study we aimed to investigate the level of the anxiety, depressive symptoms and sexual dysfunctions of patients one week before the procedure.

**Method.**– 32 patients who have undergone prostate biopsy are enrolled in this prospective study. Patients have filled out the questionnaire one week before the procedure. The patients also filled out the Beck Anxiety and Depression Inventory, Arizona Sexual Experiences Scale(ASEX), Golombok Rust Inventory of Sexual Satisfaction.

**Results.**– The median age was 66. 20 patients (62.5%) were graduated from an university and 50% of the patients were married. 25 of the patients (78%) were undergoing prostate biopsy for the first time. 40% of the patients have evaluate biopsy as an anxious procedure. 99% of them feel agitated about the procedure, 99% feel anxious about undergoing another biopsy but 93.5% would accept another biopsy if recommended. Only 2 (6.3%) patients had sexual dysfunction according to ASEX. According to GRISS frequency, communication, satisfaction, avoidance, sensuality, impotence and premature ejaculation prevalence is calculated as 72%, 60%, 50%, 41.7%, 54.2%, 72.7%, 58.3% and 59.1% respectively. Only 10 patients (31.3%) had anxiety disorder. 5 patients have moderate depressive symptoms and only one patients had severe depression.

**Conclusion.**– Although most of the patients planned to undergo Prostate Biopsy feel agitation about the procedure, clinically only one in three patients have anxiety disorder. Although more than 50% of the patients had sexual dysfunction, it is not found any relationship with anxiety.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Subjects characteristics of medical requests to the addiction liaison psychiatry unit in hospital del Mar**

D. Sanagustin Bosqued\*, J.J. Fuentes Valenzuela, A. Trabsa Briski,

E. Monteagudo Gimeno, M. De Dios Felis, S. Perez Gonzalez,

M.F. Fonseca Casals, C. Tamarit, M. Torrens Melich

Hospital Parc de Salut Mar, Psiquiatria, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Addiction Liaison Psychiatric Units are frequently requested for other medical services due to the high prevalence of medical pathologies in substance use disorders. Knowing the patient’s characteristics could improve the approach.

**Objectives.**– To describe patient characteristics of all medical requests to the Addiction Liaison Psychiatry Unit from January 2010 to December 2016.

**Materials and methods.**– Study data was obtained from all patients that were referred to the Addiction Liaison Psychiatry Unit to assess addictive disorders and withdrawal symptoms related to drugs during 7 years in Hospital del Mar (Barcelona, Spain). Demographics and clinical data (substance use, dual diagnosis and infectious comorbidity) were obtained.

**Results.**– 2011 medical requests were referred to the Addiction Liaison Psychiatry Unit (78% men; mean age: 49 + 12 years). The main medical services that requested were Gastroenterology ( $n = 756$ , 37.6%), Infectious Medicine ( $n = 504$ , 25.1%) and Internal Medicine ( $n = 230$ , 11%). Focusing in drugs, alcohol related queries came from Gastroenterology ( $n = 187$ , 54%) in most cases and heroin related ones came from Infectious Medicine ( $n = 154$ , 57.2%). When comparing the gender characteristics, alcohol and amphetamine related samples were 83% men and 90.9% men respectively meanwhile

benzodiazepines and tobacco related were 60% men. Patients were usually referred to the community addiction treatment center.

**Conclusions.**– Gastroenterology and Infectious Medicine were the main services that asked for drug problems to the Addiction Liaison Psychiatry Unit. Most of the subjects were men and the main drug was alcohol. The community addictions treatment center is the main resource at discharge.

### **Psychiatric comorbidities in patients undergoing bariatric surgery**

G. Oviedo, C. Fillizzola, J. Pacheco, H. Santamaría García\*  
Pontificia Universidad Javeriana, Psiquiatría, Bogotá, Colombia  
\* Corresponding author.

Bariatric surgery is the only proven effective therapy for long-term control of morbid obesity. This surgery can be broadly divided into procedures that limit the stomach's capacity, that interfere with digestion or a combination of both the techniques. It has been consistently shown to be effective in long-term marked weight loss and in bringing significant improvement to medical comorbidities such as metabolic syndrome, type 2 diabetes mellitus and obstructive sleep apnea. However, empirical data suggest a high prevalence of psychiatric disorders among bariatric surgery candidates. In this review, we focus on high impact of bariatric surgery on generating mental problems and mental disorders. Moreover, we studied a sample of patients who underwent recent surgery exploring which demographical, cognitive and mental health factors were crucial in predicting incidence of mental problems and mental disorders. Against this background, we run a longitudinal prospective cohort study in consecutive patients undergoing bariatric surgery assessing demographical factors, cognitive function and mental health determinants in two different stages, before surgery and 6 months after surgery intervention.

Together this study shows changes in prevalence of certain psychiatric symptoms after weight loss with bariatric surgery and a high burden of eating disorders such as binge eating disorder. In addition, the results suggest that mental problems and mental disorders after bariatric surgery are predicted by cognitive and mental health states in a previous phase to the surgery. Those results suggest new directions for psychiatric evaluation and interventions for bariatric surgery patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Feeding in postpartum: Psychological experiences associated as referred by Brazilian women with obesity from a university public outpatient service**

D.B. Faria-Schützer, F.G.C. Surita, L. Rodrigues, E.R. Turato, D.A.R. Silva\*  
Laboratory of Clinical-Qualitative Research,  
Faculty of Medical Sciences, State University of Campinas, Brazil  
\* Corresponding author.

**Introduction.**– Pregnancy is a period of high risk for body weight gain. Studies on obesity have focused mainly on diet and physical activity, however association with psychological factors is relevant for the clinical management regarding individuals with obesity.

**Objective.**– To explore psychological meanings that puerperal women with obesity attribute to their eating at this stage of life:

how they feed themselves and their relationships with themselves and their baby.

**Method.**– Clinical-qualitative study. The construction sample of subjects was intentional, with sixteen obese women selected to participate of a free individual interview. Data was treated by content analysis

**Results.**– The analysis revealed four categories: (1) Consciousness and suffering due to obesity – ignorance of the internal motivations that make them obese; (2) Eat to fill the void – to deal with the emotions coming from the puerperium; (3) Economic and cultural issues of food in the puerperium; (4) Family and health care support.

**Conclusions.**– The women in these conditions can not perceive and express their needs, however realizing that there is a relationship between the act of eating and the feelings coming from the postpartum. After the baby's first month's care, they regained weight, returning to eating habits prior to gestation. The food for these women serves as a fill, a source of pleasure amid so many waivers by the baby. These women need a family support and health service to assist and support them in caring for themselves and their baby, especially in relation to diet and a healthy behaviour.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0654

### **Emotional distress in elderly patients with diabetes**

I. Feki\*, M. Turki, R. Sellami, I. Baati, I. Zitoun, A. Feki, J. Masmoudi  
Hedi Chaker university hospital, psychiatry "A" department, Sfax, Tunisia  
\* Corresponding author.

**Introduction.**– Several studies have demonstrated an association between diabetes and impairment in mental health, especially depression. This relationship appears to be more marked in the elderly, given that depression is a frequently occurring condition among this age range.

**Objective.**– To assess the prevalence of depression in elderly patients with diabetes, as well as associated factors.

**Methods.**– We conducted a cross-sectional, descriptive and analytic study, among 50 elderly patients ( $\geq 65$  years), followed for diabetes at the outpatient department for chronic diseases of the Regional Hospital of Aguerb, Sfax, Tunisia. The Geriatric Depression Scale (GDS) was used to screen for depression.

**Results.**– The mean age was 73.3 years, with a sex-ratio of 0.62. The mean duration of diabetes was 7.7 years. Somatic comorbidities were noted in 94% of cases (hypertension 84%; dyslipidemia 34%). Psychiatric histories were reported in 18% of patients.

The mean GDS score was 9.8 points. According to this scale, the prevalence of depression was 34%. It was correlated with: smoking ( $P=0.04$ ), hypertension comorbidity ( $P=0.04$ ), psychiatric history ( $P=0.031$ ), absence of leisure activity ( $P=0.035$ ), long duration of diabetes ( $P=0.04$ ).

**Conclusion.**– Our study highlighted a high prevalence of depression among elderly patients with diabetes. This relationship seems to be bi-directional, and may darken the prognosis by increasing somatic complications and altering the quality of life. Thus, besides pharmacological treatment, psychological support is essential to ensure a better control of diabetes and improve the well-being.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Comorbidity/Dual Pathologies - Part II

PW0655

### Substances-induced psychosis: Looking for specific clinical and demographic differences

A. Alvarez Astorga<sup>1\*</sup>, A. Lubeiro<sup>2</sup>, F. Arias<sup>3</sup><sup>1</sup> HCU Valladolid, psychiatry, valladolid, Spain;<sup>2</sup> Universidad de Valladolid, Psychiatry, Valladolid, Spain;<sup>3</sup> Hospital Universitario 12 de Octubre, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– DSM-5 defines “substance-induced psychotic disorder” as the presence of delusions and / or hallucinations during or shortly after intoxication, withdrawal or exposure to a substance. Although there are some bibliography analyzing specific clinical aspects depending on the type of substance [1], specific research in that area is needed.

**Objectives.**– To search for specific clinical and demographic characteristics in patients with substance-induced psychosis depending on the type of substance abuse.

**Methods.**– A sample of patients diagnosed with substances-induced psychosis at Hospital 12 de Octubre was recruited. Demographic data were analyzed and clinical and consumption variables were collected through medical interviews and using PANSS, ASI and SCIP scales.

**Results.**– Form the whole sample (127 patients), 113 were men (89%) and 14 women (11%). Mean age was  $29.09 \pm 7.69$  (16–50). 73 (57.5%) patients consumed only cannabis, 11 (8.7%) consumed only cocaine, 24 (18.9%) consumed both cannabis and cocaine, 10 (7.9%) consumed cannabis and alcohol, 7 (5.5%) consumed alcohol and cocaine and 2 (1.6%) consumed only alcohol. We decided to divide patients in three groups (i) cocaine, (ii) cannabis and cocaine and (iii) cannabis users. There were no significant differences between groups neither on PANSS and SCIP scales nor on consumption (Table 1).

**Conclusion.**– Cannabis users suffered psychosis symptoms at earlier age and present more visual hallucinations than cocaine users. Besides cocaine abuse is associated with more alcohol abuse and legal and family problems. Limitations: the number of patients in each subgroup was relatively small so more population studies would be necessary.

Table 1.

variables	mean (sd)/ %			p
	cannabis	cannabis+cocaine	cocaine	
first symptoms age	25.51(6.5)	24.0(6.2)	30.31 (7.4)	0.26

### Influence of co-morbid (Unipolar) affective disorders on the effectiveness of pharmacotherapy for adult attention deficit hyperactivity disorder, a naturalistic cohort

N. Bothof<sup>\*</sup>, C. Kan

RadboudUMC, psychiatry, Nijmegen, The Netherlands

\* Corresponding author.

**Background.**– In clinical practice, adult attention deficit hyperactivity disorder (ADHD) complicated by a co-morbid affective disorder is prevalent in adult ADHD ranging from 5 to 40%. Evidence is scarce, about how this factor affects treatment effectiveness and treatment choice. We set out to investigate if affective co-morbidity alters the effectiveness of pharmacotherapy. Our study is relevant in testing specific efficacy of varying ADHD pharmacotherapy choices, in the common clinical situation.

**Methods.**– In 306 adult patients with ADHD that received care of outpatient academic healthcare, department of psychiatry, RadboudUMC university clinic, in Nijmegen the Netherlands between 2013 and 2017 were analyzed. Diagnosis was confirmed by Diagnostic Interview for ADHD in adults (DIVA 2.0), performed by trained clinicians. Affective disorders were determined by Structured Clinical Interview for DSM-IV Axis I Disorders (SCID-I). Measurements of ADHD symptoms were determined twice, by questionnaire: Conners Adult ADHD Rating Scales Quikscore Forms (CAARS-S-S) at baseline, and after final optimal medication titration. Information of pharmacotherapy is drawn from patient files.

**Results.**– Statistical methods used was independent-sample students *T*-test, 2 tailed, in SPSS. Treatment in subjects with a history of affective disorder had 24% ( $t=2.38$  df 216,  $P=0.018$ ) reduction – and subjects with current affective disorder had 37% ( $t=2.84$  df 216,  $P=0.005$ ) reduction of ADHD-symptom score's. In final published results, subgroup analyses for medication-type's will be presented.

**Conclusion.**– In contrast to previous literature, our study shows a negative effect of ADHD pharmacotherapy, associated with co-morbid affective disorders in adults primarily treated for ADHD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Personality traits, depression and anxiety in females diagnosed with primary Sjogren's syndrome and rheumatoid arthritis

D. Duisin<sup>1\*</sup>, V. Milic<sup>2</sup>, N. Damjanov<sup>3</sup>, J. Barisic<sup>4</sup>, B. Batinic<sup>5</sup>

<sup>1</sup> Clinic of Psychiatry, Clinical Centre of Serbia, Belgrade, Serbia, Center for Partial Hospitalisation, Belgrade, Serbia; <sup>2</sup> Institute of Rheumatology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, Rheumatology, Belgrade, Serbia; <sup>3</sup> Institute of Rheumatology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, Rheumatology, Belgrade, Serbia; <sup>4</sup> Clinic for Psychiatry Clinical Center of Serbia, Center for partial hospitalisation, Belgrade, Serbia; <sup>5</sup> Clinic for Psychiatry Clinical Center of Serbia, Faculty of Philosophy, department of Psychology Belgrade University, Center for Partial Hospitalisation, Belgrade, Serbia

\* Corresponding author.

**Introduction.**– Despite the fact that the relationship between personality, emotions and chronic somatic disorders are complex and bidirectional, there is still scant data about its interference in females diagnosed with primary Sjogren's syndrome (pSS) and Rheumatoid Arthritis (RA).

**Objectives.**– The aim of the study was to analyze and compare personality traits, depression and anxiety in females diagnosed with pSS, RA and healthy control.

**Methods.**– The total study sample ( $n=211$ ) comprised 105 females diagnosed with PSS (mean age of 51.34 years), 52 females diagnosed with RA (mean age of 51.37 years), and 54 healthy females (mean age of 51.35 years). The following assessment instruments were applied: the Revised NEO Personality Inventory (NEO-PI-R), the Zung Self-Rating Depression Scale and the Zung Self-Rating Anxiety Scale. All statistical analyses were performed using SPSS [Version 16.0. SPSS Inc., Chicago, IL, USA].

**Results.**– Females with pSS and RA had significantly higher Neuroticism scores ( $P<0.01$ ), significantly lower Extraversion and Openness to experience ( $P<0.01$ ), and significantly higher Anxiety ( $P<0.0001$ ) compared to the healthy controls. The two subgroups of patients differ only in the level of depression, which was significantly higher in the subgroup with pSS, compared to RA subgroup and healthy control ( $P<0.01$ ).

**Conclusions.**– A specificity of personality and emotional state in females diagnosed with pSS and RA should be among important treatment targets in the integrative treatment program of these chronic and disabling autoimmune diseases.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0658

### **Features of course of type 2 diabetes mellitus in patients with non-psychotic mental disorders**

N. Garganeeva<sup>1\*</sup>, M. Belokrylova<sup>2</sup>, O. Alenina<sup>3</sup>, I. Kartashova<sup>3</sup>

<sup>1</sup> Siberian State Medical University, Department of General Practice and Polyclinic Therapy, Tomsk, Russia; <sup>2</sup> Mental Health Research Institute, Tomsk National Research Medical Center, Russia, Borderline States Department, Tomsk, Russia; <sup>3</sup> Mental Health Research Institute, Tomsk National Research Medical Center, Russia, Clinics, Tomsk, Russia

\* Corresponding author.

**Objective.**– To evaluate factors of prognosis of features of the course of type 2 diabetes mellitus (DM) in patients with non-psychotic mental disorders.

**Methods.**– With method of logistic regression, prognostic significance of psychosocial factors determining the course of type 2 DM was proven in 203 patients (aged  $50.62 \pm 8.07$  years) with non-psychotic mental disorders.

**Results.**– Mental state of DM patients was determined in 44.3% of cases by neurotic, stress-related and somatoform, in 38.9% – organic, in 9.8% – affective, in 7% – personality disorders. The leading psychopathological symptoms were represented by depressive in 36.5% of cases, anxiety in 16.7%, anxiety-depressive in 10.3%, asthenic in 20.0%. The cumulative forecasting indicator of type 2 DM was from 74.5 to 92.7%. Among predictors determining features of the course of type 2 DM the most significant ones were as follows: level of glycaemia ( $P=0.0001$ ); length of DM ( $P=0.0001$ ); length of mental disorder ( $P=0.0002$ ); stress factors ( $P=0.0001$ ); age at onset of mental disorder ( $P=0.0118$ ); leading psychopathological syndrome ( $P=0.0029$ ); hypothyria ( $P=0.0002$ ); personality traits ( $P=0.0001$ ); anxiety ( $P=0.0001$ ); fear of death ( $P=0.0001$ ); vegetative disorders ( $P=0.0011$ ); body mass index ( $P=0.0001$ ); arterial hypertension ( $P=0.0005$ ); level of systolic arterial pressure ( $P=0.0001$ ); dyslipidemia ( $P=0.0001$ ); vascular disturbances ( $P=0.0035$ ); family history of DM ( $P=0.0437$ ). High risk group included patients with depressive disorders with experience of psychosocial stress the mean level of glycaemia in whom was 10.68 mmol/l.

**Conclusion.**– Psychosocial stress contributed to persistent increase of blood glucose level, progressing type 2 DM and an earlier development of diabetes in persons with previous disturbance of glucose tolerance.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0659

### **Prevalence of psychiatric symptoms in patients with treatment-resistant epilepsy with and without epilepsy surgery**

B. Hinterbuchinger<sup>1\*</sup>, F. Friedrich<sup>1</sup>, L. Weitensfelder<sup>1</sup>, S. Takacs<sup>1</sup>, E. Pataraiia<sup>2</sup>, S. Aull-Watschinger<sup>3</sup>, N. Mossaheb<sup>1</sup>

<sup>1</sup> Clinical Division of Social Psychiatry, Department of Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, Austria;

<sup>2</sup> Department of Neurology, Department of Neurology, Medical

University of Vienna, Vienna, Austria; <sup>3</sup> Department of Neurology, Department of Neurology, Vienna, Austria

\* Corresponding author.

**Purpose.**– Psychiatric comorbidities are more common in patients with epilepsy compared to individuals from the general population. The aim of this study was to examine the prevalence of psychiatric symptoms in patients with drug resistant epilepsy who underwent presurgical evaluation and were subjected to epilepsy surgery.

**Materials and methods.**– Baseline and month 4 data are reported for 23 patients, 12 patients (52.2%) had surgery (SURG patients) and 11 (47.8%) had no surgery (NO-SURG patients) either because they declined ( $n=2$ ) or because indication was not given after thorough neurological evaluation. Psychiatric symptoms were assessed by standardized instruments: the Hamilton Anxiety Rating Scale, Beck Depression Inventory, Hamilton Rating Scale for Depression, Structured Clinical Interview I & II as well as the Global Assessment of Functioning Scale at baseline and after 4 months.

**Results.**– SURG-patients were significantly younger compared to NO-SURG patients ( $P<0.05$ ). There was no significant sex difference between SURG- and NO-SURG patients ( $P=0.22$ ). Furthermore NO-SURG patients showed significantly higher scores in the Hamilton Anxiety Rating Scale compared to SURG-patients both at baseline (mean difference = 5.017,  $P<0.05$ ) and after 4 months (mean difference = 4.250,  $P<0.05$ ). No significant differences were found regarding depressive symptoms, SCID diagnoses and global functioning.

**Conclusion.**– Besides symptoms of anxiety, there were no differences in prevalence of psychiatric symptoms and diagnoses between patients with drug resistant epilepsy who underwent epilepsy surgery compared to those without surgery.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0660

### **The benefits of physical activities in patients with dual diagnosis**

J. Jaber<sup>\*</sup>, J. Verissimo Jr, J. Cardoso, S. Carvalho, A. Hollanda, B. Reys  
Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

\* Corresponding author.

**Introduction.**– The work describes the benefits of physical activities in patients with dual diagnosis in a psychiatric clinic of Rio de Janeiro city, Brazil.

**Objectives.**– Present the benefits of physical activities inside the hospital space. Evaluate the impact of the introduction of regu-

lar physical activity practice in patients having dual diagnosis in hospitalization environment.

**Aims.**– Demonstrate the decrease of the resistance to treatment in hospitalization regime, the behavioral and social improvement of patients, as well as the physical and mental capacities and the wellness promotion during and after the treatment.

**Methods.**– 45 patients carrying the dual diagnosis, hospitalized in the clinic for the period of 1 year, were monitored. All the patients were assessed by a general practitioner, a psychiatrist and a physiotherapist, before starting the physical activity, being the classification of mental disorders ICD-10 used for the diagnosis. The patients were treated with psychotropics, according to the diagnosis and the signs and symptoms presented. The therapeutic project offered physical and psychological treatment, promoting the recovery possibility through aerobic and anaerobic ludic physical activities inside the therapeutic environment.

**Results.**– All the patients presented improvement in the physical and mental capacities and in socializing. In the physical activities, the patients participated respecting their limitations, respecting the next and having a higher body perception.

**Conclusions.**– Through the development of the activities, the patients demonstrated excellent involvement and interaction with the treatment, favoring their psychological and behavioral recovery and impacting positively their response to the treatment of various mental disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0661

### Cocaine-induced psychotic symptoms and psychotic proneness in cocaine use disorder patients

E. Karsinti<sup>1</sup>, L. Romo<sup>2</sup>, K. Piani<sup>1</sup>, V. Bloch<sup>3</sup>, G. Brousse<sup>4</sup>, F. Bellivier<sup>5</sup>, M. Fortias<sup>1</sup>, F. Vorspan<sup>5</sup>

<sup>1</sup> Hôpital Fernand Widal- APHP, Service de Psychiatrie, Espace Murger, Paris, France; <sup>2</sup> Université Paris Nanterre, Laboratoire CLIPSYD, Nanterre, France; <sup>3</sup> Hôpital Fernand Widal, Pharmacie, Paris, France; <sup>4</sup> Hôpital Clermont Ferrand, Service addictologie, Clermont Ferrand, France; <sup>5</sup> Hôpital Fernand Widal- APHP, Département Universitaire de Psychiatrie et de Médecine Addictologique, Paris, France

\* Corresponding author.

**Introduction.**– It's well known that cocaine can induce transient psychotic symptoms in the hour after intake (Vorspan et al., 2012). On the other hand, frequent cannabis use is associated with transient psychotic symptoms and permanent psychosis proneness (Verdoux et al., 2003).

**Objective.**– To describe cocaine induced psychotic symptoms and psychotic proneness among cocaine users.

**Method.**– we evaluated 181 current cocaine users in clinical setting. Cocaine-induced psychotic symptoms during the worst period of cocaine use were assessed with the SAPS-CIP questionnaire (Cubells et al., 2005); psychosis proneness was evaluated using the PDI (Peters, 2004); patients with schizophrenia were excluded. Statistics: Anova's and Pearson's correlations with a .05 threshold. **Results.**– Among the 181 patients, 76% were men, they preferentially used cocaine (72% vs crack). The average cocaine age at onset was 24 years old. The mean PDI score was 7. The mean SAPS-CIP score was 7. The delusion proneness scale correlated with SAPS-CIP scores (hallucinations, delusion and total score) but not to the behavioral scale. Association with lifetime and current cocaine and cannabis use will be presented.

**Conclusion.**– High delusion proneness could predict higher delusions and hallucinations during cocaine use. It could be a

vulnerability factor for several psychotic experiences with or without substances.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0662

### Addition of psychoactive or anorectic agents to standard hypoglycemic regimens can reduce FBS and HbA<sub>1c</sub> in long term

R. Khodabakhsh Pirkalani<sup>1</sup>\*, K. Khodabakhsh Pirkalani<sup>2</sup>

<sup>1</sup> Alzahra University and Mehr Medical Group,

Internal Medicine/Clinical Psychology, Tehran, Iran;

<sup>2</sup> Mehr Medical Group, Internal Medicine/Clinical Psychology, Tehran, Iran

\* Corresponding author.

**Introduction.**– Effect of psychological factors on blood glucose levels is not fully understood.

**Objectives.**– We want to determine whether psychoactive drugs exert a positive effect on glycemic control.

**Methods.**– In a pioneering study, we have treated 156 patients with type II diabetes with Duloxetine 30–60 mg/d if female and Bupropion 150–300 mg/d if male in addition to a combination of Metformin, Sitagliptin and Repaglinide (Table 1).

Table 1.

Treatment group	Patients' number	Weight loss at 3 and 9 mo.	HbA <sub>1c</sub> day zero	HbA <sub>1c</sub> 3mo.	HbA <sub>1c</sub> 6 mo.	HbA <sub>1c</sub> 12 mo.	HbA <sub>1c</sub> 24 mo.	HbA <sub>1c</sub> 48 mo.
Duloxetine	84	7.2, 8.9	11.3	9.1	7.2	6.8	6.6	6.6
Bupropion	71	4.7, 6.2	11.5	9.0	7.4	7.0	6.9	6.8
Citalopram	32	1.8, 4.7	11.7	9.5	7.4	7.1	7.0	7.0
control	63	2.1, 4.4	11.6	9.8	7.8	7.4	7.5	7.5

**Results.**– Compliance for all drugs were fair to good with 10 patients omitted from the Duloxetine group and 5 from the Bupropion group and two for the Citalopram group. All other patients were evaluable. The group in the Duloxetine group experienced a more uniform weight reduction and the Bupropion, Citalopram and control groups followed. HbA<sub>1c</sub> reduction of was excellent in all four groups compared to patients' background and was best in the Duloxetine group and all three psychoactive groups fared better than the control group. These differences (single and cumulative) were significant at 95 and 98% interval.

**Conclusions.**– This is the first study that shows direct effectiveness of unrelated drugs on HbA<sub>1c</sub> in type II diabetes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Use of substances in obese patients candidates to bariatric surgery (Obenol project)

M. Forner, L. Nuño, G.C. Gavotti, P. Gavin, M. Monràs, R. Navinés, A. Lligoña\*, S. Cañizares

Hospital Clínic, Neuroscience Institut, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Bariatric surgery (BS) is an effective treatment to reduce overweight in patients with morbid obesity. This surgical procedure produces changes in substances' absorption. For this reason, operated patients are more sensitive to the effect of substance use (Buffington et al., 2006). A previous history of substance use has been detected in 60% of patients undergoing BS (Conason et al.,

2013). Moreover, Li & Wu (2010) reported that the prevalence of alcohol use among patients operated by BS is around 10%. The aim of this study is to evaluate alcohol consumption between patients' candidates for BS. In this poster, we present preliminary results of substance consumption.

**Methods.**– Transversal study. The sample consisted of 100 patients with morbid obesity candidates for BS. Patients were assessed through a psychiatric interview, a psychological assessment and a urinalysis to assess substance use.

**Results.**– Regarding the last 3 months, 13% of the sample reported tobacco use, 15% had drunk alcoholic drinks and 6% had smoked cannabis. 4% reported the use of benzodiazepines and 1% of cocaine. No one reported consumption of other drugs such as amphetamines, hallucinogens or opiates. None of the subjects reported risky alcohol consumption, while 8 had positive results in etilglucuronide test.

**Conclusions.**– Preliminary results show that alcohol is the most consumed substance in our sample. However, the prevalence of risky alcohol consumption appears to be lower as expected. It is important to evaluate substance abuse pre BS with questionnaires and add urine control tests, as patients tend to minimize their consumption.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Thyroid disorders in patients with schizophrenia, unipolar depression or bipolar disorder**

M. Moalla\*, R. Sellami, I. Baati, A. Feki, I. Feki, J. Masmoudi  
CHU Hédi Chaker Sfax, Tunisia, department of psychiatry "A", Sfax, Tunisia

\* Corresponding author.

**Introduction.**– The relation between thyroid function and mental disorders has long been recognized. The co-occurrence of psychiatric and thyroid diseases may be the result of common biochemical abnormalities.

**Objectives.**– The aim of this study is to investigate differences in thyroid-stimulating hormone (TSH) level in patients with acute schizophrenia, unipolar depression, bipolar depression and bipolar mania.

**Methods.**– We analyzed the TSH level of 108 patients admitted to our unit. The study included patients with schizophrenia, bipolar disorder and unipolar depression.

**Results.**– The mean age was  $39.5 \pm 12.42$ . The proportion of women was 37% ( $n=40$ ).

Mean serum TSH concentration was: schizophrenia ( $n=58$ ) 2.51 IU/mL, unipolar depression ( $n=12$ ) 2.89 IU/mL, bipolar disorder ( $n=38$ ) 4.12 IU/mL, bipolar depression ( $n=8$ ) 5.39 IU/mL and bipolar mania ( $n=30$ ) 3.79 IU/mL. No significant difference was found for TSH level between clinical groups ( $P=0.40$ ).

Depending on the normal range used (0.27–4.2 IU/mL), the overall rate of being above or below the normal range was 20.7% for schizophrenia, 16.7% for unipolar depression and 26.3% for bipolar disorder.

No significant correlations were found between TSH level and age nor sex.

**Conclusions.**– Our results confirm that there may be a higher prevalence of thyroid dysfunctions in patients with these mental disorders. Although the difference between clinical groups was not significant, patients with bipolar disorders seems particularly vulnerable to thyroid dysfunction.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0665

### **Study of C-reactive protein (CRP) levels in patients with schizophrenia, unipolar depression and bipolar disorder**

M. Moalla\*, R. Sellami, I. Baati, A. Feki, I. Feki, J. Masmoudi  
CHU Hédi Chaker Sfax, Tunisia, department of psychiatry "A", Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Studies show that elevated C-reactive protein (CRP) is strong predictor for cardiovascular risk. Patients with various mental disorders have elevated levels of CRP.

**Objective.**– The aim of the study was to determine differences in CRP serum level in patients with acute schizophrenia, unipolar depression and bipolar disorders.

**Method.**– Serum level of CRP was measured for 83 inpatients. The cut-off points for low, moderate and high levels of CRP were set according to the Centers for Disease Control and Prevention and by the American Heart Association criteria as  $< 1$  mg/l (low), 1–3 mg/l (moderate) and  $> 3$  mg/l (high). Elevated CRP level ( $> 10$  mg/l) may not reflect their usual CRP level but rather infection or inflammatory disorder.

**Results.**– There were 82.3% men ( $n=51$ ). The mean age was 39.55 years.

Twenty-one patients (25.3%) had CRP  $> 10$  mg/l and were not included in our analysis.

The mean concentration of CRP in different groups was: schizophrenia ( $n=38$ ) 3.82 mg/l, unipolar depression ( $n=9$ ) 3.48 mg/l and bipolar disorders ( $n=15$ ) 4.1 mg/l. The comparison between the three groups shows no significant difference ( $P=0.58$ ). The rate of being above the high level of CRP was 39.4% for schizophrenia, 44.4% for unipolar depression, 46.6% for bipolar disorder.

The rate of patients being above high level was higher in women ( $P=0.023$ ). CRP level was positively correlated with age ( $P=0.012$ ).

**Conclusions.**– Our study shows that more than the third of patients presents a high cardiovascular risk according to CRP level.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0666

### **Bipolar disorder in ADHD: frequent comorbidity or severe neurodevelopmental disorder?**

F. Oliva<sup>1</sup>, P. Ferreri<sup>2</sup>, A. Portigliatti Pomeri<sup>2</sup>, S. Bramante<sup>2</sup>, M. Boero<sup>1</sup>, C. Mangiapane<sup>1</sup>, G. Nibbio<sup>1</sup>, G. Maina<sup>2</sup>  
<sup>1</sup> University of Turin, Biological and Clinical Sciences department, Orbassano TO, Italy; <sup>2</sup> University of Turin, Neurosciences "Rita Levi Montalcini" department, Turin, Italy

\* Corresponding author.

**Background.**– The aim of the present study was to evaluate prevalence and clinical variables of patients with and without bipolar disorder in a sample of adult ADHD outpatients.

**Methods.**– We examined all medical records of outpatients accessing the adult ADHD center of the AOU San Luigi Gonzaga, Orbassano (TO), Italy, in order to collect data about socio-demographic factors, medical history, medical and psychiatric diagnosis. Adult DSM-IV ADHD diagnosis was made by DIVA 2.0 whereas DSM-IV comorbidities were assessed by SCID I and II.

**Results.**– Above one quarter of our sample with ADHD (26,6%) had also a bipolar disorder that was a type II in almost all of cases (90,5%). ADHD combined type (ADHD-C) is more common than inattentive type (ADHD-I) in patients with bipolar disorder

only (ADHD+DB; ADHD-C:85,7% vs. ADHD-I:14,3%; ADHD; ADHD-C:51,7% vs. ADHD-I:48,3%;  $p=0,006$ ). ADHD-C is more common in bipolar patients even in childhood (ADHD+DB; ADHD-C:65% vs. ADHD-I:25% vs. ADHD-H:10%; ADHD; ADHD-C:52% vs. ADHD-I:48%;  $P=0,048$ ).

Moreover, ADHD with bipolar disorder had more frequently a comorbid psychiatric disorder or other co-occurring conditions (personality disorder, 19% vs. 1,8%,  $P=0,006$ ; sleep disorder, 52,3% vs. 32,7%,  $P=0,009$ ; use of benzodiazepines without anxiety disorder, 47,6% vs. 10,9%,  $P=0,001$ ; immune system disease, 23,8% vs. 5,2%,  $P=0,015$ ).

**Conclusions.**– Our findings are consistent with previous studies reporting a high prevalence of bipolar II disorder among adults with ADHD. ADHD patients with comorbid bipolar disorder seem most likely to have shown a combined manifestation of inattention and hyperactivity in childhood that evolved in a complex and severe clinical picture with personality and sleep disorders co-morbidities.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0667

### Double screening for dual disorder – alcoholism and depression

B. Pavkovic<sup>1\*</sup>, M. Zaric<sup>1</sup>, M. Markovic<sup>1</sup>, M. Klacar<sup>2</sup>, A. Huljic<sup>3</sup>, A. Caricic<sup>3</sup>

<sup>1</sup> Health Center Dr Simo Milosevic Cukarica, Psychiatry, Belgrade, Serbia; <sup>2</sup> Health Center Dr Simo Milosevic Cukarica, Pediatrics, Belgrade, Serbia; <sup>3</sup> Health Center Dr Simo Milosevic Cukarica, General Practice, Belgrade, Serbia

\* Corresponding author.

**Introduction.**– Comorbidity between depressive and alcohol use disorders have been reported in samples and it is confirmed that alcohol use disorder (AUD) often co-occur with major depressive disorder (MDD).

The aim of study was to examine the relationship between alcoholism and depression in undiagnosed patients by simultaneously applying screening tests for both disorders.

**Methods.**– A total of 500 subjects were tested, of which 421 were included in the study, 175 male and 246 female. Two screening tests, Michigan Alcoholism Screening Test (MAST) and Beck Depression Inventory (BDI), were used. Collected data processed using the statistical package Statistica 13.2 and methods of descriptive and analytical statistics.

**Results.**– Of the total sample, 28,03% of respondents were any of problem drinkers and 55,82% had some level of depression, 59,14% of respondents at the same time had both, any of problem drinking and some level of depression.

Results of statistical analysis showed that more problematic alcohol use type is associated with more severe level of depression, greater positive association between problematic alcohol use and severity of depressive symptoms in female and more harmful alcohol consumption in male.

**Conclusion.**– This study points to the importance of screening for alcoholism and depression in primary health care for the early detection of these often comorbid disorders, because their timely treatment improves better quality of life in newly diagnosed individuals and reduces economic burden to society in terms of allocating funds for the health service due to their more frequent use of health services if they reach greater level of dual disorder severity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### A retrospective observational study of seasonal variation and alcohol consumption: Implementation of the sample

R.A. Colombo, M. Preve\*, E. Bolla, R. Traber  
Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

\* Corresponding author.

**Introduction.**– Seasonal and geographic variations in light exposure influence human mood and behavior, including alcohol consumption. Similarly, manipulation of the environmental lighting regimen modulates voluntary ethanol intake in experimental animals [1–3]. The aim of our study is to evaluate the relationship between alcohol consumption and seasonal variation in a sample of alcohol dependent patients.

**Method.**– 234 inpatient are assessed with: the SCID-P for axis I diagnosis. Inclusion criteria are: (1) acute alcohol intoxication at the admission. All the sociodemographic characteristics are explained.

**Results.**– There are no difference when we compare total admission of 2013 and 2014. The peak period of alcohol admission is in the spring in april-may, the lowest period is in autumn october-november in 2013, whereas the peak period of alcohol admission is in the autumn in september-october, the lowest period is in spring in april and may in 2014. The rates of comorbidity are: personality disorders (30,3%), affective disorders (28,9%) and psychotic disorders (8,8%).

**Discussion and conclusion.**– Developmental alcohol exposure produces subtle abnormalities in circadian rhythms that may contribute to the development of seasonal and nonseasonal mood disorders [4]. Seasonal variability of alcohol admission in Ticin (Switzerland) is influenced by natural factors and by social factors. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Dissociative amnesia due to acute alcohol intoxication during SSRIs (Fluoxetine) treatment: Tree case report and literature review

M. Preve\*, G. Canitano, M. Godio, R.A. Colombo, R. Traber  
Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

\* Corresponding author.

**Introduction.**– Serotonin-specific reuptake inhibitors (SSRIs) like fluoxetine are antidepressant drugs commonly used to treat a wide spectrum of mood disorders, in particular fluoxetine is used in unipolar depression, anxiety disorders, obsessive compulsive disorder, bulimia and is an option among the “serotonergic” agents that have been evaluated for alcoholism treatment [1]. Depersonalization and derealization symptoms sometimes compare during alcohol intoxication [2]. The purpose of this report is to review the presence of dissociative amnesia due to acute alcohol intoxi-

cation and explain the role of SSRIs treatment (fluoxetine) in this condition. We propose three different case reports and literature review.

**Method.**– We conducted a systematic review of the literature with the principal database (PubMed, Embase, PsychInfo) and we present three different case reports.

**Results.**– The acute alcohol intoxication during fluoxetine treatment determines a dissociative amnesia characterized by autobiographical memory compromise, compromise of subjective reliving, memory disturbances in the form of retrograde amnesia, derealization and depersonalization symptoms. Moreover in dissociative amnesia, several serious consequences were identified like impulsiveness, loss of control and aggressiveness.

**Discussion and conclusion.**– In our case reports we suppose that SSRIs treatment (fluoxetine) play a role with alcohol in significant cognitive and behavioral impairment, but also in dissociative amnesia, derealization and depersonalization, loss of control, impulsiveness as well as aggressiveness [3]. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Efficacy of pregabalin in cocaine dependence: Case series and literature review**

M. Preve\*, N.E. Suardi, M. Godio, G. Canitano, S. Casigliani, R.A. Colombo, R. Traber  
Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

\* Corresponding author.

**Introduction.**– Pregabalin has shown greater potency than gabapentin in preclinical models of epilepsy, pain and anxiety, and pregabalin may have potential in the treatment of some aspects of cocaine addiction [1-3]. The purpose of this report is to review the efficacy of pregabalin in a sample of dependence patients. We propose different cases and literature review.

**Method.**– 20 inpatients with alcohol and cocaine dependence were assessed with: the SCID-P, HAM-A, BIS-11 and BPRS. We conducted a systematic review of the literature with the principal scientific database (PubMed, Embase, PsychInfo), using the terms “pregabalin”, “alcohol”, “cocaine”.

**Results.**– There are any significant differences in sociodemographic characteristics of the sample ( $n=20$ ), only gender differences: male are more than female ( $P=.036$ ). We found a significant reduction of anxiety symptoms at the HAM-A scale, in particular item 2  $P=.001$ ; item 4  $P=.002$ ; item 7  $P=.001$ ; item 13  $P=.003$ ; item 14  $P=.001$  and HAM-A total score ( $P=.003$ ), a significant reduction of the BIS total score ( $P=.001$ ). Comorbidity and clinical correlates are explained in the table (not supplied).

**Discussion and conclusion.**– In our opinion this is the first study that explains the efficacy of pregabalin treatment in a sample of cocaine dependent patients to reduce anxiety and impulsivity. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations, clinical implications and suggestions for future research directions are considered.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Self-esteem, depression and anxiety in multiple sclerosis: Is there a link?**

N. Smaoui<sup>1\*</sup>, N. Halouani<sup>1</sup>, S. Daoud<sup>2</sup>, M. Damak<sup>2</sup>, S. Ellouze<sup>1</sup>, R. Naoui<sup>1</sup>, J. Aloulou<sup>1</sup>, C. Mhiri<sup>2</sup>, O. Amami<sup>1</sup>

<sup>1</sup> Hedi Chaker University Hospital, Department of Psychiatry B, Hedi Chaker University Hospital, Sfax, Tunisia;

<sup>2</sup> Habib Bourguiba university hospital, Department of Neurology, Habib Bourguiba University Hospital, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Studies have shown that patients with multiple sclerosis (MS) report low levels of self-esteem, high levels of anxiety and depression and reduced quality of life.

**Objectives.**– To assess self-esteem, depression and anxiety in patients with MS and to determine the relation between them.

**Methods.**– A cross-sectional and analytical study was carried out on 42 patients with MS, followed up in the outpatient neurology department of Habib Bourguiba hospital, Sfax, Tunisia, over a period of six months. The evaluation of the level of self-esteem was done by the Rosenberg Self-esteem Scale (RSS; 10-items), anxiety and depression by the Hospital Anxiety and Depression Scale (HADS), and the level of disability by the Expanded Disability Status Scale (EDSS).

**Results.**– The sex ratio was 0.9 and the mean age of the participants was  $36.9 \pm 9.6$  years. Relapsing-remitting MS occurred in 88.1% of cases. The mean duration of MS was  $8.4 \pm 5.2$  years. The mean EDSS score was  $2.8 \pm 2.1$ . Vesicosphincteric disorders were reported by 52.4% of patients. Low levels of self-esteem (RSS score  $\leq 30$ ) were found in 57.1% of patients. According to the HADS, 38.1% of patients had depressive symptoms and 54.8% had anxious symptoms. Low levels of self-esteem were correlated with anxiety ( $P=0.016$ ), depression ( $P=0.002$ ) and the presence of vesicosphincteric disorders ( $P=0.047$ ).

**Conclusions.**– It is important to consider the relationship between these aspects, since self-esteem, anxiety and depression can be positively modified through psychotherapeutic interventions, thus potentially having an important impact on quality of life of patients with MS.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Suicide attempts associated to substance use disorders; A descriptive study**

A. Trabsa<sup>1,2\*</sup>, G. Sánchez-Moncunill<sup>1</sup>, M. de Dios<sup>1,2</sup>, I. Ezquiaga<sup>1,2</sup>, Á. Palma<sup>1,2</sup>, D. Sanagustin<sup>1</sup>, E. Monteagudo<sup>1</sup>, V. Pérez<sup>1,2</sup>, M. Campillo<sup>1</sup>

<sup>1</sup> Hospital del Mar, Psychiatry, Barcelona, Spain;

<sup>2</sup> Institut de Neuropsiquiatria i Addiccions, Parc Salut Mar, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Suicide is the 15th leading cause of death worldwide being a major public health concern. Suicidal attempt and substance use disorders (SUD) are associated with increased risk for

suicide, however, relatively little is known about the real impact SUD on suicidal behaviour.

**Objective.**– To describe the presence of SUD in suicidal attempts and its characteristics, such as: age, hospitalization after suicide attempt and relapse.

**Methods.**– A total of 7911 psychiatric emergency visits were registered during 2013 in two different units in Barcelona (Hospital del Mar and Centre Emili-Mira). Suicide attempt ( $n=452$ ) were selected from the database. Afterwards, the information was completed with electronic medical records. Descriptive analysis was performed with IBM SPSS Statistics (Chicago INC).

**Results.**– From 452 suicide attempt patients sample, 165 (36.5%) were associated to substance use disorder. The highest prevalence of concomitant SUD was detected between the age of 28–47 yo (40.5%) and the lowest between 68–87 yo (0%). From total patients who required hospitalization 166 (44.50%) had SUD and 70 (24.40%) did not. Relapse suicide attempt was reported in 36 (22%) SUD patients and in 54 (18.8%) without concomitant SUD.

**Conclusions.**– Relapse of the attempt were similar between patients with SUD and patients without SUD. However, patients with concomitant SUD were more likely to require hospitalization. Therefore, SUD appears to be an important target in suicidal attempts assessment. Further studies should evaluate the clinical relevance of exploring and treating SUD in order to prevent hospitalization.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Premature ejaculation dysfunction in adult attention deficit and hyperactivity disorder: Relation with 2D:4D ratio**

A.N. Inci Kenar<sup>1</sup>, S.U. Aydin<sup>2</sup>, A. Zıblak<sup>1\*</sup>

<sup>1</sup> Pamukkale University, Psychiatry, Denizli, Turkey;

<sup>2</sup> Pamukkale University, Child and Adolescent Psychiatry, Denizli, Turkey

\* Corresponding author.

**Introduction.**– In this study, it was aimed to determine the relationship between adult ADHD and, PE frequency and 2D:4D ratio, which is accepted as a fetal testosterone exposure indicator.

**Methods.**– Twenty-four ADHD patients and 38 healthy controls were included into the study. Sign and ring fingers of the individuals, included into the study, are measured directly with digital caliper (0.01 mm accuracy). The diagnosis of PE was made by clinical interview.

**Results.**– Mean age of the adult ADHD group is  $28.67 \pm 8.55$  and control group is  $31.97 \pm 8.11$ . There was no statistically significant difference between the two groups. In the adult ADHD group, the PE frequency was found to be 45.8% and history of enuresis nocturna (EN) frequency was found to be 37.5%. Adult ADHD patients with PE were found to have lower 2D:4D ratios, but it was not statistically significant, when compared to those without PE.

**Conclusion.**– As a result; PE was found more frequent and 2D:4D ratio was found low in adults with ADHD, suggesting that high testosterone levels play a role in the etiology of both ADHD and PE, and it was supposed that high frequency of the coexistence of these two clinical diagnoses is due to the possible common etiology. This study is the FIRST one to investigate the relationship between PE frequency in adult ADHD and the 2D:4D ratio, which is considered to be a marker of fetal testosterone exposure. In addition, it is the SECOND study showing the frequency of adult ADHD and PE comorbidity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Risk assessment of dangerous behavior in persons with mental disorders**

O. Makushkina

Federal Budgetary Institution “V. Serbsky National Medical Research Center for Psychiatry and Narcology”

of Ministry of Health of the Russian Federation, Forensic Psychiatric Prevention, Moscow, Russia

\* Corresponding author.

The prediction of the risk of committing socially dangerous acts by persons with mental pathology is the important subject in the system of preventive measures in the mental science. By the way there's a low understanding of the dangerous behavior predictors of mentally ill offenders. It causes significant difficulties in the risk prevention of potential dangerous acts.

This study aimed at validation and verification the methods of structured risk assessment of dangerous behavior (SRADB).

The SRADB contains 22 characteristics that contribute to the risk of committing offence. All characteristics are distributed between three blocks: (1) clinical symptoms; (2) characteristic associated with the patient's life history; (3) characteristic associated with maladjustment. The sum of the predictive coefficients is distributed in the range from “–20” to “+20” points. “+20” points is the cut-off value that shows the high risk of committing dangerous acts. The threshold “–20” corresponds with the low risk.

506 patients (424 men and 82 women) from 22 to 85 years old were surveyed with the SRADB; median age was  $41.54 + 12.17$ . 406 patients are on the compulsory treatment, who committed dangerous actions; 100 patients are on the follow-up care with stable lawful behavior.

The reliability ( $\alpha$ -Cronbach 0.8) and the test validity (Kendall's tau coefficient from 0.5 to 0.85) of the SRADB were demonstrated. ROC-analysis shows the high predictive power of the SRADB (AUC > 0.75). The sensitivity is 93.8% and specificity is 77%.

The results of the study make it possible to recommend the SRADB for assessing the risk of dangerous behavior in persons with mental disorders.

### **The subjective truth and the will to power: Ethical issues euthanasia and physician-assisted death in the psychiatrically and neuropsychiatrically ill**

D. Banayan

Rush University Medical Center, Psychiatry, Chicago, USA

\* Corresponding author.

**Introduction.**– A number of countries in Europe and several states in the United States have developed and implemented health care policies on euthanasia and physician-assisted death. Psychiatrists play a critical gatekeeping role in maintaining the integrity and ethical administration of end-of-life laws, by identifying patients

who are incapable to make the decision or are suffering from a treatable psychiatric illness.

**Objectives.**– This session will explore ethical dilemmas in the administration and delivery of life-ending medical therapies in patients with psychiatric or neuropsychiatric disease. Participants will further elucidate their own ideas and values on the subject, and acquire more insight into patient choice and perspectives. Practice models and outcomes studies from a variety of countries will be reviewed.

**Methods.**– A brief review of core concepts in clinical ethics will set the stage for critiquing data obtained from a comprehensive literature review (PubMed, Ovid Medline) on international practices, trends and ethical issues in physician-assisted death and euthanasia.

**Results.**– Increasing numbers of patients with psychiatric or neuropsychiatric disorders are seeking physician-assisted death or euthanasia. Conceptual challenges of defining ‘unbearable suffering’, and ‘loss of dignity’ make it difficult to discern if or when life-ending treatment is appropriate or ethical. The rate of acceptance and denial of these requests is highly variable. Some studies have identified that a significant proportion of psychiatric patients have not exhausted all treatment possibilities.

**Conclusions.**– Psychiatrists need to be prepared to talk with and respond to patients who make enquiries about physician-assisted suicide / euthanasia.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

PW0676

### **Euthanasia for mental suffering perforates the therapeutic resiliency of mental health care**

A. Bazan<sup>1</sup>, G. Van de Vijver<sup>2</sup>, L. Willem<sup>3</sup>

<sup>1</sup> Université Libre de Bruxelles,

Faculté de Sciences Psychologiques et de l'Éducation, Brussels, Belgium; <sup>2</sup> Ghent University, HICO – Centre for the History of Philosophy and Continental Philosophy, Ghent, Belgium;

<sup>3</sup> Departement Wijsbegeerte, Universiteit Antwerpen, Antwerp, Belgium

\* Corresponding author.

**Introduction.**– The Belgian law on the depenalisation of euthanasia requires (1) that the suffering is unbearable, (2) that the condition is “medically hopeless”, and that (1) is due to (2). On the basis of the terms of the law, we [1,2] have been arguing before that in case of sole mental suffering the law can not be applied because (2) can not be objectified. However, the law continues to be applied, including in young adults, for which empirical evidence shows that the prognosis cannot objectively be qualified as “medically hopeless”. So, factually, the application of the law amounts to a practice of assisted suicide, sealed with a medical warrant.

**Objectives.**– We want to show how the seemingly innocuous medical seal on this practice, in fact, jeopardizes the field of mental health care.

**Methodology.**– With excerpts for clinical cases, we illustrate how patients put ultimatums on treatment trajectories, how therapists lose their patients suddenly in the midst of their careful treatment journeys, how euthanasia is played out in morbid interactions which sometimes resemble practices of grim blackmail.

**Conclusion.**– When there is a plan B, namely euthanasia, both patients and therapists are trapped and the therapeutic resiliency of the mental health care field is perforated.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Euthanasia for psychic suffering: Urgent call from Belgium**

M. Calmeyn<sup>1</sup>, M. eneman<sup>2</sup>

<sup>1</sup> Private practice ‘Lelieveld’

Loppem & Psychiatric Hospital OLV Bruges, medical department, Loppem Zedelgem, Belgium;

<sup>2</sup> University Psychiatric Centre Sint-Kamillus Bierbeek Belgium, medical directory, Bierbeek, Belgium

\* Corresponding author.

**Introduction.**– The Belgian law for euthanasia includes that people suffering from mental disorders can request it. Indeed, the number of people asking for euthanasia and getting permission for it is growing every year after the introduction of the law in 2002.

**Objectives.**– By exploring the non-evident question whether euthanasia – according to the Belgian law – for psychic suffering is permitted or not, some remarkable and unavoidable findings are explored in the presentation. Some basic question marks can no longer be neglected by the professional community.

**Methods.**– Those levels necessary to explore this question are clinical, theoretical and ethical. The authors of the presentation have extensive clinical experience as a psychiatrist and psychotherapist in the field. From a theoretical point of view philosophical principles concerning euthanasia for psychic suffering are explored and explained in the presentation. Nosological knowledge about psychopathology is crucial to surmount ideological judgments and prejudices. Ethical considerations on being human and human being, on the (im)possibility of treatment, on mental suffering itself are indispensable to (even) consider the decision for life or death.

**Results.**– It's not evident to put the question for euthanasia for mental disorders on the same level as for somatic disorders. Even more, due to the specificity of psychiatric disorders, the so called evident permission to perform euthanasia for psychic suffering should be seriously challenged.

**Conclusions.**– Euthanasia for psychic suffering is a not at all an answer for the human brokenness of which psychiatric disorders are testimonies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0678

### **Voluntary euthanasia of patients with mental illness: An inversion of psychiatry's fundamental clinical and ethical values**

M. Komrad

Ethicist-in-Residence, Sheppard Pratt Health Systems, Psychiatry, Towson, USA

\* Corresponding author.

In several European countries physician-assisted suicide and euthanasia by lethal injection are being made available to psychiatric patients with non-terminal mental illnesses, commonly administered by their own treating psychiatrists giving the injection. Canada now offers euthanasia by injection for patients who are not strictly terminally ill and is on the verge of making it available to those with psychiatric disorders only. This raises profound ethical questions, for psychiatrists in particular, who have a core

ethos and skill set to prevent suicide, help patients cope with suffering, find alternative paths to a better future, even make meaning of suffering. Allowing psychiatrists to help their patients suicide inverts the fundamental ethical framework and very definition of what it means to be a psychiatrist. This lecture examines the history of developments in Europe, Canada, and the U.S. regarding physician-assisted suicide and euthanasia of non-terminal psychiatric patients. Data from Belgium and Netherlands are reviewed. The positions of medical and psychiatric organizations around the world are shown, especially the new ethical position against such practices by the American Psychiatric Association. Fundamental ethical arguments in favor of psychiatric euthanasia are contrasted with those against. Clinical, social, and professional consequences are reviewed, including some specific cases, relevant data, and evidence for a “slippery slope” of these policies and practices. Finally, the way these activities challenge the fundamental identity of the psychiatric profession will be discussed, and how this is an unanticipated consequence of pursuing parity for the mentally ill.

*Bakirkoy Training and Research Hospital for Psychiatry, Neurology & Neurosurger, Forensic Psychiatry, Istanbul, Turkey*

\* Corresponding author.

*Objective.*– In the last two decades, parallel to the apparent increase in the number of female offenders, the number of studies investigating women’s characteristics, the nature of the crime and the conditions for the crime process have also increased. In this study, it was aimed to investigate the clinical and sociodemographic factors affecting repetitive crime in female prisoners.

*Method.*– 105 women convicts who applied for psychiatric examination in Istanbul Bakirköy Woman Closed Prison were enrolled to study. The socio-demographic data collection form created by the investigators was utilized by the Structured Clinical Interview Formulation for DSM-IV Axis I Disorders SCID-I and Taylor’s Crime Severity Grading Scale. The sample group was divided into two groups as repetitive offenders (25 people) and non-repetitive offenders (80 people), groups were socio-demographically compared according to their crime types and clinical characteristics.

*Results.*– In our study, recurring offenders had more history of disease, early onset psychiatric disorders, longer episodes, more applications to the psychiatric clinics, more self-injurious behaviors and suicide attempts, alcohol and substance abuse, and alcohol-substance abuse during the crime and their Axis II disorders were more prominent. It has been determined that substance abuse, self-injuring and seperation in the family are independent factors that significantly predict recidivism.

*Conclusion.*– Multidimensional evaluation of women who commit repetitive crimes by mental health professionals and the judicial system will be more effective in preventing new crime.

*Keywords:* Prison; Female; Crime; Substance use disorders

### **Red-teaming the panopticon (Mobilising adaptive change in secure and forensic settings)**

S. Markham

*King’s College University of London, Institute of Psychiatry- Psychology and Neuroscience, Hellingly, United Kingdom*

\* Corresponding author.

*Introduction.*– In England and Wales, secure and forensic psychiatric services impose significant restrictions upon detainees. Patients may be detained under the MHA for several years or even life, as they are deemed to present a significant risk to themselves or the public. Patients under s37/41 require Home Office approval for any increase in freedom. Best practice requires reoffending risk to be assessed before a patient is discharged. Evaluation of risk is an inexact actuarial science operating in a political arena, and research has indicated risk assessment tools have little positive predictive validity. There is concern amongst the wider psychiatric and judicial communities about the ethics of current practice.

*Objectives.*– To examine these issues and means of improving risk assessment practice.

*Methods.*– Consideration of the concept of risk and issues regarding risk assessment tools. Initiatives to make secure and forensic services more patient-centric are considered together with evidence of impact and efficacy. Further means of improving risk assessment are explored.

*Results.*– More research is required to explore the experiences of patients, especially their experience of risk assessment, and to study patient–professional interaction more closely.

*Conclusions.*– Forensic psychiatric services need to become more authentic; enabling patient offenders to both be treated fairly to seek support and give support to others. It may be argued that such changes would resonate with the ethical underpinning of clinical psychiatry and have the potential to achieve natural epistemic and cultural fit. This would work towards liberating services from the paralysing fear of the innate uncertainties of risk.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **On psychiatry in context of philosophical anthropology**

E. Neu<sup>1</sup>, M.C. Michailov<sup>1</sup>, C. Lütge<sup>2</sup>, R. Neu<sup>1</sup>, P. Birkenbihl<sup>1</sup>, U. Welscher<sup>1</sup>, M. Schratz<sup>3</sup>, G. Weber<sup>4</sup>

<sup>1</sup> *Inst. Umweltmedizin c/o ICSD e.V., Pharmaco-Physiology, Munich, Germany;* <sup>2</sup> *Techn. Univ. München, Inst. Ethics Dir., Munich, Germany;* <sup>3</sup> *Univ. Innsbruck, School Education Dean, Innsbruck, Austria;* <sup>4</sup> *Univ. Lxbg. and Vienna, Fac. Psychology Dean, Vienna, Austria*

\* Corresponding author.

*Introduction.*– Central position of psychiatry in medical sciences needs renewal by philosophical anthropology.

*Conception.*–

A. Epistemology. An integral anthropology should include essential information about human being (spiritual-mental upto physical “spheres”) and interaction with nature (geo-biospheres) & society (family-school-etc.). Individual-natural-social anthropology is related to psychiatry in context of psychosomatic (Th.von UEXKÜLL) & somatopsychic theories (Y.IKEMI).

B. Moral philosophy. Ethical-frames destination for psychiatrists (also medical personnel) acc. to KANT’s human obligations to himself, other humans, sub-human: plants-animals, supra-human

beings related to modern ethical theories (deontology-utilitarianism-etc.) & Buddhism-Brahmanism-Christianism-etc. are fundamental for psychiatry.

C. Aesthetics. Psychotherapy, psychopharmacological and surgical therapy in psychiatry must be in concordance with medical ethics (*primum non nocere*), e.g. for oncological patients (radiochemotherapy). Self-control of pathophysiological & psychopathological influences by cognitive therapy, Buddhist, Yoga practises, etc. could support mental health of patients.

*Conclusion.*– Foundation of an International Academy for Psychiatry, similar to European Acad. Neurology (EAN-2015-Berlin) by EPA/WPA and other societies, could support education, research, therapy in psychiatry about mental health, related to UNO-Agenda21 for better health-ecology-economy on global level [1–4].

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Ethical and spiritual aspects of attitudes toward euthanasia in junior medical students

E. Nikolaev<sup>1\*</sup>, A. Aleksandrov<sup>2</sup>, I. Poverinov<sup>3</sup>

<sup>1</sup> Chuvash State University,

Department of Social and Clinical Psychology, Cheboksary, Russia;

<sup>2</sup> Chuvash State University, Department of Public Law, Cheboksary,

Russia; <sup>3</sup> Chuvash State University,

Department of Philosophy- Sociology and Pedagogics, Cheboksary, Russia

\* Corresponding author.

*Introduction.*– Euthanasia is one of the ethical problems that medical professionals start to form their attitude to still studying in medical school.

*Objectives.*– This study is aimed to clarify the specifics of ethical and spiritual representations on euthanasia in junior medical students.

*Methods.*– Study participants were 221 first- and second-year medical students who filled in a 19-item questionnaire (E. Nikolaev, 2016) measuring different aspects of attitudes to euthanasia. Basic statistics and correlation analysis were used for the data interpretation.

*Results.*– Two-thirds of the students (67.3%) represent euthanasia as not a medical or legal problem, but as a moral or ethical one. Three quarters (78.2%) are confident that euthanasia legalization can lead to abuses, 64.6% believe that practicing euthanasia is contrary to the

divine nature of a human, and 63.2% indicate that since humans comes to this world not of their own free will, neither should they leave it of their own will. More than half of the students (53.4%) believe that legalization of euthanasia indicates lack of spirituality in the society. Correlation analysis shows ( $P < 0.05$ ) that this ratio is more pronounced among believing students than among non-believers. With age, the negative attitude toward euthanasia grows. Greater opposition to passive euthanasia is accompanied by greater aversion to active euthanasia, fears of possible abuses, low interest in euthanasia experience in other countries, pronounced personal time perspective for future.

*Conclusions.*– The ethical and spiritual aspects of euthanasia are closely interrelated in representations of junior medical students and can be attributed both to religious views and professional education.

### Protective factors associated with the criminal desistance in young people in conflict with the law

M. Orlando

Member of the Argentinian Criminal Law Court, Juvenile Law Court, Buenos Aires, Argentina

\* Corresponding author.

*Introduction.*– Previous studies about young people in conflict with the law (YPCL) have a tendency to focus on the risk factors that contribute to trigger antisocial criminal behaviours. Instead, this study aims to research about the protective factors that prevent the development of such behaviours and encourage the criminal desistance.

*Objectives.*– From a sample that is made up of 100 YPCL non-recidivists, the main objective is to analyze the personal and contextual factors related to criminal desistance in YPCL.

*Methods.*– Unstructured interviews have been carried out, since the technique allows a style of interaction that favors empathy, the interpenetration between the interviewer and the interviewee with sufficient confidence and naturalness so that the data obtained can be elaborated, nuanced and valid.

*Results.*– This study showed a preponderance of the following protective factors associated to the criminal desistance: educational opportunities, change of social context, harmonic relationship with at least one reliable adult, parental supervision, sense of purpose, critical awareness, ability to solve problems, hooks for change, cognitive transformations, Pygmalion effect, knifing off, social support networks, spirituality, dis-labeling process.

*Conclusions.*– Considering the desistance as a gradual process in which an adolescent with repeated criminal behaviours reduces this activity to a low or insignificant level over a prolonged period of time, it has been possible to identify personal and context protective factors that encourage the criminal desistance. The findings of this study may contribute to future policies aimed at promoting the criminal desistance of young people in conflict with the law.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **A complicated case of an obsessive homicidal patient – The Copycat effect**

H. Raai<sup>1</sup>, A. Ali<sup>2</sup>, K. Frischer<sup>3</sup><sup>1</sup> Bronx Lebanon Hospital Center,

Department of Psychiatry and Behavioral Sciences, New York, USA;

<sup>2</sup> Bronx Psychiatric Center, Forensic Psychiatry, New York, USA;<sup>3</sup> Albert Einstein College of Medicine, Psychiatry Department, New York, USA

\* Corresponding author.

A copycat crime is a criminal act that is modeled or inspired by a previous crime that has been reported in the media or described in fiction. The copycat effect is the tendency of sensational publicity about violent murders or suicides to result in more of the same through imitation. While copycat phenomenon is more frequently studied in mass killing, the effect of violent media on single acts of violence, from petty crimes to homicides, is not well studied. It is not clear whether individuals who express an interest in copycat violence have a high rate of mental illness. However it is possible that having impaired reasoning abilities combined with poor impulse control makes mentally ill patients more vulnerable to suggestibility and imitation of violent acts. Studies and reports warn of the copycat effect after mass killings. It has been indicated that threats to conduct similar attacks tend to increase dramatically in the weeks following a highly publicized mass murder. This poster will present a case of a psychiatric patient who expressed obsessive homicidal thoughts and later committed murder while being treated in a long term psychiatric hospital. The patient was fascinated with reality based historical mass murderers, as well as movies and TV shows portraying serial killers such as "Dexter". This poster aims to present the potential significance of media violence and copycat effect on mentally ill patients. It will examine whether psychiatric patients have a higher likelihood of threatening or committing copycat offenses.

### **Profiling violence: The role of pathological narcissism and maladaptive personality traits**

G. Rogier<sup>1</sup>, V. Nannini<sup>1</sup>, P. Velotti<sup>2</sup><sup>1</sup> La Sapienza, Dynamic and Clinical Psychology, Rome, Italy;<sup>2</sup> University of Genoa, Educational Sciences, Psychology Unit, Genoa, Italy

\* Corresponding author.

*Introduction.*– Aggressive behavior has been linked to both narcissistic personality traits (Lambe et al., 2016) and personality disorders (Howard, 2015). However, there is a lack of study investigating the role of the relationships between pathological narcissism and others maladaptive personality traits in relation to aggression. *Objective.*– To explore the relationships between pathological narcissism, maladaptive personality traits and aggression among a sample of violent offenders and community participants.

*Method.*– We administered to a sample of violent offenders ( $n = 70$ ) and a sample of community participants ( $N = 100$ ) the Aggression Questionnaire (AQ, Buss & Perry, 1992), the Pathological Narcissism Inventory (PNI, Pincus et al., 2009) and the Personality Inventory for DSM-5 (PID-5, American Psychiatric Association, 2013).

*Results.*– As expected, we found that violent offenders scored higher on the PNI and specific subscales of the PID-5 compared to community participants. Moreover, AQ scores correlated positively and significantly with maladaptive personality traits and with patho-

logical narcissism. Finally, among our sample of violent offenders, we observed specific and significant associations between pathological narcissism and some subscales of the PID-5.

*Conclusions.*– Our results suggest that pathological narcissism and specific maladaptive personality traits play an important role in relation to aggression. Clinical implications and future directions are discussed.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The Southend domestic violence perpetrator pilot: A multiagency project to tackle domestic abuse risk**

G. Romano<sup>1</sup>, D. Ho<sup>1</sup>, A. Kotze<sup>1</sup>, S. Jones<sup>2</sup><sup>1</sup> Essex Partnership University NHS Foundation Trust,

EPUT Secure Mental Health Services, Wickford, United Kingdom;

<sup>2</sup> Essex Partnership University NHS Foundation Trust, Criminal Justice, South Essex, Rochford, United Kingdom

\* Corresponding author.

*Introduction.*– Domestic violence (DV) is a public health concern associated with mental health morbidity and societal burden. In the UK, high risk DV offenders are managed by a multiagency panel, but there is no similar provision for low to medium risk offenders. In an attempt to deliver early intervention, the Southend Domestic Abuse Strategy Group brought together a number of stakeholder organisations to develop a joint strategy; this was a novel collaboration between Southend Borough Council and the local Mental Health Trust.

*Objectives.*– To reduce the risk of reoffending in perpetrators of DV by identifying and addressing mental health, substance use and associated social needs.

*Methods.*– The project took place between 1st February and 31st July 2017. The Criminal Justice Liaison and Diversion Team screened adult arrestees identified as requiring mental health assessment in police custody.

Three follow-up appointments were offered over the course of 6 weeks to individuals presenting with a risk of DV and offenders where a history of DV was elicited.?

*Results.*– A total of 7 referrals were received, 12 appointments were booked however only one appointment was attended over the course of 4 months.

*Conclusions.*– Significant difficulties were encountered in the recruitment process. Reluctance to engage was likely due to the impression that participation with the project may imply guilt especially in cases where no further legal action was taken. The risk of volatility, including domestically, appears to be increased in this heterogeneous group of individuals. Without statutory measures, early intervention may be difficult to achieve.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0687

### **Intimate partner violence (IPV) and associated factors: A cross-sectional survey in community psychiatry**

J. Santambrogio<sup>1</sup>, M. Bava<sup>1</sup>, E. Biagi<sup>2</sup>, M. Caslini<sup>2</sup>, F. Colmegna<sup>2</sup>,G. Gamba<sup>1</sup>, D. La Tegola<sup>1</sup>, F. Parma<sup>2</sup>, I. Riboldi<sup>1</sup>, G. Trotta<sup>1</sup>,L.E. Zappa<sup>2</sup>, M. Clerici<sup>1</sup><sup>1</sup> University of Milano-Bicocca, Department of Medicine and Surgery, Monza, Italy;<sup>2</sup> San Gerardo Hospital of Monza, Department of Mental Health, Monza MB, Italy

\* Corresponding author.

**Introduction.**– For its consequences on physical and mental health and the burden on healthcare services, Intimate partner violence (IPV) is a relevant public health issue (Campbell, 2002). The most common mental disorders associated with IPV are depression and PTSD (Golding, 1999).

**Objective.**– The purpose of this study is to evaluate the prevalence and the consequences of IPV in a sample of women with anxious-depressive spectrum disorders.

**Materials and methods.**– Subjects were recruited between October 2016 and May 2017 at the outpatient service for anxiety and depressive disorders (“VADEMECUM”) (Colmegna, 2013). We used a screening questionnaire (Hind Khalifeh, 2015) to investigate IPV and K6 questionnaire (Carrà, 2011) as index of psychological distress.

**Results.**– Among 150 women, 36 (24%) were victims of IPV: 35 with emotional abuse, 23 with physical abuse and 7 with sexual abuse. In the “abused” group, 29 (80%) women had psychic and physical health consequences, whilst 19 (53%) requested help from relatives/friends and/or healthcare staff. Conjugal status ( $P=0.024$ ), voluntary pregnancy interruptions ( $P=0.015$ ), anxiety episodes history ( $P=0.028$ ), previous or current psychological treatment ( $P=0.001$  and  $P=0.036$ , respectively), K6 average score ( $P=0.0004$ ) and child abuse ( $P=0.012$ ) were significantly associated with IPV. **Conclusions.**– “Abused” women have positive psychiatric history of anxiety, greater demand for psychological care, child abuse, and worst psychological distress status compared to “not abused”. The high prevalence in this study suggests the need of IPV screening and specific treatment pathways in psychiatric services (Howard, 2010).

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Correlation of self-esteem and aggression: Female prisoners and control group in Greece**

G. Kalemi, M.L. Psarra, D. Tsaklakidou, G. Tzeferakos\*, A. Douzenis  
University of Athens, 2nd Department of Psychiatry,  
Attikon General Hospital, Athens, Greece

\* Corresponding author.

**Background.**– Contradicting findings have been reported regarding the relationship between self-esteem and aggression. This study aimed to investigate the relationship between aggression and self-esteem in women inmates and in controls without criminal history. **Methods.**– The study included 307 women: 157 female inmates in the Attica’s “Korydallos” female prison, and 150 female controls without a criminal history. Physical aggression, Verbal aggression, Anger and Hostility were assessed with the Buss & Perry Aggression Questionnaire, while Self esteem was evaluated according to the Rosenberg’s Self-esteem Scale.

**Results.**– Lower self-esteem was associated with higher physical aggression, anger and hostility. Moreover, it emerged that the female inmates had higher physical aggression and higher hostility as well as lower self-esteem in comparison with the female controls.

**Conclusion.**– The results of the present study are consistent to previous studies which suggest that low self-esteem is connected to aggression.

**Keywords:** Self-esteem; Aggression; Female population/women

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Neuropsychological and neuroimaging findings for paedophilia**

M.L. Psarra, K. Kampouris, G. Kalemi, D. Tsaklakidou,  
G. Tzeferakos\*, A. Douzenis

University of Athens,

2nd Department of Psychiatry - Attikon General Hospital, Athens, Greece

\* Corresponding author.

**Aim.**– To present the latest neuropsychological and neuroimaging findings for pedophilia.

**Method.**– We searched the database of [www.google.com](http://www.google.com), [www.pubmed.com](http://www.pubmed.com) and [www.elsevier.com](http://www.elsevier.com), using the terms pedophilia, neuroimaging, neuropsychology, erotic visual stimulation, human face processing, and reviewed the related papers.

**Results.**– Pedophilic sex crimes cause intense emotions to the public, however, despite repeated efforts to identify a pattern of neurocognitive and neurobiological factors related to pedophilia, up to now there hasn’t been found a unique etiological factor. In the past, etiological theories supported the environment’s significant effect, contemporary research, however, suggest there are cognitive deficits, neurobiological factors (i.e hormonal alterations), neurodevelopmental disorders and acquired organic conditions, mostly related to frontal and temporal brain regions, that are associated to pedophilic desire and behavior. Contemporary neuroimaging and erotic visual stimulation, resting state fMRI, human face processing findings, neuropsychological, neurocognitive and personality factors that are related to pedophilia are presented in the poster.

**Conclusions.**– Relevant research studies are few in number, with small samples, methodological limitations and contradictory results. The above findings suggest the need for further research regarding the effect of neurobiological and neuropsychological factors contributing to pedophilia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A GP trainee’s experience of a difficult case in community psychiatry: Threat to others vs threat to self**

V. Vala<sup>1</sup>, M. Wise<sup>2\*</sup>

<sup>1</sup> CNWL NHS Foundation Trust, Brent South Recovery Team, London, United Kingdom; <sup>2</sup> Wiser Minds Ltd, Adult, London, United Kingdom

\* Corresponding author.

A new Trainee is asked to assess a complex case: XY a 47-year-old male initially seen by a CMHT with low mood following alleged sexual abuse of his 6-year-old granddaughter. He reported constant sexual thoughts, recurrent sexual urges and fantasies involving sexual activity with prepubescent children. He was diagnosed with [ICD-10 F65.4] Paedophilia and started on Cyproterone acetate whilst waiting trial at the crown court.

XY reported that he had no contact with children and was now living alone. However, he was living opposite a secondary school but could not see any children from his accommodation. He presented with active suicidal thoughts on the day of his trial. He felt anxious and like “hitting a brick wall”. He reported ongoing thoughts of “ending his life” - “drive into the river with moped” whilst “tying his foot to moped with rope” and jumping “in front of train” or from “train” whilst travelling to crown court. He reported that he “can’t get to court” himself and needed help.

The issues of confidentiality and risk to others are discussed, along with the conflicts that emerge over professional conduct vs

counter-transference, and societal norms. How does one balance the duties to a patient with the duties to unidentified others, and the vulnerable?

The trainee identified the following critical issues: Risk Assessment; Safeguarding; Countertransference; the limits of Confidentiality?

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0691

### **Local ethics committee role in resolving ethical cornerstones of clinical trials in psychiatry**

M. Yanushko\*, N. Semenova

*Bekhterev National Medical Research Centre of Psychiatry and Neurology, Local Ethics Committee, St Petersburg, Russia*

\* Corresponding author.

Patients with mental disorders, as one of the most vulnerable groups participating in the biomedical research, demand special attention to ethical requirements compliance in clinical trials.

*Objective.*– To analyze main issues in presenting clinical trials information for the patients with mental disorders

The one year (2016) operational experience of Bekhterev National Medical Research Centre of Psychiatry and Neurology Local Ethics Committee (LEC) has been analyzed. From 87 cases considered: approved without conditions – 63 (72.4%), approved after correction LEC remarks – 23 (26.4%), declined – 1 (1.1%).

ICF forms were the main area where corrections were requested by the LEC (23 trials). The primary reasons for this were the following: The use of statements, that could potentially misguide the subjects, such as “scientific research”, “physician”, “medication” (for phase I-III clinical trials) – LEC’s recommendations were to use more specific terms, such as “clinical trial”, “investigator”, “investigational product” – 13 cases (56.5%)

Clinical trial information, including ICF, cannot be labeled as confidential information, as these documents must contain a statement that the study participant can discuss it with any person he or she wishes. It is unacceptable to mark any pages with the label “Confidential information” – 8 trials (34.8%)

In 4 cases (17.4%) the ICF was not pertaining an option to inform the primary physician about participation in the study.

*Conclusion.*– LEC plays a significant role in control of in adhering to ethical principles of clinical research in patients with mental disorders.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## **Epidemiology and Social Psychiatry - Part II / Quality Management**

### **The birth and development of an inter-professional transplant psychiatry quality improvement initiative in renal transplantation**

D. Banayan\*, L. Tushla, J. Ellison, N. Kenyon, E. Hollinger, R. Dreas, G. Zingraf

*Rush University Medical Center, Psychiatry, Chicago, USA*

\* Corresponding author.

*Introduction.*– Organ transplantation is a life-saving and life-changing intervention that utilizes one of the scarcest resources of society. Psychiatric and psychological factors play a major role in transplant recipients’ outcome, such as organ survival and recipient survival.

*Objectives.*– This interactive session will explore the birth and development of a unique, inter-professional transplant psychiatry quality improvement (QI) program in renal transplantation, led by a transplant psychiatrist. It is hoped that sharing this experience will spawn increased dialogue about inter-professional collaboration in the domain of transplant surgery quality improvement.

*Methods.*– Qualitative and quantitative analysis of a QI initiative developed and implemented at our own institution.

*Results.*– The discussion opens with an exploration of the challenges that engendered the QI initiative: patient flow, time to listing from presentation and medical workup, and discovery of significant psychiatric illness either after medical workup is completed or after the surgery. We explore how all of the above factors interdigitate with patient satisfaction and the risks associated with medical investigations required to be listed for organ transplantation. Subsequently, we focus on the construction of our inter-professional quality improvement committee and the step-wise development and implementation of the multi-faceted improvement intervention. In brief, our intervention protected patients from unnecessary medical investigations, improved patient satisfaction in certain domains, and resulted in earlier treatment and identification of those patients with psychiatric illnesses.

*Conclusions.*– Transplant Psychiatrists are uniquely positioned to play leading roles in the establishment of quality improvement initiatives that can improve primary medical endpoints in organ transplantation.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0693

### **Effectiveness of psychiatric nurse and administrator personnel led quality improvement projects at a crisis resolution team**

T. Barry<sup>1</sup>, S. Manuel<sup>2</sup>, K. Heyman<sup>2</sup>, S. Jadoo<sup>2</sup>, M. Bhat<sup>1</sup>, B. Travers<sup>2</sup>

<sup>1</sup> NELFT, Medical Education, London, United Kingdom; <sup>2</sup> NELFT, Waltham Forest Home Treatment Team, London, United Kingdom

\* Corresponding author.

*Introduction.*– Quality improvement methodology has become popular among medical professionals however quality improvement projects led by nursing and administration staff at less common.

*Objectives.*– To evaluate the effectiveness of psychiatric nurse and administration personnel led quality improvement projects.

*Methods.*– Psychiatric nurses and administration staff were encouraged to conduct their own quality improvement project within their sphere of work within a Crisis Resolution team based in London. Staff were informed about basic quality improvement methodology and given support with their projects by a trainee grade psychiatrist.

*Results.*– Staff chose the focus of their own quality improvement project. Projects were completed using quality improvement methodology over a period of 12 weeks. Projects included measuring improvement patient involvement with the crisis resolution team as well improving communication with general practitioners in primary care.

*Conclusions.*– Both administration and nursing staff within the crisis resolution team enjoyed completing their respective quality improvement projects. Both parties felt empowered to tackle issues

using quality improvement methodology and felt that that they were both making a tangible difference to patient care.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The role of internet addiction on fatigue, sleep disturbances and poor life-style habits among adolescents**

A. Bener

*Istanbul University, Biostatistics&Public Health, Istanbul, Turkey*

\* Corresponding author.

*Aim.*– The aim of the study was to assess the reliability and validity of Internet Addiction Test (IAT) performing a factorial approach and its association with fatigue and sleep problems among university students.

*Subjects and methods.*– A total of 3000 students aged 18 to 25 years were approached and 2350 students (43.1% males and 56.9% females) participated in this cross-sectional study during 2017 at universities in Istanbul. Data collection was based on a structure questionnaire including socio-demographic details, lifestyle and dietary habits, Internet Addiction Test (IAT), Fatigue Scale and Epworth Sleepiness Scale (ESS). Descriptive statistics, multivariate regression and factorial analyses were performed.

*Results.*– The overall prevalence of Internet Addiction (IA) among the studied population was 17.7%. There were significant differences between gender, family income, father occupation, school performance, frequency and duration of watching TV, physical activity, internet use duration, and sleeping duration ( $P < 0.001$ ). The significant differences were found between IA and normal subjects in having headaches ( $P = 0.001$ ), blurred vision, double vision, eye hurt, hearing problem, and eating fast food frequently ( $P < 0.001$ ). Regarding to multivariate regression analysis, the duration of internet use, fatigue physical and mental symptoms, ESS, headache, eye hurt, eye tired and hearing problem were significantly associated and leading predictors for internet addiction.

*Conclusion.*– Our results confirmed that there is a sizable population of youth already showing or at risk of developing fatigue and sleeping problems with the internet use.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0695

### **Facebook use and mental health statues among Tunisians users**

S. Chebli<sup>\*</sup>, A. Maamri, J. Oueslati, O. Meziou, I. Jelalia, H. Zalila  
*Razi Hospital, outpatient department, Tunis, Tunisia*

\* Corresponding author.

*Introduction.*– Online social networking sites have become an integral part of our everyday life. Nowadays, Facebook represents the most popular social networking platform. Its excessive use has become an intriguing phenomena and a major concern by health care professional.

*Objectives.*– In the current study, we sought to investigate the demographic characteristics and the motives of Facebook use, assessing the psychological health of Tunisians users through different research instruments.

*Methods.*– We performed an online survey including five sections: (a) demographic data; (b) motives for Facebook uses; (c) Facebook addiction scale short version; (d) depression scale short version (CES-D10); and (e) Satisfaction with life scale short version (SWLS).

*Results.*– A total of 150 Facebook users participated to the study (mean age  $29.7 \pm 9$  years; 70.7% were women). Fifty seven per cent of the respondents were single. Among our cohort, 95.3% had university level and 69.3% had a professional activity. Relationship maintenance and passing time were the most advanced reasons to use Facebook. We noticed that 8% of the participants had maladaptive use of Facebook. Based on CES-D10, depressive symptoms were observed in 45.3% of participants. Participants were for 68% satisfied with their lives whether 28.7% were dissatisfied. Maladaptive use of Facebook was correlated with low satisfaction with life ( $r = -0.227$ ;  $P < 0.001$ ), as well as with low self esteem ( $r = -0.347$ ;  $P < 0.001$ ).

*Conclusion.*– Our study showed that maladaptive use of Facebook might be associated with mental health disorders. Further studies are needed to better investigate the relationship between Facebook use and mental health issues.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The relationship between suicide risk and psychotic symptoms in non-clinical populations**

B. Girela Serrano<sup>1\*</sup>, M. Guerrero Jiménez<sup>2</sup>,

C.M. Carrillo de Albornoz Calahorra<sup>3</sup>, J. Cervilla Ballesteros<sup>4</sup>

<sup>1</sup> Hospital Santa Ana Motril, Psiquiatría, Motril, Granada, Spain; <sup>2</sup> P, Granada, Spain; <sup>3</sup> Hosp, P, Granada, Spain; <sup>4</sup> Granada, Spain

\* Corresponding author.

*Introduction and objectives.*– The objective of our study is to know the prevalence of psychotic symptoms in the population of our area. There are no studies in Andalusia showing the correlation between these symptoms and the suicidal risk.

*Material and methods.*– We performed a cross-sectional epidemiological study (GRANADep). Through the Unified Database of the Andalusian Health System we obtained a randomized and stratified sample of 809 individuals living in the province of Granada. These individuals were interviewed by trained psychologists through the semi-structured MINI interview on psychotic symptoms. We also collected epidemiological data that may be associated with the presence of this psychopathology (lifestyle factors, sociodemographic, family history, childhood experiences, labor problems and social support).

*Results.*– The prevalence of psychotic symptoms in the population of Granada was 10.3%. The 6.1% of the sample reported hallucinations and 7.4% delusions. An increased of the suicide risk, less functionality, worse working memory, less verbal fluency and greater impulsivity.

*Conclusions.*– Previous studies agree on the higher risk of suicide in individuals with PS independently of other factors such as increased impulsivity or being abuse as a child. This information is relevant given the high percentage of people with non-clinical PS and should be taken into account in the prevention and supportive campaigns.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### The impact of stigma and discrimination on the quality of life and social disability in persons with a diagnosis of mental disorder

T.M. Gondek<sup>1</sup>, K. Kotowicz<sup>1</sup>, P. Ryta<sup>2</sup>, M. Janusz<sup>1</sup>, A. Kiejna<sup>3</sup><sup>1</sup> Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland; <sup>2</sup> Lower Silesian Centre of Mental Health, Lower Silesian Centre of Mental Health, Wroclaw, Poland;<sup>3</sup> University of Lower Silesia, Institute of Psychology, Wroclaw, Poland

\* Corresponding author.

Stigma and discrimination of persons with mental disorder has been a significant problem in the last decades. In the majority of the European countries, researches on this issue have been conducted to quantify this phenomenon and provide data to tackle this problem more effectively. In Poland, such studies had only been conducted on very limited samples or with a small number of variables.

The objective of the study was to assess the prevalence of stigma and discrimination regarding the patients hospitalized between 2016–2017, as well as to investigate the relationship between stigma and quality of life and social disability in persons diagnosed with a mental disorder classified within the spectrum of F20-F48 under ICD-10 classification, aged 18–65, admitted to a psychiatric day unit or an in-patient ward.

The main questionnaire gathers the sociodemographic and medical data from the patient. Stigma and discrimination is measured using the Consumer Experiences of Stigma Questionnaire (CESQ). Quality of life is assessed with WHOQOL-Bref, WHO-5 questionnaire and Rosenberg Self-Esteem Scale, while social disability is measured with the second version of the Groningen Social Disabilities Schedule. The severity of psychopathological symptoms is measured with Brief Psychiatric Rating Scale Expanded Version 4.0.

The assessment of the prevalence of stigma and its impact on social disability and quality of life can be useful in the context of developing evidence-based interventions for persons with mental, while it could also provide scientific data to support public information campaigns designed to tackle the stigma against persons with mental disorders in Poland.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Suicide attempts by self-poisoning in children: The past 34 years in Morocco

L. Amiar<sup>1</sup>, H. Hami<sup>2</sup>, N. Rhalem<sup>3</sup>, A. Aarab<sup>1</sup>, A. Mokhtari<sup>2</sup>, A. Soulaymani<sup>2</sup>, R. Soulaymani-Bencheikh<sup>3</sup><sup>1</sup> Faculty of Science and Techniques, Abdelmalek Essaadi University, Tanger, Morocco;<sup>2</sup> Laboratory of Genetics and Biometry- Faculty of Science, Ibn Tofail University, Kenitra, Morocco; <sup>3</sup> Moroccan Poison Control Center, Rabat, Morocco

\* Corresponding author.

*Introduction.*– Suicide is an important public health problem in children and adolescents around the world.

*Objectives.*– The present study aims to determine the epidemiological features of deliberate self-poisoning in children.

*Methods.*– This is a descriptive retrospective study of suicidal poisoning in children under the age of 15 years, reported between 1980 and 2013 to the Moroccan Poison Control Center.

*Results.*– There were 1312 cases of suicidal poisoning among children under 15 years of age, which was 5.5% of all suicidal poisoning cases reported during the study period (among the 23,710 cases

for whom the age is known). Nearly three-quarters of the cases (73.4%) were girls with a female-male ratio of 2.7. The average age of the patients was  $12.6 \pm 2.1$  years. The drugs were the primary means employed by victims (54.8%), followed by pesticides (28.8%). According to the results, the poisoning symptoms were varied, depending on the toxins involved, the quantity of substance ingested and the delay before treatment. Among the 922 cases for whom the outcome was known, 19 (2.1%) of them died. For other cases, the outcome was favorable with or without sequelae.

*Conclusions.*– Suicide and suicide attempts in children and adolescents continue to be a major public health problem, and topical research and surveys have clearly highlighted suicide as one of the commonest causes of death among young people.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0699

### Comparison of buprenorphine and methadone exposures reported to U.S. poison centers, 2013–2016

C. Holstege<sup>1</sup>, S. Rege<sup>1</sup>, A.D. Ngo<sup>2</sup>, J. Rizer<sup>1</sup>, S. Sharma<sup>3</sup>, N. Ait-Daoud Tiouririne<sup>3</sup><sup>1</sup> University of Virginia, Emergency Medicine, Charlottesville, USA;<sup>2</sup> University of Virginia, Student Health. Division of Student Affairs, Charlottesville, USA; <sup>3</sup> University of Virginia, Psychiatry and Neurobehavioral Sciences, Charlottesville, USA

\* Corresponding author.

*Background.*– Buprenorphine and methadone are widely used within the U.S. society. We compared the patterns of buprenorphine and methadone exposures reported to the U.S. Poison Centers (PCs).

*Methods.*– We retrospectively identified all closed, human exposures to buprenorphine and methadone as reported to the National Poison Data System (NPDS) from 2013 to 2016. Trends in exposures were evaluated by using Poisson regression. We descriptively assessed key demographic and clinical characteristics of the exposures.

*Results.*– Buprenorphine exposures increased by 12.3% ( $P=0.01$ ) from 2013 (3321) to 2016 (3731). Conversely, methadone exposures decreased by 23.1% ( $P<0.001$ ) from 2013 (3777) to 2016 (2906). Adults between 20 and 39 years (40.2% and 40.1%), and males (53.2% and 52.4%,  $P=0.16$ ) constituted the highest percentage of buprenorphine and methadone cases. Suspected suicides (15.7% vs 29.7%,  $P<0.001$ ) and drug abuse (20.6% vs 22.1%,  $P<0.001$ ) were higher in methadone exposures. Compared to buprenorphine exposures, major clinical effects (4.7% vs 13.7%,  $P<0.001$ ) and deaths (0.3% vs 1.27%,  $P<0.001$ ) were more frequent with methadone. Methadone exhibited a significantly higher number of deaths due to intentional exposures (85% vs 53.5%,  $P<0.001$ ). Buprenorphine exposure cases were less frequently admitted to the critical care unit (CCU) as compared to methadone exposures (26.1% vs 34.1%,  $P<0.001$ ). Multiple substance exposures accounted for a higher proportion of major medical outcomes in buprenorphine exposures (73.1% vs 32.9%). The most common products reported for buprenorphine exposures were Suboxone films (37.8%).

*Conclusions.*– Buprenorphine exposures were more frequent but demonstrated fewer mortalities, admissions to the CCU and major outcomes compared to methadone.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Affective temperaments and problematic Internet use in adolescence

J. Jovic<sup>1</sup>, D. Ignjatovic-Ristic<sup>2,3</sup>, D. Hinic<sup>4,5</sup>, I. Ristic<sup>6</sup>, Z. Bukumiric<sup>6</sup>, D. Ilic<sup>1</sup>, G. Trajkovic<sup>6</sup>, A. Corac<sup>1</sup>

<sup>1</sup> University of Pristina, Kosovska Mitrovica, faculty of medicine, Kosovska Mitrovica, Serbia; <sup>2</sup> University of Kragujevac, faculty of medical sciences, Kragujevac, Serbia; <sup>3</sup> Clinical center "Kragujevac", psychiatric clinic, Kragujevac, Serbia; <sup>4</sup> University of Kragujevac, faculty of science, Kragujevac, Serbia; <sup>5</sup> University of Kragujevac, faculty of philology and arts, Kragujevac, Serbia; <sup>6</sup> University of Belgrade, faculty of medicine, Belgrade, Serbia

\* Corresponding author.

**Introduction.**– Investigating temperament types in adolescents is very important. Studies have suggested that certain affective temperament types are considerably more important for the development of symptoms of certain affective disorders. On the other hand hyperthymic temperament is considered to be a protective factor for the development of some disorders. Also it is important to examine today's adolescent Internet use, which has become one of the most essential factors in their environment.

**Objectives.**– The purpose of this paper was to examine the differences between hyperthymic and other types of affective temperaments (depressive, anxious, cyclothymic, irritable) in relation to internet use.

**Methods.**– The final sample included 2113 adolescents, 56% girls and 44% boys, with mean age of 16.73. The research was conducted in 10% of all high schools in Serbia. Internet Use Disorder Scale (IUDS) and Temperament Evaluation of Memphis, Pisa, Paris and San Diego scale (TEMPS-A) for adolescents (Cronbach  $\alpha = 0.77$ ), were used. A two-part questionnaire (about content and activity on the internet) was also used.

**Results.**– Adolescents with hyperthymic temperament in a statistically significantly lower percentage spend more than 20 hours per week online ( $\chi^2 = 25.92, P < 0.05$ ) and they statistically significantly more often search for the following content (sports, religious content, education, pornography). The score on IUDS scale is statistically significantly smaller lower in subjects with hyperthymic temperament ( $Z = -9.57, P < 0.05$ ).

**Conclusions.**– Adolescents with different types of affective temperaments act differently online, which offers us opportunities for prevention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Personalized value development in adolescences and health and well-being in adulthood: A retrospective Study

N. Kawakami<sup>\*</sup>, K. Watanabe

The University of Tokyo, department of mental health, graduate school of medicine, Tokyo, Japan

\* Corresponding author.

**Introduction.**– The establishment of own personalized value may act as an important psychological resource to affect health and well-being in adulthood.

**Objectives.**– This cross-sectional study aimed to investigate the association between retrospectively reported own personalized value in adolescent and current health and well-being of adult workers.

**Methods.**– An Internet-based self-report questionnaire survey was conducted in 2016 of 516 Japanese adult workers (sex ratio, 1:1) aged from 30 to 49 years. Respondents were asked to fill in two sets of the Personal Values Questionnaire-II (PVQ-II) (Blackledge et al., 2010), one for their adolescence (15–16 years old) and the other for the current. A total score of PVQ-II was used as a measure of their commitment to own value. For current health and well-being, the followings were measured: psychological distress (K6), health-related quality of life (SF8), life satisfaction, and happiness. We used SEM to identify a direct and indirect effect of adolescent PVQ-II score on current health and well-being outcomes.

**Results.**– Adolescent and current PVQ-II scores correlated each other ( $r = 0.54$ ), and with all four health and well-being outcomes ( $|r| = 0.09 - 0.34, P < 0.05$ ). Adolescent PVQ-II scores was only indirectly associated with SF8, life satisfaction, and happiness, mediated by current PVQ-II scores. No significant association between sex, age, parents' education and socioeconomic status and adolescent PVQ-II scores was found.

**Conclusions.**– Adolescent personalized value may be associated with health and well-being in adulthood, but only mediated by the current value.

### Psychiatrists ability to interpret ECGS

C. Maddock<sup>1</sup>, D. McColgan<sup>2</sup>, F. Kelly<sup>3</sup>

<sup>1</sup> Stewarts Care, Psychiatry, Dublin, Ireland; <sup>2</sup> Our Lady of Lourdes Hospital, paediatrics/general practice training scheme, Drogheda, Co Louth, Ireland; <sup>3</sup> Drogheda department of psychiatry, psychiatry, Drogheda, Ireland

\* Corresponding author.

**Introduction.**– Many psychiatric medications may deleteriously impact the heart. Besides prescribed medications, psychiatric patients have high rates of smoking and metabolic disorders, which predispose to cardiac issues. Being able to correctly interpret an Electrocardiogram (ECG) is therefore an important skill for psychiatrists.

**Methods.**– A questionnaire comprising 18 ECG rhythms was given to 21 psychiatrists. The questionnaire comprised 4 normal and 14 abnormal rhythms. Of the 14 abnormal rhythms 9 were considered emergencies, which would require medical review and intervention within 24 hours.

**Results.**– Respondents correctly identified 92.54% of abnormal rhythms. They correctly identified normal sinus rhythm only 69% of the time. While respondents could identify a rhythm as abnormal 92.54% of the time they were only able to identify which abnormal rhythm it was 30.27% of the time. Only one respondent (4.7%) correctly identified Long QT and Digoxin Toxicity. Only 2 respondents (9.4%) correctly identified Pericarditis and only three (14.1%) correctly identified Posterior Myocardial Infarction and Hyperkalaemia, both medical emergencies.

**Conclusions.**– While psychiatrists have responsibility for ordering and reviewing ECGs on admissions and established in-patients it is clear that there are significant deficiencies in their ability to correctly differentiate between abnormal and normal rhythms and to differentiate abnormal rhythms requiring urgent medical review from those which only require a more routine review.

In the first instance psychiatric trainees may benefit from additional training to aid them in identifying ECG rhythms more accurately.

It may also be beneficial to arrange a system whereby the nearest cardiology department reviews all psychiatric in-patient ECGs.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0703

### **The Effect of parental mental health on a child's risk of poor mental health and death by suicide: A population-wide data-linkage study**

A. Maguire<sup>\*</sup>, D. O'Reilly

Queen's university Belfast, centre for public health, Belfast, United Kingdom

\* Corresponding author.

*Background.*– Death by suicide is a major public health concern and identifying those most at risk is vital to ensure the implementation of effective interventions. Mental health is known to have a genetic component and parental mental health is associated with a child's mental health. However, little is known on the effect of parental mental on a child's risk of death by suicide.

*Methods.*– This population-wide data linkage study utilised data from the 2011 Northern Ireland Census linked to 5 years' death records (2011–2015) to construct regression models to determine if children living with parents with poor self-rated mental health are at an increased risk of poor mental health themselves or at an increased risk of death by suicide.

*Results.*– Of the 618,970 individuals who live with their parents, 13.7% live with parents with poor mental health, 11.6% have poor mental health themselves and 0.1% (225) died by suicide. Living with a parent with poor mental health was associated with likelihood of poor mental health in children. After adjustment for age, gender, physical illness, socio-economic status and own mental health status, children of parents with poor mental health were 73% more likely to die by suicide compared to children of parents with good mental health ( $OR = 1.73$ , 95%CI 1.25, 2.40). The effect size increases for children living with  $\geq 2$  parents with poor mental health.

*Conclusions.*– Parental mental health is associated with a child's suicide risk even after adjustment for their own mental health status. This is an at-risk group.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0704

### **Is there a relationship between adherence to therapy and depressive symptoms in people facing type 1 and type 2 diabetes?**

I. Massano-Cardoso<sup>1\*</sup>, A. Galhardo<sup>1</sup>, F. Daniel<sup>1</sup>, V. Rodrigues<sup>2</sup>

<sup>1</sup> Miguel Torga Institute, Portugal, Coimbra, Portugal; <sup>2</sup> Faculdade de Medicina da Universidade de Coimbra, Coimbra, Coimbra, Portugal

\* Corresponding author.

*Introduction.*– Diabetes mellitus (DM) integrates a heterogeneous group of metabolic disorders characterized by the body's inability to maintain glucose homeostasis. This public health problem affects 425 million people in world (8.8% of adults from 20–79 years old). The number increases to 451 million if age is expanded to 18–99 years. It is estimated that by 2045, 693 million people will have diabetes. The centrality of the patient's role in self-administered health care management is a crucial topic. Adherence to treatment does not imply simply the scrupulous following of the medical reg-

imen; it also entails engaging in several health-related behaviours, such as eating or physical activity.

*Objectives.*– The current study aims to explore whether depressive symptoms are associated with adherence in diabetes mellitus (DM).

*Methods.*– A descriptive correlational study with cross-sectional design was conducted. Patients attending diabetes consultations ( $n = 347$ ) completed the Beck Depression Inventory (BDI). Adherence was established based on HbA1c criteria.

*Results.*– The BDI mean score, for either DM type 1 or type 2, was higher than in general population but not clinically significant. The association between depression and adherence was significant in both types of DM. Type 2 diabetes participants presenting more depressive symptoms were those with greater adherence. Type 1 and type 2 diabetes differences regarding depressive symptoms were in somatic symptoms.

*Conclusion.*– In type 2 DM depressive symptoms may be confused with DM physical consequences. There is the possibility that negative mood plays a mediating role in mobilizing survival strategies that activate adherence.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0705

### **Gender differences in self-esteem and quality of life among patients with type 2 diabetes**

I. Massano-Cardoso<sup>1\*</sup>, A. Galhardo<sup>1</sup>, F. Daniel<sup>1</sup>, V. Rodrigues<sup>2</sup>

<sup>1</sup> Miguel Torga Institute, Portugal, Coimbra, Portugal; <sup>2</sup> Faculdade de Medicina da Universidade de Coimbra, Portugal, Coimbra, Portugal

\* Corresponding author.

*Introduction.*– The prevalence as well as incidence of type 2 diabetes are increasing worldwide, mostly in developing countries. Previous research has shown that there are gender differences concerning social support, acceptance of the disease, quality of life, and adherence behaviors in people facing type 2 diabetes but other psychological variables such as self-esteem have deserved less attention.

*Objectives.*– The aim of this study was explore whether there were gender differences regarding self-esteem and quality of life in patients with type 2 diabetes.

*Methods.*– A descriptive correlational study with cross-sectional design was carried out. Patients with a type 2 diabetes diagnosis attending endocrinology consultations participated in the study ( $n = 175$ ). Participants completed the Rosenberg Self-esteem Scale (RSE) and Quality of Life Scale Abbreviated Version (WHOQOL-BREF).

*Results.*– Mean score on RSE, for type 2 diabetes patients are different between males ( $M = 32.50$ ;  $SD = 4.42$ ) and females ( $M = 30.46$ ;  $SD = 4.08$ ). Women reported lower self-esteem when compared to male patients ( $t = 3.09$ ;  $P = 0.002$ ). Men reported higher quality of life (QoL) in all dimensions (physical, psychological and environment), except for the social dimension [ $(t = 2.70$ ;  $P = 0.008$ );  $(t = 4.34$ ;  $P < 0.001$ );  $(t = 1.20$ ;  $P = 0.231$ );  $(t = 3.35$ ;  $P = 0.001$ )].

*Conclusion.*– QoL and self-esteem might be considered as important targets for prevention in type 2 diabetes patients. Identifying strategies to improve self-esteem and QoL in diabetic patients, in a solid, organized public health organization, involving health professionals and patients can be effective.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Clinical and sociodemographic profile of psychotic patients receiving long-acting antipsychotic injectable in mental health centre.

L. Pérez Gómez<sup>1\*</sup>, A. González Fernández<sup>2</sup>, L. García González<sup>3</sup>, C.M. Rodríguez Mercado<sup>4</sup>, L. Rubio Rodríguez<sup>5</sup>, A. Sánchez Palacio<sup>6</sup>, M. Jalón Urbina<sup>7</sup>

<sup>1</sup> Consultant psychiatrist, CSM Langreo, Oviedo, Spain; <sup>2</sup> Consultant psychiatrist, AGC Salud Mental, Hospital de Cabueñes, Gijón, Spain; <sup>3</sup> Consultant psychiatrist, hospital universitario central de Asturias, Oviedo, Spain; <sup>4</sup> Consultant psychiatrist, AGC Salud Mental, hospital de Cabueñes, Gijón, Spain; <sup>5</sup> Psychiatry trainee, AGC Salud Mental, Hospital de Cabueñes, Gijón, Spain; <sup>6</sup> Psychiatry trainee, servicio de psiquiatría, hospital universitario de Cruces, Barakaldo, Spain;

<sup>7</sup> Consultant psychiatrist, CTI, Montevil, Gijón, Spain

\* Corresponding author.

**Introduction.**– Since their introduction in sixties decade, long-acting antipsychotic injectable drugs, commonly known as LAIs, have looked for improving therapeutic adherence. Nowadays they are widely used both, in hospital and ambulatory care. There are limited studies attending to demographic and social features of psychotic patients receiving this pharmaceutical formulation in Spain and more specifically in our region, the Principality of Asturias.

**Objectives.**– The main objective is to describe clinical and sociodemographic features of psychotic patients treated with LAIs in two mental health centres of the region.

**Methods.**– This is a descriptive retrospective study. A total of 311 clinical histories of every psychotic patient receiving LAIs in two mental health centres of Gijón and Avilés were checked. We selected those patients who fulfilled the inclusion criteria previously established resulting a sample size of 107.

**Results.**– The studied population had similar proportions by sex and the average age was 49.8 years, slightly higher in men. More than 60% of the subjects were singles and almost the half coexisted with their origin family. Just over 30% of studied patients had completed primary school and only 7.4% of them had university degree. Most patients (40%) were retired, followed by unemployed (34.3%). The most frequent diagnosis was schizophrenia.

**Conclusions.**– In our study women seem to have better adaptation to psychosis with higher rates of autonomy and own family coexistence but vastly lower unemployment rates. The work activity and the level of studies attained by our patients is reduced compared with general population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

VII, Paris, France; <sup>8</sup> Assistance publique-Hôpitaux de Paris AP-HP, Bichat Claude Bernard hospital, department of psychiatry and addictive medicine, Paris, France; <sup>9</sup> Paris hospital group, psychiatry and neurosciences, Sainte-Anne hospital, psychiatry-precarioussness division, Paris, France

\* Corresponding author.

**Introduction.**– Social characteristics may influence mental health care pathways. However, few studies have described the social vulnerability dimensions of psychiatric patients.

**Objectives.**– To assess social conditions of patients present on January 31, 2017, in the five public psychiatric hospitals in Paris, to identify distinct social profiles and their correlates.

**Methods.**– Information about patients' sociodemographics, housing and social conditions (including employment status, economic resources and medical insurance coverage), long-term illness exemption, involuntary care and psychiatric diagnoses were collected by health care professionals using a standardized questionnaire. We determined social profiles by factorial analysis and hierarchical clustering on housing and social data.

**Results.**– Among 4005 patients included, 3.0% were homeless, 7.4% lived in poor or inadequate housing conditions and 10.1% stayed at the hospitals without a home address. Only 21.2% were employed, 63.8% were social benefits recipients- among whom 70.6% received disability-related benefits and 94.3% were covered by the general public health insurance system. We identified a "very deprived" group of 97 patients (2.4%). Most of them were homeless or in an unstable and inadequate housing situation, were living without any resources, were covered by the free-state medical assistance or had no health insurance. This cluster was associated with male gender, younger age, being born abroad and living outside Paris. It was also linked to involuntary care and to substances-induced disorders but inversely associated with mood disorders (all  $\chi^2$ :  $P < 0.05$ ).

**Conclusions.**– Parisian mental health facilities provide care to a substantial part of socially vulnerable patients. These results could help developing joint medical and social strategies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Suicides and mortality from tuberculosis in Russia

Y. Razvodovsky

Grodno State medical university, pathological physiology, Grodno, Belarus

**Introduction.**– Until recently the mortality from tuberculosis and the suicide rates in Russia were both among the highest in the world. The mortality rates from tuberculosis and suicide are considered as the indicators of psychosocial distress. The theoretical premises and empirical evidence suggests the positive association between suicide and mortality from tuberculosis at the individual and population levels.

**Objectives.**– The present study aims to assess the aggregate level link between the mortality from tuberculosis and the suicide rates in Russia.

**Methods.**– Trends in age-adjusted sex-specific tuberculosis mortality and suicide (as an integral indicator for psychosocial distress) rates from 1980 to 2015 were analyzed employing a time series analysis in order to assess bivariate relationship between the time series.

**Results.**– The results of analysis indicate the presence of a statistically significant association between tuberculosis mortality and suicide rates for men at lag zero ( $r = 0.71$ ;  $SE = 0.169$ ). The association between tuberculosis mortality and suicide rates for

women was also positive, but statistically not significant ( $r=0.26$ ;  $SE=0.169$ ).

**Conclusions.**– The results of this study suggest positive aggregate-level association between tuberculosis mortality and suicide rates. This study indirectly supports the hypothesis that tuberculosis mortality can be considered as an indicator of psychosocial distress  
**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Urban-rural differences in the correlates of female parasuicide in the regions affected by Chernobyl nuclear disaster

Y. Razvodovsky

Grodno State medical university, pathological physiology, Grodno, Belarus

**Introduction.**– Chernobyl nuclear reactor accident was the greatest technological disaster in history. There is evidence that the accident has had a significant long-term impact on psychological well-being of the affected population. In particular, the rate of suicidal behavior has increased dramatically among the exposed population. At the same time, little epidemiological information about parasuicidal individuals is available.

**Objectives.**– This study was design to extend our understanding of suicidal behavior by examining urban-rural differences in the sociodemographic and mental health characteristics of female suicide attempters in the region affected by Chernobyl nuclear disaster.

**Methods.**– We interviewed 207 female suicide attempters [137 urban residents (UR) and 70 rural residents (RR)] received treatment at Gomel regional psychiatric hospital (Belarus).

**Results.**– The most important risk factors identified were younger age (18–29), being single (71.7% of RR and 59% of UR), being unemployed (35% of RR and of 34.5% UR), having mental disorders (100% of RR and 96.7% of UR), having previous suicide attempts (36.7% of RR and 16.8% UR). The most frequent diagnoses were mental disorders due to psychoactive substances use (43.3% of RR and 37% of UR). The prevalence of alcohol dependence was higher among RR compared with UR (30% vs. 20.4%). Consumption of alcohol at the time of the parasuicidal act was reported more commonly by RR than by UR (48.3% vs. 27.3%).

**Conclusions.**– These findings are consistent with previous research indicating a causal role for mental health problems and alcohol abuse in suicidal behavior.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– An extensive evidence exists on the effects of maternal depression on infant cognitive development, but little is known about how postpartum depression (PPD) affects morbidity of infants during the first year of life.

**Objectives.**– To examine whether any maternal self-reported or physician-determined health conditions of infants during first year of life are more frequent in PPD group than in non-PPD group.

**Methods.**– Altogether, 846 mothers from the Kuopio Birth Cohort Study ([www.kubico.fi](http://www.kubico.fi)) were included. Depression during pregnancy and postpartum were evaluated with the Edinburgh Postnatal Depression Scale. Infant health variables were gathered from the questionnaire at one year after delivery and based on self-reports of physician-determined diagnoses or of parental observation. Associations were examined using logistic regression adjusted for maternal age at delivery, primiparity, need for neonatal intensive care unit admission, depression during pregnancy and Cohen's Perceived Stress Scale.

**Results.**– The prevalence of PPD was 11.3%. PPD was associated with an increased likelihood of belonging to the groups of mothers who reported physician-determined infant gastroesophageal reflux (adjusted odds ratios (aOR) 3.39, 95% confidence interval (CI) 1.63–7.07), physician-determined infant food allergy (aOR 3.65, 95% CI 1.41–9.45) and infant wheezing (aOR 2.77, 95% CI 1.4–5.37).

**Conclusions.**– PPD is associated with a higher likelihood of gastroesophageal reflux, food allergy and wheezing in the infants. It is urgent to replicate these findings and determine the underlying reasons.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Audit on completeness of documentation by medical officers at a mental health inpatient unit in Sri Lanka

V. Seneviratne<sup>1\*</sup>, M. Ranasinghe<sup>1</sup>, J. De Silva<sup>1</sup>

<sup>1</sup> University of Sri Jayawardenepura, department of psychiatry, faculty of medical sciences, Depanama, Pannipitiya, Sri Lanka

\* Corresponding author.

**Introduction.**– Psychiatric diagnosis is based on detailed history taking and mental state examination. Documentation of the same is essential for diagnosis, communicating of patient related information, as well as, for medico-legal purposes.

**Objectives.**– To audit completeness of admission-assessment notes in an inpatient mental health unit

**Methods.**– The audit standard was based on the Shorter Oxford Textbook of Psychiatry (6th Edition) recommendations, on the essential components in history and mental state examination. Thirty consecutive paper based admission notes from admissions to the Colombo South Teaching Hospital, Psychiatry unit in January

2016 were assessed. Prior to the re-audit, a single session of education was provided to medical officers on components of assessments, along with reading material. After six months, performing a re-audit completed the audit cycle.

**Results.**– Documentation of presenting complaint was 100%. The re audit demonstrated, improvements in documenting forensic history 40 to 56.7%, developmental history 26.7 to 40% and personality 53.3 to 60%. However, there was a decline in recording past medical history 83.3 to 80%, past psychiatric history 90 to 83.3%, family history 96.7 to 86.7% and substance use 63.3 to 56.7%. Recording of cognitive functions increased from 40 to 63.3% and insight from 76.7 to 96.7%. Noting down of the other components of the mental state examination was close to 100%

**Conclusion.**– This audit led to a higher percentage of notes being complete. However, there continued to be clear deficits in key components of the history and mental state.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Domain specific physical activity in pregnancy and postpartum depression risk in the French EDEN and ELFE cohorts**

J. van der Waerden<sup>1\*</sup>, A. Nakamura<sup>1</sup>, J. Salla<sup>2</sup>, L. Pryor<sup>1</sup>, M.A. Charles<sup>3</sup>, F. El-Khoury<sup>1</sup>, P. Dargent-Molina<sup>3</sup>

<sup>1</sup> Inserm-IPLESP, social epidemiology research team, Paris, France;

<sup>2</sup> University of Bordeaux, faculty of psychology, Bordeaux, France;

<sup>3</sup> Inserm, UMR1153 epidemiology and biostatistics Sorbonne Paris Cité Center CRESS, Villejuif, France

\* Corresponding author.

**Introduction.**– The potential beneficial effects of physical activity during pregnancy on postpartum depressive symptoms remain inconclusive. Using data from two large prospective French mother-child cohorts (EDEN and ELFE), the objective of the current study was to examine the relationship between total and domain-specific physical activity in pregnancy and the occurrence of postpartum depressive symptoms.

**Methods.**– Participants of the ELFE cohort ( $n=15,538$ ) completed the Pregnancy Physical Activity Questionnaire which assesses the following physical activity domains: household/caregiving, occupational, sports/exercise and transportation during the third pregnancy trimester. In the EDEN cohort ( $n=1745$ ) women completed the Baecke Questionnaire measuring occupational, sports/exercise, leisure-time physical and locomotive activity, and overall activity during the first trimester of pregnancy. Depressive symptoms during the first year postpartum were measured using the Edinburgh Postnatal Depression Scale in both cohorts. Analyses were controlled for confounding factors.

**Results.**– Outcomes from multivariate logistic regression analyses showed that higher levels of household/ caregiving activities ( $OR=1.07$  (95% CI 1.00–1.14),  $P=0.04$ ) and overall activities ( $OR=1.08$  (95% CI 1.02–1.14),  $P=0.01$ ) in the third pregnancy trimester were significantly associated with postpartum depression. No significant associations were found for the different physical activity domains or overall activity during the first pregnancy trimester.

**Conclusion.**– Higher levels of household and caregiving activities and overall physical activity in the last trimester of pregnancy appear to increase the risk for postpartum depression. Purpose and context of physical activity should be taken into account when encouraging physical activity as a strategy to help prevent postpartum mental health problems from pregnancy onwards.

### **Advanced concepts in neuroprotection: An animated journey into the complex cellular protective mechanisms of psychotropics and nutraceuticals**

D. Banayan

Rush university medical center, psychiatry, Chicago, USA

**Introduction.**– There has been explosive growth in the scientific ability to study the post-receptor, down-stream intracellular effects of numerous psychotropic agents and nutraceutical compounds. This expansion of knowledge is setting the stage for enhanced prevention, recovery, or delayed progression in the context of neuropsychiatric and psychiatric disorders.

**Objectives.**– Custom-made animations will bring to life, in real time, mechanisms of cellular insult, and specific endogenous neuroprotective pathways activated by psychotropic and nutraceutical compounds. Participants will learn about recent discoveries in the field and develop greater capacity to read and critique literature on the subject.

**Methods.**– Focused, comprehensive literature review on specific psychotropics (e.g. lithium, SSRIs, dextromethorphan) and nutraceuticals (e.g. curcumin, epigallocatechin-3-gallate) using the PubMed, Ovid Medline, and Embase databases.

**Results.**– Both psychotropic agents and nutraceutical compounds have pleiotropic effects on cellular processes. Classification by receptor binding fails to capture the importance and complexity of their spectrum of biological activities. For example: Mitochondrion integrity, calcium homeostasis, membrane lipid metabolism, enhancement of defenses against oxidative stress, and up-regulation of neurotrophic factors, are all important in neuroprotection. While certain agents strengthen neuronal resilience to toxic insult, others can halt progressive neurodegenerative processes or even reverse neuronal damage.

**Conclusion.**– A deeper understanding of the neuroprotective properties of psychotropic drugs and nutraceutical compounds is becoming more and more important as science uncovers the mysteries behind psychiatric and neurodegenerative disorders. In some cases this knowledge is already impact clinical decision-making.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Lipid profile of patients taking antipsychotic**

R. Ben Soussia<sup>\*</sup>, W. Bouali, S. Younes, I. Marrag, L. Zarrouk  
CHU Tahar Sfar, psychiatry, Mahdia, Tunisia

\* Corresponding author.

**Introduction.**– Patients with psychiatric conditions are more vulnerable to metabolic abnormalities related mainly to genetic exposure, their particular lifestyle, and the side effects of psychotropic drugs.

**Objective.**– The aim of our work was to describe the lipid profile of patients on antipsychotics.

**Methodology.**– This is a cross-sectional and descriptive study carried out in the department of psychiatry with patients on antipsychotics for at least 3 months. Plasma concentrations of total cholesterol (CT), triglycerides (TG) and HDLc (high-density lipoprotein cholesterol) were determined by a colorimetric enzyme assay.

**Results.**– 148 patients were included in our study. The mean age was 38 years, the sex ratio was 2.6, the association between two antipsychotics was revealed in more than half of the patients. The median duration of antipsychotic medication was 96 months with adherence considered good in 79.7% of patients. The mean BMI of the patients was  $26.8 \pm 6.1$ . The mean TG score was  $1.48 \pm 1.1$  mmol/L and an elevation of triglyceridemia was found in 25.7% of patients. The mean HDL count was  $1.21 \pm 0.28$  mmol/L and 33.8% of the patients had a decrease in HDL cholesterol. The mean cholesterol level was  $4.5 \pm 1.2$  mmol/L, a hypercholesterolemia was found in 23% of the patients.

**Conclusion.**– In order to prevent morbidity and mortality from cardiovascular diseases, the clinical and biological monitoring of these patients, the regular monitoring of their lipid balance and advice on their lifestyle should be recommended as part of their overall burden.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Study of QT interval in patients treated by antipsychotics

W. Bouali<sup>\*</sup>, R. Ben soussia, I. Marrag, L. Zarrouk  
Hospital, psychiatrie, Mahdia, Tunisia

\* Corresponding author.

**Introduction.**– Cardiovascular mortality of patients on antipsychotics is higher than that of the general population, and most unexplained sudden deaths may be due to ventricular arrhythmia or QT prolongation caused by antipsychotics.

**Objective.**– The purpose of our work is to study the QT interval in patients treated with antipsychotics.

**Methodology.**– This is a cross-sectional and descriptive study carried out in the department of psychiatry. The calculation of the QT interval is measured from the beginning of the Q wave to the end of the T wave. The duration of QT must be corrected by the Bazett formula. An interval that exceeds 440 ms can be suspect of QT prolongation. The risk of arrhythmia becomes greater when the QT interval is greater than 500 ms.

**Results.**– 148 patients were collected. The mean age was 38 years, the association between two antipsychotics was revealed in more than half of the patients. The median duration of antipsychotic medication was 96 months with adherence considered good in 79.7% of patients. More than half the sample with a frequency of 55.4% ( $n = 82$ ) were smokers. An ECG was performed in 130 patients. The QT interval had an average value of  $387.1 \pm 39.9$ , ranging from 280 to 484.

**Conclusion.**– Patients in psychiatry have an excess mortality associated in part with sudden death, favored by certain antipsychotics and other psychotropic drugs. The poor cardiac tolerance of these drugs is related to the prolongation of the QT interval which increases the risk of sudden death.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Hypnotics and sedatives use in São Paulo, Brazil; results from the megacity mental health survey

A. Campanha<sup>\*</sup>, A.B.R. Salto, I.A. Milhorança, M.C. Viana, Y.P. Wang, M.A. Bernik, L.H. Andrade

Institute of Psychiatry, Clinicas Hospital, University of Sao Paulo, School of M, Psychiatry, Sao Paulo, Brazil

\* Corresponding author.

**Introduction.**– Few studies are conducted between individuals with diagnostic of mental disorders.

**Objectives.**– This report estimated the prevalence and the factors associated with the use of hypnotics and sedatives (HS) in the general population and among subjects with different diagnose of 12-month psychiatric disorders.

**Methods.**– Data were from the São Paulo Megacity Mental Health Survey, the Brazilian segment of the World Mental Health Survey Initiative. A sample of 5,037 individuals (response rate: 81.3%) was assessed using the World Mental Health version of the Composite International Diagnostic Interview, designed to generate DSM-IV diagnoses. Participants were asked about prescription medicines that used in the previous 12-months for “problems with emotions, nerves, mental health, substance use, energy, concentration, sleep or ability to cope with stress”. Anxiety disorder, mood disorder, substance Use Disorders and Impulse-control Disorders were included in the diagnostic.

**Results.**– The prevalence of the use of HS in the general population was 3.6% and in between subjects diagnosed was 7.8%. The use was more frequent in subjects with mood (14.7%) than anxiety (8.1%) disorder. Subjects with panic disorder and bipolar I and II (33.7% and 23.3% respectively) reported higher use. Individuals aged 50 or more (11.1%), workers/retirees (11.8%), with two or more disorders (11.2%), with disorders considered moderate/severe (9.9%;  $OR = 2.8$ ;  $95\% CI = 1.7-4.8$ ;  $P = 0.0001$ ), who reported the use of psychiatric services (29.8%;  $OR = 25.0$ ;  $95\% CI = 13.7-45.6$ ;  $P < 0.0001$ ) and with health insurance (10.7%) reported higher use.

**Conclusion.**– Individuals diagnosed with any mental disorders are being inconsistently treated considering the higher use in subjects with mood than anxiety.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0717

### Paliperidone for the treatment of Tourette syndrome: A case report and literature review

M. Díaz Durán

Hospital Dr. R. Lafora, psychiatry, Madrid, Spain

**Introduction.**– Tourette syndrome (TS) is an early onset disease characterized by brief, repetitive, uncontrollable movements or sounds [1]. Although some studies show positive results, there is little evidence on the treatment with atypical antipsychotics [2].

**Objectives.**– To determine whether paliperidone was effective in the treatment of TS.

**Methods.**– A clinical case of a patient suffering from TS is exposed. A search was conducted in PubMed database using the terms Tourette's syndrome, treatment, paliperidone, tics.

**Results.**– A 23 year old woman who had been presenting with tics since childhood was treated with risperidone. While tics disappeared, upper limb paresthesias were produced. After switching risperidone by paliperidone, the sensation of paresthesia ceased, but tics severely recurred. Whilst five reviews published in the last

5 years were found on TS and atypical antipsychotics [1–5], none of them provides information about treatment with paliperidone.

**Conclusions.**– There is no evidence in the existing scientific literature concerning paliperidone and TS. Despite paliperidone was proved ineffective in the case reported, further research is needed.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Hyponatremia in a psychiatry of later life mental health service in North West of Ireland

C. Dolan<sup>1</sup>\*, B. McMorrow<sup>2</sup>, M. Corcoran<sup>3</sup>, M. Cryan<sup>2</sup>, J. Perlinska<sup>2</sup>, F. Nagra<sup>2</sup>, G. McCarthy<sup>4</sup>

<sup>1</sup> Sligo mental health services, psychiatry of later life, Sligo, Ireland;

<sup>2</sup> Sligo Leitrim mental health services, psychiatry of old age, Sligo, Ireland;

<sup>3</sup> HSE, Sligo university hospital, pharmacy, Sligo Miche, Ireland;

<sup>4</sup> Sligo Leitrim mental health service, psychiatry of old age, Sligo, Ireland

\* Corresponding author.

**Introduction.**– Antidepressants are associated with hyponatraemia and incidence varies from 0.5–32%, and increases with age. Acute hyponatraemia is a medical emergency while chronic hyponatraemia is associated with an increased length of stay in hospital and increased risk of death.

**Aims/objectives.**– To evaluate presentations of hyponatraemia and measure antidepressant monitoring in a psychiatry of later life mental health service.

**Method.**– Data associated with hyponatraemia presentations among patients attending the service from January to September 2017 was gathered. Maudsley guidelines were used to set standards on monitoring of sodium for individuals prescribed antidepressants.

**Results.**– Eighteen cases (87.5% female) of hyponatraemia were found, mean age at presentation was 78.9 years, 61.1% were prescribed an antidepressant, Figure 1 shows medication use. One third were asymptomatic, two thirds had moderate symptoms and half required hospital admission (average stay 21.3 days). Of the remainder, 22.2% cases were managed by psychiatry services, 5.5% in primary care. Maudsley guidelines were poorly adhered to; (i) 45.4% of patients had sodium measured at baseline, (ii) 36.4% at 2 weeks, (iii) 27.3% at 4 weeks, (iv) 18.2% at 12 weeks. Risk factors for hyponatraemia included; 94.4% with existing co-morbidities, 44.4% aged over > 80, 33.3% with low baseline sodium.

**Conclusions.**– Hyponatraemia associated morbidity among patients attending a psychiatry of later life service was high with poor compliance with guidelines for monitoring of sodium in context of antidepressant use found. Prescribers of antidepressants including primary care physicians need further education on best practice for sodium monitoring to reduce risk of hyponatraemia associated morbidity.

### Monotherapy and polytherapy with psychotropic drugs is more likely in women of lowest socio-economic status during pregnancy

J. Fairthorne<sup>1</sup>\*, M. Park<sup>1</sup>, T. Oberlander<sup>1</sup>, G. Hanley<sup>2</sup>

<sup>1</sup> British Columbia children's hospital research institute, pediatrics,

Vancouver, Canada; <sup>2</sup> University of British Columbia, obstetrics and gynaecology, Vancouver, Canada

\* Corresponding author.

**Introduction.**– Prenatal use of psychotropic drugs (PTs) may be harmful to the fetus and polytherapy with different PTs may increase the harm. There is limited evidence that women of lower socio-economic (SES) are more likely to be prescribed psychotropic drugs prenatally than other women.

**Objectives.**– We aimed to assess the odds of prenatal monotherapy and polytherapy with PTs by drug category and SES.

**Methods.**– We linked registry datasets from British Columbia. Prescriptions for PTs were categorized as Anti-depressants, Anti-epileptic, Anti-psychotics and Anxiolytics. The outcome monotherapy was defined as filling a prescription from exactly one of these four categories. Two outcomes related to polytherapy. Dual therapy described maternal exposure to exactly two drug categories and other polytherapy described maternal exposure to more than two categories. To estimate SES, we used area-based disposable family income data from the infant's year of birth where Decile-1 represented the most disadvantaged. By pregnancy and outcome, we calculated odds ratios using logistic regression and adjusted for maternal age, parity, having a psychiatric disorder and having an epilepsy diagnosis.

**Results.**– Mothers from Decile-1 were more likely to experience monotherapy and particularly with anti-psychotic drugs [AOR = 1.73 (95% CI (1.16, 2.57), *P*-value = 0.007]. They were also more likely to be exposed to dual therapy [AOR = 1.34 (95% CI 1.15, 1.56), *P*-value < 0.0005] or other polytherapy [AOR = 2.59 (95% CI 1.39, 4.85), *P*-value < 0.003].

**Conclusions.**– Prenatally, women of lowest SES are more likely to experience monotherapy and polytherapy with PTs than other

women. Further research is needed to ascertain the reason in this already vulnerable group.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Update on the in vitro actions of loxapine on dopaminergic and serotonergic receptors. Can loxapine be considered as an atypical antipsychotic?

F. Ferreri<sup>1</sup>, D. Drapier<sup>2</sup>, E. Baloche<sup>3</sup>, M. Ouzid<sup>3</sup>, L. Zimmer<sup>4</sup>, P.M. Llorca<sup>5</sup>

<sup>1</sup> Upmc, AP-HP, hospital Saint-Antoine, psychiatry, Paris, France;

<sup>2</sup> Université de Rennes 1, Rennes university hospital, department of psychiatry, Rennes, France; <sup>3</sup> Eisai sas, psychiatry, La Défens, Paris, France; <sup>4</sup> Université Claude-Bernard-Lyon1, CNRS, Inserm, Lyon, France, CERMEP, imaging platform, hospices civils de Lyon, Lyon, France; <sup>5</sup> CMP B, CHU de Clermont-Ferrand, EA 7280, université Clermont-Auvergne, psychiatry, Clermont-Ferrand, France

\* Corresponding author.

The first aim is to focus on dopamine and serotonin receptors. Our second aim is to transfer this receptor exploration toward in vitro positron emission tomography neuroimaging (PET) by the use of clinical radiopharmaceutical in autoradiography performed with non-human primate brain tissues.

*Method.*– Competition binding experiments were performed on expressed human recombinant receptors in CHO cells and HEK-293 cells. PET autoradiographies on non-human primate brain tissue.

*Results.*– The measured K<sub>b</sub> demonstrated high affinity of loxapine succinate for the D<sub>2</sub> receptor and 5-HT<sub>2A</sub> receptor with a value below 2 nM. Using the PET autoradiographies, a competition occurred at low concentrations of loxapine on D<sub>2</sub> receptors (–50% of [<sup>11</sup>C]–Raclopride displacement at 10 nM, –80% at 50 nM and –90% at 100 nM of loxapine, respectively). In a similar manner, the displacement of [<sup>18</sup>F]–altanserin (5-HT<sub>2A</sub> receptors) was significant at 10 nM, 50 nM and 100 nM of loxapine (–30%).

*Conclusion.*– Loxapine succinate has a high affinity for the D<sub>2</sub> receptor and 5-HT<sub>2A</sub> receptor, in an in vitro binding study with humans' cell, with a 5-HT<sub>2A</sub>/D<sub>2</sub> ratio superior to 1. These in vitro results are confirmed by the PET study in non-human primates, that displays a high affinity of loxapine for D<sub>2</sub> receptors and for 5-HT<sub>2A</sub> receptors at different concentrations. The PET study, confirms the affinity of loxapine for other 5HT (5-HT<sub>1A</sub> and 5-HT<sub>6</sub>), that can be related to the clinical profile this compound.

### A Case of early-onset tardive dyskinesia with paliperidone palmitate

D. Göverti<sup>\*</sup>, N. Ozcelik, H. Kaya, E. Goka

Ankara Numune education and research hospital, psychiatry, Ankara, Turkey

\* Corresponding author.

*Introduction.*– Tardive dyskinesia (TD) is a disorder characterized by involuntary, repetitive and purposeless movements, typically of the orofacial muscles and also of the extremities and other muscle groups. TD is generally a late-onset and occasionally persistent complication expected with long-term treatment with neuroleptics. Paliperidone palmitate (PP) is a long-acting injectable (LAI) formulation of paliperidone. We present a case of TD in a schizophrenia case developing with only 2 PP injections.

*Case description.*– We report the case of a 35-year-old male who has been diagnosed with schizophrenia for 7 years. Quetiapine(600 mg) was started at the time of diagnosis. With this treatment, his psychotic symptoms relieved. But recently he stopped using oral treatment and his symptoms started. PP was chosen due to its advantage of once-monthly dosing. A loading dose was used with 150 mg on day 1 followed by 100 mg on day 7. And 10 days later he developed facial, lingual and perioral dyskinesic movements. On Abnormal Involuntary Movement Scale (AIMS) he scored 3 in three areas (facial, lingual and perioral) which showed positive AIMS examination. PP was stopped and quetiapine was restarted. After 1 month, dyskinetic movements resolved.

*Discussion.*– It should be noted that as 3-monthly or 6-monthly LAI antipsychotics are developed, clinicians must be aware of this side effect which is hard to treat and most often persistent.

*Conclusion.*– PP is a LAI antipsychotic described to have lower risks of extrapyramidal symptoms. However, it should be in mind that TD can occur with any antipsychotic.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### A preclinical assessment of the antidepressant-like effect of isoflurane

A.J. Harpoeth<sup>\*</sup>, G. Wegener, B. Elfving, H.K. Müller

Aarhus university hospital, translational neuropsychiatry unit, institute of clinical medicine, Risskov, Denmark

\* Corresponding author.

*Introduction.*– New research points to sleep abnormalities as a key component of major depression and a target for new treatments. Isoflurane, an anaesthetic agent, shares mechanisms of action with ketamine. It has been suggested that isoflurane might have rapid antidepressant effects in low doses.

*Objective.*– The objective of the study was to examine the effect of isoflurane treatment in Sprague-Dawley rats on depressive-like behaviour and examine possible pathways.

*Method.*– The treatment groups received treatment with 2.5% isoflurane for five minutes as a single treatment or once daily for five days. They were compared to a sham treated control group and tested for locomotor activity with the open field test and depressive-like behaviour with the forced swim test.

*Results.*– Neither of the treatment groups showed a significant effect on the immobility measured in the forced swim test. However, we observed a significant reduction in locomotor activity in the open field test in the group which received five consecutive treatments indicative of residual sedation.

**Conclusion.**– Our study cannot support the hypothesis that isoflurane should have a rapid antidepressant effect. However, the presented study holds large positive implications for the many studies on antidepressants and antidepressant behaviour performed in labs around the world. This is because isoflurane is used extensively to sedate prior to sacrifice and during surgical procedures.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Effects of chlorpromazine, haloperidol and sulpiride On GLUT2 of cells of isolated rat's islets

H. Liu\*, W. Xiao, Z. Liu, G. Wang

Renmin hospital of Wuhan university, psychiatry dep, Wuhan, China

\* Corresponding author.

**Objective.**– To clarify its metabolites result from influence the expression of glucose transporter 2 (GLUT<sub>2</sub>) located in cell membrane of isolated rat's islets.

**Methods.**– The cells of isolated rat's islets were prepared by a modified collagenase digestion methods. At 5.5 mmol/L glucose, the cells of islets was treated with 1 mmol/L chlorpromazine, haloperidol and sulpiride, respectively, blank control group was also set. Following longer exposures to the drugs (48 h), the cells of isolated rat's islets in each group were detected GLUT<sub>2</sub> mRNA level with RT-PCR and GLUT<sub>2</sub> protein expression with Western-blot. All the data are statistical analyzed with SPSS 20.0.

**Results.**– The mRNA and protein expression of GLUT<sub>2</sub> in chlorpromazine group was both significantly lower than control group ( $P=0.045 < 0.05$ ,  $P=0.038 < 0.05$ , respectively), and no significant difference between haloperidol group, sulpiride group and control group ( $P > 0.05$ ).

**Conclusion.**– Chlorpromazine can inhibit GLUT<sub>2</sub> expression of cells of islets, and then hamper glucose transport through cell membrane, which was one of mechanisms to explain the effect of clozapine on insulin secretion.

**Keywords:** Chlorpromazine; Haloperidol; Sulpiride; Glucose transporter

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

There is emerging evidence that individual differences in head motion (HM) might be an indicator of certain disorders and reflect a trait-like property of the individuals, rather than a confounding factor. The features of HM evaluation are person-centered repeated measurements, linking to another core neurocognitive concept— intraindividual variability (IIV).

We conducted a RT-based task, structural MRI and resting-state functional MRI in forty-one elderly. Intraindividual coefficient of variation of reaction time (ICV-RT) is used to evaluate the IIV enu-

merated with the formula:  $ICV-RT = (SD \text{ of } RT / \text{mean of } RT) \times 100$ . Similar to IIV of RT, IIV of HM was calculated based on the realign file with mean HM adjusted. Gray matter volume (GMV) was calculated by surface-based morphometry analysis.

Psychometrically, IIV of RT was correlated with the elevated mean HM of x-axis, IIV-HM of x-axis and y-axis. Morphometrically, mean HM of y-axis was correlated with reduced GMV of OpIFG, GRe, POrg, tmp and STG. Mean HM of x-axis was associated with decreased GMV of tmp and STG. As to the IIV of HM, IIV-HM of x-axis was correlated with reduced GMV of tmp and STG. IIV-HM of y-axis was associated with decreased GMV of GRe, POrg, tmp, STG and fusiform gyrus. IIV-HM of z-axis was correlated with reduced GMV of OpIFG, tmp and STG.

IIV of HM exhibits the similar psychometric features as IIV of RT; meanwhile, it also shows the overlapping regions as HM has. The findings suggest that IIV of HM might use as a potential indicator connecting the behavior and brain in neuroimaging study (fig 1).

### Psilocybin: Antidepressive, anxiolytic and antiaddictive effects

C. Machado\*, L. Monteiro, C. Fragoeiro, B. Almeida

Hospital Magalhães Lemos, psychiatry, Porto, Portugal

\* Corresponding author.

Psilocybin, a psychoactive alkaloid contained in hallucinogenic mushrooms, has recently been tested for its safety and efficacy in clinical populations for the treatment of depression, anxiety disorders and substance dependence.

The main objective of this study is to summarize the mechanism of action of psilocybin and its efficacy in the treatment of different psychiatric conditions. We also present the ethical issues concerning psilocybin use in clinical practice and its safety profile.

We did a review using the Pubmed database with the Mesh terms: “psilocybin” and “depression” or “anxiety” or “dependence”. We selected clinical trials and reviews published in the last 20 years written in English, Portuguese or Spanish according to our aims.

Psilocybin and psilocin (the psychoactive metabolite of psilocybin) are substances with predominant agonist activity on serotonin 5HT<sub>2A/C</sub> and 5HT<sub>1A</sub> receptors. Psilocybin acts as a hallucinogen and has a profound effect on cognition, perception and emotion, producing transient psychosis-like symptoms.

Clinical trials showed that the administration of psilocybin resulted in significant reductions in Yale– Brown Obsessive–Compulsive Scale, in anxiety scores and in tobacco and alcohol craving. The

analysis of the psilocybin safety profile showed that it can be safely administered in controlled settings.

The evidence overall strongly suggests that psilocybin should be re-examined in modern clinical trials for their use in non-psychotic mental health conditions.

### **Paresthesias and quetiapine: A case report**

E. Mancha<sup>1</sup>, Y. D' Hiver Cantalejo<sup>2</sup>, M.J. Leñero Navarrete<sup>3</sup>, H. Saiz García<sup>4</sup>

<sup>1</sup> Servicio Navarro de Salud, CSM Ansoain, Pamplona, Spain;

<sup>2</sup> Sescam, Hospital Universitario de Guadalajara, Guadalajara, Spain;

<sup>3</sup> Sacyl, hospital universitario Río Hortega, Valladolid, Spain;

<sup>4</sup> Servicio Navarro de Salud, Complejo Hospitalario de Navarra, Pamplona, Spain

\* Corresponding author.

*Objectives.*– Differentiate the symptoms of the conversive disorder of possible pharmacological secondary. A wide variety of diffuse symptoms, such as motor paralysis or blindness, disorders of the nervous system and paresthesias are presented in conversion hysteria.

*Methods.*– To analyze the case of a 58-year-old woman, with a history of histrionic personality disorder and recurrent depressive disorder, after suffering a new depressive relapse and attending a long admission to Day Hospital and a new psychopharmacological treatment consisting of zonisamide 100 mg/día and quetiapine 600 mg/día, develops paresthesias in the left side of her body with great affective repercussion and functional limitation.

*Results.*– These symptoms are identified as a possible conversion, so that the patient could be turning the psychological conflict into a physical disorder. Psychotherapeutic treatment is carried out, without achieving any result. A neurological evaluation is then made but the examination is normal. The progressive withdrawal of zonisamide is then attempted, considering a possible pharmacological etiology, but the symptomatology persists, and finally the gradual decrease in the dose of quetiapine is carried out. Paradoxically, within three weeks of its withdrawal the symptomatology returns completely.

*Conclusions.*– We would think of a drug origin and more specifically in a possible secondary use of quetiapine in elderly patients. It is of vital importance to evaluate the importance of this type of pictures in our usual clinical practice and the need for a correct detection, evaluation and intervention of the same, being essential the study of the individual symptoms beyond the psychiatric tags.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Antipsychotic's plasma level variability and its influence on treatment response in schizophrenia exacerbation**

M. Morozova\*, S. Potanin, D. Burminskiy, A. Beniashvili

<sup>1</sup> Mental health research center, laboratory of psychopharmacology, Moscow, Russia

\* Corresponding author.

*Introduction.*– Up to 40% of patients with schizophrenia exacerbation don't achieve satisfactory treatment response. One of the

explanations for that may be significant individual variability of antipsychotic's pharmacokinetics.

*Objective.*– To investigate the individual variability of the antipsychotics concentration in plasma and its influence on the treatment efficacy among patients with schizophrenia exacerbation.

*Methods.*– 41 patient (23 women and 18 men, aged 23–60 years), hospitalized to the city mental health hospital and treated according to the routine practice were included in the study. The patients were treated by the following antipsychotics: haloperidol, risperidone, zuclopenthixol, paliperidone, clozapine, aripiprazole, quetiapine, or olanzapine. On 2–5 and 26–30 days PANSS rating was conducted. Blood sampling for antipsychotics plasma level was performed twice – at 7–10 day and at 26–30 day.

*Results.*– In 66% of patients (27 subjects) were found deviations from the optimal antipsychotic's plasma level in at least one of the test points. Patients with optimal concentration showed a significantly better treatment response. Significant differences between the groups were found in changes of the total score in PANSS, negative and anxiety/depression Marder factors, general pathology PANSS subscale ( $p < 0.05$ ). The greatest difference between the groups was observed in regard to the changes of the negative Marder factor scores (1.7 points versus 0.3 points to the 26–30 day of treatment in average).

*Conclusion.*– The study shows the benefit of further research on the use of antipsychotic's therapeutic drug monitoring for the purpose of acute schizophrenia treatment personalization.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

<sup>7</sup> Stanford University, center for neuroscience in women's health, Palo Alto, USA

\* Corresponding author.

Mechanistic insights from animal studies can inform the development of diagnostics and better treatments for major depressive disorder (MDD), which is a leading cause of ill health and disability worldwide. Converging evidence from our and other groups revealed that animals with an endogenous reduction in the levels of the epigenetic modulator of glutamatergic function with insulin-sensitizing properties, acetyl-L-carnitine (LAC), in plasma and mood-regulatory brain regions (hippocampus and prefrontal cortex) showed depressive and metabolic-like dysfunctions that were rapidly rescued by LAC supplementation. Therefore, our objective was to determine whether patients with MDD differed in LAC levels in comparison to healthy controls(HC).

Plasma distribution of LAC and of internal control free-carnitine were determined in 71 patients with MDD and 45 age- and sex-matched HC using UPLC-MS/MS and ESI-MS/MS. The psychiatric

examination included: SCID and MINI, and the two psychiatric scales HDRS-17 and MADRS. Childhood Trauma Questionnaire was used to assess childhood trauma. Two-tailed t-tests, chi-square, and multiple regression were used as appropriate.

LAC was lower in patients with MDD compared to HC ( $P < 0.0001$ , effect size = 0.8). Of note, LAC was lower in patients who exhibited greater severity and earlier age-of-onset of MDD. Moreover, in those patients with TRD, the reduction in LAC was stronger, and emotional neglect and being a female predicted decreased LAC ( $P = 0.04$ ,  $r = 0.66$ ). Our new findings suggest that LAC may serve as marker to delineate a MDD phenotype, providing a target for precision medicine and rational path forward for novel pharmaceuticals. Future studies will test whether such biologically-defined MDD phenotype could benefit by LAC treatment.

### **Three-month injection of paliperidone palmitate (3MPP), for whom? Informed consent, patients preferences, and clinical decision making**

S. Navari<sup>1</sup>, M. Curto<sup>1,2</sup>, C. Silvestrini<sup>1</sup>, A. Manzi<sup>1</sup>, V. Bianchini<sup>1</sup>, P. Pompili<sup>1</sup>, G. Nicolo<sup>1</sup>, E. Pompili<sup>1</sup>

<sup>1</sup> Department of mental health and drug abuse, ASL Roma 5, Rome, Italy; <sup>2</sup> Sapienza University of Rome, department of neurology and psychiatry, Rome, Italy

\* Corresponding author.

*Introduction.*— Long-acting injectable antipsychotics (LAIAs) were introduced to improve treatment adherence of antipsychotic medication. After risperidone was introduced as the first LAI-second-generation antipsychotic, olanzapine pamoate, once-monthly paliperidone palmitate and once-monthly aripiprazole were also approved for schizophrenia. Recently, a three-month injection of paliperidone palmitate (3MPP) is available in Europe, offering a substantially longer dosing interval than previously options.

*Objectives.*— To identify, among patients under LAIAs, potential candidates for 3 MPP, with the favorable risk/benefit profile. First, to characterize patients clinically suitable to 3MPP, then, to evaluate their understanding of risks and benefits of 3MPP and to assess patients preferences.

*Methods.*— The study sample includes 150 patients under LAIAs, in the Mental Health Community Treatment Team of Colferro/Palestrina, ASL Roma 5, Italy. Clinical and socio-demographic parameters are collected in details, Visual Analogue Scales (VAS) measure satisfaction with current treatment and informed consent of 3MPP, including a test to check patients understanding, as well as VAS to measure patients treatment preferences, are administered. *Results.*— 65% of the patients sample is under atypical LAIAs (37% paliperidone, 28% risperidone, 17% olanzapine), 79% male, mean age  $43.6 \pm 11.73$  and 35% under typical LAIAs, 66% male, mean age  $57.3 \pm 8.63$  years. We expect, from updated results, to identify a sub-population of patients under LAIAs who could benefit and might prefer to switch to 3MPP.

*Conclusions.*— The sub-population who could benefit from switching to 3MPP should be clinically identified on the basis of socio-demographic and clinical data and, therefore, evaluated in terms of awareness and preferences regarding the new treatment.

### **Do brain/behavioral systems mediate the relationship between Internet addiction and executive functions?**

F. Nebtoun<sup>\*</sup>, N. Nazarboland, S. Ghanbari  
Shahid Beheshti university, psychology, Tehran, Iran

\* Corresponding author.

Internet addiction, a behavioral dependency on internet, results in psychological, educational and job-related problems. Given that internet addiction is related to individuals' cognitive, behavioral and emotional functions and that personality is one of the determinants of how individuals behave, the present study attempts to shed light on the relationship between 'internet addiction', 'executive functions' and biologic indexes of personality regarding 'brain/behavioral systems' in adolescent students. The participants included 463 Iranian high school students (234 females and 229 males) aging 13–18 years old who were selected using multi-stage cluster random sampling. Young's Internet Addiction Questionnaire (1998), Cognitive Abilities Questionnaire (Nejati, 2013) and the short-form of Gray-Wilson Personality Questionnaire (2001) were completed by the participants. Data analysis was conducted through regression and path analysis. Results indicated that there was an inverse relationship between executive functions and internet addiction, and a significant relationship between behavioral activation system and internet addiction. However, no significant relationship was found between behavioral inhibition system and internet addiction. Besides the direct paths, executive functions affect internet addiction through indirect paths and behavioral activation system, i.e., the behavioral activation system functions works as a mediating variable in the relationship between executive functions and internet addiction. According to obtained goodness-of-fit the validity of the using model was approved. Such results may help to understand cognitive and personality aspects of the problems associated with internet addiction, and take necessary preventive measures and prepare therapy packages and cognitive rehabilitation.

<sup>3</sup> Consultant psychiatrist, AGC Salud mental hospital de Cabueñes, Gijón, Spain; <sup>4</sup> Psychiatry trainee, AGC Salud Mental Hospital de Cabueñes, Gijón, Spain; <sup>5</sup> Psychiatry Trainee, Hospital Universitario de Cruces, Barakaldo, Spain

\* Corresponding author.

*Introduction.*— Since long-acting antipsychotic (LAI) drugs appeared in the market there have been arguments for and against their use in clinical practice. While LAIs seem to improve therapeutic adherence and their range of application is comfortable for some patients, other voices notice that they could be perceived as stigmatizing.

*Objectives.*— The main objective is to describe the differences derived from the prescription of LAIs versus oral antipsychotics in patients diagnosed with psychosis in two ambulatory care centers of the region.

**Methods.**– This is a descriptive retrospective study. A total of 311 clinical histories of every psychotic patient receiving LAIs in two mental health centres of Gijón and Avilés were checked. We selected those patients who fulfilled the inclusion criteria established, being one of them previous treatment with oral antipsychotic. At last 107 subjects took part in the research.

**Results.**– In this study 72.9% of the cases changed from oral to injectable formulation because of the lack of adherence, and only 14% of replacements were due to patient choice. The number of hospital admissions, hospital emergencies and suicide attempts were significantly lower with long acting formulation.

**Conclusions.**– The results, favorable to LAIs are concordant with other researches with similar design. These data must be carefully interpreted considering the own investigation limitations.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Verbal memory research in adolescents following traumatic brain injury of mild severity**

S. Pervichko

Moscow State university, psychology, Moscow, Russia

**Introduction.**– The effect of the traumatic brain injury of mild severity (mTBI) on the memory influences on the educational activities of adolescents in school.

**Objectives.**– To study of verbal and visual memory in adolescents after mTBI in acute period (3–5 days after trauma).

**Materials and methods.**– The study is based on the original set of techniques designed by A.R. Luria. We used the technique of “remembering 5 words” and “2 groups of 3 words” for investigate the verbal memory.

31 patients with mTBI (mean age was 11.5 + 1.3) and 20 healthy subjects (mean age was 12 + 1.5) took part in the study.

**Results.**– Analysis of the results showed that 26% of adolescents with mTBI has a decrease in auditory memory. In the method of “remembering 5 words” the reproduction of words after interference caused difficulties in 13% of patients who manifested themselves in the form of a reduction in the volume of direct reproduction ( $P < 0.05$ ) and an increase in the number of presentations for the reproduction of words in the correct order ( $P < 0.005$ ). When performing the “2 groups of 3 words” method 23% of patients had difficulty remembering words in the correct order ( $P < 0.05$ ). Errors in the form of verbal paraphases and selectivity errors predominated more often ( $P < 0.05$ ).

**Conclusions.**– The study of memory in the acute period after mTBI revealed the presence of modal-nonspecific subclinical disorders, in the form of a reduction in direct reproduction and pathological inhibition of memory traces.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Triple-blind randomized placebo-controlled clinical trial of oral naloxone for opioid-induced constipation in patients with opioid use disorder receiving methadone maintenance treatment**

A.V. Samokhvalov<sup>1</sup>, J. Rehm<sup>2</sup>

<sup>1</sup> Centre for Addiction and mental health, addictions division, institute for mental health policy research, Toronto, Canada; <sup>2</sup> Centre for addiction and mental health, institute for mental health policy research, Toronto, Canada

\* Corresponding author.

**Introduction.**– Constipation is a very common and one of the most persistent side effects of opioids. In many cases constipation causes severe discomfort and puts limitations on methadone maintenance treatment (MMT). Conventional laxatives are not always effective and do not address the pathophysiological basis of constipation. It was suggested that opioid receptor antagonists with low oral bioavailability e.g. naloxone might reverse constipation while not affecting the course of MMT.

**Objectives.**– Primary objective is to assess the effectiveness of oral naloxone for methadone-induced constipation in MMT patients. Secondary objective is to evaluate the side effects of this treatment, specifically – potential opioid withdrawal symptoms.

**Methods.**– Randomized triple-blind placebo-controlled clinical trial ( $n = 20$ ). Crossover design. Each subject received oral naloxone or placebo for 1 week in a random order. The dose of naloxone was proportional to the methadone dose (1:50). Statistical analysis: descriptive statistics; mixed effect models.

**Results.**– Twenty patients were enrolled into the study. All of them completed the 16-day study protocol. While majority of patients demonstrated improvement in their bowel functioning as measured by Bowel Functioning Index, there was no significant difference between naloxone and placebo arms ( $P = 0.86$ ). There was also no difference in side effects between the two groups as per Subjective Opioid Withdrawal Scale ( $P = 0.48$ ).

**Conclusions.**– The results of the study indicate that oral naloxone is a safe option for constipation in MMT patients, but lacks effectiveness at the 1:50 dose. Further research with different formulations of oral naloxone needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Proteomics study of the striatum of mice chronically exposed to haloperidol**

J.F. Coelho<sup>1</sup>, C. Santa<sup>1\*</sup>, D. Bessa-Neto<sup>2</sup>, S.I. Anjo<sup>1</sup>, G. Baltazar<sup>2</sup>, D.R. Cotter<sup>3</sup>, M.J. Dunn<sup>4</sup>, B. Manadas<sup>1</sup>

<sup>1</sup> CNC, center for neuroscience and cell biology, university of Coimbra, life sciences mass spectrometry, Coimbra, Portugal; <sup>2</sup> CICS, university Beira interior, health sciences research centre, Covilhã, Portugal;

<sup>3</sup> Royal College of Surgeons in Ireland, department of psychiatry, Dublin, Ireland; <sup>4</sup> UCD Conway Institute of Biomolecular and Biomedical Research, Proteome Research Centre, Dublin, Ireland

\* Corresponding author.

Haloperidol is one of the most frequently used antipsychotic in the treatment of schizophrenia (SCZ). SCZ is a severe mental disorder characterized by a combination of positive, negative and cognitive symptoms. Haloperidol is thought to alleviate the positive symptoms by antagonizing dopamine D2 receptors widely expressed in the striatum. What is less clear are the long-term

molecular effects of this medication. Many studies have assessed the molecular alterations induced by antipsychotic medication in schizophrenic patients however, the reports from these studies are inconsistent and not able to assure if the identified changes are disease or drug-related or a consequence of chronic impairment. The main aim of this study was to evaluate the molecular effects of chronic Haloperidol in mice striatum. Mice striatum protein samples were analyzed by a relative quantitative LC-MS approach, SWATH. In total, 3311 proteins were identified and 1366 confidently quantified. Among these quantified proteins, the majority of the ones considered as altered were involved in three several biological key pathways, such as metabolism, synaptic or calcium signaling. Disturbances in the mitochondrial respiratory chain, particularly in oxidative phosphorylation were observed, as well as proteins involved in GABAergic, glutamatergic and dopaminergic neurotransmission. Changes in CaM-related proteins and Ca<sup>2+</sup> extrusion proteins were also detected, suggesting disturbances in calcium signaling pathway.

Altogether, these findings highlight several pathways affected in the striatum by haloperidol chronic treatment suggesting the long-term molecular mechanisms of action of the drug. This study also elucidates new directions for recognizing and differentiating disease from medication-related changes.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **A lesion model of legal, deservingness and moral dimensions of socio-moral emotions as revealed by neurodegeneration**

H. Santamaría García\*, S. Baez, J. Santamaría García, P. Reyes, J.M. Santacruz Escudero, D. Matallana, A. García, A. Ibanez  
Pontificia Universidad Javeriana, Psiquiatría, Bogotá, Colombia

\* Corresponding author.

The study of moral emotions (i.e., Schadenfreude and envy) is critical to understand the ecological complexity of everyday interactions between cognitive, affective, and social cognition processes. Most previous studies in this area have used correlational imaging techniques and framed Schadenfreude and envy as unified and monolithic emotional domains. Here, we profit from a relevant neurodegeneration model to disentangle the brain regions engaged in three dimensions of Schadenfreude and envy: deservingness, morality, and legality. We tested a group of patients with behavioral variant frontotemporal dementia (bvFTD), patients with Alzheimer's disease (AD), as a contrastive neurodegeneration model, and healthy controls on a novel task highlighting each of these dimensions in scenarios eliciting Schadenfreude and envy. Compared with the AD and control groups, bvFTD patients obtained significantly higher scores on all dimensions for both emotions. Brain anatomy findings confirmed the partially dissociable nature of the moral emotions' experiences and highlighted the importance of socio-moral brain areas in processing those emotions. In all subjects, an association emerged between Schadenfreude and the ventral striatum, and between envy and the anterior cingulate cortex. By contrast, bvFTD patients exhibited a negative association between increased Schadenfreude and envy across dimensions and critical regions supporting social-value rewards and social-moral processes (dorsolateral prefrontal cortex, angular gyrus and precuneus). Our results offer new insights into the mechanisms subsuming complex emotions and moral cognition in neurodegeneration. Moreover, this study presents the exacerbation of envy and Schadenfreude as a new potential hallmark of bvFTD that could impact in diagnosis and progression.

### **Vestibular dysfunction impairs visuospatial working memory independently of co-morbid depression, anxiety, fatigue and sleep disturbance**

S. Surenthiran<sup>1</sup>, L. Smith<sup>2\*</sup>, D. Wilkinson<sup>2</sup>, M. Bodani<sup>2</sup>, R. Bicknell<sup>2</sup>

<sup>1</sup> Medway Maritime Hospital, neurosciences, Kent, United Kingdom;

<sup>2</sup> University of Kent, psychology, Canterbury, United Kingdom

\* Corresponding author.

*Introduction.*– Beyond the acute effects of vertigo and unsteadiness, vestibular dysfunction is commonly accompanied by subjective reports of memory loss and problems concentrating. The co-morbid presence of psychiatric illness, fatigue and difficulty sleeping, coupled with the lack of comprehensive, validated neuropsychological assessment, has left questions unanswered about the origin and nature of these underlying cognitive impairments.

*Methods.*– 100 patients diagnosed with primary vestibular disorder (mostly vestibular migraine) at their initial neuro-otology appointment completed validated neuropsychological assessments of depression, anxiety, depersonalisation, fatigue, sleep, memory and attention. Vestibular pathology was characterised using a range of behavioural and physiological assessments.

Statistical analyses first calculated the prevalence of cognitive and other comorbid impairments. A series of structural equation models then tested whether vestibular function exerted a direct influence on cognition, or influenced performance indirectly via psychiatric, fatigue/ sleep mechanisms.

*Results.*– The majority of patients presented with a combination of anxiety, depression, sleep disturbance, fatigue, working memory and attentional impairments. Most important, balance function, assessed via balance platform (a measure of unassisted posture), influenced visuospatial memory performance independently of any age, psychiatric or fatigue/ sleep-related effects.

*Conclusions.*– The present findings identify new clusters of impairment in vestibular patients and highlight a direct effect of vestibular dysfunction on short-term visuospatial memory. We suggest that the most likely anatomical route is via the vestibulo-thalamo-cortical pathway which passes vestibular signals to several areas associated with working memory and visuospatial processing. From a clinical perspective, the results suggest that psychiatric treatments may do little to reduce co-morbid cognitive symptoms.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **The first pre-sapiens awareness: psychopathology of the homo erectus**

C.J. Vera Scamarone

EsSalud, Psychiatry, Lima, Peru

*Introduction.*– Around the world, the *Homo sapiens* has been considered as the first ancestor with self-awareness. His cranial capacity was the evidence about complex neuro connections with the use of his total capacity. This reminds about feelings, about soul, perdurable life after death and psychopathological behavior. The advances in paleo neurology (see Figure 1) were supported in archaeological findings (cranial scalps, culture manifestations like burials, rock art, and manufacture of weapons). Burials lead to the

conclusion of social structure, believing of persistence of the soul. Thus, cultural beliefs predispose to depression. The evolution of brain volume make possible the expansion of awareness (Fig. 2).

Figure 1 Comparison between Homo erectus brain (left) and Homo sapiens (right). Both have upper area of Broca and prefrontal area. Source: Smithsonian Human Origins Program and Field Research, 2016.

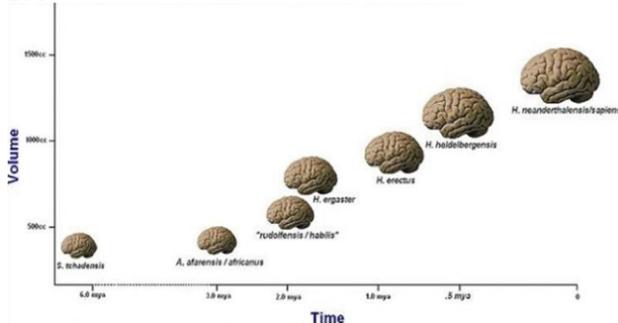

Figure 2 Comparison of brain volume. Source: Smithsonian Human Origins program and Field Research, 2016.

**Objective.**– Associate homo erectus art samples with the appearance of self-awareness.

**Methods.**– Review of scientific articles.

**Results.**– However, recent findings about *Homo erectus* deposits (see Figure 3) approach the emergence of awareness long before the emergence of *Homo sapiens*. With the reconstruction of a 3-D model of the *Homo erectus* brain, we can suspect paleo neurological complex, ancient, but enough for the archaic psychopathology of the awareness. Just for an adventure conclusion, the *Homo erectus* was our first ancestor with the capability of awareness.

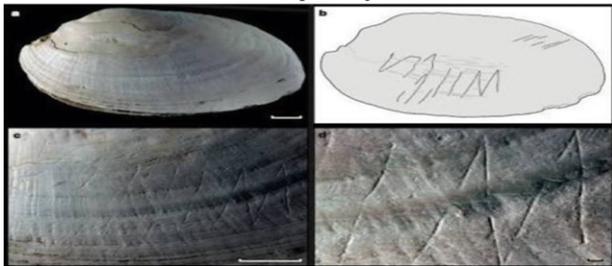

Figure 3 Art associated to Homo erectus (540 000 BC) Source: Smithsonian Human Origins program and Field Research, 2016.

**Conclusion.**– Therefore, one can surmise that the psychological and psychiatric manifestations probably were present from *Homo erectus*.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### Methamphetamine sensitization enhances the rewarding efficacy of ketamine via an enhancement in ketamine-stimulated dopamine release in nucleus accumbens

W.Y. Tzeng, L. Yu

National Cheng Kung University College of Medicine, Department of Physiology, Tainan, Taiwan R.O.C.

\* Corresponding author.

**Introduction.**– Per illicit drug users' polydrug use in local area, methamphetamine (MA) sensitization development is suspected to prime later ketamine (KE) use.

**Objectives.**– Mice pretreated with repeated saline or MA injections received KE-induced conditioned place preference (CPP) training and test.

**Methods.**– A 10-day repeated MA treatment (2 mg/kg/day) followed by a 10-day withdrawal was used to prime for the development of MA sensitization. Following a standard 3-day CPP training protocol, KE-induced CPP magnitude was used to reveal the rewarding efficacy of KE (1 mg/kg/conditioning). In vitro superfusion methods were used to reveal the remaining dopamine content in dopaminergic terminals in brain slab containing the nucleus accumbens.

**Results.**– We found that MA sensitized mice exhibited greater KE-induced CPP as compared with the saline-treated controls. Moreover, MA-sensitized mice exhibited a greater KE-stimulated dopamine (DA) release in the nucleus accumbens than saline-treated ones as revealed in in vitro superfusion experiment.

**Conclusions.**– These results, taken together, suggest that MA sensitization development may enhance the rewarding efficacy of KE.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Minimal size of social buffering and oxytocin buffering effects against robust stress-induced decreases in dentate cell proliferation and early neurogenesis

L. Yu

National Cheng Kung University College of Medicine, department of physiology, Tainan, Taiwan R.O.C.

**Introduction.**– The presence of three conspecific companions, serving as social support, has been known to prevent a compound stress regimen-induced decreases in newly proliferated cell and neuroblast in mouse dentate gyrus (DG).

**Objectives.**– In an attempt to control for mouse physical interaction throughout the stress regimen, a 1-hr restraint and immersed in water stressor preventing any physical interaction in mice, was used instead in this study. We sought to determine the minimal size of companions necessary for exerting the afore-mentioned stress-preventing effects. Moreover, experiments were done to study on the buffering effects of oxytocin in this regard.

**Methods.**– Bromodeoxyuridine (BrdU) staining was used to reveal newly proliferated cell, while BrdU and doublecortin co-staining was used to indicate newly proliferated neuroblast.

**Results.**– We found that the presence of one companion exerted comparable stress-preventing effects as the presence of three companions. Furthermore, the presence of one saline- or oxytocin-treated mouse both prevented the stress-induced decreases in newly proliferated cell and neuroblast in DG. Finally, the presence of oxytocin (evaporating from a cotton-tip) alone effectively pre-

vented the stress-induced decreases in DG newly proliferated cell and neuroblast.

**Conclusions.**– These results, taken together, prompt us to draw two provisional conclusions. First, social support consisting of one conspecific companion is effective in preventing the stress-induced decreases in newly proliferated cell and neuroblast in DG. Second, the presence of oxytocin is a feasible substitute for the social support consisting of companions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction.**– Recognising, describing and differentiating emotions is significant for social communication as well as for emotion regulation. Impaired social cognition is considered a contributor to unfavorable psychosocial functioning in Schizophrenia Spectrum Disorders.

**Objectives.**– Evaluation of alexithymia and the capacity of emotional face recognition in subjects who are part of the schizophrenia spectrum.

**Aims.**– To establish a correlation between alexithymia and emotion recognition ability.

**Methods.**– A sample of 26 subjects were analysed in this trial, diagnosed with Schizophrenia Spectrum (according to ICD 10 criteria), who were hospitalised in the Psychiatry Clinic of Timisoara. Subjects were introduced in the trial based on inclusion/exclusion criteria. The analysed parameters were: socio-demographic (age, gender, marital status, education level), clinical (diagnosis, evolution of disease), alexithymia (Toronto Alexithymia scale) and the ability to identify emotions (Reading the Mind in the Eye Test).

**Results.**– 57.69% of the subjects had alexithymia, 19.23% had possible-alexithymia and 23.07% were non-alexithymic. Most of the subjects had a low ability to identify emotions (84.61%). 66% of the non-alexithymic patients had a normal capacity to recognise emotions.

**Conclusion.**– The subjects with Schizophrenia Spectrum Disorders have deficits expressing, describing and identifying emotions. Difficulties recognising facially expressed emotions and alexithymia could possibly be linked.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Schizophrenia – innovations in programmatic interventions and integrated care to improve recovery

A.I. Ahmed<sup>1</sup>, A. Choudhury<sup>1</sup>, R. Singh<sup>2</sup>, G. Sharma<sup>2</sup>

<sup>1</sup> PsyCare, psychiatry, Delhi, India; <sup>2</sup> PsyCare, Psychology, Delhi, India

\* Corresponding author.

Schizophrenia is a chronic disabling illness with relapses worsening the outcomes with serious implications for disease progression. Majority of the patients are partially or non adherent. Relapse prevention is a key therapeutic goal which may result in functional recovery

**Objectives.**– To study various modalities of intervention after inpatient treatment of patients of schizophrenia in a 30 bedded psychiatric hospital for followup and adherence to achieve functional recovery

**Significance.**– Time to Discontinuation for any cause is the main variable to compare effectiveness of different treatments. Any program designed to provide longer pharmacological treatment combined with psychosocial treatments improves the possibility of functional recovery

**Methodology.**– The study is naturalistic, prospective in nature. 32 patients of schizophrenia consecutively admitted and managed over a 2 year period were subjects of the study. At discharge they were continued on oral antipsychotics with conventional psychosocial interventions (PSI) ( $n = 14$ ) or Long Acting Injectibles with PSI and telepsychiatry (TP) (Recovery program) ( $n = 18$ ).

**Result.**– Out of the 14 patients on oral antipsychotic group 10 were lost to follow up (71.4%). Of the 18 patients in LAI+PSR+TP, 5 patients (27.7%) were lost to follow up. Of the 13 remaining in Recovery Program, 3 shifted to LAIs+PSI, opting out of TP. The results were statistically analysed

**Conclusion.**– The patients remaining under follow up were significantly higher when on LAIs with psychosocial interventions and Telepsychiatry than those on Oral antipsychotics with psychosocial interventions. It is likely that the patients remaining in follow up have better outcomes and possibility of recovery.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Co-morbid obsessive-compulsive disorder and schizophrenia in highly endogamous population: Which came first?

A. Bener

Istanbul university, biostatistics & public health, Istanbul, Turkey

**Background.**– Co-occurrence of Schizophrenia (SZ) and obsessive compulsive disorder (OCD) is a common and difficult co-morbid condition to manage. Also, the relationship between SZ and OCD remains unclear.

**Aim.**– The study was to determine the prevalence of co-morbidity with obsessive-compulsive disorder (OCD) among Schizophrenia (SZ) patients in order to assess the impact of OCD on the socio-demographic and clinical features of patients in endogamous population.

**Subjects and methods.**– A cohort study was carried out on 396 patients. We employed the WHO Composite International Diagnostic Interview (WHO-CIDI) and Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition-IV/Clinical Version for diagnoses, the Yale-Brown Obsessive Compulsive Scale Symptom Checklist for scoring OCD.

**Results.**– Patients were grouped in SZ patients with OCD (SZ-OCD) and SZ patients without OCD. Groups were compared for socio-demographic and clinical variables. There were no significant differences for age, gender, marital status, education, occupation, cigarette smoking, and place of living between SZ patients with and without OCD. Number of hospitalizations and Young Mania Rating Scale score were not different among SZ patients with or without OCD whereas there were significant differences in Hamilton-Depression score, Clinical Global Impression-SZ Score,

duration of illnesses, and Global Assessment of Functioning (GAF). Also specific phobia, somatization, depression, mania, any mood disorder, oppositional defiant disorder, ADHD and personality disorder were more common in SZ than OCD–SZ group.

**Conclusion.**– This study confirms that SZ-OCD is a common comorbidity, largely under-recognized in clinical practice, which may significantly change SZ presentation and outcome.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

<sup>11</sup> Karolinska institute, division of psychology of the department of clinical neurosciences, Stockholm, Sweden

\* Corresponding author.

**Introduction.**– Schizophrenia (SZ) is a very debilitating psychiatric disorder, associated with deficits in the detection of facial expressions. Although recent evidence has suggested that patients with SZ exhibit a perception bias towards happy faces, most psychotic experiences are threat-related, having a negative impact on patients' functioning. However, to our knowledge, the access to visual awareness by different emotional facial expressions in SZ is still unclear.

**Objectives.**– To analyze the conscious detection of fearful and happy faces, in comparison to neutral faces, in patients with SZ.

**Methods.**– 11 patients with SZ-spectrum disorder and 10 healthy controls, age- and gender-matched, performed a breaking-Continuous Flash Suppression task. Suppressors were presented to the dominant eye while faces were gradually introduced to the non-dominant eye. Participants were asked to indicate on which quadrant the face became visible. The speed of access to visual awareness was analyzed via response time (milliseconds).

**Results.**– Patients exhibited a significantly slower access to visual awareness of facial expressions than controls. In SZ, happy faces broke suppression significantly faster, in comparison with fearful faces. In controls, no significant differences between emotions were found.

**Conclusions.**– SZ may be related to abnormal facial expression detection at an early stage of information processing. SZ is associated with a constant perception of threat and patients may tend to attribute threat to positive social cues, leading to a preferential

access to visual awareness by happy faces. Investigating the conscious detection of facial expressions will provide new insight on the comprehension and treatment of SZ.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Violent behavior in first psychotic episode: An overview**

C. Ferreira<sup>1\*</sup>, L. Castanheira<sup>1</sup>, L. Ferreira<sup>2</sup>, F. Coelho<sup>1</sup>, T. Queirós<sup>1</sup>

<sup>1</sup> Centro Hospitalar Lisboa Norte, Psychiatry Department, Lisboa, Portugal; <sup>2</sup> Hospital Distrital de Santarém, psychiatry department, Santarém, Portugal

\* Corresponding author.

**Introduction.**– Violent behaviour can be a presenting sign of first-episode psychosis (FEP). It is important to consider the possible explanations and implications for this association.

**Objectives.**– To discuss the findings about the prevalence of violent behavior before and after treatment in FEP and the relation with duration of untreated psychosis (DUP).

**Methods.**– Searched Internet databases indexed at MEDLINE using the key-words “violent”, “aggressive”, “behaviour”, “first psychotic episode” and selected the articles published in the last 10 years in English.

**Results.**– A substantial proportion of patients in FEP commit an act of violence before presenting for treatment, including an act of more serious violence causing injury to another person. The prevalence of violent behavior in the FEP is greater than during the later stages of the illness, dropping gradually to rates close to those of the general population. FEP is also associated with an increased risk of homicide. The data is inconsistent about the existence of significant relation between DUP and violent behavior in FEP, with some studies showing contradictory conclusions. Comorbid substance abuse, male gender, lower educational level and past history of violence were found to independently predict occurrence of serious violence after commencement of treatment and may be more important than psychotic symptoms in the development of aggressive behavior in patients with FEP.

**Discussion and conclusion.**– Close monitoring of patients with history of violence and treatments to reduce substance abuse seem to be the best way to lower long-term risk for violent behavior in FEP patients. It would be crucial to clarify the relation with DUP and violent behavior to support a more preventive approach.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Clozapine: Anti-aggressive effects in schizophrenia**

P. Ifteni<sup>1</sup>, A. Teodorescu

Universitatea Transilvania din Brasov, Facultatea de Medicina, Brasov, Romania

\* Corresponding author.

**Background.**– In the entire world, restraint and seclusion are common interventions in psychiatric in-patient settings due to aggressive behavior.

**Objectives.**– Our objective was to test for the immediate anti-aggressive property of clozapine compared to other antipsychotic treatments in a cohort with high rates of restraint during early hospitalization.

**Methods.**– We present a retrospective chart review of all admissions for aggressiveness of patients with schizophrenia during

2011–2014 in Psychiatry and Neurology Hospital, Brasov, Romania. Timing and number of restraints in addition to clinical, demographic and treatment characteristics were extracted. Based on our earlier observation of clinical efficacy of clozapine, we tested the hypothesis that clozapine treatment was associated with reduced use of restraint, and with longer restraint-free periods.

**Results.**– In 115 patients with schizophrenia (age = 39.7 ± 11.1 years; male = 59%) involuntarily admitted due to externalized (74.78%) or self-directed violence (25.22%), restraint was used in 89.6%; with a median duration of 3 hours until restraint past admission. Antipsychotics used immediately after hospitalization included haloperidol (70.4%), clozapine (11.3%), olanzapine (10.4%) and other second-generation antipsychotics (7.9%). Comparison of restraint characteristics favored immediate clozapine use with highly reduced rates of restraint (38.5% vs. 95.6%,  $P < 0.001$ ) and significantly extended hours until restraint ( $P < 0.001$ ) relative to the remaining cohort. These effects remained highly significant after controlling for potential moderators of restraint use in multivariate models.

**Conclusions.**– These retrospective data suggest an early anti-aggressive effect of clozapine during the immediate use of clozapine in highly problematic patients.

**Keywords:** Restraint; Aggressiveness; Clozapine; Schizophrenia

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Coronary artery calcification in patients diagnosed with severe mental illness**

P. Kugathasan<sup>1\*</sup>, M. B. Jensen<sup>1</sup>, J. Aagaard<sup>1</sup>, M. B. Johansen<sup>2</sup>, S. E. Jensen<sup>2</sup>

<sup>1</sup> Centre for Psychosis research, psychiatry, Aalborg University Hospital, Aalborg, Denmark; <sup>2</sup> Department of cardiology, Aalborg university hospital, Aalborg, Denmark

\* Corresponding author.

**Introduction.**– Patients with severe mental illness (SMI) have an excess mortality causing 15–25 years of life lost. Mortality is primarily caused by coronary heart diseases, and while the general population is declining in mortality from ischemic heart disease, this decline is not observed in patients with SMI. Coronary artery calcification is a clinical predictor of coronary artery disease, which can be measured by CT-Coronary Angiography (CT-CAG). Little is known about the level and progression of premature coronary atherosclerosis in patients suffering from SMI.

**Objectives.**– The objective is to investigate the prevalence and extent of coronary artery calcification in patients diagnosed with SMI and compare the results to controls from the general population.

**Methods.**– The study included all patients with a CT-CAG registered in the Western Denmark Heart Registry from 1st January 2008 to 31st December 2016. We identified patients with schizophrenia (ICD-10; F20) and bipolar disorder (ICD-10; F30-31) from the National Patient Registry and the Psychiatric Central Research Registry.

**Results.**– We observed that patients with schizophrenia were younger than controls and bipolar disorder patients with an average difference in age of 8–10 years. In addition, patients with schizophrenia had much higher rate of cardiovascular risk factors. Despite these characteristics, the frequency of patients presenting with high calcium score were lowest in patients with schizophrenia when comparing to the other groups.

**Conclusions.**– The conclusion is that even with the characteristics of developing atherosclerosis is present in patients with schizophrenia, these patients are not demonstrating signs of early coronary artery calcification.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Abnormal neural hierarchy in processing of verbal information in patients with schizophrenia and their non-manifesting siblings**

Y. Lerner<sup>1\*</sup>, M. Bleich-Cohen<sup>1</sup>, W. Madah<sup>2</sup>, T. Eisenstein<sup>3</sup>, S. Solnik<sup>1</sup>, I. Kremer<sup>2</sup>, T. Hendler<sup>1</sup>

<sup>1</sup> Tel Aviv Sourasky Medical Center, the functional brain center, Tel-Aviv, Israel; <sup>2</sup> Mazra mental health center, psychiatry, Akko, Israel; <sup>3</sup> Tel Aviv University, Medical School, Tel Aviv, Israel

\* Corresponding author.

Previous research pointed to abnormal comprehension of verbal information in patients with schizophrenia. Yet, the neural mechanisms underlying the breakdown of verbal information processing in schizophrenia are poorly understood. Imaging studies in healthy populations have shown a network of brain areas involved in hierarchical processing of verbal information over time.

Here, we identified critical aspects of this hierarchy, examining patients with schizophrenia. Using functional magnetic resonance imaging, we examined various levels of information comprehension elicited by naturally presented verbal stimuli; from a set of randomly shuffled words to an intact story. Specifically, patients with first episode schizophrenia, their non-manifesting siblings and healthy controls listened to a narrated story and randomly scrambled versions of it. To quantify the degree of dissimilarity between the groups, we adopted inter-subject correlation (inter-SC) approach, which estimates differences in synchronization of neural responses within and between groups. The temporal topography found in healthy and siblings groups were consistent with our previous findings – high synchronization in responses from early sensory toward high order perceptual and cognitive areas. In patients with schizophrenia, stimuli with short and intermediate temporal scales evoked a typical pattern of reliable responses, whereas story condition (long temporal scale) revealed robust and widespread disruption of the inter-SCs. In addition, the more similar the neural activity of patients with schizophrenia was to the average response in the healthy group, the less severe the positive symptoms of the patients.

Our findings suggest that system-level neural indication of abnormal verbal information processing in schizophrenia reflects disease manifestations.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Increased delayed reward during intertemporal decision-making in schizophrenic patients and their unaffected siblings**

L. Wang

The first affiliated hospital of Anhui medical university, neurology, Hefei, China

Intertemporal choices are decisions with consequences in multiple time periods and constitute a significant part of social cognition. The shared neuropathological characteristics of patients

with schizophrenia and their siblings might express intermediate phenotypes in behavior that could be used to further characterize the illness. Schizophrenic patients, unaffected siblings, and healthy controls underwent a computerized version of the “Intertemporal Choice Task”. All participants could choose between sooner-smaller (SS) and later-larger (LL) options in now-trials and in not-now-trials. Subjects also underwent a battery of cognitive neuropsychological assessment. Our results indicated that schizophrenic patients and unaffected siblings both had a tendency to choose LL options in now-trials or not-now-trials compared to healthy controls. Schizophrenic patients had significantly lower scores in several cognitive tasks, including MoCA, attention, executive functions, and information processing when compared with the other two groups. Moreover, within the schizophrenic patient group, significant correlations were found between intertemporal decision-making performance and executive function. The present study showed that schizophrenic patients and unaffected siblings both have intertemporal decision-making impairments, which may result from fronto-striatal and fronto-parietal networks dysfunction. Moreover, this impairment was associated with differences in executive function performance.

### **Schizophrenia, dopamine and eeg resting-state functional connectivity: A systematic review**

A. Mackintosh<sup>1</sup>, L. Golz, C. Andreou  
University of Basel Psychiatric Clinics UPK, centre for psychotic disorders ZPE, Basel, Switzerland

\* Corresponding author.

*Introduction.*– EEG resting-state functional connectivity in various frequency ranges and cortical networks is altered in schizophrenia. However, it is not clear how these connectivity disturbances are connected to dopaminergic dysfunction – a core neurobiological substrate of schizophrenia.

*Objectives.*– In this systematic review, we examine the effects of dopaminergic agents on EEG resting-state functional connectivity in healthy individuals and screen evidence on aberrant functional connectivity in various schizophrenia patient groups, including high risk, first episode, drug-naïve, treatment refractory and remitted schizophrenics.

*Methods.*– We searched for suitable publications in the Pubmed database using the following search string: (schizophren\* OR dopa\* OR antipsychot\*) AND (EEG) AND (connectivity OR coher\* OR synchron\*) AND (resting). A total of 135 hits were subsequently screened for relevance. 44 publications matched predefined criteria for inclusion.

*Results.*– Complex patterns of deviant EEG resting-state connectivity are reported in patient groups; results vary depending on the population, medication status, networks studied and applied connectivity measures. Some of the changes reported in patient populations have been observed in healthy individuals after administration of the dopamine agonist dexamphetamine. Few studies have assessed the effects of antipsychotic medication on EEG resting-state connectivity in schizophrenia; in some, but not all studies medication has been reported to normalize some aspects of aberrant resting-state EEG connectivity in patients.

*Conclusions.*– Some aspects of abnormal EEG resting-state connectivity in schizophrenia might be associated with aberrant dopamine function. Further research is warranted to assess longitudinal effects of antipsychotic medication in patients.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Exploring treatment discussions in schizophrenia: Results from a survey of psychiatrists in Europe**

C. Maria<sup>1</sup>, K. Pungor<sup>2</sup>, A. Wooller<sup>3</sup>

<sup>1</sup> Janssen Pharmaceutica N.V., Communications & Public Affairs, Beerse, Belgium; <sup>2</sup> Janssen Cilag, EMEA Medical Affairs, Neuss, Germany; <sup>3</sup> Janssen Cilag, EMEA Medical Affairs, High Wycombe, United Kingdom

\* Corresponding author.

*Objective.*– To explore the discussions about treatment options that psychiatrists have with their patients living with schizophrenia, and to understand their outlook for those living with the condition. Analysing these discussions is fundamental to improving patient care.

*Methods.*– An independent market research agency commissioned by Janssen performed an online pan-European survey among 347 psychiatrists from 8 countries in Europe. Those who took part in the survey had between 3 and 35 years in practice and treated at least 20 people living with schizophrenia each month (at least 10 in Sweden and Hungary).

*Results.*– At diagnosis, only 22% of psychiatrists discuss long-acting ‘injectable’ treatments (LATs) with their patients, whilst 35% discuss the full range of treatments options. A third of psychiatrists (34%) delay conversations about the full range of treatment options with their patients living with schizophrenia, and 22% limit discussions with their patients about different treatments to avoid upsetting the relationship they have with their patients. Despite the majority of psychiatrists not discussing LATs with their patients, 63% of psychiatrists think long-term management of schizophrenia is best achieved by LATs. In fact, 85% of psychiatrists believe that their patients who remain on treatment can maintain functional personal relationships.

*Conclusions.*– These findings highlight the need for more open, earlier dialogue around available treatment options between psychiatrists and their patients, especially LATs.

*Disclosure of interest.*– I am employed by Janssen Pharmaceutica NV. The other authors have not supplied a conflict of interest statement.

\* Corresponding author.

Social cognition difficulties are present in both persons with schizophrenia (SCZ) and those with autism spectrum disorders (ASD). However, similarities and differences in this field remain unclear. The aim of this study was to explore attribution of inten-

tionality in patients with SCZ in comparison to those with ASD, and to explore relationships between attribution alterations and clinical profile. Animated shapes are a non-verbal Theory of Mind (ToM) task involving the interpretation of geometric figure interactions in three conditions: random, goal-directed and ToM. We compared 51 young adults with SCZ, 32 with ASD and 23 healthy controls (HC) matched for age and gender. In random, goal-directed and ToM conditions, subjects with SCZ attributed less intentionality and their answers were less appropriate than those of HC, while in subjects with ASD, the same anomalies were found in the ToM condition only. In SCZ, thought and language disorganization and earlier age at onset were related with intentionality score in the random condition. Animated Shapes revealed a mixed ToM impairment in SCZ, combining undermentalizing (for movements involving a mental state) similar to that found in ASD, and overmentalizing (for random movements), related to disorganization and precocity of the first psychotic episode. These results partly support the hypothesis of a continuum between autism and schizophrenia.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Folie à deux: Spotting the commonalities among the differences**

F. Martins Silva<sup>1</sup>, F. Caetano<sup>2</sup>

<sup>1</sup> Centro Hospitalar do Porto, Psiquiatria da Infância e Adolescência, Porto, Portugal; <sup>2</sup> Hospital de Magalhães Lemos, Departamento de Psiquiatria, Porto, Portugal

\* Corresponding author.

*Introduction.*– Folie à Deux (FAD) is a rare clinical syndrome, conceptualized as the transference/induction of delusional ideas from one person to another. It is a heterogeneous concept, which has been recurrently redefined.

*Objectives.*– Analyse FAD main characteristics, mapping the specificities and generalities among the cases described in the literature.

*Methods.*– A literature search was conducted and articles concerning FAD were included. The disorder main characteristics were abstracted and a narrative synthesis was performed.

*Results.*– FAD is a broad concept, including disorders such as schizophrenia, paranoid/delusional disorder and reactive psychosis. Several subcategories have been described, which may be important for clinicians to understand the various patterns of the delusional contagion and, ultimately, aetiology. Despite its heterogeneity, general conditions required for the delusional contagion are described: one individual (the active element) is more intelligent, creating the delusion and gradually imposing it upon the second one (the passive element); individuals typically live very close and isolated from external influences; the plausibility of the delusion makes it communicable. Treatment should include separating the two patients, allowing the second one to recover, once disconnected from the “delusional source”. The active element, truly psychotic, usually needs pharmacological intervention.

*Conclusion.*– Although FAD can present diversely, basic commonalities can be spotted in the different cases. It is particularly relevant to note that relational issues are evident in the analysis of cases and in the therapeutic approach.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Clinical-psychopathological peculiarities of the prodromal period of psychosis in patients with paranoid schizophrenia and acute polymorph psychotic disorder**

N.O. Maruta<sup>1\*</sup>, V.S. Bilous<sup>2</sup>

<sup>1</sup> Institute of neurology, psychiatry and narcology of the NAMS of Ukraine, department of neuroses and borderline conditions, Kharkov, Ukraine; <sup>2</sup> Ternopil State Medical University of the MoH of Ukraine, department of psychiatry, narcology and medical psychology, Ternopil, Ukraine

\* Corresponding author.

*Introduction.*– An opportunity to identify persons who are at high risk of formation of psychosis is stipulated by a necessity of early intervention in formation of psychosis in order to prevent its further development and consequences.

*Objective.*– The aim of the investigation was to study clinical characteristics in the prodromal period of psychosis (PPP) in patients with paranoid schizophrenia (PSch) and acute polymorph psychotic disorder (APPD).

*Methods.*– In the study 137 patients with the firstly identified psychosis were examined, including 65 patients (2nd or 3rd hospitalization) with PSch (F20.0) as the main group and 72 patients (1st hospitalization) with APPD (F23.0, F23.1) as the control group. PANSS, SOPS, and PAS-SI scales were used (in real time and retrospectively).

*Results.*– It was demonstrated that in patients with PSch in PPP significantly more frequent there were disorders of thinking (32.3%;  $P < 0.01$ ); passive-apathy social detachment (30.8%;  $P < 0.05$ ); social isolation (33.8%;  $P < 0.01$ ); emotional alienation (40.0%;  $P < 0.01$ ), and persecution ideation (30.8%;  $P < 0.05$ ). In patients with APPD it was registered a prevalence of a decreasing stress tolerability (43.1%;  $P < 0.01$ ); hallucinatory behavior (26.4%;  $P < 0.01$ ); excitation (25.0%;  $P < 0.05$ ); anxious conditions (31.9%;  $P < 0.01$ ); tension (34.7%;  $P < 0.01$ ); impairments of attention (30.6%;  $P < 0.05$ ); sleep disturbances (27.8%;  $P < 0.01$ ), and odd meaning of thinking (27.8%;  $P < 0.01$ ).

*Conclusions.*– These results suggest that negative symptoms predominate in patients with PSch, whereas symptoms of disorganization and general symptoms prevail in patients with APPD. That is a prognostic criterion for persons in PPP.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0754

### **Recognizing dopamine supersensitivity and clozapine withdrawal symptoms in a schizophrenic patient**

R. Patel

Bronx-Lebanon Hospital, Mt Sinai health system, psychiatry, Bronx, USA

*Introduction.*– Dopamine supersensitivity has been described as the response to chronic dopamine blockage induced by neuroleptics, which in turn causes a relative increase in dopamine functions in the mesolimbic pathway. Symptoms can include perceptual, mood and movement disturbances, delusions and cognitive deficits. Clozapine withdrawal symptoms have similarly been reported to cause a rapid deterioration in mental state and can be severe with abrupt onset. Symptomatology can include agitation, movement disorders and additional psychotic features.

**Methods.**– Here we describe the case of a 35 year old male who presented to the Comprehensive Psychiatric Emergency Program (CPEP) after cessation of Clozapine, with subsequent worsening of psychotic symptoms contextual to treatment noncompliance and substance use. The patient presented as combative, paranoid, internally preoccupied, observed responding to internal stimuli, with waxing and waning cognitive states.

**Results.**– After medical stabilization, patient was resumed on typical antipsychotic haloperidol and mood stabilizer Depakote, titrated according to effectiveness with potential side effects monitored. The patient's behaviors were likely due to delirium, perhaps the result of central cholinergic rebound. The withdrawal symptoms and delirium resolved rapidly following medical stabilization and resumption of medications. Patient continues to follow up in outpatient psychiatry.

**Conclusions.**– This case aims to bring awareness to practicing clinicians the potential for combative, agitated behavior and psychotic symptoms after Clozapine cessation and withdrawal. Severe withdrawal symptoms may be avoided by slowly tapering Clozapine or simultaneously substituting another psychotropic with high anticholinergic activity.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Predictors of treatment with long-acting injectable antipsychotics among inpatients with schizophrenia-spectrum disorders: An exploratory study**

I. Riboldi<sup>1</sup>, F. Bartoli, M. Bava, E. Capuzzi, G. Castagna, L.C. Colzani, C. Di Brita, G. Trotta, E. Verrengia, M. Clerici  
University of Milano Bicocca, department of medicine and surgery, Monza, Italy

\* Corresponding author.

**Introduction.**– The predictors of treatment initiation with long-acting injectable antipsychotics (LAI) among inpatients with schizophrenia-spectrum disorders are poorly explored.

**Objectives.**– We aimed at estimating if there might be individual characteristics associated with LAI treatment initiation.

**Methods.**– We selected adults with schizophrenia-spectrum disorders consecutively admitted to an Inpatient Acute Care in Northern Italy. We collected information on age, gender, alcohol/substance misuse, history of suicide attempts and violence, current suicidal ideation (as measured by Columbia Suicide Severity Rating Scale), current aggression (Modified Overt Aggression Scale), psychological distress (K-10 scale), impulsivity (Barratt Impulsiveness Scale), biochemical parameters (from routine blood samples), and QTc interval. Standard statistical tests were used to estimate relevant correlations. Due to the exploratory nature of this study, statistical significance was set at  $P < 0.10$ .

**Results.**– We identified 61 adults with schizophrenia-spectrum disorders (mean age:  $43.0 \pm 13.6$  years). 29.5% received LAI treatment before discharge. Subjects receiving LAI treatment were more often males ( $P = 0.07$ ), younger ( $P = 0.07$ ), and have less prolonged QTc interval ( $P = 0.01$ ). No associations were estimated for other variables, including alcohol/substance misuse, history of suicide attempts and violence, suicidal ideation, aggression, psychological distress, impulsivity, and biochemical parameters.

**Conclusions.**– Our preliminary findings showed that inpatients with male gender, lower age, and lower QTc interval, were more likely to receive LAI treatment. No further individual correlates were identified. Despite controversial evidence has been found for the relationship between QTc prolongation and antipsychotics, it

seems confirmed that treatment choice is significantly influenced by ECG reports.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction.**– There is compelling evidence on the increased peripheral interleukin-6 (IL-6) and C-reactive protein (CRP) levels in patients with schizophrenia across different stages of the disease. However, the data regarding their concentration in patients with treatment-resistant schizophrenia (TRS) are scarce and inconsistent.

**Objective.**– The aim of this study was to compare IL-6 and CRP concentration between patients with TRS and non-treatment-resistant schizophrenia (non-TRS).

**Patients and methods.**– This cross-sectional study included 210 male inpatients diagnosed with schizophrenia, who were evaluated by Positive and Negative Symptom Scale (PANSS), Calgary Depression Scale for Schizophrenia (CDSS) and International Suicide Prevention Trial (InterSePT) Scale. Serum IL-6 and CRP levels were measured and patients were also evaluated for the presence of Metabolic Syndrome (MetS).

**Results.**– Serum IL-6 and CRP levels were similar in patients with TRS and non-TRS, and were also not associated with PANSS total, positive, negative, cognitive and general scores, CDS scores and with the presence of MetS. However, both serum IL-6 and CRP levels were significantly associated with age ( $P < 0.0001$ ;  $P = 0.0002$ ), duration of the disease ( $P = 0.0002$ ;  $P = 0.0003$ ), and body mass index (BMI) ( $P = 0.0342$ ;  $P = 0.0048$ ). In addition, IL-6 levels were associated with smoking ( $P < 0.0001$ ), whereas there was a positive correlation between IL-6 and CRP levels ( $P < 0.0001$ ).

**Conclusions.**– While IL-6 and CRP serum levels were associated neither with treatment-resistance nor with severity of symptoms, there is a complex relationship between those inflammatory parameters and some cardiovascular risk factors such as obesity and smoking in male inpatients with schizophrenia.

### **Antipsychotics drugs during pregnancy**

H. Saiz Garcia<sup>1\*</sup>, M.Á. Álvarez de Mon<sup>2</sup>, V. Pereira<sup>2</sup>, Á.S. Rosero<sup>1</sup>, L. Montes<sup>1</sup>, E. Mancha<sup>1</sup>

<sup>1</sup> Complejo Hospitalario de Navarra, Psychiatry, Pamplona, Spain;

<sup>2</sup> Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

\* Corresponding author.

**Introduction.**– Women with stable psychotic or affective disorders treated with antipsychotic drugs face treatment dilemmas as they become pregnant. Non treated psychosis face problems both to the mother and the newborn. Psychiatric illness during pregnancy predicts post-partum psychosis. Women with previous affective disorders, mainly with a bipolar disorder, have a risk of about 50% of perinatal psychosis. The choice of antipsychotic treatment during treatment remains controversial. Ethical reasons make clinical trials almost impossible.

**Methodology.**– A review was conducted aiming to clarify the biological mechanisms of antipsychotic and the risk and benefits of treating psychosis during pregnancy. The literature search was conducted in PubMed data reviewing articles dating between 2013 and 2017 and reviewing prescribing guidelines.

**Results.**– 1. First generation antipsychotics are more likely to produce pre-term birth and low birth weight than second generation antipsychotics.

2. First generation antipsychotics can cause neonatal dyskinesia.

3. Olanzapine can cause increased risk of intensive care admission of the fetus and also lower birth weight.

4. Gestational diabetes may be increased with all second generation antipsychotics.

5. NICE recommends avoiding depot preparations and anticholinergic drugs during pregnancy.

**Conclusions.**– It is important to assess the risk and benefits of treating pregnant or breastfeeding women with antipsychotic drugs, including anomalies and developmental problems on the fetus. Evidence from the literature on antipsychotic is controversial. Future research is needed to clarify which antipsychotic drugs are safer during the pregnancy period and which drugs are more effective if an affective or psychotic disorder is onset during the pregnancy period.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Higher BMI in 25-OH vitamin D deficit than non-deficit patients treated with MARTA antipsychotics

P. Švancer<sup>1\*</sup>, V. Andrashko<sup>1</sup>, P. Knytl<sup>1</sup>, B. Kohútová<sup>1</sup>, D. Protopopová<sup>1</sup>, J. Hanka<sup>2</sup>, P. Mohr<sup>1</sup>, M. Kopeček<sup>1</sup>

<sup>1</sup> National Institute of Mental Health, inpatient ward 3: psychotic disorders, Klecany, Czech Republic; <sup>2</sup> National Institute of mental health, outpatient clinic, Klecany, Czech Republic

\* Corresponding author.

**Introduction.**– The metabolic syndrome is a side effect of treatment with multi-acting receptor target antagonist (MARTA) antipsychotics. Recent data-mining study found that vitamin D decreased the occurrence of atypical antipsychotic-induced, DM-related adverse events.

**Objectives.**– The purpose of our study was to evaluate if the metabolic parameters in patients treated with MARTA antipsychotics are influenced by the vitamin D level.

**Methods.**– We measured both 25-OH vitamin D plasma levels and metabolic parameters in 33 patients treated with MARTA antipsychotics ( $\geq 1$  months). Since 25-OH vitamin D level has circannual rhythm, we used corrected vitamin D level for patients assessed during the whole year. Mann-Whitney U test with significant p value below 0.05 was used for analysis.

**Results.**– Eleven patients were 25-OH vitamin D deficient (corrected vitamin D value less than 25 nmol/l). The BMI was significantly higher in MARTA vitamin D deficient patients than in non-deficient patients (median (1–3 quartile) 28.05 (26.03–34.53) vs 24.94 (21.20–28.47),  $P=0.044$ . There was no significant difference

between groups in age, serum glucose, total cholesterol, HDL, LDL, TAG or duration of MARTA antipsychotics treatment.

**Conclusions.**– The vitamin D deficiency could be a risk factor for MARTA-induced obesity that is not routinely assessed in clinical practice. Further intervention study with cholecalciferol supplementation in patients treated with MARTA antipsychotics is needed to evaluate cost and benefit of the supplementation. Lower 25-OH vitamin D levels can also be a consequence of limited outdoor activities of patients, reduced physical activity is a risk factor for a BMI increase.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparison of inflammatory markers between patients with the first episode psychosis and bipolar mania

R. Tekdemir<sup>\*</sup>, H. Tomar Bozkurt, O. Imre, V. Erbasan, M. Aydin, K. Altınbaş

Selcuk University, psychiatry, Konya, Turkey

\* Corresponding author.

**Introduction.**– There is growing evidence about the role of inflammation in the underlying pathology of major psychoses. Early diagnosis and intervention strategies are thought to be excessively important lately.

**Objectives.**– Neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR) and monocyte-lymphocyte ratio (MLR) have recently been used as indicators of inflammation. In this study, we aimed to compare inflammatory markers between hospitalized patients with the first episode psychosis and bipolar mania.

**Methods.**– Patients hospitalized with the diagnosis of first episode bipolar mania ( $n=44$ ) or psychosis ( $n=44$ ) were recruited for the study. Patients with comorbid medical conditions were excluded from the study. White blood cell (WBC), neutrophil, lymphocyte, platelet and monocyte counts, Neutrophil-lymphocyte ratio(NLR), platelet-lymphocyte ratio(PLR) and monocyte-lymphocyte ratio(MLR) were evaluated.

**Results.**– There were no significant difference between diagnostic groups in terms of age ( $P=0.2$ ,  $\chi^2=1.6$ ), gender ( $P=0.06$ ,  $z=-1.6$ ), neutrophil ( $P=0.67$ ,  $t=-1.86$ ), lymphocyte ( $P=0.45$ ,  $t=0.76$ ), monocytes ( $P=0.49$ ,  $t=-0.69$ ) platelet ( $P=0.98$ ,  $t=0.03$ ) counts, NLR ( $P=0.09$ ,  $z=-1.18$ ), MLR ( $P=0.29$ ,  $t=-1.07$ ) and PLR ( $P=0.85$ ,  $z=-0.18$ ) values.

**Conclusions.**– Even though inflammation markers were higher in psychotic disorders than bipolar disorder, we could not find any significant difference between patients with the first episode psychosis and bipolar mania. It could be concluded as there is no difference at the first episode of mood and psychotic disorders and the difference is related with the chronicity and duration of illness. However, it is difficult to make further comments due to the lack of a healthy control group and relatively small sample size in our study.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Extrapyramidal side-effects with antipsychotics: Prevalence and Risk factors from the French National Face-schizophrenia cohort**

A. Tessier<sup>1</sup>, D. Misdrahi<sup>1</sup>, A. Daubigney<sup>2</sup>, W. Meissner<sup>3</sup>, P.M. Llorca<sup>4</sup>, G. Fond<sup>5</sup>

<sup>1</sup> CH Charles Perrens, psychiatrie, Fondation FondaMental, Bordeaux cedex, France; <sup>2</sup> CHU Pellegrin, neurologie, Bordeaux, France; <sup>3</sup> CHU de Bordeaux, Neurologie, Bordeaux, France; <sup>4</sup> CHU de Clermont-Ferrand, Psychiatrie, Fondation FondaMental, Clermont-Ferrand, France; <sup>5</sup> Hôpital Universitaire Henri Mondor, Psychiatrie, Fondation FondaMental, Créteil, France

\* Corresponding author.

**Introduction.**– Extrapyramidal side effects (EPS) were identified as a complication of antipsychotics treatment (Browne et al., 1996). Meta-analysis had investigated EPS prevalence and risk factors through clinical trials (Leucht et al., 2009; Rummel-Kluge et al., 2012). Because clinical trial are not representative of the general population, especially about antipsychotic polytherapy, multiple episode, treatment resistance, studies in real-world schizophrenia are needed.

**Objectives.**– In the present study we utilized the FACE-SZ (FondaMental Academic Centers of Expertise for Schizophrenia) cohort based on a French multicentric network baseline data to examine the prevalence and clinical correlates associated with EPS.

**Method.**– Clinical and socio-demographic factors were collected during an extensive standardized evaluation. The Simpson and Angus Scale (SAS) and the Abnormal Involuntary Movement Scale (AIMS) were used to assess respectively Dug-Induced Parkinsonism (DIP) and Tardive Dyskinesia (TD).

**Results.**– 674 patients were included. The overall prevalence of DIP and TD were respectively 13.2% and 8.3% in our community-dwelling sample of patients. After adjustment for confounding factors, PANSS negative factor (*aOR*=1.10, *p*<.001), prescription of first generation of antipsychotic (*aOR*=2.04, *P*=.047) and prescription of anticholinergic (*aOR*=2.10, *P*=.017) were associated with a higher prevalence for DIP (table 1). Disorganization (PANSS disorganized factor) (*aOR*=1.10, *P*=.049) was associated with a higher prevalence for TD (Table 2).

**Conclusion.**– Our results indicate a reduced prevalence of EPS compared to previous studies. The roles of negative and disorganized symptoms are highlighted for the prognosis of schizophrenia. Clinical exploration of EPS should be systematically implemented to reduce such antipsychotic associated side effects.

**Is metabolic profile of the patients with first episode mania and psychotic disorder different?**

H. Tomar Bozkurt<sup>1</sup>, R. Tekdemir<sup>2</sup>, V. Erbasan<sup>2</sup>, O. Imre<sup>2</sup>, M. Aydın<sup>2</sup>, K. Altınbaş<sup>2</sup>

<sup>1</sup>Selcuk University, Psychiatry, Konya, Turkey; <sup>2</sup>Selcuk University, Psychiatry, Konya, Turkey

\* Corresponding author.

**Introduction.**– Several studies indicated that patients with chronic mood and psychotic disorders have higher blood fasting glucose and lipid levels than general event at the first episode of the illness. Metabolic disturbances were reported to be related with the disease severity and chronicity.

**Objectives.**– From here, we aimed to compare fasting glucose and lipid levels of the patients with first episode psychosis and first episode bipolar mania.

**Methods.**– 44 inpatients with first episode psychosis and 44 patients with first episode bipolar disorder mania recruited for the study. Sociodemographic variables, blood fasting lipid and glucose levels were compared.

**Results.**– Groups did not differ in terms of age(*P*=0.06; *z*=-1.6), gender(*P*=0.2;  $\chi^2$  = 1.6) and duration of hospitalization (*P*=0.87; *t*=0.17). There were no statistically significant differences in plasma levels of fasting glucose (*P*=0.07; *t*=1.83), high density lipoprotein (*P*=0.51; *z*=-0.66) and low density lipoprotein (*P*=0.06; *t*=1.87) cholesterol between patient groups. Mean triglyceride and total cholesterol levels were significantly higher in patients with first episode psychosis than first episode bipolar mania, respectively(*P*=0.003, *z*=-2.95; *P*=0.02, *t*=2.39).

**Conclusions.**– Higher triglyceride and total cholesterol levels in the first episode psychosis than first episode bipolar are consistent with the view that metabolic syndrome is more likely to occur in psychotic patients comparing with the chronic mood disorders. However, we could not find a difference in fasting glucose, HDL and LDL levels. This could be related with the lack of control group, relatively small size and evaluation of only the first episode patients. Further longitudinal follow-up studies are required for better understanding of this condition.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

Possibility to properly recognize and diagnose the aggressiveness of patients in an acute state of mental disorder may be suitable not only for the treatment itself and for the determining of prognosis, but can guide the choice of suitable approach to patients to eliminate the risk of aggressive behavior.

The aim of this study was to explore and to show possibilities of objective evaluation of the risk of violent / aggressive behavior in patients diagnosed with psychotic disorder. This paper is presenting partial preliminary outcomes of wider study.

Study group was made up of 65 patients hospitalized in Psychiatric Hospital Hronovce with the diagnose of psychotic disorder. The cohort was divided into 2 sections according to required criteria. The first group of aggressive patients included 21 inpatients with history of aggressive behavior at baseline or prior and leading to hospitalization (age 18 to 61 years; Mean = 32.09; SD = 11.81). The second nonaggressive group included 44 inpatients without the history of aggressive behavior (age 19 to 61 years; Mean = 33.77; SD = 10.44).

The risk of violent behavior was assessed by the use of HCR – 20. Its total score and the outcomes of its subscales (H factors – history of problems, C factors – recent Problems, R factors – future problems) were compared between two study groups.

Results show statistically significant differences in comparison between study groups in each of HCR – 20 subscale.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Social cognition and their relation to individual domains of psychopathology in psychotic disorders with depressive-paranoid symptoms**

O. Zubatiuk

*Shupyk National Medical Academy of postgraduate education, Psychiatry, Psychotherapy and Medical Psychology, Kyiv, Ukraine*

**Introduction.**– Cognitive dysfunction in mental disorders is a relevant field of research at present. Violation of social cognition is particularly important.

**Objectives.**– The study of social cognition (SC) in patients with depressive-paranoid symptoms in schizophrenia (Sch), schizoaffective disorder (SchD) and recurrent depressive disorder (RDD)

and their relation to individual factors of psychopathological symptoms and the level of social functioning.

**Participants.**– The study involved 70 patients divided into three groups according to the nosology: group 1–24 patients with Sch (F 20.0 ICD-10), group 2–23 patients with SchD (F 25.1) and group 3–23 patients with RDD (F 33.3).

**Methods.**– MATRICS Consensus Cognitive Battery (MCCB) – Social cognition, PANSS (five-factor model) and PSP.

**Results.**– Patients in Sch and RDD with depressive-paranoid symptoms have a decrease in SC, but in the SchD group this decrease is not observed. Decreasing in SC correlates with a decrease in the level of social functioning. At Sch, a negative correlation of SC with cognitive and excitement domains of psychopathology is detected, and with RDD there is a positive one. At the same time, at Sch, a positive correlation between SC with depression domain of psychopathology is observed, and with RDD – negative. In both SchD and RDD, a positive correlation of SC with the cognitive domain of psychopathology is detected.

**Conclusion.**– Social cognitive dysfunction is of transdiagnostic nature, but it has a different nature in different nosologies. Detecting its general tendencies and characteristics will allow improving existing psycho-rehabilitation programs for these patients.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

<sup>3</sup> *Ministry of health, child and adolescent psychiatry, Muscat, Oman;*

<sup>4</sup> *Sultan Qaboos university, psychology, muscat, Oman*

\* Corresponding author.

**Background.**– A number of studies suggested that the rates of depression in Western populations are higher among caregivers of children with Autism spectrum disorder (ASD) than typically-developing children. There is a dearth of studies in this field among non-Western populations. Therefore, this study aimed to find the predictors of depressive symptoms among caregivers of children with a diagnosis of ASD in Oman.

**Methods.**– A cross-sectional analytical study was conducted among a sample of caregivers of children with a diagnosis of ASD who sought consultation from a child and adolescent mental health services unit in Muscat. Depressive symptoms was quantified using the Patient Health Questionnaire-9. A logistic regression model was used to depict predictors of depression.

**Results.**– 117 caregivers participated, with a response rate of 82%. The prevalence of depressive symptoms was 75%. Logistic regression analysis indicated that low income, being the only caregiver in the family and severity of ASD were significant predictors of depression

**Conclusion.**– Depression is common among caregivers of children with ASD in Oman, especially among those with financial difficulties, sole caregivers and whose children suffer from severe type

of ASD. Therefore, detecting, and promptly treating, depression among these caregivers is essential.

**Introduction.**– ASD have a wide impact on the children life, and more likely to have negative implication for the children, their parents and the community. There are many studies indicating caring for children with Autism spectrum disorder (ASD) is critically associated with psychological burden. In non western countries like Oman, there is dearth of studies exploring the factors related to the burden of care

**Objectives.**– The study aims to measure the level of burden of care among caregivers of children diagnosed with ASD and the relationship between the degree of burden with socio-demographic factors.

**Methods.**– This is a cross sectional study conducted in Oman. Arabic-version of the Zarit Burden Interview (ZBI) was used to evaluate the level of burden among caregiver of children with ASD. Socio-demographic background and clinical data were gathered either from medical records or from the caregivers.

**Results.**– The study included caregivers of 100 children with ASD with a response rate of 78%. The mean ZBI score of the burden of care was higher for the parents of children with ASD. a regression analysis indicated Factors such as income, number of siblings in the household, duration of the illness were associated with high perceived burden.

**Conclusion.**– This study showed that burden of care is common among caregiving individuals of ASD children in Oman . Some of the socio-demographic and appear to have direct bearing on the level of burden so optimizing their psychological well-being and prognosis of their children eventually is needed.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Association between Autism Spectrum Disorder (ASD) and immune mediated conditions**

\* Corresponding author.

A. Alshiban<sup>1\*</sup>, M. Alomar<sup>1</sup>, L. AL-Ayadhi<sup>2</sup>

<sup>1</sup> College of medicine- King Saud University, Autism Research and Treatment Center, Riyadh, Saudi Arabia; <sup>2</sup> College of medicine, King Saud University, Department of Physiology, Autism Research and Treatment Center, Riyadh, Saudi Arabia

**Introduction.**– Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder with significantly increasing prevalence over the last decades. Although, there are multiple theories regarding the etiology, the cause of ASD is still unknown. Immune system

dysregulation hypothesis got its popularity in the past decades. Association between ASD and other comorbid immune mediated conditions seems controversial.

**Objectives.**– To evaluate the prevalence of immune mediated conditions in patients with ASD and their families and compare it to control group.

**Methods.**– Case control observational study ( $n=293$ , ratio = 1:1.5). ASD cases ( $n=115$ ) were approached through autism schools in Riyadh. Age and gender matched controls ( $n=178$ ) were obtained from primary and intermediate schools. Data was collected through an Arabic questionnaire contains questions assessing the presence of diagnosed immune mediated conditions. Questionnaire were filled by the parents.

**Results.**– Autoimmune diseases were significantly higher in ASD children (11.3%) compared to (4%) in the control group ( $P=0.01$ ). Similarly, ASD group mothers reported to have significantly higher prevalence of immune mediated disorders compared to control group, 25.2% and 10% respectively ( $P=0.001$ ).

Allergic diseases were also reported more in ASD children and mother compared to control group. 58% of ASD children ( $n=55$ ) have at least one allergic disease compared to 27% ( $n=48$ ) in control group ( $P \leq 0.0001$ ). Child asthma, eczema, urticaria and drug allergy were reported more in ASD group than controls with statistically significant difference.

**Conclusion.**– ASD children and their mothers reported to have more immune mediated conditions than controls. However, fathers of ASD children showed no statistical significant difference compared controls.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Weight gain and metabolic risk associated with treatment with second-generation antipsychotics in antipsychotic-naïve children and adolescents: A 12- month follow-up study**

A. Andreu Bernabeu<sup>\*</sup>, C. Diaz-Caneja, C. Arango Gregorio Marañón Research Institute IISGM-Gregorio Marañón University Hospital, Child and Adolescente Psychiatry, Madrid, Spain

\* Corresponding author.

**Objectives.**– To evaluate the risk of weight gain and alteration of metabolic parameters after antipsychotic treatment of naïve or quasi-naïve children and adolescents in follow-up at 12 months.

**Methods.**– Observational, longitudinal, naturalistic and multicenter study with a total sample of 243 patients. Among the 243 patients, 138 were treated with Risperidone, 51 with Olanzapine, 43 with Quetiapine and 11 with Haloperidol. Of the 243 patients, 84 (43.3%) had a diagnosis of the psychosis spectrum, 54 (22.2%) mood disorders and 105 (43.2%) had behavioral disorders and others.

**Results.**– In the three groups of antipsychotics, a significant increase in BMI z-scores was detected during the 12 months of follow-up. Patients treated with Olanzapine had greater weight increases than patients treated with Risperidone. Significant alterations in glucose metabolic parameters were obtained in patients treated with Risperidone. Other alterations in TG and LDL are dependents of the antipsychotic. We do not appreciate differences regarding HDL levels. There was an increase in the percentage of At-risk patients in the three groups during the 12 months of follow-up. No significant differences were detected among the three antipsychotic groups in the % of At-Risk patients

**Conclusion.**– Second-generation antipsychotics have an effect on weight gain with profiles of different metabolic side effects with respect to time. Olanzapine is the drug in which the weight gain is greater with a tendency of the other antipsychotics to equal to 12 months but without reaching it. Weight and metabolic profile should be monitored closely in children and adolescents treated with SGAs.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– The psychobiological model of temperament and character indicates that personality traits are heritable and, during development, constantly influence one's susceptibility to psychotic disorders.

**Objectives.**– The aim of this study was to investigate temperament and character in ultra-high risk (UHR) for psychosis helpseeking adolescents compared non-UHR ones.

**Methods.**– A sample of 75 help seeking adolescents, including 12 UHR and 63 non-UHR subjects, aged 14–19 years, with anxiety, mood and bipolar spectrum disorders were included in the study. All were recruited at the first visit and evaluated with the Temperament and Character Inventory-Revised (TCI-R) and the Structured Interview for Prodromal Symptoms (SIPS).

**Results.**– UHR patients showed significantly lower temperament traits of Novelty Seeking (NS) and Self Directedness (SD) with respect to non-UHR adolescents (NS:  $95.9 \pm 12$  and  $106.2 \pm 12$  respectively,  $U = 157$ ,  $P = 0.02$ ; SD NS:  $106.1 \pm 21$  and  $120.5 \pm 17$  respectively,  $U = 157$ ,  $P = 0.02$ ). Conversely, UHR adolescents showed a higher temperament trait of Harm Avoidance (HA) ( $125.1 \pm 14$  and  $110 \pm 19$  respectively,  $U = 145$ ,  $P = 0.01$ ).

**Conclusions.**– UHR adolescents show reduced novelty seeking and self directedness temperament traits and increased harm avoidance with respect to non-UHR patients with mood and anxiety disorders.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The Automatic and intentional inhibitory control mechanisms in children with ADHD**

R.A. Fabio<sup>1</sup>, T. Capri<sup>2</sup>, A. Sara<sup>1</sup>, G. Martino<sup>1\*</sup>

<sup>1</sup> University of Messina, Cognitive Science- Psychological, Educational and Cultural Studies, Messina, Italy; <sup>2</sup> University of Messina, Cognitive Sciences, Psychological, Educational and Cultural Studies, Messina, Italy

\* Corresponding author.

**Introduction.**– The inhibitory control of attention has been categorized in two processes: automatic inhibitory control mechanisms and intentional inhibitory control mechanisms. A deficit of inhibitory control has been recognized as a clinical feature of children with attention-deficit/hyperactivity disorder (ADHD).

**Objectives.**– The main aim was to examine.

**Methods.**– A sample of 20 children with ADHD and 20 typically developing children, matched for age and gender, participated in this study. These participants were recruited from an initial sample of 435 participants. A saccadic interference (SI) task and a delayed ocular response (DOR) task were employed. The DOR and SI tasks were operated using eye-tracking technology.

**Results.**– The ADHD group showed a general deficit in the inhibitory control. More precisely, the ADHD group performed poorly the DOR task than the typically developing group. In SI task, the ADHD group did not differ significantly from the typically developing group.

**Conclusions.**– This study suggests a dissociation between automatic and intentional inhibitory deficits in children with ADHD. The results are discussed in light of theories on inhibitory control of attention in childhood.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Mental health indicators in parents of children with adhd and their relation to parenting styles**

L.R.R. Carreiro<sup>1</sup>, M.C.T.V. Teixeira, C.N. Cantiere, A.D.F. Ribeiro, A.P.R. Micieli, M. Regina Luisa de Freitas

Universidade Presbiteriana Mackenzie, Programa de Pós-graduação em Distúrbios do Desenvolvimento, São Paulo, Brazil

\* Corresponding author.

Attention deficit hyperactivity disorder (ADHD) is characterized by inattention and/or hyperactivity-impulsivity impacting on personal, academic, and social functioning of the child and family. The characteristic behaviors of children with ADHD contribute to parents experiencing less adaptive educational strategies.

**Objective.**– Evaluate correlations parents' behavioral profiles, their perceptions of quality of life (QOL) and social support, and adopted parenting practices in 26 mothers of children and adolescents with ADHD.

**Method.**– Spearman correlations were performed between scores for the Parenting Styles Inventory (PSI) and Family Support Perception Inventory (FSPI), and the WHOQOL-BREF scores for QOL. To assess the relationship between parental educational practices and their behavioral profiles, Spearman correlations were performed between PSI scores and scales of the Adult-Self-Report/18-59 (ASR).

**Results.**– Negative parental practices of inconsistent punishment and physical abuse presented greater correlation with indicators of social support and QOL. These practices are associated with lower satisfaction of parents in all domains QOL, as with lower scores in the family adaptation factors ( $r = -0.641$ ,  $P = 0.001$  and  $-0.705$ ,  $P < 0.001$ ), and in the affective-consistent factors ( $r = -0.435$ ,

$P=0.030$  and  $r=-0.798$ ,  $P<0.001$ ). The parental practice of inconsistent punishment was associated with higher aggression rates ( $r=0.769$ ,  $P<0.001$ ), externalizing problems ( $r=0.702$ ,  $P<0.001$ ) and with lower means of adaptation ( $r=-0.760$ ,  $P<0.001$ ).

**Conclusion.**– The family should be considered in the intervention for treatment of children with ADHD to develop skills for managing the difficulties arising from the symptomatology of the disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The physis child: identification of cognitive and emotional factors in relation to acoustic-verbal hallucination in non-psychotic children**

L.E. Dumas<sup>1\*</sup>, V. Bonnard-Couton<sup>1</sup>, B. Golse<sup>2</sup>, F. Askenazy<sup>1</sup>

<sup>1</sup> *Hopitaux Pédiatriques de Nice, CHU Lenval, service universitaire de psychiatrie de l'enfance et de l'adolescence SUPEA, NICE, France;*

<sup>2</sup> *Centre hospitalier universitaire Necker-Enfants Malades AP-HP, service de pédopsychiatrie, Paris, France*

\* Corresponding author.

**Introduction.**– Hallucinations in nonpsychotic children represent a high prevalence on symptomatology in child psychiatry. This experience is often considered as a transitional and benign developmental phenomenon. However, recent research suggests that the persistence and aggravation of the hallucinatory experience would signal a possible evolution towards psychotic disorders.

**Objectives.**– The objective of this study was to explore social cognition and emotional experience like factors favoring the presence and persistence of non-psychotic hallucinations to improve diagnostic and therapeutic management.

**Methods.**– This prospective multicenter case-control study, longitudinal over 6 months, will include participants with acoustic-verbal hallucinations (AVH) and without diagnosis of psychosis. Social cognition is assessed using NEPSY II with “theory of mind” and “emotion recognition” tasks. The emotional experience is assessed using Differential Emotion Scale IV (DES IV), to establish an emotional profile of child, and the Revised Beliefs About Voices Questionnaire (BAVQ-R), categorizing child's emotions about AVH. **Results.**– This study included 40 subjects (75% girls) with mean aged of 12.8 years. There was no significant association between presence of AVH and social cognition and emotional factor. At 6 months, 50% of subjects had persistents AVH: they were significantly associated with emotional factor and post-traumatic stress disorder (PTSD). In case group, 18% evolved towards psychotic disorder at 6 months, significantly associated with malevolence interpretation of voices.

**Conclusion.**– Even if social cognition was not associated with hallucinations, emotional factor could promote their persistence. A dimensional regard of this symptom could promote a better understanding of the child disorder and deliver targeted therapies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **The effect of melatonin on sleep disorders in children with ASD: A meta-analysis**

L. Fusar-Poli<sup>1</sup>, F. Grasso, M. Vercesi, N. Brondino, P. Politi, M. Rocchetti

*University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy*

\* Corresponding author.

**Introduction.**– Sleep disorders are very common in people with autism spectrum disorders (ASD). They may exacerbate problem behaviors and represent a considerable burden for caregivers.

**Objectives.**– To evaluate the effect of melatonin on sleep problems in people with ASD.

**Methods.**– A systematic literature search was performed in Web of Science, PsycINFO, Embase, and CINAHL up to March 2017. We included all randomized controlled trials comparing melatonin to placebo. Outcomes included total sleep time, sleep latency onset and number of night awakenings.

**Results.**– Three studies involving children with ASD (age range: 4–16 years) met inclusion criteria and contained appropriate data for meta-analysis. Random-effects meta-analyses showed a significant effect of melatonin on total sleep time (Hedges'  $g=1.58$ , 95% CI 0.82 to 2.34,  $P\leq 0.001$ ) and sleep latency onset (Hedges'  $g=-1.33$ , 95% CI  $-1.79$  to  $-0.87$ ,  $P\leq 0.001$ ). The effect on the number of night awakenings was in favour of melatonin, but not significant.

**Conclusions.**– Melatonin appears to be useful in the treatment of sleep disorders of ASD children. More trials involving patients of different ages and with different type and dosages of melatonin are needed to better elucidate its effect in ASD.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– Investigations have shown increased evidence of an association between some obstetric risk factors and autism spectrum disorders (ASD) but more robust studies are still needed. **OBJECTIVE:** To identify pre-, peri- and neonatal risk factors for ASD.

**Methods.**– We performed a case-control study (51 children with ASD versus 50 control children) to identify whether risk factors related to family history, pregnancy (including all medication and substances taken during pregnancy and infection history), gestational age, delivery, birth milestones and the neonate's condition at birth could be associated with a higher prevalence of ASD (Approval of the local ethical committee: USJ-2016-910).

**Results.**– A bivariate analysis showed that sex, excessive vomiting, vaccines, number of children, diabetes and pregnancy assistance were significantly correlated to ASD ( $P$ -value  $<0.05$ ). All factors with a  $P$ -value  $<0.2$  were included in a multivariate analysis (Table 1). Only the first four variables remained significant.

**Conclusion.**– The results presented here are preliminary and inclusion is still ongoing in an attempt to identify a combination of factors that could be considered as potential risk factors, hence improving earlier detection and better treatment of the disease.

order to establish this treatment modality as standard of care for children and adults with ADHD

### Mindfulness-based cognitive-behavioral therapies for treatment of attention deficit hyperactivity disorder in children and adolescents: A literature review

T. Khan<sup>1\*</sup>, R. Cosme<sup>2</sup>

<sup>1</sup> Rush University Medical Center, Child and Adolescent Psychiatry, Chicago, Usa; <sup>2</sup> Rush University, Child and Adolescent Psychiatry, Chicago, USA

\* Corresponding author.

**Introduction.**– Attention-deficit/hyperactivity disorder (ADHD) is a common psychiatric disease in children. Despite the demonstrated effectiveness of current ADHD medications, treatment discontinuation is fairly common. In recent years, there has been evidence that mindfulness meditation strengthens attention regulation [1–3] and improves some executive functions [4]. This approach offers a novel and potentially useful tool in the multimodal treatment of ADHD.

**Objective.**– Our objective is to evaluate and review the current literature on the effectiveness of implementation of mindfulness techniques in children and adolescents suffering from ADHD.

**Methods.**– We examined a total of 7 studies [5–11], 3 interventional studies and 4 literature reviews. Interventional studies, as described in detail in Table 1, use mindfulness techniques with treatment and control groups. 4 literature reviews are described in detail in table 2.

**Results.**– All interventional studies favor the beneficial effects of mindfulness techniques in improving symptoms of ADHD. Out of the 4 literature review studies, 1 provides support for the feasibility of mindfulness-based interventions, 1 remains inconclusive due to high risk of bias and 2 provide evidence of benefit in both adults and children suffering from ADHD.

**Conclusion.**– Thus we conclude that there is strong evidence to support that mindfulness-based therapies have a beneficial effect on improving attention, behavior and in some cases lifestyle of the patients suffering from ADHD and their parents. However, there is much need for further evidence-based research in this area, in

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Impact of the Maternal mindfulness training during pregnancy on cognitive development in young children

N. Kiseleva\*, S. Kiselev

Ural Federal University, Laboratory for brain and neurocognitive development, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– There is evidence that maternal anxiety during pregnancy affects child outcomes. However, there is lack of studies that have evaluated the effects of maternal psychosocial factors during pregnancy on child cognitive outcomes. This study evaluates the effect of the maternal mindfulness training during pregnancy on cognitive development in 4–5 years old children.

**Method.**– In the current study we included 28 women who participated in the maternal mindfulness training during pregnancy. The control group included 28 women who did not participate in this training during pregnancy. When the offspring of the target pregnancies were between 4 to 5 years of age, their cognitive development was assessed by Lurias's child neuropsychological assessment battery that enables to assess five functional domains, including executive abilities, language, memory, sensorimotor and visuospatial abilities.

**Results.**– One-way ANOVA was used to reveal group differences in performing subtests from five functional domains of Luria's battery. We have revealed the significant differences ( $P < .05$ ) between groups in two functional domains. The children from the experimental group performed better on subtests from language and memory functional domains.

**Conclusion.**– These results suggest that maternal mindfulness training during pregnancy may have positive effect on cognitive development of young children, particularly on the development of language and memory abilities in preschool children.

**Funding.**– The research was supported by Act 211 Government of the Russian Federation, agreement 02.A03.21.0006

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Specific deficit in executive abilities in children with hypoxic-ischaemic encephalopathy

N. Kiseleva\*, S. Kiselev

Ural Federal University, Laboratory for brain and neurocognitive development, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– It is known that children, born with Hypoxic-ischaemic Encephalopathy (HIE), have a risk for neurodevelopmental disorders. The goal of this research was to examine the hypothesis that preschool children, born with HIE, have a specific deficit in executive abilities.

**Participants and methods.**– The experimental group included 28 children aged 5–6 years (mean age = 5.2). They were born full-term with perinatal Hypoxic-ischaemic Encephalopathy. The control group included 28 typically developing children. The children from experimental and control group were matched for gender and age. Children from both groups were assessed with subtests from Luria's child neuropsychological assessment battery. These subtests are designed to assess voluntary attention and abilities for programming.

**Results.**– One-way ANOVA has revealed group differences in voluntary attention. However, we have not revealed significant ( $p < .05$ ) differences between children from experimental and control group in abilities for programming.

**Conclusion.**– In view of the obtained results it can be assumed that the Hypoxic-ischaemic Encephalopathy has specific (not global) negative effect on development of executive abilities in children. Particularly, preschool children, born with HIE, have deficit in voluntary attention.

**Funding.**– The research was supported by Russian Foundation for Basic Research, grant no. 15-06-06491A.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

Castro-Fornieles<sup>4</sup>, M.I. Baeza Pertegaz<sup>4</sup>, E. De la Serna Gómez<sup>5</sup>, C. Martínez-Cantarero<sup>6</sup>, J.A. Alda Díez<sup>7</sup>, C. Arango López<sup>2</sup>

<sup>1</sup> Hospital General Universitario Gregorio Marañón, Hospital Dr. Rodríguez Lafora, Psychiatry, Madrid, Spain; <sup>2</sup> Hospital General Universitario Gregorio Marañón, IISGM. CIBERSAM, School of

Medicine, Universidad Complutense. Madrid, Child And Adolescent Psychiatry, Madrid, Spain; <sup>3</sup> Hospital General Universitario Gregorio Marañón, Institute of Psychiatry, Psychology & Neuroscience- King's College London., Child And Adolescent Psychiatry, Madrid, Spain;

<sup>4</sup> Hospital Clinic de Barcelona, Child and Adolescent, Barcelona, Spain; <sup>5</sup> Centro de Investigación Biomédica, Barcelona, Red de Salud Mental CIBERSAM, Barcelona, Spain; <sup>6</sup> Hospital Infantil Universitario Niño Jesús, Psychiatry, Madrid, Spain; <sup>7</sup> Hospital Sant Joan de Déu, Child and Adolescent Psychiatry, Barcelona, Spain

\* Corresponding author.

**Background.**– Second-generation antipsychotics (SGAs) have been associated with increased risk of metabolic adverse events such as weight gain, insulin resistance and metabolic syndrome (1). The information on the long-term metabolic effects of treatment with SGAs in antipsychotic-naïve young people is still scarce (2).

**Objective.**– To assess changes in weight and metabolic parameters after one year of treatment with SGAs in naïve or quasi-naïve children and adolescents (i.e. lifetime exposure to antipsychotics  $\leq$  30 days).

**Methods.**– We conducted a 12-month prospective study in children who were prescribed SGAs for the first time for any DSM-IV diagnosis. We assessed them at baseline and 1-, 3-, 6- and 12-month follow-up visits. Age- and sex-adjusted body mass index (BMI) z-scores were calculated. Metabolic parameters: glucose, total cholesterol, LDL-cholesterol, HDL-cholesterol and triglycerides were assessed.

**Results.**– We included 232 patients (age  $14.46 \pm 2.94$  years, 62.5% male). There were prescribed risperidone in 138, 51 olanzapine and 43 quetiapine. There were significant changes in BMI z-scores during the first twelve months of treatment with risperidone ( $F=22.046$ ,  $P<0.001$ ), quetiapine ( $F=16.830$ ,  $P<0.001$ ) and olanzapine ( $F=54.948$ ,  $P<0.001$ ). Olanzapine was associated with significantly greater increase in BMI z-scores than both risperidone, (SMD=0.317,  $P<0.001$ ) and quetiapine (SMD=0.265,  $P<0.001$ ) during this period. In all antipsychotic groups, there was no significant increase in BMI z-scores from the 6- to the 12-month visits.

**Conclusions.**– The effect of SGAs on weight gain and metabolic changes during the first twelve months of treatment appears to be drug-dependent. The specific safety profile of each drug should guide treatment choices in this population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental condition encompassing symptoms of inattention, hyperactivity, and impulsivity that interfere with a person's daily functioning. There is a clear association between ADHD and learning disabilities, with comorbidity rates ranging from 31 to 45%. Studies have consistently demonstrated that children with attention-deficit/hyperactivity disorder (ADHD) perform significantly lower than controls on word recognition and spelling tests.

A problem with this approach is that such studies rely on the assumption that those groups are comparable in these measures. Measurement invariance indicates if, in a certain measure, the same construct is tested across different groups. This study investigates comparability of word recognition and spelling tests based on diagnostic status for ADHD through measurement invariance methods. The participants ( $n=1,935$ ; 47% female; 11% ADHD) were children aged 6 to 15 with normal IQ ( $\geq 70$ ). Measurement invariance was investigated through Confirmatory Factor Analysis and Multiple Indicators Multiple Causes models. Measurement invariance was attested in both methods, demonstrating the direct comparability of the groups. Children with ADHD were 0.51 s.d. lower in word recognition and 0.33 s.d. lower in spelling tests than controls. Results suggest that differences in performance on word recognition and spelling tests are related to true mean differences based on ADHD diagnostic status. Implications for clinical practice and research are discussed.

### Comparison of psychiatric disorders in children without caregiver in welfare centers of Gorgan with a control group, 2017

H. Moheimani<sup>1</sup>, M.Z. Kamkar<sup>2</sup>

<sup>1</sup> Medical student, golestan university of sciences, Gorgan, Iran;

<sup>2</sup> Sazar hospital, golestan university of medical sciences, gorgan, Iran

\* Corresponding author.

**Introduction.**– Because of deprivation and failure of children without caregiver, they often have psychological and behavioral problems that require the attention and care of mental health professionals. In recent years, various measures have been taken to improve the status of day care centers for abortive and mentally handicapped children so that children and adolescents who develop in this center are less likely to experience problems and behavioral disorders, so knowing the prevalence of mental disorders and The condition of psychiatric disorders among these children is also very important.

**Materials and methods.**– To carry out the research and collect data, firstly, the relevant authorities in Gorgan Welfare Centers were coordinated. The children were included in the study and their demographic information was collected by census method. The children's symptom questionnaire (CSI-4) was used to assess the mental status of the participants in the study.

**Results.**– Out of the total number of children, 78 (46.2%) were male and 90 (53.3%) were female. The mean age of the children was  $9.55 \pm 1.78$  years. In our study, there were significantly more cases of attention deficit disorder, hyperactivity, impulsivity, conduct, behavioral disorder, PTSD, motor tics, outism, urinary tract disorder and defecation disorder in the case group.

**Conclusion.**– The level of mental disorders among overweight children is much higher than that of the normal population, which, given the management status of these children, needs to be further investigated so that, if possible, the development of these disorders To be prevented.

**Keywords:** Welfare centers; (CSI-4); Orphans children

### Neurocognitive profile and onset of psychotic symptoms in individuals with 22q11DS: A longitudinal study

M. Pontillo<sup>1</sup>, D. Menghini, S. Vicari

Children Hospital Bambino Gesù, Neuroscience and Neurorehabilitation, Rome, Italy

\* Corresponding author.

**Introduction.**– The neurobehavioral phenotype of 22q11 deletion syndrome (22q11DS) include cognitive dysfunction and high rates of psychiatric disorders, in particular schizophrenia. IQ, executive functioning, attention and working memory are cognitive domains that are impaired often in 22q11DS. The aim of this study was to investigate, in a longitudinal perspective, the role of IQ and other cognitive domains (especially executive functions) to predict a later psychosis onset in a sample of children and adolescents with 22q11DS.

**Methods.**– 75 participants with 22q11DS, aged between 6 and 27 years at baseline, were included in the study.

All participants completed neurocognitive assessment at baseline. The cognitive domains evaluated were IQ, lexical comprehension, visual-spatial abilities and executive functions. All participants were assessed with SIPS/SOPS at baseline and at the one-year follow-up.

Out of 75 participants, two groups were selected based on the early onset of psychosis at the one-year follow-up.

The first group of participants with 22q11DS who had developed psychosis (early onset -EO) at the one year follow-up was composed of 18 participants and the second group who had not developed a psychosis (without early onset - WEO) was composed of 57 participants

**Results.**– At baseline, participants with EO showed lower IQ and more perseverative errors and a reduced number of correct categories on Wisconsin Card Sorting Test (WCST) compared to participants WEO. Discussion: In 22q11DS, low IQ and deficit of cognitive set-shifting are both traits that are preexisting and raise the risk for psychosis.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Variability of C-heterochromatin of 1, 9, 16 Chromosomes in Girls with Phobic-anxiety Disorders

T. Proskurina<sup>1\*</sup>, N. Bagatska<sup>2</sup>, E. Mykhailova<sup>1</sup>, T. Matkovska<sup>3</sup>, A. Goloborodko<sup>4</sup>

<sup>1</sup> SI<sup>1</sup>Institute for Children and Adolescents Health Care of the Nat, psychiatry, Kharkov, Ukraine; <sup>2</sup> SI<sup>2</sup>Institute for Children and Adolescents Health Care of the Nat, V. N. Karazin Kharkiv National University, Ukraine, Laboratory of Medical Genetics, Kharkiv, Ukraine; <sup>3</sup> SI<sup>3</sup>Institute for Children and Adolescents Health Care of the Nat, V. N. Karazin Kharkiv National University, Ukraine, department of psychiatry, Kharkiv, Ukraine; <sup>4</sup> V. N. Karazin Kharkiv National University, Ukraine, medical faculty student 3rd year of education, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**– The C-heterochromatin regions of chromosomes are mitotic form of existence of constitutive heterochromatin. Connection between some variants of the heterochromatin polymorphism with susceptibility to distinct disorders has been established in a series of investigations. The aims: To study polymorphism of C-heterochromatin regions of chromosomes 1, 9, 16 in adolescents with phobic-anxiety disorders (PAD).

**Methods.**– Investigation of heterochromatin area sizes 1gh, 9gh, 16gh has been performed in 10 probands with PAD and in age-matched healthy adolescents. PAD was diagnosed in the psychiatric department of the Institute on the basis of complex clinical and psychopathological examination of patients. Statistical analysis of the research results has been carried out using Microsoft Excel and SPSS Statistics 17.0 software.

**Results.**– Analysis of chromosomal morphofunctional peculiarities has testified to the fact that the karyotype in the patients with PAD corresponded with normal female karyotypes (46,XX). Based on the research, we identified options with polymorphism-heterochromatins regions of chromosomes 1, 9, 16 in girls with PAD. Prevalence of reduced size with segments in patients in comparison with healthy girls has been revealed. C-blocks with estimated scores of 1 and 2 in all the studied chromosomes of girl-patients have been registered more often, whereas healthy age mates had scores of 3 and even 4 to 5. The greatest variability has been detected in segments of chromosome 1 which assessed score of 2 (88.8%).

**Conclusion.**– Prevalence of reduced size with segments of chromosomes 1, 9, 16 has been revealed in girls with TGF in comparison with healthy girls.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Features of Depression in adolescents

T. Proskurina<sup>1\*</sup>, E. Mykhailova<sup>2</sup>, T. Matkovska<sup>3</sup>, A. Goloborodko<sup>4</sup>

<sup>1</sup> SI<sup>1</sup>Institute for Children and Adolescents Health Care of the Nat, psychiatry, Kharkov, Ukraine; <sup>2</sup> SI<sup>2</sup>Institute for Children and Adolescents Health Care of the Nat, psychiatry, Kharkov, Ukraine; <sup>3</sup> SI<sup>3</sup>Institute for Children and Adolescents Health Care of the Nat, V. N. Karazin Kharkiv National University, Ukraine, psychiatry, Kharkov, Ukraine; <sup>4</sup> V. N. Karazin Kharkiv National University- Ukraine, student 3rd year of education, Kharkiv, Ukraine

\* Corresponding author.

**Background and aims.**– The notion of adolescence includes somatic and psychoendocrine status of puberty, characteristics of ontogenetic development, psychic sphere with its features of behavioral and adaptation response to stress factors (Brent.D.A. 2007; Levis C.C. Simons A.D., 2009). Clinical phenomenology of depression comorbid with endocrine diseases in adolescents still remains insufficiently studied.

**Methods.**– 156 adolescents with depression aged from 12 to 18 years have been examined. Design of investigation: clinical psychopathological, somatic neurological, psychological (rating scale for depression by Boyko V.M. MADRS: pathological diagnostic personal questionnaire by Lichko A. Ye.).

**Results.**– In the patients aged from 12 to 14 years, asthenic, anxiety and hypochondriac syndromes have been found: in the patients aged from 14 to 18 years, behavioral, dysmorphic, apathy syndromes were present. Depression severity was positively correlated with insuline- resistant obesity ( $r=0.776$ ,  $P<0.001$ ); apathy – with thyroid pathology ( $r=0.338$ ,  $P=0.020$ ), behavioral symptoms were positively correlated with hypothalamic pubertal syndrome ( $r=0.654$ ,  $P<0.001$ ), dysmorphia with anorexia nervosa syndrome ( $r=0.556$ ,  $P<0.001$ ).

**Conclusion.**– Depression in adolescents is comorbid with certain endocrine diseases; it generates the risk of late recognition of affective disorders and untimely therapeutic intervention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Positive mental health and coping styles in a sample of university students

I. Ramos Vidal<sup>1\*</sup>, I. Villamil Benitez<sup>2</sup>, A.M. Romero Otalvaro<sup>2</sup>, J. Palacio Sañudo<sup>3</sup>, A. Uribe Urzola<sup>2</sup>, M. Muñoz Argel<sup>2</sup>

<sup>1</sup> Faculty of Psychology, Department of Social Psychology, Sevilla, Spain; <sup>2</sup> Faculty of Psychology, Department of Social Psychology, Montería, Colombia; <sup>3</sup> Faculty of Psychology, Department of Social Psychology, Barranquilla, Colombia

\* Corresponding author.

**Introduction.**– The empirical evidence suggests that a positive mental health is associated with the coping styles deployed by youth and adolescents.

**Objectives.**– To characterize and correlate the coping styles and the positive mental health of the participants.

**Methods.**– Quantitative and cross-sectional research, consisting of a sample of 123 university students, 73 males and 50 females, who were intentionally selected (mean age was 18, and ranging from 16 to 19, SD = 0.7). The participants completed a survey which included the Positive Mental Health Scale (Lluch 2001) and the Scale of Coping Styles (Lazarus and Folkman 1986).

**Results.**– It was shown that as personal satisfaction increases, avoidance styles, self-blame and fantasy are used less frequently. Likewise, a significant correlation was found between self-control and problem solving and social support styles. At the same time, there was a negative correlation between autonomy and styles of avoidant coping, self-blame and fantasy. In general, correlations show a direct and significant relationship between interpersonal skills and problem solving and social support styles.

**Conclusions.**– There is a significant correlation between the variables positive mental health and coping styles of first semester students, especially Interpersonal Relations Skills and problem solving ( $r = .53$ ,  $P < .01$ ). The more mastery they present for their positive mental health in general, they will use coping styles focused on solving the problem and seeking for social support. Likewise, to the extent that they employ positive mental health dimensions such as personal satisfaction and autonomy, they will use less avoidance, self-blame, and fantasy styles. These preliminary results are discussed in order to understand the relationships among coping strategies and mental health in adolescent population.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Prognostic factors in ASD. Pilot study in Georgia

M. Zirkashvili<sup>1\*</sup>, M. Gabunia<sup>1</sup>, G. Lomidze<sup>2</sup>

<sup>1</sup> Mental Health Center, child and adolescent Psychiatry, Tbilisi, Georgia; <sup>2</sup> Institute of Neurology and Neuropsychology, Child Neurology, Tbilisi, Georgia

\* Corresponding author.

**Introduction.**– Autism spectrum disorders are common behavioral syndromes characterized by impairments in social interaction, abnormalities in verbal and nonverbal communication, and restricted and stereotyped interests and behaviors. Their onset occurs in early childhood and often results in severe lifelong impairments. According to longitudinal observation on children with ASD, literature suggests that a minority of individuals with an ASD will lose the diagnosis. However, the existence of this phenomenon is

still controversial. Are there any already identified factors, which can help clinicians to predict any kind of outcome.

**Patients and methods.**– Retrospective medical chart review in a tertiary care clinic of Tbilisi (Mental Health Center) were conducted of 2–6 years old 49 children, diagnosed as having ASD based on ICD-10 criteria, ADI-R and the ADOS. They were reassessed after min 2 years: obvious progress in symptom severity were identified.

**Results.**– The pattern of autistic symptom severity varied over time by domain. Standard assessments at earlier ages (before 30 month) did not predict outcome later even within the same domain of functioning. In contrast, standard assessments at age 3 did predict outcome. Early intervention, high IQ, less stereotype behavior and the development of communicative and language skills at an early age could be the most powerful factors contributing to an optimal outcome.

**Conclusion.**– These results reveal some evidence of the possibility of 'recovering' from ASD and demonstrate that it is, in fact, possible to reach a level of typical functioning, while not eliminating the possibility of residual deficits in the problematic fields of ASD

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## Substance Related and Addictive Disorders - Part III

### A drug of choice psychopathological profile: Focus on clinical, sociodemographic, personality, attachment and parental bonding characteristics

M. Antonioli<sup>1</sup>, A. Nivoli, L. Folini, L. Floris, G. Ricci, P. Milia, L. Loretta

Institute of Psychiatry, Psychiatry, Sassari, Italy

\* Corresponding author.

**Introduction.**– Literature on psychopathological and attachment/parenting profiles amongst drug abusers is inconsistent.

**Objectives.**– To investigate psychopathology and attachment/parenting profiles related to the drug of choice.

**Methods.**– 146 patients from a rehabilitation community in Sardinia were assessed through the Millon-Clinical-Multiaxial-Inventory (MCMI-III), the Aggression Questionnaire, the Attachment Questionnaire and the Parental Bonding Instrument in Cocaine, Heroin, Alcohol and Cannabis abusers. Student's *t*-tests and Pearson Chi-square were performed.

**Results.**– Cocaine addicted had low level of education, were single and polyabusers, with low comorbidity of Axis I disorders and high hospitalizations. Showed more Histrionic and Narcissistic and less Dependent and Avoidant personality. They showed less frequent perceived maternal "Affectionate Constraint" parenting style high level of Secure attachment.

Heroin addicted showed low level of education, were separated, polyabusers, with high familiarity for detentions, with high score in MCMI-III drug dependence scale and Avoidant attachment style. Alcohol addicted reported higher level of education, were married and with lower chance of polyabuse, low frequency of crime and detention, higher hospitalization and suicidal ideation. They showed more Dependent and Obsessive Compulsive and less Antisocial personality. Prevalent attachment style was Anxious-Ambivalent.

Cannabis addicts had a younger age of onset, low level of education and singles. They had high frequency of crime detentions and

younger age of the first suicide attempt. They showed less Obsessive compulsive personality and “Affectionless Control” as prevalent perceived paternal parenting style.

**Conclusions.**– Our results showed that Drug abusers have different psychopathological characteristics as well as different parenting and attachment styles related to the specific Drug of Choice.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Temperamental characteristics related to the drug of choice. changes in a 1-year follow up at a rehabilitation community program based in Sardinia**

M. Antonioli\*, A. Nivoli, L. Floris, L. Folini, G. Ricci, P. Milia, L. Loretto

*Institute of Psychiatry, Psychiatry, Sassari, Italy*

\* Corresponding author.

**Introduction.**– Prior findings revealed how specific temperamental characteristics are related to the Drug of Choice in substance abusers. Little is known on how these temperamental traits can be modified by rehabilitation treatment.

**Objectives.**– To investigate temperamental characteristics associated with the Drug of choice in a population of drug abusers at baseline and at 1-year follow up.

**Methods.**– 146 patients from a rehabilitation community in Sardinia were recruited. Data were collected through the Temperament Character Inventory (TCI) in Cocaine, Heroin, Alcohol and Cannabis abusers. Student's *t*-tests and Pearson Chi-square were performed.

**Results.**– Cocaine addicts scored lower in Enlightened second nature, Empathy and Self Forgetfulness at baseline. At follow up they showed a general increase in Self Directedness scores. Heroin addicts showed no specific TCI scores at baseline. At follow up they showed a decrease in Novelty Seeking and Harm Avoidance and an increase in Self Directedness scores.

Alcohol addicts scored high in Enlightened Second Nature, high in Fear of Uncertainty and low in Novelty Seeking at baseline. At follow up they showed a reduction of Harm Avoidance and an increase in Self Directedness.

Cannabis addicts scored high in Exploratory Excitability and low in Fear of Uncertainty at baseline. No variations were registered at follow up.

**Conclusions.**– Drug of Choices appear associated with different Temperamental characteristics. Rehabilitation community programs are a useful treatment strategy to create changes in substance abusers personality. Interestingly, these modifications seems specific and different in relation to the drug of choice.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Filling the gap between lab and clinical impact: an open randomized diagnostic trial comparing urinary ethylglucuronide and ethanol in alcohol dependent outpatients**

P. Barrio<sup>1</sup>, L. Teixidoar<sup>2</sup>, L. Ortega<sup>2</sup>, A. Lligoña<sup>2</sup>, N. Rico<sup>3</sup>, J.L. Bedini<sup>3</sup>, E. Vieta<sup>4</sup>, A. Gual<sup>2</sup>

<sup>1</sup> *Clinical Neuroscience Institute, Clinic Hospital, Addictive Behaviours Unit, Barcelona, Spain;* <sup>2</sup> *Clinical Neuroscience Institute, Clinic Hospital, Addictive Behaviors Unit, Barcelona, Spain;* <sup>3</sup> *Clinic*

*Hospital, Biochemistry Department, Barcelona, Spain;* <sup>4</sup> *Clinical Neuroscience Institute, Clinic Hospital, Psychiatry Department-Bipolar Disorder Program, Barcelona, Spain*

\* Corresponding author.

**Background.**– Alcohol use disorders represent a major health burden. Efforts aiming at reducing alcohol-related harm includes detection of early relapse in patients with alcohol dependence who are detoxified and committed to abstinence. Ethyl glucuronide has been proved to be a good biomarker for the detection of recent drinking. However, to date, no randomized diagnostic trial has tested its impact on drinking outcomes. The aim of this study was to assess, with a randomized design, the implications of ethyl glucuronide screening on alcohol outcomes.

**Methods.**– Alcohol dependent outpatients were randomized to either 24 weeks of continuous screening with ethyl glucuronide or ethanol. Patients were aware of screening methods and results. After 24 weeks, all participants were screened with ethyl glucuronide. Self-reports were also gathered. A logistic regression model was performed comparing the rate of ethyl glucuronide positive results at study end between groups. Generalized estimating equations were performed to evaluate the descending rate of EtG positive patients in the EtG group, measured month to month.

**Results.**– A total of 162 patients were randomized. During the study period, ethanol subjects showed a lesser number of positive screens. However, after 24 weeks, patients in the EtG group showed a greater probability of having a negative screening test compared to ethanol subjects, provided they were all screened with ethyl glucuronide. A significant decrease in the rate of EtG positive patients was found for the first three months of the study.

**Conclusions.**– Routine screening with ethyl glucuronide improves abstinence rates in alcohol dependent outpatients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0788

### **Recognition of emotional faciale expressions and hemispheric asymmetry differentiate in abstinent heroin abusers**

T. Bayram Kuzgun

*Istanbul Arel University, Psychology, Istanbul, Turkey*

**Introduction.**– Emotional facial expressions are accepted as a quick, reliable way to understand the feelings of others. Recent studies have shown that patients who were hospitalized with alcohol and substance abuse showed worse performance than healthy controls in ability to recognize facial expressions.

**Objective.**– There is an increasing body of literature on the role of hemispheric asymmetry in perceiving the universally accepted facial expressions such as happiness, sadness, anger, surprise, fearfulness, disgust, and neutrality. No such studies exist for heroin addicts.

**Method.**– The goal of this study was to investigate the recognition of emotional facial expressions by heroin addicts and to examine the accuracy and response times of their brain hemispheres by employing the divided visual field (DVF) technique. There are 31 heroin addicts and 32 healthy participants in the study. Informed Consent, Demographic Information Form, Edinburgh Handedness Inventory, Beck Depression Inventory, State Trait Anxiety Inventory, and The Symptom Checklist (SCL-90-R) were applied to all subjects. Then each subject took the PHP-based Emotional Facial Expression test in a computer environment.

**Results.**– The results indicated that abstinent heroin abusers detected fewer correct facial expressions for the sad, angry, sur-

prised, and fearful emotions, and their response times were longer than those of healthy controls. Healthy controls showed right hemispheric (RH) superiority in recognizing angry faces, while the AHs showed RH superiority in recognizing sad and angry faces, and LH superiority in recognizing disgusted faces.

**Conclusion.**– AHs have an impaired capacity for emotional perception and different hemispheric asymmetry patterns. rds: emotional facial expressions, abstinent heroin abusers, hemispheric asymmetry

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

PW0789

### **Impact of depression on smoking cessation: Are depressed patients more dependent?**

M. Bernardo<sup>1\*</sup>, S. Nascimento<sup>2</sup>, S. Viveiros<sup>3</sup>, I. Carvalho<sup>3</sup>, A. Alves<sup>3</sup>, J. Pereira<sup>3</sup>, E. Freire<sup>3</sup>, A. Lopes<sup>3</sup>

<sup>1</sup> Hospital Garcia de Orta, Department of Psychiatry and Mental Health, Lisboa, Portugal; <sup>2</sup> University Hospital Center of Algarve, Department of Psychiatric and mental health, Faro, Portugal;

<sup>3</sup> Hospital Center of Oporto, Department of Psychiatric and mental health, Oporto, Portugal

\* Corresponding author.

**Introduction.**– One of the mental illnesses most common among smokers is depression. A depressed humour and expectations that smoking modulates humour may be associated with higher dependency rates and more failed attempts to quit smoking.

**Objectives.**– To evaluate the impact of depression on smoking cessation.

**Methods.**– A retrospective analysis was performed using data from patients that attended smoking cessation consults provided by the liaison psychiatry service of a central hospital, between 2006 and 2016. The data concerned demographic parameters, smoking habits, as well as results from Fagerstron and Richmond tests and the Hospital Anxiety and Depression Scale (HADS).

**Results.**– Of the 1278 patients comprised in the sample, 531 (41.6%) could be classified as having depression. The mean degree of nicotine dependence in patients with depression was significantly higher than in non-depressed patients ( $P < 0.05$ ). A statistically significant and positive correlation was found between depression severity and the degree of dependence ( $r = 0.77$ ,  $P < 0.05$ ). A statistically significant difference between those two groups was also found in the mean degree of motivation to quit smoking, however, no statistically significant correlation was found between the severity of the depressive disorder and the degree of motivation. **Conclusions.**– Depressed patients are less motivated to stop smoking and are more dependent on nicotine. There is a correlation between the severity of the depressive disorder and the degree of addiction.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Psycho-emotional determinants of binge drinking among 15-year-old adolescents in Latvia**

N. Bezborodovs<sup>1\*</sup>, A. Villerusa<sup>2</sup>

<sup>1</sup> Riga Stradins University, Department of Psychiatry and Narcology, Riga, Latvia; <sup>2</sup> Riga Stradins University, Department of Public Health and Epidemiology, Riga, Latvia

\* Corresponding author.

**Introduction.**– Adolescence is a time when youngsters start engaging in binge drinking, a high-risk behaviour that is linked to a number of negative health outcomes, high persistence rate and risk of alcohol addiction in adulthood.

**Objectives.**– To examine the relationship between individual and environmental psycho-emotional risk factors and binge drinking in a representative sample of 15-year-old adolescents in Latvia.

**Methods.**– The study was conducted using data from the international Health Behaviour in School-aged Children (HBSC) study year 2013/2014 Latvian database. Statistical modelling was performed to explore the link between binge drinking and a number of socio-demographic and psycho-emotional risk factors.

**Results.**– The sample consisted of 1674 15-year-old 9th grade students. Only 399 (23.8%) students reported never having used alcohol, and 181 (10.8%) students reported drinking more than 5 standard drinks (binge-drinking) in an episode of alcohol use during last month. Boys were 1.82 (CI 1.25–2.67) times more likely to binge drink than girls. Adolescents with low self-perceived family support were 1.81 (CI 1.19–2.75) times more likely to binge drink. Adolescents with good self-perceived peer relationships were 1.59 (CI 1.05–2.39) times more likely to binge drink. The odds of binge drinking in the study population did not statistically significantly depend on ethnicity, family income level, self-reported health status, quality of life or school-related factors.

**Conclusions.**– The rate of binge drinking among Latvian 15-year-olds is significant, with as much as 10.8% admitting to binge drink during last month. Male gender, low self-perceived family support and good self-perceived peer support appear to be important risk factors.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Lifetime prevalence and risk factors of drug use in North Cyprus: 2003–2017**

M. Çakıcı<sup>\*</sup>, E. Çakıcı, A. Babayigit, M. Karaaziz  
Near East University, psychology, Nicosia, Cyprus

\* Corresponding author.

**Background.**– Drug use has become widespread with extreme proportions recorded globally and studies of psychoactive substance use becoming more prevalent throughout the world.

**Objectives.**– The purpose of this study is to determine the characteristics and prevalence of cigarette, alcohol and other psychoactive drug use among adults in North Cyprus (NC).

**Methods.**– A random multi-staged, stratified sampling quota was used for sampling method in May-June 2017. Household survey interviews were conducted with 1000 people within the 18–65 age groups. A survey questionnaire was used, which is the Model European Questionnaire of Council of Europe adapted to the Turkish language. The prevalence data are given in comparison with surveys conducted using the same questionnaire in 2003 (825 people), 2008 (804 people) 2013 (1040 people) and 2015 (994 people).

**Results.**– The survey shows that the lifetime prevalence of smoking is 60.9%, alcohol use is 63.5% and illicit drug use is 11.7%. Lifetime cannabis use is 5%, synthetic cannabinoid is 5.8%, ecstasy is 2.7%, sedatives/hypnotic drugs is 5.7% and volatiles were found as 1.1%. The cocaine, heroin, amphetamines, LSD and codeine syrups use proportions were between 0.6 and 2.5%.

**Conclusion.**– It has been observed that the lifetime cigarette and alcohol use is decreasing among adults in NC; however, the lifetime use of other psychoactive drugs is increasing. NC has higher proportion of cigarette use than Asian, European and African countries. Alcohol and substance use is similar to the high prevalence propor-

tions of United States. NC needs efficient prevention programs in order to combat drug use.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Do cannabis users develop tolerance for the psychoactive effects of delta-9-tetrahydrocannabinol? An fMRI study**

M. Colizzi<sup>1\*</sup>, P. McGuire<sup>1</sup>, V. Giampietro<sup>2</sup>, S. Williams<sup>2</sup>, M. Brammer<sup>2</sup>, S. Bhattacharyya<sup>1</sup>

<sup>1</sup> Institute of Psychiatry, Psychology and Neuroscience, Psychosis Studies, London, United Kingdom; <sup>2</sup> Institute of Psychiatry, Psychology and Neuroscience, Neuroimaging, London, United Kingdom

\* Corresponding author.

*Introduction.*– Cannabis can induce transient psychotic and anxiety symptoms and long-lasting disorders. The acute psychoactive effects of the main active ingredient in cannabis, (–)-trans- $\Delta$ 9-tetrahydrocannabinol ( $\Delta$ 9-THC), may be modulated by previous cannabis exposure.

*Objectives.*– To test whether modest previous cannabis exposure modulates the acute effects of  $\Delta$ 9-THC on attentional salience and emotional processing and their neurophysiological substrates.

*Methods.*– Twenty-four healthy men participated in a double-blind, randomized, placebo-controlled, repeated-measures, within-subject,  $\Delta$ 9-THC challenge study using an fMRI paradigm.

*Results.*– Compared to non-users ( $n = 12$ ; < 5 lifetime cannabis joints smoked), abstinent modest cannabis users ( $n = 12$ ;  $24.5 \pm 9$  lifetime cannabis joints smoked) showed less efficient attentional salience processing, also recruiting different/additional brain areas to process both attentional salient and emotional stimuli (all  $P \leq 0.01$ ).  $\Delta$ 9-THC challenge disrupted attentional salience and emotional processing-related brain activity, also inducing transient anxiety and psychotic symptoms (all  $P \leq 0.02$ ). However,  $\Delta$ 9-THC-induced psychotic symptoms and attentional salience behavioral impairment were more pronounced in non-users compared to users (all  $P \leq 0.04$ ). Intriguingly, while non-users under  $\Delta$ 9-THC shifted towards recruitment of other brain areas to perform the tasks, cannabis users were less affected by the acute challenge, showing a neurophysiological pattern similar to that of non-users under placebo. Only in non-users, the  $\Delta$ 9-THC-induced psychotic symptom and cognitive impairment severity was associated with a more pronounced neurophysiological alteration (all  $P \leq 0.048$ ).

*Conclusions.*– Abstinent modest cannabis users display residual effects of cannabis exposure but more blunted responses to the acute symptomatic, behavioral, and neurophysiological effects of  $\Delta$ 9-THC, which are more marked in people who have never used cannabis.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Drinking among high risk students receiving the brief alcohol screening and intervention in a public university in the United States**

C. Holstege<sup>1\*</sup>, D.A. Ngo<sup>2</sup>, S. Redge<sup>3</sup>, N. Ait-Daoud<sup>4</sup>

<sup>1</sup> University of Virginia, Emergency Medicine, Charlottesville, USA;

<sup>2</sup> University of Virginia, Student Health and Emergency Medicine, Charlottesville, USA; <sup>3</sup> University of Virginia, Emergency Medicine, Charlottesville, USA; <sup>4</sup> University of Virginia, Department of

Psychiatry and Neurobehavioral Sciences, Charlottesville, USA

\* Corresponding author.

*Introduction.*– Alcohol abuse in the collegiate population continues to be a significant problem.

*Objectives.*– This study examined the brief alcohol screening and intervention of college students (BASICS) with the negative effects of excessive drinking in a major public university in the United States.

*Methods.*– Questionnaire-based interviews were administered to students prior to the BASICS session during 2016–2017 academic year. Data on students' demographics, frequency and amount of drinking, knowledge on the effects of alcohol use, experience with negative effects of excessive drinking was descriptively analyzed.

*Results.*– A total of 122 students (75% males) visited the BASICS clinic. The median age was 19 (77% under 20). The median age of first time drinking was 17. Students reported failing to do something (66%), feeling of guilt (78%), reduced memory (83%), and feeling bad (70%) following their drinking. Furthermore, 92% ever felt sick, 77% ever felt tired, and 24% ever had an injury. A significant proportion of students reported problems with study due to their alcohol use: 25% doing poorly on the test, 53% not getting things done, 26% missing class, 83% having trouble with police, 53% having fight or argument, 46% passing out, 25% having unwanted sex, 11% drinking driving; they also had problems with family (30%) and partners (27%).

*Conclusion.*– The majority of students reported negative physical and mental consequences of risky drinking. Findings indicate that timely referral of such high risk students to BASICS could mitigate the risk and requires further study.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Characteristics and predictors of hydrocodone misuse: Results from the 2015 National Survey on drug use and health**

C. Holstege, S. Rege

University of Virginia, Emergency Medicine, Charlottesville, USA

\* Corresponding author.

*Background.*– The abuse and diversion of prescription opioids, especially hydrocodone, continue to be a serious concern. This study aims to identify predictors of hydrocodone misuse using the National Survey of Drug Use and Health (NSDUH) data.

*Methods.*– The 2015 NSDUH data were used to identify past year hydrocodone users and misusers. Demographics, clinical factors, substance use and misuse were assessed descriptively. Logistic regression was used to identify predictors of hydrocodone misuse.

*Results.*– The survey comprised of 57,146 respondents, of which 10,884 respondents (19%) reported using hydrocodone. In the sample, 1,812 reported hydrocodone misuse. Hydrocodone misusers were more likely to be males (54.8% vs 39.9%,  $P < 0.001$ ), unmarried (64.5% vs 40.7%,  $P < 0.001$ ), and non-Hispanic whites (67.4% vs 66.2,

$P < 0.001$ ). Past year use and misuse of substances was significantly higher in hydrocodone misusers. Previous year use of tramadol (OR: 1.66, 95% CI: 1.16–2.38) and ecstasy (OR: 3.05, 95% CI: 1.46–6.36) were significant predictors of hydrocodone misuse. Males were 53% more likely to be hydrocodone misusers. Hydrocodone misuse was significantly more likely among misusers of other substances including sedatives (OR: 3.31, 95% CI: 1.57–6.97), hydromorphone (OR: 3.91, 95% CI: 1.04–14.64), and methamphetamines (OR: 2.31, 95% CI: 1.05–5.58). Conversely, previous year oxycodone misusers (OR: 0.52, 95% CI: 0.40–0.68) were significantly less likely to misuse hydrocodone.

**Conclusions.**– The results indicate a high prevalence of hydrocodone misuse within a nationally representative sample of survey respondents. Use and misuse of substances were important predictors of hydrocodone misuse.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Introduction.**– Phenazepam is the Russian original benzodiazepine tranquilizer. We have performed first pharmacogenetic study of Phenazepam's safety in patients with alcohol withdrawal syndrome.

**Aim.**– To determine associations of adverse reactions to Phenazepam with haplotypes of CYP3A5, CYP2C9, CYP2C19 and CYP2D6 genetic polymorphisms.

**Materials and methods.**– 102 male patients with non-complicated alcohol withdrawal syndrome (F 10.3 by ICD-10) were involved into the study in 24 hours after their admission to hospital and were prescribed Phenazepam. 5 mL of venous blood was collected from each participant for genotyping to detect CYP3A5\*3, CYP2C9\*2, CYP2C9\*3, CYP2C19\*2, CYP2C19\*3, CYP2C19\*17 and CYP2D6\*4 polymorphisms by real-time polymerase chain reaction. Safety of therapy was evaluated with UKU Side Effects Rating Scale at 6th day of treatment. Haplotype analysis was performed by SNPStats online-tool.

**Results.**– There were established protective role of haplotypes against several adverse drug reactions. Thus, CYP2C9\*2-CYP2C9\*3 (C-C) decreased risk of "Increased duration of sleep" (OR=0.18 (95%CI 0.04 - 0.91),  $P=0.042$ ). CYP2C9\*2-CYP2C9\*3-CYP2C19\*2 (C-A-A) was associated with less frequency of "Orthostatic dizziness" (OR=0.21 (95%CI 0.06–0.73),  $P=0.015$ ) and "Palpitations/Tachycardia" (OR=0.11 (95%CI 0.02–0.70),  $P=0.022$ ).

**Conclusion.**– Significant associations of haplotypes CYP2C9 and CYP2C9-CYP2C19 with decreased risk of adverse reactions to phenazepam's treatment in patients with alcohol withdrawal syn-

drome. Our data confirm role of different pharmacokinetic genetic markers in safety of Phenazepam.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Altered frontoparietal grey matter volume in internet gaming disorder with childhood attention deficit hyperactivity disorder**

Y.C. Jung<sup>\*</sup>, N. Kee

Yonsei University, Psychiatry, Seoul, Republic of Korea

\* Corresponding author.

**Objective.**– Attention deficit/hyperactivity disorder (ADHD), characterized by delayed cortical development, is one of the most common comorbid conditions with internet gaming disorder (IGD). We hypothesized that IGD with and without childhood ADHD may differ in the neurobiological basis underlying loss of control over gaming. This study investigated whether IGD subjects with childhood ADHD had specific alterations of gray matter volume (GMV) reflecting their distinct pathophysiology of uncontrolled gaming.

**Method.**– Whole-brain voxel-based morphometry (VBM) analysis with diffeomorphic anatomical registration using an exponentiated Lie algebra algorithm (DARTEL) was conducted on 40 male IGD subjects (ages 19–29) with and without childhood ADHD and 20 age-matched, healthy male controls. GMV of IGD subjects with childhood ADHD were compared to that of IGD subjects without childhood ADHD and matched controls.

**Results.**– Compared to controls, IGD subjects with childhood ADHD showed smaller GMV in the anterior cingulate cortex (ACC) and the left inferior frontal gyrus (IFG), whereas IGD subjects without childhood ADHD had smaller GMV in the ACC, the left orbitofrontal cortex (OFC), and the left insula. IGD subjects with childhood ADHD also had smaller GMV in the left superior parietal lobule (SPL) than did IGD subjects without childhood ADHD. Within IGD subjects with childhood ADHD, the GMV in the SPL was inversely correlated with hyperactivity/restlessness.

**Conclusions.**– IGD subjects with childhood ADHD showed specific alterations of GMV in frontoparietal regions, which are related to diminished executive control. Our findings suggest that structural abnormalities from childhood ADHD may distinctly influence the development and maintenance of uncontrolled gaming.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Association between alcohol withdrawal and sequence variation in the GABRA2 and TDO2 gene regions**

V. Karpyak<sup>1\*</sup>, D. Liu<sup>2</sup>, J. Geske<sup>3</sup>, A. Batzler<sup>3</sup>, M. Frye<sup>1</sup>, R. Weinshilboum<sup>4</sup>, D.S. Choi<sup>5</sup>, J. Biernacka<sup>6</sup>

<sup>1</sup> Mayo Clinic, Psychiatry and Psychology, Rochester, USA; <sup>2</sup> Mayo Clinic, Molecular Pharmacology and Experimental Therapeutics, Rochester, USA; <sup>3</sup> Mayo Clinic, Biomedical Statistics and Informatics, Rochester, USA; <sup>4</sup> Mayo Clinic, Pharmacology and therapeutics, Rochester, USA; <sup>5</sup> Mayo Clinic, Psychiatry and Psychology, Molecular Pharmacology and Experimental Therapeutics, Rochester, USA; <sup>6</sup> Mayo Clinic, Psychiatry and Psychology, Biomedical Statistics and Informatics, Rochester, USA

\* Corresponding author.

**Background.**– Alcohol withdrawal syndrome (AWS) is a fundamental component of alcohol use disorder (AUD). We conducted a pilot

genome-wide association study of the two commonly used definitions of the AWS phenotype.

**Methods.**– Illumina HumanCore genotyping array was used to genotype DNA samples from 400 European Americans meeting DSM-IV criteria for alcohol dependence. SNP genotypes were tested for association with two phenotypes: (a) hand tremor plus on or more of the AWS symptoms; (b) the total number of AWS symptoms in a single subject. Top signals were queried in the GTEx database for potential expression quantitative trait loci (eQTLs).

**Results.**– The presence of tremor together with at least one other AWS sign was associated with a peak located on chromosome 4 ( $P=1.11E-07$  for the top SNP) close to promoter and regulatory regions of the *GABRA2* gene previously associated with alcohol dependence. Based on the GTEx dataset, the variant SNP allele is significantly associated with decreased *GABRA2* expression in brain cortex, hippocampus and cerebellar hemisphere. The analysis that focused on the number of AWS symptoms revealed two SNPs on chromosomes 14 and chromosome 2 ( $P=1.8E-08$  and  $2.5E-08$ , respectively) and a strong signal ( $P=1.43E-07$  for the top SNP) on chromosome 4 located 11 kb 5' of the *TDO2* gene encoding tryptophan dioxygenase.

**Conclusions.**– Our pilot study revealed that two phenotypic definitions of AWS included in the analyses revealed strong, albeit different association signals. The strength of association indicates that the selected phenotypes have the potential to reveal significant associations in larger samples.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Buprenorphine implant in opioid use disorder

B. Martins<sup>1\*</sup>, C. Agostinho<sup>1</sup>, A. Aleixo<sup>2</sup>, M. Martins<sup>3</sup>

<sup>1</sup> Hospital de Portalegre, Unidade Local de Saúde do Norte Alentejano, Departamento de Psiquiatria e Saúde Mental, Portalegre, Portugal;

<sup>2</sup> CHPL, Centro Hospitalar Psiquiátrico de Lisboa, Lisboa, Portugal;

<sup>3</sup> ARSLVT, Centro de Respostas Integradas de Lisboa Oriental, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Buprenorphine is an effective therapeutic option in treatment of opioid use disorder (OUD). Yet, Buprenorphine's efficacy and safety are sometimes limited by irregular intake, diversion for illicit reasons and accidental ingestion by other people. In order to minimize the disadvantages of its oral formulation, some sustained release systems have been developed in USA, namely a subcutaneous implant, approved in 2016 by the Food and Drug Administration (FDA).

**Objectives.**– To review the characteristics of Buprenorphine implant.

**Methods.**– Research in Medline for “sustained released buprenorphine” and “buprenorphine implant”. Only the relevant articles, published from 2007 to November 2017, were considered.

**Results.**– 8 articles were selected: 4 clinical trials and 4 reviews. The use of Buprenorphine implants has been shown to be effective in reducing the use of opioids (negative urine tests) and in reducing withdrawal symptoms compared to placebo implants. Additionally, it was not inferior in terms of efficacy compared to sublingual buprenorphine. Some local adverse reactions were verified as the main disadvantages of its use. In addition, interpretation of the data is limited by the fact that some participants of the trials had required supplemental oral doses of buprenorphine because of remaining withdrawal symptoms.

**Discussion.**– The use of buprenorphine implants aims to respond to the risks of sublingual formulation. The pertinence of its pre-

scription implies the recognition of groups of patients who would benefit from this formulation (eg. patients with children in their households). However, besides medication, therapeutic success also implies the availability of other types of intervention, namely of psychosocial nature.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Awakening the hedonic response in cocaine addiction: Which role for repetitive transcranial magnetic stimulation (rTMS)?

M. Pettorosso<sup>1\*</sup>, C. Montemitro<sup>2</sup>, I. Petrucci<sup>3</sup>, G. Baroni<sup>2</sup>, A. Miuli<sup>2</sup>, M.C. Spano<sup>2</sup>, L. Marchionno<sup>4</sup>, F. Fanella<sup>3</sup>, M. Di Giannantonio<sup>2</sup>, G. Martinotti<sup>2</sup>

<sup>1</sup> Università Cattolica del Sacro Cuore, Department of Neuroscience, Roma, Italy; <sup>2</sup> Department of Neuroscience Imaging and Clinical Science, “G. d’Annunzio” University, Chieti, Italy; <sup>3</sup> TMS Addiction Unit, La Promessa Onlus, Roma, Italy; <sup>4</sup> Institute of Neurology, ASL 2 Abruzzo “Lanciano Vasto Chieti”, Chieti, Italy

\* Corresponding author.

**Introduction.**– Cocaine use disorder (CUD) is associated with dysregulation of reward, mainly represented by the presence of craving and occurrence of anhedonia for pleasurable stimuli other than cocaine intake. CUD alterations in reward functioning may relate to changes induced by cocaine or to pre-existing differences related to vulnerability to addiction.

**Objectives.**– In this study, we explore the possible utility of repetitive Transcranial Magnetic Stimulation (rTMS), a non-invasive brain stimulation intervention, to improve hedonic response in cocaine-dependent subjects.

**Methods.**– Fifteen CUD subjects entered the study. Hedonic response was studied by using: the Cocaine Selective Symptoms Scale (CSSA; Anhedonia subscale) and the Temporal Experience of Pleasure Scale (TEPS). The assessment was performed before and after five days of high frequency rTMS (twice a day, 15 Hz, 100% rMT, 2400 pulses/session) over the left dorsolateral prefrontal cortex (DLPFC).

**Results.**– In this study, we report the improvement of hedonic response in CUD subjects after rTMS treatment (Figure 1).

**Conclusions.**– We provide preliminary results that rTMS reduces hedonic tone dysfunctions, improving response to natural non-drug rewards. rTMS possibly targets the deficits in dopaminergic circuitry and corresponding anhedonic symptoms. These results support the notion that brain stimulation treatments may modulate neurocircuits involved in the maintenance of the addiction cycle and are a promising therapeutic option that deserves further exploration in sham-controlled trials.

### **Baclofen is more efficacious than oral naltrexone in individuals with severe alcohol dependence for maintaining abstinence – a preliminary report**

S. Karthik<sup>1</sup>\*, B. holla<sup>1</sup>, R.D. Bharath<sup>2</sup>, G. venkatasubramanian<sup>1</sup>, V. benegal<sup>1</sup>

<sup>1</sup> National Institute of mental Health and Neuro Sciences, Psychiatry, Bangalore, Karnataka, India; <sup>2</sup> National Institute of mental Health and Neuro Sciences, Neuro Imaging and Interventional Radiology, Bangalore- Karnataka, India

\* Corresponding author.

*Introduction.*– Anti-craving agents form the backbone of pharmacological treatment for alcohol use disorders without which majority of patients relapse. Evidence about comparative efficacy of different anti-craving agents is limited. No study has compared the effects of baclofen and naltrexone on craving reduction and maintenance of abstinence among people with severe alcohol dependence.

*Objective.*– The present study aimed at comparing the effect of baclofen v/s oral naltrexone treatment on reduction of craving and period of abstinence.

*Methods.*– The study was conducted on 32 treatment-seeking right-handed in-patients with severe alcohol dependence (average SADQ=29.53 ± 7.14) who were recruited for the study after informed consent. Following detoxification and drug-washout, craving scores were measured using Penn alcohol craving scale (baseline PACS=23.84 ± 4.01), which was repeated after 15 days of treatment (post treatment PACS=4.48 ± 2.46) with either baclofen or naltrexone (baclofen-60-80 mg/d, n=16; naltrexone-50-100 mg/d, n=16) all patients were prospectively followed-up till their first alcohol lapse.

*Results.*– There was significant level of reduction in craving scores in those who completed study, calculated using RMANOVA. The mean difference was 19.023, which was Significant at P=0.05, irrespective of the medication received. The survival function analysis with Kaplan – Meier (KM) curves indicated significantly higher (log-rank P=.035) median survival with Baclofen (67 days) than Naltrexone (37 days). Suggesting longer period of abstinence in people treated with baclofen.

*Conclusion.*– These findings indicate that craving scores reduced following treatment with any drug whereas baclofen was more efficacious as compared to naltrexone in maintaining abstinence in the population studied.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Investigating the relationship between family affective atmosphere and self-differentiation with addiction tendency in addicts referring to addiction treatment center**

S.H. Sayed Alitabar<sup>1</sup>\*, A. Sarvestani<sup>2</sup>, M. Manoochehri<sup>3</sup>, Z. Zadhanan<sup>4</sup>

<sup>1</sup> Ph. D, Career Counseling- Department of Psychology- University of Isfahan- Isfahan, Psychology, Babolsar, Iran; <sup>2</sup> Shahid Beheshti University, Psychology, Tehran, Iran; <sup>3</sup> Islamic Azad University of Roodehen, Psychology, Tehran, Iran; <sup>4</sup> Islamic Azad University of Ahvaz, Psychology, Ahvaz, Iran

\* Corresponding author.

*Introduction.*– Family factors play an important role in the tendency toward psychological and sociological traumas such as addiction. The purpose of this study was to determine the relationship between family affective atmosphere and self-differentiation with addiction tendency in addicts referring to addiction treatment centers.

*Materials and methods.*– The present study was descriptive and correlational. 220 addicts who were referred to addiction treatment centers in Sari city were selected by random sampling and responded to addiction, family affective and self-differentiation questionnaires. The collected data were analyzed by Pearson correlation coefficient and regression analysis.

*Results.*– The results of Pearson correlation coefficient showed that there is a significant relationship between the family's emotional atmosphere and the tendency to addiction. Also, the results showed that there was a significant relationship between their differentiation bar and its components: interconnection with others, emotional responsiveness, my position And there is anxiety with the desire for addiction. The results of regression analysis also showed that family emotional atmosphere and self-differentiation variables significantly predict addiction (P<0.001).

*Conclusion.*– The study showed that the family's emotional atmosphere and self-differentiation predict the tendency to addiction. Therapists need to pay more attention to these categories in the treatment of substance abuse.

*Keywords:* Family affective atmosphere; Self-differentiation; Addiction tendency

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Original anticonvulsant galodif (meta-chloro-benzhydryl urea) is GABA-modulating in treating patients with compulsive habits**

T. Shushpanova<sup>1</sup>\*, N. Bokhan<sup>2</sup>, A. Mandel<sup>2</sup>, T. Novozheeva<sup>3</sup>

<sup>1</sup> Mental Health Research Institute- Tomsk National Research Medical Center, Russian Academy of Science, Department of Psychoneuroimmunology and Neurobiology, Tomsk, Russia; <sup>2</sup> Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Science, Addictive States Department, Tomsk, Russia; <sup>3</sup> Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Science, Department of Psychoneuroimmunology and Neurobiology, Tomsk, Russia

\* Corresponding author.

*Background.*– GABA-stimulating effect of substances, enhancing braking processes in the brain, is effective for stopping the symptoms of anxiety and depression, reducing irritability and aggressiveness, reducing alcohol withdrawal symptoms and compulsive attraction to alcohol.

*Methods.*– Modeling of the interactions of Galodif with GABA receptors - docking was performed in MolegroVirtual Docker. The clinical study included 68 male alcoholics and 23 healthy volunteers. Galodif was administrated at dose 300 mg/day to alcoholic patients with diagnosis according to ICD-10: F10.232 and F10.302. during the ongoing course of treatment 21 days. Cortisol, DHEA and DHEA-S were determined with ELISA (immunosorbent assay).

*Results.*– Molecular docking showed that the anticonvulsant Galodif is complementary to the benzodiazepine binding site and interacts with key amino acids on the alpha1-gamma2 interface: Y159, T206 (hydrogen bonds); F77, F99 (pi-pi interaction). Galodif showed a positive trend in the reduction of craving for ethanol in alcoholic

patients. The increase in the index of the ratio of Cortisol/DHEA in alcoholics with abstinence is significantly reduced against the background of the course therapy. An increase in the level of DHEA on the background of Galodif therapy testifies to the stimulation of DHEA synthesis. DHEA and DHEA-S are able to protect neurons from glucocorticoid-induced neurotoxicity.

**Conclusion.**– The ratio of Cortisol/DHEA is of particular importance, since the antiglucocorticoid effects of DHEA lead to a reduction in anxiety and depression in humans. An increase in DHEA levels can increase overall GABAergic conductivity and is a positive predictive response to Galodif anticonvulsant therapy [1,2].

### **Predicting re-offending from self-reported criminal behavior after residential drug use treatment: A prospective data linkage study**

B. Thylstrup\*, K. Rømer Thomsen, M. Hesse

Department of Psychology and Behavioural Sciences, Centre for Alcohol and Drug Research, Aarhus, Denmark

\* Corresponding author.

Criminal involvement is common among people with drug use disorders. This study assessed the predictive validity of self-reported offending items in a consecutive cohort of 5011 patients enrolled in residential rehabilitation 2000–2010 who had been administered the European Addiction Severity Index. Patients were tracked through national criminal justice registers and the central person register until any offending, death, or by December 2012, and competing risks regression was used to assess predictors of offending, using items from the EuropASI legal problems area.

Offending was positively associated with main income from criminal activities, awaiting charges, trial or sentencing, perceived seriousness of legal problems ( $P < .01$ ), but unrelated to days of offending or perceived importance of counselling about legal problems. Self-reported legal problems can identify patients with need for targeted interventions to prevent post-treatment offending. Given the cost and consequences of crime, such counselling should be a priority in treatment services.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

**Background.**– Many of our biological functions follow circadian rhythms like sleep, body temperature, mood regulation, etc. These circadian rhythms are under the control of an internal clock ruled

by clock genes and of external time indicators like light/darkness, meal/fasting, or the use of psychoactive substances.

**Objective.**– To test if polymorphisms in core clock genes were associated with specific patterns of stimulants or sedatives use in patients with polysubstance use disorders, thus exposed to all types of substances.

**Methods.**– Patients with polysubstance use disorders were assessed for age at onset and lifetime dependence for stimulants (tobacco, cocaine) and sedatives (alcohol, opiates, and benzodiazepines). Genotyping: Illumina PsychArrays were used to characterize 560 snps located in 18 core clock genes (ARNTL; ARNTL2; BHLHE40; BHLHE41; CLOCK; CRY1; CRY2; CSNK1D; CSNK1E; DBP; GSK3B; NR1D1; PER1; PER2; PER3; PPARGC1A; RORA; TIMELESS). Statistical analysis: Quality check of the genetic data included MAF, HWE, SNP/individual missingness. Gene-based tests were performed with plink software. To further correct for ethnic diversity within Caucasian subjects, we used the first two dimensions of Multi-Dimensional Scaling plots of the sample as covariates. At the end, the analysis was performed in 329 subjects and 173 snps. Significance threshold was chosen at  $P = 3.10^{-4}$ .

**Results.**– Polymorphisms in RORA, the gene encoding for the RAR-related orphan receptor a (RORA), a nuclear hormone receptor required for the consolidation of daily locomotor activity, were found statistically associated with older age at onset of opiates and alcohol use (empirical  $P$  value  $P = 1.10^{-4}$ , and  $P = 3.10^{-4}$ ).

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

## **Training in Psychiatry**

PW0805

### **The medical student will see you now: How can we improve the educational value of the psychiatry ward round?**

E. Abrol

University College London UCL, Division of Psychiatry, London, United Kingdom

**Introduction.**– In the UK, the ward round is a cornerstone of day-to-day clinical practice, and an excellent learning opportunity for medical students. Uniquely in psychiatry, a large proportion of the apprenticeship is occupied by the ward round, lasting up to one hour per patient. If not properly engaged, students risk losing interest, engagement and enthusiasm.

**Objectives.**– The present study aimed to qualitatively analyses third year medical student experience, views and perceptions of the educational value of the psychiatry ward round.

**Methods.**– A qualitative semi-structured focus group study of a convenience sample of six third year medical students was performed. The focus group was audio-recorded (Olympus® WS-852 Dictaphone), transcribed, and coded into relevant themes.

**Results.**– The average number of ward rounds attended by students ( $n = 6$ ) was 2.8 (range: 0–4). Key themes were subdivided into: (a) features of the session: “efficient use of our time,” “relevance to our learning,” “prior knowledge and understanding,” (b) engagement between doctors and students: “interaction amongst doctors and students,” “development of professional values,” and (c) what is taken away from the session: “yield of knowledge” and “long term learning.”

**Conclusions.**– Learners overwhelmingly craved ‘time-efficiency’ from their ward rounds. Whilst they appreciated that observing professional behaviours and how to “be a doctor” was essential, learners felt this could be observed from one session, and further

sessions should focus on interaction and engagement. A ward round worksheet was designed in order to consolidate their learning and complete Kolb's learning cycle.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### **Skills-training to improve care for psychiatric and physiological comorbidities: An interprofessional approach to mind and body care**

C. Attoe

South London and Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom

\* Corresponding author.

*Introduction.*– Providing better care for psychiatric and physiological comorbidities is a significant priority for healthcare systems, to address health inequalities, improve patient experience, and tackle mounting financial costs (Naylor et al., 2016). Health and education systems have been called to action internationally to better equip healthcare workforce with the skills to provide this care, with a focus on providing effective multi-disciplinary, interprofessional training for clinicians (Frenk et al., 2010). However, implementing interprofessional skills training for clinicians from mental and physical healthcare settings has proved challenging and requires further attention.

*Aim.*– To evaluate the effectiveness of skills training for interprofessional groups of clinicians from mental and physical healthcare settings.

*Methods.*– Participants in the skills teaching ( $n=131$ ) were doctors, nurses, and allied health professionals from primary care, community, and hospital settings working with patients with psychiatric and physiological needs. Participants completed self-report questionnaires assessing confidence and knowledge in meeting psychiatric and physiological health needs, as well as the Readiness for Interprofessional Learning Scale (RIPLS) on attitudes towards interprofessional working. Participants also completed post-course surveys with open questions to collect qualitative data.

*Results.*– There were statistically significant increases in confidence and knowledge following training, as well as in attitudes towards interprofessional working. Thematic analyses of qualitative data highlighted valuable aspects of the training relating to interprofessional working, group learning, and skills-focused training.

*Conclusions.*– Skills training can improve clinicians ability to address psychiatric and physiological health needs, while training interprofessionally in this area brings added benefits.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

PW0807

### **Simulation training to improve care for psychiatric and physiological comorbidities: A review of the evidence**

C. Attoe\*, S. Cross

South London and Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom

\* Corresponding author.

*Introduction.*– The prevalence of psychiatric and physiological comorbidities continues to increase, along with health inequalities experienced by patients and the associated financial costs to healthcare systems (Naylor et al., 2016). Worldwide, contempo-

rary education and training methods must be devised to support healthcare professionals and services to better address this field of health (Frenk et al., 2010). Simulation training in psychiatry has been posited as part of the solution to this problem, and is receiving increased support in the literature (Attoe et al., 2016). However, existing evidence is yet to be collated and reviewed in a coherent manner

*Aim.*– To comprehensively review the impact of simulation training for psychiatric and physiological comorbidities on participants and their clinical practice.

*Methods.*– Existing simulation training courses addressing psychiatric and physiological comorbidities across various healthcare settings in South London were identified ( $n=5$ ). Courses generally focused on patient journeys through mental and physical healthcare settings, using simulated scenarios and patients followed by debriefing and reflection. Evaluations of these training courses, both published and unpublished, were collected and screened for suitability for inclusion in this review. Subsequent data was collated and interpreted.

*Results.*– Analyses demonstrated quantitative improvements to the knowledge, confidence, and attitudes in working with psychiatric and physiological comorbidities. Qualitative findings demonstrated skills development in key areas, such as teamwork, reflective practice, communication, and interprofessional collaboration.

*Conclusions.*– Simulation training can be an effective contemporary educational tool for clinicians working with psychiatric and physiological comorbidities, and should be considered for wider use across healthcare systems.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0808

### **Integrating neuroscience into psychiatric training in the United Kingdom: the Royal College of Psychiatrists Gatsby/Wellcome neuroscience project**

G. Cuttle<sup>1\*</sup>, M.J. Travis<sup>2</sup>, W. Burn<sup>1</sup>

<sup>1</sup> Royal College of Psychiatrists, Gatsby/Wellcome Neuroscience Project, Professional Standards, London, United Kingdom; <sup>2</sup> Western Psychiatric Institute and Clinic WPIIC, Department of Psychiatry, Pittsburgh, PA, USA

\* Corresponding author.

*Introduction and objectives.*– The Royal College of Psychiatrists has launched a 2-year initiative to integrate a modern neuroscience perspective into psychiatrists' clinical work: the Gatsby/Wellcome Neuroscience Project. This involves a full review of the Core Curriculum and examination syllabus for trainee psychiatrists.

*Methods and results.*– UK-wide consultation (face-to-face, email, social media) with over 1000 key stakeholders showed:

Overwhelming support for the integration of more, and more modern, neuroscience into psychiatric training

An unmet need for support and training opportunities for educators teaching neuroscience to psychiatric trainees

Strategies being developed to proactively facilitate and support neuroscience teaching include:

Regional training events – 'Inspiring Excellence in Neuroscience' – for educators in psychiatry, with expert teachers of neuroscience from universities/research institutions, to promote exchange of knowledge and skills

Regional 'Neuroscience in Psychiatry Networks', a forum for interaction and collaboration between neuroscientists and clinicians to enable the sharing of best practice in neuroscience teaching

An annual Neuroscience Spring Conference, bringing together leading scientists, academics and clinicians to discuss the role of neuroscience in contemporary psychiatry, to strengthen networks of scientific and clinical professionals and to forge new links. The development of teaching materials to support the delivery of neuroscience.

**Conclusions.**– Implementation of these strategies is underpinned by close collaboration with the British Neuroscience Association and colleagues working in psychiatric training in the USA, including the National Neuroscience Curriculum Initiative. Through this project, UK trainees will be ‘neuroscientifically literate’ and better prepared for the advances that will be made during their working lives, leading to better patient care.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Proactivity enhancement in schizophrenia: An ecological training and smartphone application**

D. Fabre<sup>1\*</sup>, G. Chabridon<sup>2</sup>, D. Guyot<sup>3</sup>, J.M. Dorey<sup>2</sup>

<sup>1</sup> Inserm U1028, CNRS UMR5292, CRNL, PsyR2, Lyon, France; <sup>2</sup> CH le Vinatier, Pole EST, Lyon, France; <sup>3</sup> Université de Lyon, Institut de Psychologie, Lyon, France

\* Corresponding author.

Trouble to generate goal directed actions is one hallmark behavioural deficit in schizophrenia (Frith et al., 1991). This is related to a deficit of the cognitive control mechanism, split into a reactive and a proactive mode (Braver et al., 2012). The first one is triggered by contextual stimuli (bottom-up), and products a goal reactivation to adapt the current behaviour. Contrary, the proactive mode is triggered by goal-relevant information (top-down). It is well known that schizophrenia deals with a proactivity deficit, thought to depend on the lateral prefrontal cortex (Lesh et al., 2011), which can be trained and improved (Edward et al., 2010). In keeping with these results, we designed a software training program for a more ecological application of proactivity improvement. Hence, participants with schizophrenia are trained to imagine themselves achieving a daily life goal, with contextual cue and strategy to prepare them (proactivity reinforcement). They then answer whether a target is useful or not to complete the goal (Fabre et al., 2016). Pre and post training outcomes have been collected in a double blind protocol.

First results show a session (pre-post training) and a group training (active-inactive) effect: an improvement of proactivity for the active group is observed. Hence, part of Edward’s et al., results are replicated. Furthermore, this work leads to the current development of a smartphone application for a largest use. The final benefit for patients is to use the right training strategy at the right time in their personal environment.

PW0810

### **Descriptive analysis of referrals to psychiatry performed from primary care in a mental health center in Madrid**

F.J. Gómez Beteta<sup>\*</sup>, J. Ibañez Vizoso, J. Peman Rodriguez, M. Villanueva Gallego, I. Alberdi Paramo, G. montero hernandez, C. Carrascosa Carrascosa

Hospital Clinico San Carlos, Instituto de Psiquiatria y Salud Mental, Madrid, Spain

\* Corresponding author.

**Introduction and objectives.**– The role of the Primary Care Physician (MAP) in the management of psychiatric pathology is very relevant, with the most prevalent psychiatric diseases being treated and followed for the most part by Primary Care. An analysis of the referrals to other Mental Health specialists that occur after the first psychiatric consultation is presented.

To highlight the importance of adequate training in the screening of psychiatric illness in Primary Care for the efficient management of resources.

**Material and methods.**– Cross-sectional descriptive study in which the Inter-Consultation Parties (PIC) were collected from 9 Health Centers attached to the MSM of Las Águilas of the Latin District (Madrid) between October 2015 and March 2017 with different demographic, clinical and administrative data. Total sample of 170 PICs.

**Results.**– Among the patients evaluated in a first interview by a psychiatrist:

- 38.2% required specialized follow-up by a psychiatrist;
- 52.3% did not present any specialized follow-up pathology;
- 23% required psychotherapeutic treatment;
- 19.4% had an anxious symptomatology subsidiary of treatment through relaxation therapy;
- 5% were referred to specific centers to help drug addicts.

**Discussion and conclusions.**– A high percentage of patients evaluated by psychiatry are referred to other specialists (psychologist, nurse). Correct training in primary care on the screening of mental pathology and the different competencies of qualified mental health personnel would improve the management of resources and reduce waiting times in Public Health.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **New ways to learn psychopharmacology: Side effects polygomis**

C. Gómez Sánchez-Lafuente<sup>1</sup>, R. Reina Gonzalez<sup>2</sup>

<sup>1</sup> Hospital Universitario Virgen de la Victoria, Psychiatry, Málaga, Spain; <sup>2</sup> Hospital Universitario Virgen de la Victoria, General Medicine, Málaga, Spain

\* Corresponding author.

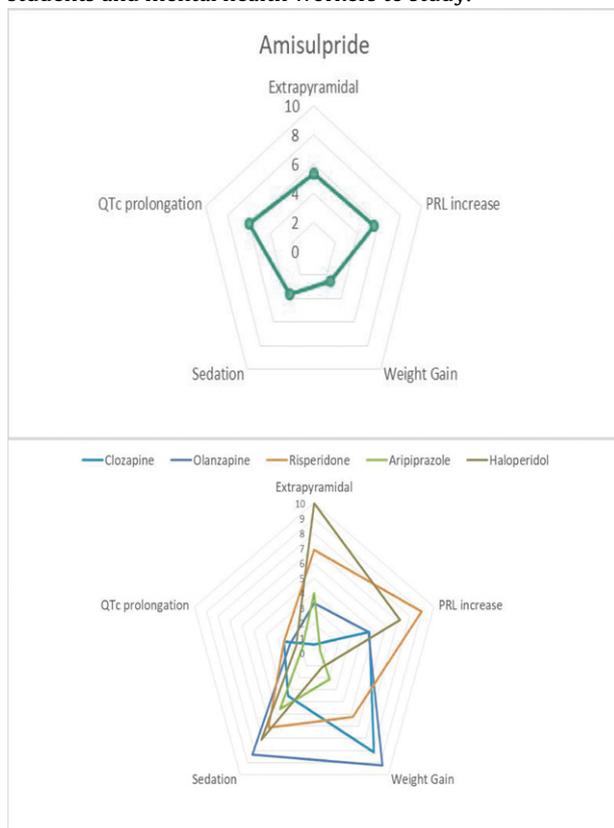

**Introduction.**– Psychopharmacology is a difficult matter to be learned for mental health workers because there are so many drugs and their mechanism of action, efficacy, usage and side effects are wide.

**Objectives.**– We are currently developing this graphics, formally called “Polygomis” because the polygon shape to help students understand and apply basic science concepts,

**Methods.**– We made a systematic computerized literature search of clinical studies using MEDLINE, The Cochrane Library and Trip looking for papers with comparing data about antipsychotics side effects. The metanalysis from Leucht et al [4] showed the largest

amount of data computerised. We took side effects Odds Ratio and transform it in Microsoft Excel into a decimal base table counting from 1 to 10, where one was the lowest effect size and ten the most. That table was used to make a flexible pentagon-shaped graphics. *Results.*– The results are shown in figures. Figure 1 is the amisulpiride polygomi and Figure 2 is a comparison between 5 polygomis: risperidone, aripiprazole, olanzapine, clozapine and haloperidol. Each vertex of the pentagon is one side effect (Prolactin increase, extrapyramidal side-effect, weight gain, QTc prolongation and sedation).

*Conclusion.*– We consider this way to learn antipsychotics visual and easy to get an idea of the side effects. Polygomis can be shown individually or taking specifics side effects or drugs. Any graphic could be build, like one with two or more antipsychotics to compare them. Polygomis make an issue such as antipsychotics easier for students and mental health workers to study.

### How competent is our competency training? Evaluation of the RANZCP training program

K. Jenkins

The Royal Australian and New Zealand College of Psychiatrists, OPCEO, Melbourne, Australia

*Introduction.*– In December 2012, the Royal Australian and New Zealand College of Psychiatrists (RANZCP) introduced the Competency Based Fellowship Program.

The RANZCP undertook an evaluation of Stages 1 and 2 in November 2015, and an initial evaluation of Stage 3 in 2017.

*Objectives.*– The aim was to gather feedback on key areas such as Entrustable Professional Activities (EPAs), Workplace-based

Assessments (WBAs), assessments, examinations, regulations, supervision arrangements, and the overall impact of the new program.

*Methods.*– Links to online surveys were sent out to all active trainees and accredited supervisors in November 2015, and survey details were communicated through newsletters, Psyche and via Directors of Training. The surveys were closed at the end of December 2015. *Results.*– 39% of trainees and 38% of supervisors responded to the surveys. This presentation provides a summary of the results from the trainee and supervisor surveys, a comparison of the responses, and key findings.

*Conclusions.*– Overall, the results from trainees and supervisors were comparable with minimal differences across most survey items. Trainees and supervisors did, however, differ on the time taken to prepare for and complete the WBA activities, on supervision arrangements, and perceptions of supervision.

Based on the survey responses, the RANZCP Education Committee developed a series of recommendations for action in 2016/2017, including improved communication from RANZCP, continued prioritisation of trainee welfare, increased clarity regarding assessment requirements and standards, and consideration of development of an online e-portfolio. Indicative data on Stage 3 will investigate how these recommendations improved or changed trainees' perspectives.

*Disclosure of interest.*– The author has not supplied a conflict of interest statement.

### Workforce migration in the Scandinavian countries – do trainees still want to leave from what is perceived by everyone else as the paradise?

K. Jesper Noergaard<sup>1\*</sup>, T. Mogren<sup>2</sup>, M. Asztalos<sup>3</sup>, M. Pinto da Costa<sup>4</sup>

<sup>1</sup> Aarhus University Hospital, Department of Affective Disorders,

Risskov, Denmark; <sup>2</sup> General Psychiatry, Säter's sjukhus,

Allmänpsykiatriska kliniken Falun/Säter, Säter, Sweden; <sup>3</sup> Aalborg

University Hospital, Department of Psychiatry, Aalborg, Denmark;

<sup>4</sup> University of Porto, Institute of Biomedical Sciences Abel Salazar, Porto, Portugal

\* Corresponding author.

*Introduction.*– Workforce migration in high-income countries remains poorly understood and under researched. It is unclear if psychiatric trainees earning higher salaries would still be motivated to move abroad and what opportunities could pull them out.

*Objectives.*– To assess opinions and experiences of workforce migration in the Scandinavian countries (Denmark, Finland and Sweden).

*Method.*– Data collected between 2013–2014 through a cross-sectional study (the EFPT Brain Drain study) has been analysed in the Scandinavian countries (Denmark, Finland and Sweden).

*Results.*– In the Scandinavian countries trainees earn > 3000 € per month. Among the Swedish trainees (n=88) 36% had another nationality which indicates a frequent migratory background, as it is one of the main host countries in Europe. In Finland, all participants (n=25) had Finnish nationality and in Denmark 12% of 33 participants had another nationality. In Sweden, Finland and Denmark the main reasons for trainees to emigrate were academic, work and personal.

*Conclusions.*– Scandinavia receives plenty of “brain gain” with the immigration of psychiatric trainees from abroad. Still, there are trainees that leave these host countries for short and long term, and the main reasons expressed are academic, work-related or personal.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Psychiatry trainees go on exchange. Trends from the EFPT exchange programme**

A. Kjellstenius<sup>1\*</sup>, A. Lengvenytė<sup>2</sup>

<sup>1</sup> Queen Silvia Children's hospital, Sahlgrenska, Child and Adolescent Psychiatry, Göteborg, Sweden; <sup>2</sup> Vilnius University, Faculty of Medicine, Clinic of Psychiatry, Vilnius, Lithuania

\* Corresponding author.

*Introduction.*– Intercultural competence has become a vital skill for a successful psychiatrist working with patients from various backgrounds and participating in international collaborations. To address it, European Federation of Psychiatric Trainees (EFPT) started an exchange programme led by trainees in 2011. It consists of 2-6 weeks observerships in various European healthcare facilities and is completely free of charge.

*Objectives.*– To overview the trends from the first five years of exchange programme.

*Methods.*– After exchange trainees were asked to fill an online questionnaire consisting of sociodemographic and exchange-related questions.

*Results.*– 140 (30 male and 110 female) out of 183 confirmed exchange participants filled the questionnaire after their exchange. Average age was 29.3 years, average year in training – 3.4. Most common destination was United Kingdom ( $n=32$ ), country of origin – Portugal ( $n=22$ ). Respondents with previous exchange experience were significantly younger (28.22 years, SD 2.22 vs. 29.91, SD 3.58;  $P=0.03$ ) and in earlier stage of training (3.06, SD 1.46 year vs. 3.64, SD 1.35;  $P=0.02$ ). 90% ( $n=126$ ) of trainees said that they were very satisfied with the experience, 73% ( $n=102$ ) rated it as very useful for their practice and 94% ( $n=129$ ) would recommend it to their colleagues. Language level of the recipient country was not correlated with exchange satisfaction, and only 9 trainees (6.5%) reported language barrier as an issue in communication with the staff.

*Conclusions.*– Most trainees rated the exchange experience very positively. The EFPT Exchange Programme is an accessible way to gain international experience and may help to increase intercultural competence.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0815

### **A review of constructs and evidence-based interventional methods to enhance resilience in medical education**

C. Lamschtein<sup>1\*</sup>, P. Gallagher<sup>2</sup>, T.J. Chaffer<sup>3</sup>

<sup>1</sup> Dalhousie, Psychiatry, Rothesay, Canada; <sup>2</sup> University of New Brunswick, Biology, Fredericton, Canada; <sup>3</sup> Acadia university, Science, Wolfville, Canada

\* Corresponding author.

*Background.*– Multiple influences contribute to medical students' well-being. Resilience is an emotional competence and can be considered as a behavior that can be acquired during training

*Study Goals:*

– 1-Synthesize resilience paradigms relevant to training in medicine;

– 2-Identify current evidence regarding the effectiveness of resilience promoting interventions.

*Methods.*– A literature search was conducted through 4 online databases Pubmed, EMBASE, PsycINFO, and ERIC.

*Inclusion criteria:*

– Published in English within the last 10 years, studies focused on proposed resilience promoting intervention techniques or aimed at clarifying resilience paradigms relevant to training in medicine, only original research papers examining resilience promoting resilience techniques and studied population must be medical students.

*Study selection:*

– Article titles and abstracts were screened for relevance according to the search criteria and duplicates were removed.

*Results.*– Twenty-two of the articles were original studies investigating the effectiveness of resilience promoting interventions. The main intervention types were mindfulness, cognitive behavioral techniques, resilience workshops, reflection and curricular reform. A few resilience-promoting programs combine a variety of intervention techniques. Five resilience paradigms relevant to training in medicine were identified.

*Discussion.*– Relatively few studies examined the effectiveness and long-term implications of resilience interventions.

– Mindfulness based programs: Most studied intervention technique in medical education

– Results from the mindfulness based interventions are promising: Most studies found significant improvements in resilience related concepts such as self compassion, self-awareness, empathy, and self-efficacy post intervention.

– Paradigms indicate that resilience is a complex interplay of factors and concepts

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Violence against psychiatric trainees in Europe: Data from surveys in Spain and Turkey**

V. Pereira Sánchez<sup>1\*</sup>, G. Erzin<sup>2</sup>, A. Gürcan<sup>2</sup>, C. Gomez Sanchez-Lafuente<sup>3</sup>, H. Saiz<sup>4</sup>, M. Asztalos<sup>5</sup>, T. Mogren<sup>6</sup>, A. Szczegieliński<sup>7</sup>

<sup>1</sup> Clinica Universidad de Navarra, Psychiatry and Medical Psychology, Pamplona, Spain; <sup>2</sup> European Federation of Psychiatric Trainees EFPT, EFPT Research Group, Ankara, Turkey; <sup>3</sup> European Federation of Psychiatric Trainees EFPT, EFPT Research Group, Malaga, Spain;

<sup>4</sup> European Federation of Psychiatric Trainees EFPT, EFPT Research Group, Pamplona, Spain; <sup>5</sup> European Federation of Psychiatric Trainees EFPT, EFPT Research Group, Budapest, Hungary; <sup>6</sup> European Federation of Psychiatric Trainees EFPT, EFPT Research Group, Säter, Sweden; <sup>7</sup> European Federation of Psychiatric Trainees EFPT, EFPT Research Group, Katowice, Poland

\* Corresponding author.

*Introduction.*– Psychiatric trainees sometimes face violence while working with patients, risking their safety and the quality of their clinical care. Aggressions against medical staff have been reported, but have not been thoughtfully studied among psychiatric trainees in Europe.

*Objective.*– To estimate the prevalence and consequences of physical aggressions from patients against psychiatric trainees in different European countries, as part of the Violence Against Psychiatric Trainees (VAPT) project of the European Federation of Psychiatric Trainees (EFPT).

*Methods.*– A survey was conducted among psychiatric trainees in Spain and Turkey, combining quantitative and qualitative ques-

tions: prevalence of physical aggressions, factors associated and consequences for the victims and questions on institutional support. The open questionnaire was spread via National Trainees Associations. The results were analyzed with SPSS.

**Results.**– 265 trainees responded (Spain: 63; Turkey: 202). 74.5% of the participants suffered violence during their training: 23.45% were assaulted once and 40.8% 2–5 times. 39.6% of them were assaulted during their first year of training, and 42.3% did not feel the support of their institution. 43% of the participants felt fear and anxiety due to the violence. Turkish trainees suffered violence more frequently than the Spanish ( $P < 0.01$ ) and received less support ( $P < 0.01$ ), although reporting an institutional protocol in case of violence ( $P < 0.01$ ).

**Conclusion.**– Psychiatric trainees in Spain and Turkey report a relevant prevalence of physical aggressions against them and a deficiency in the policies to manage it. These results indicate that further studies are needed to address this issue and to promote national and international policies.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0817

### **Physician associates: The future of European healthcare? Evaluation of a novel clinical placement in a new profession**

D. Rigby\*, E. Lumley, P. Carter, M. Bhat  
North East London NHS Foundation Trust, Medical Education,  
Rainham, United Kingdom

\* Corresponding author.

**Introduction.**– Physician Associates (PAs) are a new health professional in Europe who assist doctors in the diagnosis and management of patients. 260 were estimated to be working in the UK in 2016 but 2000 are expected by 2020. PA numbers are also increasing across Europe, including Germany and the Netherlands. **Objectives.**– Our healthcare trust developed a new 5 week clinical placement for 20 PA students in psychiatry. Our objective was to provide a high quality training experience, to evaluate feedback from students and supervisors, and to use this feedback to improve future placements and assess the students' clinical competencies. **Methods.**– The students were taught in a variety of methods including use of simulated patients, a hearing voices simulator, reflective practice and lecture based teaching. Students were allocated supervisors and a clinical placement. Feedback was gathered on each of these components from the students and the supervisors.

**Results.**– The students gave more positive feedback on simulation based training compared to lecture based teaching. They wanted shorter lectures and more use of simulated patients. The supervisors reported that the students showed a high level of interest and good attitudes but variable clinical knowledge and skills. The results suggest that some students would need a high level of supervision in future employment.

**Conclusions.**– Evaluating feedback from supervisors suggests that PAs require further clinical training to meet educational objectives. Considering the increased use of the PA, this could have important implications for European healthcare. Feedback from students has guided future improvements to the placement including increased use of simulation training.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0818

### **How to develop an academic career in psychiatry? Results from the world psychiatric association section on education in psychiatry international survey**

M. Luciano, G. Sampogna\*, V. Del Vecchio, C. De Rosa, G. Vincenzo, B. Poci, G. Borriello, M. Savorani, A. Fiorillo  
University of Naples SUN, Department of Psychiatry, Naples, Italy

\* Corresponding author.

**Introduction.**– Choosing an academic career in psychiatry is challenging, since it is a demanding and time-consuming career that requires a balance between personal and professional life.

**Objectives.**– To evaluate the current status of training on academic skills worldwide, and to identify gaps and unmet needs.

**Methods.**– In the period January–December 2016, the Section on Education in Psychiatry of the World Psychiatric Association has promoted an on-line survey on the status of training in academic psychiatry. An ad-hoc questionnaire consisting of 19 multiple choice or open-ended items was administered. The items are divided in 2 sections: (a) description of the training programmes; (b) personal experience in academic career.

**Results.**– 620 participants completed the questionnaire; they were mainly female (60%), 31–40 years old (63.5%) and 40% of them work in European countries (40%). The majority of participants (60%) reported not to have a dedicated mentor for academic skills. As regards, 70% of participants reported that their received training on academic skills was inadequate, with a poor level of personal satisfaction. As regards personal experiences on academic skills, more than 70% of respondents reported to have performed lessons and/or presentations during the training course to medical students or at national or international congresses or scientific meetings.

**Conclusion.**– The quality of training on academic career skills is not satisfying: there is the need to counterbalance this trend, if we want to train future academicians in psychiatry.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0819

### **Balint group training and physician empathy – systematic review**

G. Santos<sup>1</sup>, M. Alves<sup>1</sup>, A. Moreira<sup>2</sup>

<sup>1</sup> Hospital Magalhães Lemos, Psiquiatria, Porto, Portugal; <sup>2</sup> Hospital Magalhães Lemos, Psiquiatria Comunitária Porto, Porto, Portugal

\* Corresponding author.

Physician empathy is a complex concept involving cognitive and affective domains. Given the general recognition of its importance in the medical relationship, several interventions have been proposed in order to improve empathy among medical students and doctors in training. The Balint Group (BG) is one of the earliest methods of clinical supervision, used in Psychiatry and General Medicine, yet there is still little knowledge about its potential relationship with empathy.

The aim of this systematic review was to access the effectiveness of BG training to increase empathy in physicians.

We systematically searched EMBASE, PsycINFO, Web of Science and MEDLINE databases with the following meSH terms: "EMPATHY AND ("BALINT GROUP)". Only articles written in English or Spanish were included. We excluded studies with no specific health intervention and no outcomes or outputs. Bibliographical references to the relevant articles were also analyzed. Risk of bias assessments was carried out independently by all authors. Meta-analysis was not possible because of the heterogeneity of data.

Preliminary findings suggest that overall BG training might have a positive, albeit small, impact on empathy. BG training has shown to prevent burnout syndrome and to enable physicians to better handle difficult clinical situations, in which the core conditions of empathy are at stake. Still, the association between BG training and physician empathy remains to be fully understood. There is limited research on outcomes of BG training, and a huge lack of randomized controlled studies with valid measures of empathy and long-term efficacy assessments.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Where sits Poland in Europe in the middle of the current workforce migration trends? Findings from the EFPT brain drain study

A.R. Szczepielniak<sup>1,2\*</sup>, D. Frydecka<sup>3</sup>, M. Pinto da Costa<sup>4,5,6</sup>

<sup>1</sup> Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland; <sup>2</sup> Multidisciplinary District Hospital, General Psychiatry Unit, Tarnowskie Góry, Poland;

<sup>3</sup> Wrocław Medical University, Department of Psychiatry, Wrocław, Poland; <sup>4</sup> Queen Mary University of London, Unit for Social and Community Psychiatry WHO Collaborating Centre for Mental Health Services Development, London, United Kingdom; <sup>5</sup> Hospital de Magalhães Lemos, Psychiatry Unit, Porto, Portugal; <sup>6</sup> University of Porto, Institute of Biomedical Sciences Abel Salazar ICBAS, Porto, Portugal

\* Corresponding author.

*Introduction.*– Brain drain among health care professionals is a known issue threatening the quality of healthcare in Central and Eastern Europe, with many doctors leaving. Poland is no different, yet little is known about the extent of this phenomenon.

*Aim.*– The main aim of this work has been to assess the experiences of short-term mobility and long term migration among psychiatric trainees in Poland.

*Methods.*– Data from Poland collected in 2013–2014 through a European cross-sectional study (the EFPT Brain Drain study) has been analysed.

*Results.*– In Poland, 75 psychiatric trainees were approached from the three main teaching institutions and those that attended a nationwide conference in the country. From these, 41.3% ( $n=31$ ) psychiatric trainees (27 adult psychiatric and 3 child and adolescent psychiatric trainees) responded to the survey. 32% ( $n=10$ ) of psychiatric trainees in Poland had a short-mobility experience. These experiences changed the attitude towards migration for the majority of these Polish respondents (90%), in favour of migration for most of them (80%). The reasons for these short-mobility experiences were mostly for work and education purposes, enabling these junior trainees with the possibility to travel. In regards to long-term migration, 84% of the psychiatric trainees in Poland have “ever” considered leaving the country, of which 45% had taken practical steps towards migration, planning to move abroad to a different country.

*Conclusions.*– According to the EFPT Brain Drain study, across Europe 13.3% of psychiatric trainees are already immigrants. Of which, many are and may continue being of Polish nationality as these findings suggest.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0821

### Are junior doctors getting adequate induction training about mental health legislation?

F. Wood<sup>\*</sup>, I. Adebekun

Oxleas NHS Foundation Trust, Bexleyheath Centre, Kent, United Kingdom

\* Corresponding author.

*Introduction.*– Many junior doctors will complete an attachment in psychiatry during their training, even if not specialising in this area. Knowledge of relevant parts of mental health legislation is low among junior doctors (1). This restricts the ability to provide high quality patient-centred care.

*Objectives.*– To assess if local induction training about mental health legislation is adequate and how it can be improved.

*Methods.*– A survey was sent online to junior doctors working in psychiatry posts locally except those completing specialist training in psychiatry. The questions assessed general knowledge about mental health legislation and opinions about the recent induction training. The implications for practice were then considered [1].

*Results.*–

Key themes	Significance
Inadequate understanding among junior doctors surrounding mental health legislation	Junior doctors lack confidence in their roles.
Induction is failing to provide any substantial addition to the awareness of mental health legislation	Junior doctors feel frustrated by the induction; it does not equip them for their roles
Induction needs to be improved	Junior doctors agree that significant improvement needs to be made to the induction process

*Conclusions.*– There is a need to improve induction training in mental health legislation for junior doctors. The use of both face-to-face sessions and written information packs was considered.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Suicidology and suicide prevention – part II

PW0822

### Interventions for prevention of self-harm in young people: An update

U. Arshad<sup>1\*</sup>, F. ul-Ain<sup>1</sup>, P. Talyor<sup>2</sup>, N. Gire<sup>3</sup>, N. Chaudhry<sup>4</sup>, N. Husain<sup>2</sup>

<sup>1</sup> Pakistan Institute of Learning and Living, Research, Lahore, Pakistan; <sup>2</sup> University of Manchester, Psychology, Manchester, United Kingdom; <sup>3</sup> Lancashire Care NHS Foundation Trust, Research, Accrington, United Kingdom; <sup>4</sup> Pakistan Institute of Learning and Living, Research, Karachi, Pakistan

\* Corresponding author.

*Introduction.*– Globally suicide is a serious public health issue, and is amongst the leading causes of death in many countries. Up to 75% of all suicides occur in low- and middle-income countries (LAMICs)

where resources and health services are limited. Self-harm is one of the strongest predictors of death by suicide, with an approximate 10-fold increase in risk. We are not aware of any randomized control trials of intervention for self-harm in adolescents within LAMICs.

**Objectives.**– We present an update of the Cochrane review (Hawton et al., 2015) on psychosocial and pharmacological interventions for the prevention of self-harm in children and adolescents and to identify any trial published from LAMICs.

**Methods.**– A search of electronic databases; CCDAN Specialized Register, MEDLINE, EMBASE, PsycINFO was conducted from January 2015 to August 2017. The inclusion criterion for studies was; repetition of self-harm as primary outcome, age up to 18 years, and both male and female participants (of any ethnicity).

**Results.**– Through our search strategy a total of 5 trials (n=5) of interventions for the prevention of self-harm in young people were found, however none of these were conducted within the LAMICs. We also explored clinical trial registers for planned or ongoing trials of interventions for self-harm in children and adolescents, but again we were unable to identify any trials within LAMICs.

**Conclusion.**– There is limited research concerning the evaluation of interventions for prevention of self-harm in young people living in LAMICs, indicating a clear need for further research.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Serum levels of pro-inflammatory cytokines after a suicide attempt

A. Souilem<sup>1</sup>, A. Ben Dhia<sup>1\*</sup>, A. Mtiraoui<sup>1</sup>, M. Achour<sup>2</sup>, S. Ben Nasr<sup>1</sup>  
<sup>1</sup> CHU Farhat Hached, Psychiatry Department, Sousse, Tunisia; <sup>2</sup> CHU Farhat Hached, Biophysic Department, Sousse, Tunisia

\* Corresponding author.

**Introduction.**– Immune hypothesis has been advanced postulating an association between suicidal behavior and a dysregulation of the immune system. The role of inflammatory cytokines (especially IL-6 and TNF -  $\alpha$ ) has been widely studied. However, results remain controversial. Our research hypothesis assumes that patients with suicidality would present aberrant levels of pro-inflammatory.

**Methods.**– It is a case-control study that will be conducted among all patients having made a suicide attempt in the health region of Sousse during the period between November 2016 to July 2017. A form of data collection with three parts will be previously designed. The first part will concern the socio-demographic and clinical patient data collection. The second part will concern data related to attempted suicide. The third part will include an assessment of psychopathology. A blood sample will be performed for all patients between 8: 00 and 12: 00 pm and sent to the Department of Biophysics. All Sera will be explored for the determination of biomarkers following IL-6, TNF -  $\alpha$ . Healthy controls subjects will be recruited in the near people posing to the blood bank.

**Results.**– This study was conducted among 40 patients who have made a suicide attempt and 60 healthy control subjects. Levels of interleukin6 (IL6) and Tumor necrosis factor (TNF $\alpha$ ) were significantly increased in blood of patients with suicidality compared with healthy control subjects ( $P < 0.05$ )

**Conclusions.**– Levels of IL6 and TNF $\alpha$  were significantly increased in blood of patients with suicidality and these cytokines may help distinguish suicidal from non suicidal patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Suicidal ideation in Parkinson's disease: A control study

I. Berardelli<sup>1\*</sup>, D. Belvisi<sup>2</sup>, V. Corigliano<sup>1</sup>, M. Costanzo<sup>1</sup>, G. Fabbri<sup>3</sup>, A. Berardelli<sup>3</sup>, M. Pompili<sup>1</sup>

<sup>1</sup> Sapienza University of Rome, Department of Neuroscience, Mental Health and Sensory Organs. Suicide Prevention Center- Sant'Andrea Hospital., Rome, Italy; <sup>2</sup> IRCCS Neuromed Institute, Pozzilli, IS, Italy, IRCCS Neuromed Institute- Pozzilli, IS, Italy, Isernia IS, Italy;

<sup>3</sup> Sapienza University of Rome, Department of Neurology and Psychiatry, Rome, Italy

\* Corresponding author.

**Background.**– Previous studies investigating the risk of suicide in patients with Parkinson's disease (PD) reported conflicting results and it is still unclear whether suicidal ideation is increased in PD patients compared to controls.

**Objective.**– To evaluate past and current suicidal ideation in PD patients in a controlled study designed to compare PD patients with patients affected by a different chronic disease (open-angle glaucoma-OAG).

**Methods.**– We consecutively enrolled 73 PD patients and 91 age- and sex-matched patients with OAG. All patients underwent a psychiatric evaluation with the Columbia-Suicide Severity Rating Scale (C-SSRS), the Italian Perceived Disability Questionnaire (IPDQ) the Beck Hopelessness Inventory (BHS). The diagnosis of PD was based on clinical criteria. The severity of the disease was assessed by the Hoehn and Yahr scale and Movement Disorder Society-sponsored revision of the Unified Parkinson's Disease Rating Scale part III. Non-motor symptoms were evaluated by the Non-Motor Symptoms assessment scale for PD.

**Results.**– PD patients were more likely to have past (32% vs 23%) and current (21% vs 5%) suicidal ideation than OAG patients. C-SSRS ( $P = 0.04$ ) and IPDQ ( $P = 0.0001$ ) scores were significantly higher in PD than in OAG. In PD C-SSRS scores positively correlated with IPDQ scores ( $P = 0.005$ ). IPDQ scores positively correlated with parkinsonian motor ( $r = 0.44$ ;  $P = 0.0001$ ) and non-motor symptoms severity ( $r = 0.52$ ;  $P < 0.0001$ ).

**Conclusions.**– We found that in PD patients suicidal ideation is increased in comparison to OAG patients. This result suggest that the risk of suicide is higher in PD in comparison to other chronic disease.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Hormonal and cholesterol status of persons who suicide attempts

S. Davidouski<sup>1\*</sup>, J. Ibragimova<sup>2</sup>

<sup>1</sup> Belarusian Medical Academy of Post-Graduate Education, Department of Psychotherapy and Medical Psychology, Minsk, Belarus; <sup>2</sup> Belarusian state medical university, laboratory of biochemical research, Minsk, Belarus

\* Corresponding author.

Prior suicide attempt is the most important single of risk factors for suicide, but through the next year suicide is committed by no more than 1% of those who had suicide attempt, after 2 years – 12%, what makes it important to search for predictors of the risk of suicidal behavior.

**Object of study.**– The persons who suicide attempt (20 people, 5 of whom committed violent suicidal actions - hanging), persons with diagnosis of adjustment disorder (9 people) and a control group (mentally healthy persons - 6 people).

**Methods.**– Cholesterol, high-density lipoprotein (HDL) and low (LDL) density, adrenocorticotropic hormone, cortisol were evaluated. The results obtained are processed using the Statistika for Widows software package.

**Results.**– The study revealed no significant differences in the content of triglycerides, as well as high-density lipoproteins, the level of low-density lipoprotein content was significantly higher in the group of patients with violent suicidal actions compared with the control group and a group of patients with suicide attempt. When determining the content of cortisol, its highest level was determined in the group of patients with violent suicidal actions. A direct correlation between the level of ACTH and cortisol in a group of patients with violent suicidal actions.

**Conclusions.**–

– revealed low levels LDL values and high rates of cortisol in the blood of individuals who suicide attempt, especially those with violent suicidal actions;

– patients with violent suicidal actions are characterized by low levels of lipoproteins that are associated with high levels of cortisol in the blood.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0826

### Severity assessment in suicidal behaviour according to diagnosis and previous history of suicidal behaviour: a descriptive study

M. De Dios<sup>\*</sup>, A. Trabsa, I. Ezquiaga, G. Sánchez-Moncunill, E. Monteagudo, D. Sanagustin, S. Pérez, V. Pérez-Solà, M. Campillo  
*Institut de Neuropsiquiatria i Addiccions, Psychiatry, Barcelona, Spain*

\* Corresponding author.

**Introduction.**– Suicide is the 15th cause of death worldwide. Improved understanding of who is at risk and development of interventions to reduce suicide in high risk groups are priority targets.

**Objectives.**– To describe the frequency of the different psychiatric diagnoses in suicidal attempts (SA), and previous history of suicidal behaviour (SB).

**Methods.**– Cross-sectional description of patients attending two Psychiatry Emergency Units (PEU) in Barcelona. Severity of the attempts was classified as low (suicidal ideation or mild medical injuries), intermediate (short observation required or non life threatening injuries) and high (urgent medical attention or psychiatric hospitalization).

**Results.**– 7911 patients were admitted during 2013 in our PEU. 452 consulted for SA or SB, assessed as: low-severity 347 (76.6%), intermediate-severity 71 (15.7%) and high-severity attempts 35 (7.7%). Previous history of (SB) was: low severity group 116 (33.4%), intermediate group 39 (54.9%) and high group 17 (48.6%). Diagnosis was also compared with the severity of the attempts; results in the following Table 1:

Table 1.

	No diagnose	Affective and Substance anxiety disorders	abuse	Personality disorders	Psychotic disorders	Other diagnoses
Low	78 (22.5%)	114 (32.9%)	46 (13.3%)	58 (16.7%)	32 (9.2%)	19 (5.3%)
Intermediate	15 (21.4%)	31 (44.3%)	6 (8.6%)	10 (14.3%)	7 (10.0%)	1 (1.4%)
High	3 (8.8%)	15 (44.1%)	2 (5.9%)	7 (20.6%)	5 (14.7%)	2 (5.9%)

Other diagnoses: eating disorders, obsessive-compulsive disorders, intellectual impairment, somatoform disorders, delirium and dementia.

**Discussion.**– Low-severity attempts are more frequent than high-severity ones, that predominate in patients with an established

diagnosis. Previous history of SB predominates in the intermediate and high-severity groups. Specific prevention programmes considering these data should be conducted to improve clinical outcomes.  
**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0827

### Risk factors for suicide attempts repetition

I. Ezquiaga Bravo<sup>1,2\*</sup>, G. Sánchez-Moncunill<sup>3</sup>, M. De Dios<sup>1,2</sup>, A. Trabsa<sup>1,2</sup>, E. Ribera<sup>1</sup>, L. Martínez<sup>1</sup>, M. Angelats<sup>1</sup>, L. Pujol<sup>1,2</sup>, V. Pérez-Sola<sup>1,2</sup>, M.T. Campillo<sup>1</sup>

<sup>1</sup> Institut de Neuropsiquiatria i Addiccions, Parc de Salut Mar, Barcelona, Spain, Psychiatry, Barcelona, Spain; <sup>2</sup> Hospital del Mar d'Investigacions Mèdiques-IMIM, Parc de Salut Mar, Barcelona, Spain., Neuroscience, Barcelona, Spain; <sup>3</sup> Universitat Pompeu I Fabra, Medicine, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Over 800,000 people die due to suicide every year worldwide, one every 40 seconds. Suicides are preventable and studying their main risk factors is crucial for developing prevention strategies. Female gender, previous attempts and mental disorders have been described as the most important risk factors for re-attempts.

**Objectives/aims.**– To study the role of gender, previous suicide attempts and psychiatric diagnosis as risk factors for relapse in suicide attempts.

**Methods.**– Cross-sectional descriptive analysis of visits attended at two different psychiatric emergency units in Barcelona (Hospital del Mar and Centre Emili-Mira) during 2013 ( $n=452$ ). Database information was completed with electronic medical records. Bivariate and multivariate logistic regression models and Kaplan–Meier curves with Log-Rank tests were used to estimate the risk of new attempts within the mentioned risk factors.

**Results.**– During 2013, from a total of 7911 visits assisted at our psychiatric emergency units, 452 visits were attended for suicide ideation or suicide attempt ( $n=452$ , female rate: 58.6%; mean [SD] age in years: 42.78 [17.72]). 92 of them (20.4%) visited the emergency room again for suicide attempts the following year. Having previous suicide attempts (OR=4.25;  $P<0.001$ ) and being diagnosed with a psychiatric disorder (OR=4.73;  $P<0.01$ ) showed statistically significant association with higher risk of re-attempts. Gender did not achieve statistically significant results in our sample.

**Conclusions.**– Our results agree with current literature and show previous attempts and psychiatric disorders as outstanding risk factors for relapse. Specific prevention programmes taking into account these markers should be conducted in order to develop new strategies and improve clinical outcomes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0828

### Suicidal behavior in the psychiatric emergency room: 20 years ago and today

N. Garrido-Torres<sup>1\*</sup>, J. Piedra Cristobal<sup>2</sup>, P. Diaz Cordero<sup>3</sup>  
<sup>1</sup> Juan Ramón Jiménez Hospital, Psychiatry, Huelva, Spain; <sup>2</sup> La Palma del Condado Mental health unit, Social work, Huelva, Spain; <sup>3</sup> Seville, Spain

\* Corresponding author.

**Objective.**– Determine the difference between the prevalence of suicidal behavior in patients admitted in the psychiatric emergency

room in 1996 and in 2016 and to outline the characteristics of this population.

**Methods.**– Data on 74 consecutive admissions visited in a psychiatric emergency room of a general teaching hospital during a period of six months in 1996 were collected and were compared with data on 74 consecutive admissions in a psychiatric emergency room in 2016.

**Results.**– 122 admissions were included.

Differences among groups of years (1996 and 2016) were found in the number of cases, age and method. Drug intake by younger people (< 18) is more frequently in 2006 than 1996. 32% of the cases were related with alcohol intake too.

**Conclusions.**– The number of admissions to the psychiatric emergency room for drug overuse in teenagers have increased significantly.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Deliberate self-poisoning with drugs in Morocco: A 34-year retrospective study**

L. Amiar<sup>1</sup>, H. Hami<sup>2\*</sup>, Z. Nabih<sup>2</sup>, N. Rhalem<sup>3</sup>, A. Aarab<sup>1</sup>, A. Mokhtari<sup>2</sup>, A. Soulaymani<sup>2</sup>, R. Soulaymani-Bencheikh<sup>3</sup>

<sup>1</sup> Faculty of Science and Techniques, Abdelmalek Essaadi University, Tanger, Morocco; <sup>2</sup> Laboratory of Genetics and Biometry- Faculty of Science, Ibn Tofail University, Kenitra, Morocco; <sup>3</sup> Moroccan Poison Control, Center, Rabat, Morocco

\* Corresponding author.

**Introduction.**– Suicide is a major hidden public health problem, causing almost half of all violent deaths and resulting in almost one million fatalities every year, as well as economic costs in the billions of dollars, says the World Health Organization (WHO).

**Objectives.**– This study was conducted to determine the main characteristics of suicidal poisoning with drugs in Morocco.

**Methods.**– This is a descriptive retrospective analysis of deliberate self-poisoning cases, reported between 1980 and 2013 to the Moroccan Poison Control Center.

**Results.**– During the period of study, 12,068 suicide attempts by self-poisoning including 59 cases of successful suicide are recorded. Of these, 76.7% are females with a female-male ratio of 3.3. Most victims are teenagers and young adults aged 15–24 years (58.3%). For this age group, the number of suicide attempts is 183 times higher than that for successful suicides. The average age of the patients is 23.8 ± 8.9 years. The combination of two or more drugs affecting the nervous system are present in the most severe cases. The poisoning effects vary depending on the type of drug consumed, the dose taken and the delay before treatment.

**Conclusions.**– Drug self-poisoning remains a major public health problem in Morocco. The number of victims is probably underestimated because of undiagnosed and unreported cases (hidden suicide).

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0830

### **A Linked e-cohort study of self-harm in young people aged 10–24 years across healthcare settings: Contacts and trends over time**

A. John<sup>1\*</sup>, A. Marchant<sup>1</sup>, S. Wood<sup>2</sup>, K. Lloyd<sup>1</sup>, M. Dennis<sup>1</sup>, R. Lyons<sup>1</sup>, S. Turner<sup>1</sup>, D. Fone<sup>2</sup>

<sup>1</sup> Institute of Life Science, College of Medicine, Swansea, United Kingdom; <sup>2</sup> Cardiff University, Medicine, Cardiff, United Kingdom

\* Corresponding author.

**Background.**– Self-harm is a significant public health issue. Routinely collected and linked data in the SAIL databank presents a unique opportunity to compare rates of self-harm among children and young people presenting to primary care, emergency department, and hospital inpatient settings

**Methods.**– An electronic cohort study of routinely collected healthcare data in Wales UK was conducted. Rates of incident, recurrent and prevalent self-harm across primary care, emergency department attendances and hospital admissions were examined. Individuals were split into mutually exclusive groups based on the service(s) to which they presented. Information regarding self-harm method and demographics was collected. Data was also collected on all-cause mortality following contact for self-harm in either primary or secondary care.

**Results.**– A total of 937,697 individuals aged 10–24 years contributed 5,369,794 person years of data from the 1st January 2003 to the 30th September 2015. Preliminary results suggest that incidence of self-harm is highest in primary care with lower but increasing rates of emergency department attendances and hospital admissions related to self-harm. Individuals who presented to primary care only made up the largest group. Results suggest a risk of increased all-cause mortality for those with a history of self-harm.

**Conclusions.**– Results of this study are the first to compare rates of self-harm in people aged 10–24 years across primary care, emergency department attendances and hospital admissions in the UK. The high rates of self-harm among primary care attenders highlight an important setting for intervention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0831

### **Caregivers – suicide intervention assisted by messages (C-SIAM): The development of a post-acute crisis text messaging outreach for suicide prevention**

V. Le Moal<sup>1\*</sup>, C. Mesmeur<sup>1</sup>, M. Gravey<sup>2</sup>, M. Walter<sup>1</sup>, S. Berrouguet<sup>1</sup>

<sup>1</sup> Adult Psychiatry, Brest Medical University Hospital, Bohars, France;

<sup>2</sup> P.G3 IMT Atlantique, cs 83818, 29238 Brest cedex 03, France

\* Corresponding author.

**Context.**– Suicidal behaviour and deliberate self-harm are common among adults. Feasibility trials demonstrated that intervention through text message was also effective in preventing suicide repetition amongst suicide attempters. The due care of caregivers was put in contribution to reveal of a suicidal crisis at their at-risk close relatives, encourage them in this case to consult a healthcare professional.

**Objectives and methods.**– A prospective, open-label, 2-months study will be conducted in the Emergency department (ED) and psychiatric unit (PU) of the Brest University Hospital, France. Participants will be adults discharged after self-harm, from emergency services

or after a hospitalization. The intervention is comprised of an SMS that will be sent at h48, D7, D15 and monthly. SMS are addressed at the relative designed by the suicide attempt survivor during the including. The text message enquires about the patients' and careers' well-being and includes information regarding sources of help and evidence-based help strategies. After the reception of SMS, the careers have 24 hours to send a SMS back to the patient and it must contain information regarding sources of help.

Our aim is to assess the feasibility and acceptability of text message intervention including a close relative of suicide attempters.

*Discussion and conclusion.*– This paper describes the design and deployment of a trial C-SIAM. It utilizes several characteristics of interventions (SMS and caregivers) that have shown a significant reduction in the number of suicide reattempts. We propose to assess its feasibility and acceptability in a sample of suicide attempters (SA).

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0832

### **The use of mental health care in students with suicide risk: A transversal study in the i-Share cohort**

N. Lecat<sup>1\*</sup>, M. Tournier<sup>1,2</sup>

<sup>1</sup> University of Bordeaux, Bordeaux population health research center, UMR 1219 INSERM, Bordeaux, France; <sup>2</sup> Centre hospitalier, Charles Perrens, 33000 Bordeaux, France

\* Corresponding author.

*Background.*– While suicide ideas or behaviour are prevalent among university students, healthcare renunciation is frequent among them.

*Objective.*– We aimed to evaluate factors associated with use of mental health care among students at suicide risk.

*Methods.*– Study population was all the enrolees in the i-Share cohort, included between April 2013 and March 2017. Suicidal risk was defined at inclusion as suicidal ideation over the previous year or a suicide attempt lifetime. The use of prescribed anxiolytic/hypnotic over the previous 3 months was investigated at inclusion, as well as visits with a psychiatrist or a psychologist in the previous year. Renunciation to health care was collected. Multivariate logistic regression models with backward stepwise were performed to assess factors associated with “psy” consultation and the use of anxiolytic/hypnotic drugs among students at suicide risk.

*Results.*– Among 12,112 students who completed the inclusion questionnaire, 2916 were at suicide risk. Almost 27% of them had “psy” consultation versus 9% of students without suicide risk ( $P < 0.0001$ ) and 19% used anxiolytics/hypnotics versus 7% ( $P < 0.0001$ ). Among students at suicide-risk, the use of “psy” consultations and of these drugs were both associated with female gender and a history of diagnosed psychiatric disorders. Other factors were associated with the use of a specific type of care: being an orphan, dissatisfaction with lifestyle, disability, family psychiatric history with “psy” consultations and physician consultation, somatic disease, poor sleep quality, poor relationships with parents with drugs use.

*Discussion.*– These findings provide a better understanding of determinants of care use among students at suicide risk.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0833

### **Factors of a suicidal behavior in patients with dementia (age, gender aspects, psychotraumatic factors)**

N.O. Maruta<sup>1\*</sup>, I.H. Mudrenko<sup>2</sup>

<sup>1</sup> Institute of Neurology, Psychiatry, and Narcology of the NAMS of Ukraine, Department of Neuroses and Borderline Conditions, Kharkov, Ukraine; <sup>2</sup> Medical Institute of Sumy State University, Department of Neurosurgery and Neurology, Sumy, Ukraine

\* Corresponding author.

*Introduction.*– It is known that one of suicidal behavior peaks is observed in elderly people. Factors influencing on a suicidal behavior formation in old age are the presence of mental/somatic disease, financial difficulties, loneliness, changes in social status, narrowing of social contacts. The frequency of dementia in the population increases with age. Taking into account the process of aging of the nation, this problem becomes relevant.

*Objection.*– The aim of study was to investigate clinical-psychopathological factors determining suicidal behavior in patients with dementia.

*Methods.*– In the study, 144 patients with dementia were examined in health facilities in Sumy (Ukraine). Methods included clinical-psychopathological, and psychometric (Scale for Assessing Suicide Risk, Los Angeles Suicide Prevention Center Scale).

*Results.*– Patients in the age of 78–88 years old were more likely at high suicide risk, than those of aged of 56–66 years old. It was determined that the lack of emotional support from family and friends ( $t = 4.346$ ;  $P < 0.0001$ ); violation of relations accompanied by refusal to renew them ( $t = 3.223$ ;  $P < 0.002$ ); lack of financial support sources ( $t = 3.412$ ;  $P < 0.001$ ); feelings of guilt, on the one hand, and hostility, on the other hand ( $t = 2.311$ ;  $P < 0.025$  and  $t = 2.467$ ;  $P < 0.01$ , respectively) caused the suicidal behavior formation. It was found, that suicidal intentions ( $P < 0.0001$ ;  $r = 0.561$ ), suicidal attempts in the past ( $P < 0.0001$ ), and depressive episodes in the past ( $P < 0.0001$ ;  $r = 0.782$ ) were the risk factors of suicide in the future.

*Conclusions.*– The obtained data can be used for the purpose of psychodiagnosics and prevention of suicide in patients with dementia.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0834

### **Has information provided via the internet negatively impacted suicide rates by increasing the lethality of suicidal behaviour?**

E. Paul<sup>1\*</sup>, U. Hegerl<sup>1</sup>, R. Mergl<sup>2</sup>

<sup>1</sup> German Depression Foundation, Psychiatry and Psychotherapy, Leipzig, Germany; <sup>2</sup> University of Leipzig, Psychiatry and Psychotherapy, Leipzig, Germany

\* Corresponding author.

The suicide rate in Germany steadily decreased from 1998 to 2006, but this decline ended and was even slightly reversed from 2007 to 2010. This unfavorable change was mainly due to increases in suicides by self-poisoning due to gasses and coincided with a tripling in the availability of factual (how-to) information on specific suicide methods on the internet. This paper examines current trends in suicide rates in Germany and whether there have been increases specifically in self-poisoning methods, especially due to gassing. Further tested are whether these relatively new suicide methods are associated with online searches for related terms.

During the period 2007–2015, the overall suicide rate significantly increased in females (Average Annual Percentage Change

(AAPC=2.37%), but not in males. Increases in self-poisonings (AAPC=2.86%) were significantly more pronounced than the increases in all other suicide methods (AAPC=0.71%). Of the self-intoxication suicide methods, those due to gasses increased the most (by 500% in females and 164% in males). Significant positive correlations were found between the intensity of Google searches concerning carbon monoxide poisoning and the frequency of all self-poisonings and specifically self-poisoning by gasses, but not with other terms.

The findings are in line with the hypothesis that information via the internet may have negative impact on suicide rates, possibly via increasing lethality of suicidal intoxications. Together, these results underscore the importance of ongoing systematic surveillance not only of suicide methods, but also the internet that may provide suicidal individuals with information on suicide methods.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0835

### Neutrophil to lymphocyte ratio: Useful peripheral biomarker of suicidal behavior?

P.A. Sáiz Martínez<sup>1</sup>, A. Velasco<sup>2</sup>, J. Rodríguez-Revuelta<sup>1</sup>, I. Abad<sup>1</sup>, A. Fernandez-Pelaez<sup>1</sup>, E. Olié<sup>3</sup>, A. Cazals<sup>3</sup>, S. Guillaume<sup>3</sup>, P. Garcia-Portilla<sup>1</sup>, P. Courtet<sup>3</sup>, J. Bobes<sup>1</sup>

<sup>1</sup> Universidad de Oviedo, Área de Psiquiatría, Oviedo, Spain;

<sup>2</sup> Universidad de Oviedo, Department of psychiatry, Oviedo, Spain;

<sup>3</sup> University of Montpellier, University of Montpellier, Montpellier, France

\* Corresponding author.

*Background.*– Suicidal behavior (SB) is a severe public health concern. No useful predictive biomarkers of SB have been described. Neutrophil/lymphocyte (NLR) and the platelet/lymphocyte (PLR) ratios have emerged as important peripheral inflammatory biomarkers.

*Objective.*– The aim of this study is to evaluate the predictive value of NLR and PLR in the prediction of SB in patients diagnosed of major depressive disorder (MDD).

*Methods.*– 641 patients with MDD [Males: 33.7%; mean age (SD)=43.74 (14.17) years]. Sociodemographic, clinical and peripheral blood samples were recorded after written consent. Logistic regression model was estimated to determine the independent predictors of suicide risk in suicide attempters and non-attempters. Receiver operating characteristic (ROC) curve analysis was performed to determine the cut-off level of NLR and PLR to predict the suicide attempt.

*Results.*– 476 (74.3%) have personal history of SA [Males: 149 (31.3%); mean age (SD)=41.13 (13.65) years]. Mean age at first SA was 33.16 (14.58) years and mean number (SD) of SA was 2.09 (3.09). Patients with previous SA were more frequently females (68.7% vs 59.4%;  $P=0.029$ ), significantly younger [41.13 vs 51.29;  $P=0.000$ ], have lower severity of their depression ( $P=0.000$ ) and have significantly higher mean NLR and PLR ratios (2.37 vs 1.69;  $P=0.000$ ; 127.12 vs 111.64;  $P=0.000$ , respectively).

In the final logistic regression model, after controlling by sex, only NLR was included [ $\beta=0.379$ ,  $P=0.000$ ; OR (95% CI)=1.461 (1.192–1.790)]. The optimal cutoff value of NLR was 1.93 (sensitivity 43% and specificity 76%).

*Conclusion.*– Data suggest that NLR could be an easy to obtain, inexpensive indicator for suicidal risk.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0836

### Further support of a common factor behind electrodermal hyporeactivity and vulnerability to suicide

L.H. Thorell

Director of Research, Research & Development, Linköping, Sweden

*Introduction.*– A series of blind studies have reported very high sensitivity and negative predictive value of electrodermal hyporeactivity to vulnerability to suicide in depressed patients, thus establishing a solid support for the existing of a common factor of vulnerability to suicide.

*Objectives.*– To investigate the electrodermal test in naturalistic conditions when test result is used in suicide risk assessment and prevention.

*Methods.*– A special habituation test classifying patients in reactive or hyporeactive, was applied in 1574 patients with a primary diagnosis of depression in 15 centres in 9 European countries.

*Results.*– The test was very well accepted and most of the clinicians used the test result so hyporeactives were reassessed to a higher risk. Consequently, each saved hyporeactive reduced the number of true positives and the sensitivity. Although the number of suicides was low, it was statistically significantly reduced in the hyporeactive group compared to the reactive group and to a previous study of 783 depressed patients.

*Conclusion.*– This is the first study investigating possible influence on the suicide rate in clinics that considered the electrodermal test result in risk assessments and suicide prevention. The classical terms sensitivity and specificity showed to be irrelevant in this type of research. The most important and relevant statistical parameter negative predicted value (raw sensitivity) was even more favourable in this investigation: 1986 = 100%; 1987 = 100%, 2009 = 93%; 2013 = 98% and 2017 = 99.5%.

Further details and discussion will be given at the presentation.

*Disclosure of interest.*– TFounder and shareholder of, and employed by the Swedish Medical Technical Company Emotra AB.

### Prevalence of adult attention deficit hyperactivity among university students and its impact on academic achievements

H. Alharthi<sup>1</sup>, E. Soliman<sup>2</sup>, M. Alharbi<sup>1</sup>, S. Odeh<sup>1</sup>, A. Alsaleem<sup>1</sup>

<sup>1</sup> 4th year medical student, CM, Princess Nourah Bint Abdelrahman University, Riyadh, KSA, Clinical department, Riyadh, Saudi Arabia;

<sup>2</sup> Lecturer of Psychiatry, Psychiatry Department, Faculty of Medicine, Zagazig University, Egypt, Assistant Professor of Psychiatry, College of Medicine, Princess Nourah Bint Abdelrahman University, Riyadh, KSA, Clinical department, Riyadh, Saudi Arabia

\* Corresponding author.

*Introduction.*– One of the overlooked psychiatric disorders in the adult age group is Attention Deficit Hyperactivity disorder (ADHD). There has been a deficit in surveilling the adult groups who are affected by this disorders in Saudi Arabia.

*Objectives.*– To estimate the prevalence of ADHD among university students and to determine the effect of ADHD on academic achievement.

*Methods.*– Cross sectional study using questionnaire among purposive sample of 771 consented university students. The questionnaire composed of sociodemographic data, history of med-

ication, family history of psychiatric disorder and Adult Self-Report Scale (ASRS) Symptom Checklist which consists of 18 questions in two parts: part A serves as screening of adult ADHD. Part B confirms the diagnosis with answers in the form of Likert five response. A Grade Point Average (GPA) was used as assessment for the students' performance.

**Results.**– The average age of participants was ( $20.9 \pm 1.63$ ) years. Most of them were Females (78.9%), single (94.7%) and Saudi (96.6%). Their GPA was ( $4.095 \pm 0.661$ ). Among the studied sample, 129 students were found to have adult ADHD (16.73%), the majority was female (73.6%). Inattentive type was more prominent in females and hyperactive type in males. There's significant inverse relation between adult ADHD and student GPA.

**Conclusion and recommendations.**– There is a high prevalence of Adult ADHD among university students with significant impact on academic achievements.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Clinical predictors of response to methylphenidate in adult attention deficit/hyperactivity disorder: Preliminary results from a longitudinal, naturalistic study**

B. Barahona-Corrêa<sup>1\*</sup>, S. Pinho<sup>2</sup>, C. Filipe<sup>3</sup>

<sup>1</sup> NOVA Medical School, Faculdade de Ciências Médicas de Lisboa, Department of Psychiatry and Mental Health, Lisbon, Portugal;

<sup>2</sup> CADIN, Neurodesenvolvimento e Inclusão, Psychology Unit, Lisboa, Portugal; <sup>3</sup> NOVA Medical School, Faculdade de Ciências Médicas de Lisboa, Department of Physiology, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Stimulants are the mainstay of treatment in adult ADHD with methylphenidate (MTPH) the first-line choice in Europe. Response to MTPH is variable, with scarce evidence on predictive factors of improvement in medicated adults. We report the preliminary findings on predictors of symptom improvement in a sample of successive adults assessed and treated for ADHD.

**Methods.**– Initial diagnostic assessment: Mini International Neuropsychiatric Interview; Conner's Adult ADHD Diagnostic Interview; Symptom Checklist 90 Revised; Conner's Adult ADHD Rating Scale self-assessment module (CAARS); Quality of Life Enjoyment and Satisfaction Questionnaire – Short Form (Q-LES-Q-SF). CAARS and Q-LES-Q-SF scores were collected regularly at subsequent visits.

**Results.**– Up to the present, complete follow-up data are available for 22 patients (14 males, 8 females) treated with MTPH. All subjects showed a decrease in CAARS scores (mean decrease  $12.1 \pm 10.4$ ,  $P < 0.001$ ) and an improvement in Q-LES-Q-SF scores (mean increase  $7.8 \pm 9.5$ ,  $P = 0.001$ ). Regression analysis: CAARS score decrease is predicted by CAARS scores and anxiety scores at baseline ( $B = 0.464$ ,  $P = 0.013$ ; and  $B = -7.79$ ,  $P = 0.013$ , respectively), and MTPH dose in mg/kg ( $B = 12.56$ ,  $P = 0.022$ ). Predictors of quality of life at last assessment were age ( $B = -0.532$ ,  $P = 0.023$ ) and CAARS score improvement ( $B = 0.534$ ,  $P = 0.005$ ).

**Conclusions.**– Our results suggest that, in adults with ADHD, early treatment with an adequate dose of MTPH and effective control of anxiety symptoms are essential to ensure improvement, both in terms of ADHD symptoms and quality of life.

**Disclosure of interest.**– Bernardo Barahona-Corrêa has received honoraria as member of the advisory board for Ritalin LA (Novartis) and for paliperidone palmitate (Janssen-Cilag)

### **Emotional intelligence and personality characteristics of psychiatric nurses and their situations of exposure to violence**

C. Baçoğul<sup>1\*</sup>, L. Baysan Arabacı<sup>2</sup>, A. Büyükbayram<sup>2</sup>, Y. Aktaş<sup>3</sup>, G. Uzunoğlu<sup>4</sup>

<sup>1</sup> Adıyaman University, School of Health, Adıyaman, Turkey; <sup>2</sup> İzmir Kâtip Çelebi University, Faculty of Health Sciences, İzmir, Turkey;

<sup>3</sup> İzmir Kâtip Çelebi University Hospital, Psychiatric Clinic, İzmir, Turkey; <sup>4</sup> Manisa Mental Health and Diseases Hospital, Psychiatric Clinic, Manisa, Turkey

\* Corresponding author.

**Introduction.**– Nurses working in psychiatry clinics can be under risk of being exposed to violence in terms of the environment and the patient profile characteristics of the psychiatric working area. Emotional intelligence and personality characteristics of the individual can affect the situation of being or not being exposed to violence.

**Objective.**– The objective of this study is to examine the relationship between the emotional intelligence and sociotropic-autonomic personality characteristics of the nurses working in psychiatry clinics and their situation of being subject/exposed to violence.

**Methods.**– This study was carried out with 103 nurses working in a district hospital between March and May in 2016, in Turkey. The research data were collected by Emotional Intelligence Evaluation Scale (EIES), Sociotropy–Autonomy Scale (SAS), and Descriptive Information Form which was developed by the researchers.

**Results.**– The rate of being exposed to physical violence was 32% and the rate of being exposed to psychological violence was 66%. A statistically meaningful relationship was determined between the “awareness of emotions” dimension EIES and the number of physical violence that was exposed and “management of emotions” dimension of EIES and the number of psychological violence that was exposed ( $P < .05$ ). It was determined that there was a meaningful relationship between the situation of being exposed to psychological violence with socio-tropic personality characteristics and the number of violence ( $P < .05$ ).

**Conclusion.**– There were an inversely proportional relationship between the situation of being exposed to violence and emotional intelligence levels of the nurses and a directly proportional relationship with their personality characteristics.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Prenatal and postnatal attachment among mothers diagnosed with a mental disorder: A controlled study**

N. Özcan<sup>1</sup>, N.E. Boyacıoğlu<sup>1\*</sup>, G. Dikeç<sup>2</sup>, H. Dinç<sup>1</sup>, S. Enginkaya<sup>3</sup>

<sup>1</sup> Istanbul University, Health Science Faculty, Istanbul, Turkey;

<sup>2</sup> İstinye University, Health Science Faculty, İstanbul, Turkey;

<sup>3</sup> Bakırköy Ruh ve Sinir Hastalıkları Hastanesi, Psychiatry, İstanbul, Turkey

\* Corresponding author.

**Introduction.**– The presence of a mental disorder in the mother is one of the key factors affecting attachment.

**Objectives.**– The present study aimed to evaluate prenatal and postnatal attachment among mothers diagnosed with a mental disorder by comparing them to a healthy control group.

**Methods.**– The patient group included women who received follow-up care in a psychiatric clinic (74 pregnant & 75 postpartum), and the control group consisted of women who attended a follow-up

polyclinic (118 pregnant & 82 postpartum). Data were collected using questionnaire forms, including the Prenatal Attachment Inventory and the Maternal Attachment Scale.

**Results.**– Among the pregnant women diagnosed with a mental disorder, it was found that they received less antenatal care during pregnancy, was less satisfied with the baby's assigned gender, and was subject to more trauma. Among the postpartum mothers diagnosed with a mental disorder, it was found that they breastfed their babies less often during the postnatal period, expressed more concerns about infant care, were subjected to more trauma during puerperium, and relied on others to care for their babies more often than themselves. It was determined that the attachment scores among mothers diagnosed with a mental disorder were lower, both during pregnancy and the postnatal period, compared to the control group

**Conclusions.**– The present study determined that pregnant and postpartum mothers diagnosed with a mental disorder were insecurely attached to their babies during the prenatal and postnatal periods, compared to a control group consisting of pregnant and postpartum women with satisfactory mental health.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### The demographic and psychosocial predictors of depression among university students in Turkey

N.E. Boyacıoğlu\*, N. Özcan

Istanbul University, Health Science Faculty, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Recent research indicates that university students experience increased levels of depression. It is less clear what strategies university health care providers might use to assist students in decreasing depression.

**Objectives.**– This study was carried out to determine the predictors of depression among university students in Turkey

**Methods.**– This descriptive and cross-sectional study was conducted. The sample consisted of 2567 undergraduate students from various faculties of Istanbul University. Data were collected through a questionnaire based on the literature and prepared by the researchers, which was designed to determine the demographic (gender, study subject, economic status, academic performance) and psychosocial factors (religious, happiness, history of violence, problematic internet use, nutrition, body mass index, psychical activate) that may be related to depression. Depressive symptoms assessed by using the 10-item version of the Centres for Epidemiologic Studies Depression Scale (CES-D). Bivariate logistic regression models examined the associations between depression, and demographic and psychosocial characteristics.

**Results.**– Of the participants, 30.8% were male and 69.2% were female. The prevalence of severe depression was 15.8% and depression score  $9.45 \pm 5.72$ . A higher likelihood of depression score was observed among female gender, problematic internet users, describing their health status negatively, having no religious beliefs, using cigarettes/alcohol/drugs, having sleep problems, having less social support and describing themselves as unhappy.

**Conclusions.**– The implications of our findings include the need for more integrated approaches to the development of resilience, mental health promotion, and early intervention among this vulnerable student population.

**Keywords:** Health behaviour; Problematic internet use; Turkey; University students

### Neurocognitive and mood disorders in Parkinson's disease

E.I. Davidescu<sup>1</sup>\*, E.R. Tănăsioiu<sup>2</sup>

<sup>1</sup> University of Medicine and Pharmacy Carol Davila, Clinical Neurosciences-Colentina Clinical Hospital, Bucharest, Romania;

<sup>2</sup> University of Medicine and Pharmacy Carol Davila, Clinical Neurosciences, Bucharest, Romania

\* Corresponding author.

**Introduction.**– Parkinson's disease (PD) is a neurodegenerative disorder (synucleinopathy) in which motor signs are essential for clinical diagnosis, but non-motor manifestations can be very troubling especially in evolution of the disease, affecting quality of life both for patients and caregivers.

**Objectives.**– To assess neurocognitive troubles and mood disorders in a lot of 77 patients with PD (45.45% men and 54.55% women, with a mean age of 69.3 years old, a mean time of evolution of the disease of 6.5 years and a mean Hoehn Yahr score 2.5) admitted in Neurology Department during July 2016–May 2017. Patients had not been diagnosed with cognitive disorders or psychiatric ones.

**Methods.**– Patients were assessed for associated mood disorder with scales like Beck Depression Inventory and Hamilton Anxiety Rating Scale and for neurocognitive troubles, by performing Mini Mental State Examination and Sunderland clock test; caregivers were assessed with Neuropsychiatric Inventory for checking patients' behavioural troubles.

**Results.**– We found that 45.45% patients had a depressive disorder, 23.38% had anxious troubles and 22.08% of them had a mixed state. In the same time we diagnosed 24.68% of the lot with a mild cognitive impairment and 11.69% with an associated major neurocognitive disorder according DSM 5.

**Conclusions.**– Affective symptoms are an important non motor sign in neurodegenerative disorders as PD is, sometimes starting even before cardinal motor signs of the disease; neurocognitive impairment is as well a frequent associated feature, affecting management of these patients, mainly because of associated behavioural disorders that can aggravate medical care.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Clinical effectiveness of inhaled loxapine for the treatment of acute agitation

P. De Jaime Ruiz<sup>1</sup>\*, A. Porras Segovia<sup>1</sup>, M.B. Vela Sánchez<sup>2</sup>, A. Oria Espinosa<sup>2</sup>, M.Á. Rosales Muñoz<sup>2</sup>

<sup>1</sup> Campus de la Salud, Psychiatry, Granada, Spain; <sup>2</sup> Hospital Virgen de las Nieves, Psychiatry, Granada, Spain

\* Corresponding author.

**Introduction.**– Agitation is a common complication of severe mental disorders and it can entail a physical risk to the patient and the people surrounding him. Classical treatment of agitation is based on intramuscular medication. Sometimes, physical restraint is necessary. This treatment usually takes time and can be perceived as highly invasive by patients.

Loxapine is a first-generation antipsychotic agent. Inhalatory administration was approved in 2012 for the treatment of acute agitation in patients with schizophrenia or bipolar disorder. The medication is contained in a 10 mg/single-use inhaler.

**Objectives.**– We aim to explore the tolerability and satisfaction with inhaled loxapine in agitated patients.

**Methods.**– Patients suffering from agitation in an acute inpatient psychiatry unit were recruited to participate in the study. Only patients with a minimum level of cooperation were considered. Group assignment was performed using an alternate sequence. Cases received inhaled loxapine, while controls were administered intramuscular medication.

The Global Clinical Impression (GCI) scale and the Agitation and Calmness Evaluation Scale (ACES) were administered at baseline, 10 minutes after treatment and 30 minutes after treatment.

**Results.**– Our sample consists on 30 patients who were diagnosed either with schizophrenia or with bipolar disorder. Use of inhaled loxapine resulted effective in the treatment of acute agitation, showing clinical improvement in the GCI scale and a reduction of the level of agitation in the ACES scale.

**Conclusions.**– Inhaled loxapine may allow for a quick reduction of symptoms, rendering it helpful in the urgent treatment of acute agitation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Cultural adaptation, internal consistency and test–retest reliability of the Turkish version of the Body Exposure During Sexual Activities Questionnaire**

H. Dinç<sup>1\*</sup>, N. Kızılkaya Beji<sup>2</sup>

<sup>1</sup> Istanbul University, Health Science Faculty, Istanbul, Turkey;

<sup>2</sup> Biruni University, Health Science Faculty, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– The Body Exposure during Sexual Activities Questionnaire (BESAQ) is a measure of body image experiences in the specific context of sexual relations.

**Objectives.**– This study was planned in order to examine the Turkish validity and reliability of The Body Exposure during Sexual Activities Questionnaire, which was developed by Cash et al, on pregnant women and to adapt the questionnaire into Turkish.

**Methods.**– Language and context validity studies for the validity of the scale were performed, and its internal consistency, item total score correlations, and test retest compliance were examined for its reliability.

**Results.**– The relationships between the item scores and item total scores of the BESAQ, which was applied to 169 pregnant women, were evaluated, 24 of the 28 items were found to be meaningful while the effect of 4 items on the item score average was not statistically significant. The highest contribution to the total score was made by the item “I try to hide certain parts of my body during sexual intercourse” ( $r = 0.678$ ). Positive, strong, and statistically highly significant relationships between item-total score correlation reliability coefficients were found for most of the items. In the internal consistency analysis of the scale, the cronbach alpha reliability coefficient was found to be  $\alpha = 0.80$ . Test retest analyses were performed in order to evaluate the time invariance of the scale, and no differences between the applications were found.

**Conclusions.**– The Turkish version of the BESAQ is a valid and reliable tool that can be used in studies in our country with pregnant women.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Synesthesia in bipolar and schizophrenic patients: A study of its relationship with abstract thinking**

M. Erfanian

Maastricht University, Faculty of Psychology and Neuroscience, Maastricht, The Netherlands

The neurological condition ‘synesthesia’ may explain the links underlying metaphor perception and comprehension of abstract concepts in humans. Schizophrenia and bipolar disorders share certain similarities regarding symptomology which often inhibits and attenuates differentiating between them. A unique characteristic of schizophrenics’ thought and language disturbance is concretism. In other words, schizophrenic patients fail to understand metaphors. On the other hand, an intellectual ability such as metaphor perception remains intact in bipolar patients. The current study determines if schizophrenic patients are weaker at metaphor comprehension than bipolar and normal individuals, if the schizophrenics are weaker in synesthesia comprehension than bipolar and normal individuals, if bipolar patients can understand metaphors as well as healthy people, and whether bipolar patients can understand synesthesia as well as healthy controls. Twenty-eight schizophrenic patients, 28 patients with bipolar disorder, and 28 healthy controls, were analyzed in two subgroups of male and female participants, who completed Synesthesia battery and a designed metaphor task. The results of battery and the task in schizophrenic patients were significantly lower, in comparison with bipolar patients’ ( $P < 0.01$ ). The responses to the metaphor task were more literally comprehended in the schizophrenic group as compared with the bipolar and control groups. No significant differences were observed in the results between the healthy control and bipolar group tasks. The results revealed a strong correlation between synesthesia and metaphor recognition which could stem from co-existing common neurological structures. Thus, synesthesia may determine a causal role in the ability to develop understanding abstract concepts and abstract thinking.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Predictors of the agreement between instrumental and clinical diagnosis in a sample of adults with autism spectrum disorders**

L. Fusar-Poli<sup>\*</sup>, N. Brondino, M. Rocchetti, U. Provenzani, S.

Damiani, P. Politi

University of Pavia, Department of Brain and Behavioral Sciences, Pavia, Italy

\* Corresponding author.

**Introduction.**– Diagnosing autism spectrum disorders (ASD) in adulthood often represents a challenge. Clinical diagnosis should be supported by the use of standardized tools, such as the ADOS (direct observation of the patient) and the ADI-R (interview to parents).

**Objectives.**– To evaluate potential predictors of the agreement between diagnostic instruments (ADOS-2 and ADI-R) and clinical diagnosis in a population of adults with ASD.

**Methods.**– After an extensive clinical evaluation, 95 adults with an IQ  $\geq 70$  were diagnosed with ASD according to DSM-5 criteria. ADOS-2 was separately administered to all participants and 81 caregivers underwent ADI-R interview. Binary logistic regressions were conducted to find potential predictors of the agreement (gender, age, IQ, severity levels of criteria A and B of DSM-5).

**Results.**– Female gender was a negative predictor of the agreement between ADOS-2 and clinical diagnosis ( $B = -1.59$ ,  $P = 0.03$ ). IQ seemed to negatively predict the agreement between ADI-R and DSM-5 ( $B = -0.03$ ,  $P = 0.04$ ), while people with higher severity levels at criterion B better agreed with clinical diagnosis ( $B = 1.20$ ,  $P = 0.03$ ).

**Conclusions.**– Clinicians' training and experience remains of primary importance while assessing adults who could potentially belong to the autism spectrum. Women and individuals with higher IQs, in fact, seem to have more camouflaging strategies and less pronounced symptoms. In these subsamples, it is thus more difficult to correctly identify ASD by means of standardized instruments.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Long-term weight gain in psychiatric inpatients: A meta-analysis

C. Lazzari<sup>\*</sup>, A. Shoka, B. Papanna, G. Mousailidis  
Essex Partnership University NHS Foundation Trust- United Kingdom, Kingswood Centre- General Adult Psychiatry, Colchester, United Kingdom

\* Corresponding author.

**Introduction.**– Weight gain in adult patients is a common concern in psychiatric wards.

**Objectives.**– To reject the null hypothesis  $H_0$  that there is no long-term weight gain in mental-health patients during their consecutive admissions to psychiatric hospitals.

**Methods.**– Electronic data for body weight relative to a period from 1 to 10 years were collected for  $n = 136$  patients (females  $n = 64$ ; age 39.53 [ $\pm 13.3$ ]; males  $n = 72$ ; age 39.56 [ $\pm 11.72$ ]) resident in general adult psychiatric wards in Essex, United Kingdom. Statistical methods included the Coefficient of Determination  $R^2$  computing the longitudinal data, Cohen's  $d$  effect size for the  $R^2$ , and the heterogeneity factor  $I^2$  from meta-analysis measuring differences in observations.

**Results.**– Mean  $R^2$  for females was 0.34 (95% CI [0.29–0.39];  $d = 0.86$ ;  $I^2 = 79.52\%$ ;  $P < 0.001$ ) and males 0.18 (95% CI [0.14–0.21];  $d = 0.43$ ;  $I^2 = 93.59\%$ ;  $P < 0.001$ ). Therefore, the effect size  $d$  of time was large for females and small to medium for males. Furthermore, meta-analysis revealed a statistically significant heterogeneity in females' body weights ( $I^2 = 99.87\%$ ;  $P < 0.01$ ) with mean weight of 79.20 kg (95% CI [74.55–84]) and BMI of 30.3 corresponding to the obese spectrum. Additionally, in the male population, the meta-analysis showed a statistically significant heterogeneity in their body weight ( $I^2 = 99.82\%$ ;  $P < 0.01$ ) with mean weight of 83.13 kg (95% CI [79.45–88.82]) and with BMI of 27 placing males in the overweight spectrum.

**Conclusions.**– Overweight in males and obesity in females are commonly found in psychiatric inpatients. Moreover, weight gain is more significant in female than male patients during their admissions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Folic acid enzymes genes' condition significant in infants and toddlers with arterial ischemic stroke

O. Lvova<sup>1\*</sup>, A. Dron<sup>2</sup>

<sup>1</sup> Ural Federal University named after the first President of Russia B.N. Yeltsin, Laboratory of Brain and Neurocognitive Development, Yekaterinburg, Russia; <sup>2</sup> MAI City Clinic Pediatric Hospital, Pediatric Neurology, Yekaterinburg, Russia

\* Corresponding author.

**Introduction.**– Arterial ischemic stroke in children (PedAIS) can result in motor and mental delay as it occurred in the early stage of life. Inherited thrombophilia is described to be the most frequent reason for PedAIS in infants and toddlers. But the role of the certain genes combinations is not investigated thoroughly.

**Methods.**– Case-control study. 56 patients' blood samples with PedAIS debut at 0–24 month and confirmed by brain MRI were compared with 117 controls. 4 single nucleotide polymorphisms (SNPs) of folic acid enzymes genes (MTR:2756A>G, MTRR:66A>G, MTHFR:677C>T, MTHFR:1298A>C) were investigated by polymerase chain reaction.

**Results.**– We sorted out all the existed SNPs combinations, presented in both groups, and found out the most significant (Table 1).

Table 1.

SNPs combinations	Controls	Cases	OR	95% CI	Fisher
MTR:2756A>G+MTRR:66A>G+MTHFR:677C>T	5	10	4.87	1.54–15.38	0.012
MTR:2756A>G+MTRR:66A>G+MTHFR:1298A>C	6	10	4.02	1.35–11.97	0.009
MTRR:66A>G+MTHFR:677C>T	27	32	4.78	2.38–9.62	0.000
MTRR:66A>G+MTHFR:677C>T+MTHFR:1298A>C	5	16	8.96	3.02–26.62	0.000
MTHFR:677C>T+MTHFR:1298A>C	10	13	3.23	1.30–8.08	0.009

Only patients with PedAIS had all four SNPs combination ( $n = 6$ ).

**Conclusion.**– We assume the folic acid enzymes genes SNPs to play the important role in early life stroke's debut. Combinations, which include MTHFR:677C>T, have the most diagnostic value and must be investigated in these patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Assessment of psychiatric features in patients convicted of sexual offenses

S. Maroua<sup>1\*</sup>, A. Aissa<sup>2</sup>, H. Maatallah<sup>3</sup>, A. Maamri<sup>4</sup>, R. Ridha<sup>5</sup>

<sup>1</sup> Razi Hospital, psychiatry A, Mannouba, Tunisia; <sup>2</sup> Razi Hospital, psychiatry F, Mannouba, Tunisia; <sup>3</sup> Razi Hospital, psychiatry E, Mannouba, Tunisia; <sup>4</sup> Razi Hospital, Consultation, Mannouba, Tunisia; <sup>5</sup> Razi Hospital, psychiatry, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Sexual crime has historically been more recognized as a legal not psychiatric phenomenon. The proportion of sexual offenses attributable to mental illness has been estimated at less than 10%. In spite of its higher risk of recidivism, a little is known about sexual offenses subscribed under a psychiatric illness.

**Objective.**– To examine the psychopathologic profile of sexual offenders whose charges have been dismissed due to a psychiatric illness.

**Methods.**– A descriptive retrospective study has been led on patients convicted of a sexual offense with dismissed charges and hospitalized in the legal psychiatric department in Razi hospital, Tunisia. Demographic, offense history, and psychiatric data were recorded from patients' medical records. The clinical investigation questionnaire for sexual assault offenders (QJCPAAS) was used to investigate the patients' perceptions and descriptions of their acts, as well as their psychopathologic traits.

**Results.**– Fifty three male patients have been hospitalized in the legal psychiatric department after sexual offenses during the period between 1990 and 2015. The average age at the time of commission of the offense was 33.6 years. Molestation had the vast majority of cases with 49.1%. A delusional activity motivating the offense had been observed in 26.08% of cases. In the words of the DSM-IV-TR, 70% of patients suffered from schizophrenia, 46.15% had a mental retardation and 26.41% had a personality disorder.

**Conclusion.**– A few studies have been conducted on psychiatric morbidity in sexual offenders. Consequently, these patients often do not receive specific care. Several therapeutic and preventive challenges remain to be taken.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Executive function in a sample of Egyptian patients with fibromyalgia**

A. Meshref<sup>1</sup>, M. Abouzed<sup>2</sup>, A. Negm<sup>3</sup>

<sup>1</sup> Al-Azhar university, faculty of medicin, psychiatry, Cairo, Egypt;

<sup>2</sup> Al-Azhar university, faculty of medicine, psychiatry, Cairo, Egypt;

<sup>3</sup> Al-Azhar university, faculty of medicine, rheumatology and physical medicine, Cairo, Egypt

\* Corresponding author.

**Background.**– Fibromyalgia is suggestive to be a systemic disorders with some evidence of an executive dysfunction in these people.

**Aim of study.**– To compare subjective and objective executive function between patients with fibromyalgia and a control group by using cognitive tests.

**Method.**– 96 patients diagnosed with fibromyalgia and 55 healthy controls, matched by age and years of education, were assessed using the Montreal Cognitive Assessment, the Stroop Test, Wisconsin Card Sorting Test, Digit Span and Spatial Span subtests, Trail Making Test (TMT) Form B; Verbal Fluency Test (Clock Drawing Test (CDT) Hamilton scale for depression and Hamilton for anxiety used to assess depression and anxiety. and self-reported pain intensity scale.

**Results.**– Patients with fibromyalgia had greater impairment than the control group on all of the executive function. Correlation between executive dysfunction and depression, anxiety was positive, also the correlation with positive between executive function and pain intensity, female were greater affected with executive dysfunction than male.

**Conclusions.**– Patients with fibromyalgia showed executive dysfunction in subjective and objective measures, although most of this impairment was associated with mood disturbances and pain intensity.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0851

### **Survey of mental health professionals views on, and use of, e-mail correspondence out of normal contracted working hours (OOHs) – The right to disconnect?**

R. Mudawi<sup>\*</sup>, L. Chandra, M. Clarke, M. Khwaja, M. Silvert

Central & North West London NHS Foundation Trust, psychiatry, London, United Kingdom

\* Corresponding author.

**Introduction.**– Email has become a necessary tool in our work. Many of us are 'connected all the time'. Although this may have its advantages, the impact on wellbeing is a concern. In France, some workers have 'the right to disconnect from email to avoid the intrusion of work into their private lives'.

**Objectives.**– To explore mental health professional's views on, and use of, work E-Mails OOHs.

**Methods.**– Qualitative survey of 20 questions using software provided by online platform Survey monkey sent to teams in Central & North West London NHS Foundation Trust. Total number of respondents was 378 from: 24/03/16–18/01/2017.

**Results.**– 72.12% of respondents reported using a smart phone or tablet to access their work emails.

Key results in this survey revealed:

– 83.78% reported sending work emails OOHs; of those 43.77% on a daily basis;

– 88.52% reported that they were receiving emails OOHs; almost 60% on a daily basis;

– 85.76% respondents reported that < 25% of emails received OOHs were deemed urgent;

– 44% thought that there should not be an expectation to respond to OOHs e-mails, 10% thought there should be, – 4% were not sure and the remaining 42% expressed no view;

– 35.2% reported that a policy would be helpful, whilst 43.7% said maybe and 21% said no.

**Conclusions.**– Results support the need for policy regarding OOH email usage in healthcare as well as other sectors. This would support staff to 'disconnect', to manage technology in a healthier way, prevent burnout, redress the work-life imbalance and be also benefit the organisation.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **A pilot study evaluating the use of a mindfulness Smartphone App in adult ADHD patients**

F. Oliva<sup>1\*</sup>, A. Portigliatti Pomeri<sup>2</sup>, P. Ferreri<sup>2</sup>, S. Bramante<sup>2</sup>, G.

Nibbio<sup>1</sup>, C. Mangiapane<sup>1</sup>, G. Chiccoli<sup>1</sup>, G. Maina<sup>2</sup>

<sup>1</sup> University of Turin, Biological and Clinical Sciences Dpt., Orbassano TO, Italy; <sup>2</sup> University of Turin, Neurosciences "Rita Levi Montalcini" Dpt., Torino, Italy

\* Corresponding author.

**Introduction.**– Mindfulness meditation showed to improve core symptoms of ADHD (Cairncross and Miller, 2016; Gu et al., 2016; Zylowska et al., 2008). This study aims to evaluate the use of a mindfulness smartphone app in adult ADHD patients focusing on the impact of face-to-face mindfulness training in term of app utilization and clinical condition.

**Methods.**– Thirteen outpatients with Adult ADHD were randomly assigned either to the training group or to the only-app group. The former only underwent mindfulness training before using the mindfulness app (once-a-day/month). Pairwise comparison

between groups and a MANOVA for repeated measures were performed using data provided by Adult ADHD Self Report Rating Scale (ADHD-RS), Profile of Mood States (POMS), Five Facet Mindfulness Questionnaire (FFMQ), Depression Anxiety Stress Scale (DASS-21). Previous meditation experiences and data about app utilization were also collected.

**Results.**– The training group used the app more frequently than the only-app group ( $P=0.002$ ), which promptly decreased the app utilization after the first week of observation ( $P=0.01$ ). The training group only showed an improvement on the confusion item of POMS ( $P=0.043$ ) and on the non-judging item of FFMQ ( $P=0.006$ ). Patients having previous meditation experiences showed a higher frequency of app utilization than other participants ( $P<0.001$ ).

**Conclusions.**– The mindfulness app utilization seems to improve both self-esteem and cognitive functioning in adult ADHD only when preceded by a face-to-face mindfulness training.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **RANZCP's new member welfare and support program**

A. Peters

*The Royal Australian and New Zealand College of Psychiatrists, OPCEO, Melbourne, Australia*

**Introduction.**– In December 2012, the Royal Australian and New Zealand College of Psychiatrists (RANZCP) introduced the Competency Based Fellowship Program.

The RANZCP undertook an evaluation of Stages 1 and 2 in November 2015, and an initial evaluation of Stage 3 in 2017.

**Objectives.**– The aim was to gather feedback on key areas such as Entrustable Professional Activities (EPAs), Workplace-based Assessments (WBAs), assessments, examinations, regulations, supervision arrangements, and the overall impact of the new program.

**Methods.**– Links to online surveys were sent out to all active trainees and accredited supervisors in November 2015, and survey details were communicated through newsletters, Psyche and via Directors of Training. The surveys were closed at the end of December 2015.

**Results.**– 39% of trainees and 38% of supervisors responded to the surveys. This presentation provides a summary of the results from the trainee and supervisor surveys, a comparison of the responses, and key findings.

**Conclusions.**– Overall, the results from trainees and supervisors were comparable with minimal differences across most survey items. Trainees and supervisors did, however, differ on the time taken to prepare for and complete the WBA activities, on supervision arrangements, and perceptions of supervision.

Based on the survey responses, the RANZCP Education Committee developed a series of recommendations for action in 2016/2017, including improved communication from RANZCP, continued prioritisation of trainee welfare, increased clarity regarding assessment requirements and standards, and consideration of development of an online e-portfolio. Indicative data on Stage 3 will investigate how these recommendations improved or changed trainees' perspectives

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

### **Hopelessness and coping strategies as possible predictors of suicidal risk**

G. Serafini<sup>1</sup>, M. Pompili<sup>2</sup>, P. Girardi<sup>3</sup>, M. Amore<sup>1</sup>

<sup>1</sup> *University of Genoa, Neuroscience DINOGMI, Genoa, Italy;* <sup>2</sup> *Suicide Prevention Center, Sant'Andrea Hospital, Sapienza University of Rome, Rome, Italy, Neurosciences, Rome, Italy;* <sup>3</sup> *Sant'Andrea Hospital, Sapienza University of Rome, Rome, Italy, Neurosciences, Rome, Italy*

\* Corresponding author.

**Introduction.**– Suicidal behavior may be considered a multifactorial event associated with a significant disability and psychosocial impairment.

**Objectives.**– Our aim was to explore the role of hopelessness and coping strategies as possible predictors of suicidal risk.

**Methods.**– We recruited a sample of 322 inpatients who have been admitted at the Section of Psychiatry, University of Genoa (Italy) and were in stable psychopathological conditions when assessed. Participants completed the following psychometric instruments: the Beck Hopelessness Scale (BHS), Suicidal Score Intent (SSI), Beck Depression Inventory, second version (BDI-II), and Coping Orientation to Problems Experienced (COPE). Clinicians also completed the Montgomery-Asberg Depression Scale (MADRS) and Intent Score Scale (ISS).

**Results.**– Patients with lifetime suicide attempts were more likely to have current suicidal ideation ( $P\leq 0.001$ ), and nonsuicidal self-injury episodes ( $P\leq 0.001$ ) relative to those without. In addition, suicide thoughts and wishes derived by the item 9 of BDI-II were significantly correlated with nonsuicidal self-injury episodes ( $r=.219$ ), current suicidal ideation ( $r=.245$ ), active suicidal desire ( $r=.318$ ), venting emotion ( $r=.227$ ), behavioral disengagement ( $r=.258$ ), and substance use ( $r=.236$ ). After multivariate analyses, the only significant predictor of suicide thoughts/wishes was depression ( $P\leq .001$ ). When depression was removed by multivariate regression model, suicide risk was also predicted by hopelessness levels ( $P\leq .05$ ).

**Conclusions.**– In line with existing evidence, depression and later hopelessness resulted significant predictors of suicidal risk, while coping strategies did not predict suicide risk. These findings need to be further tested in more selective samples of patients.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Typological and personal determinants of stress resistance in high risk sportsmen**

S. Tukaiev<sup>1</sup>, O. Dolgova<sup>2</sup>, A. Ruzhenkova<sup>2</sup>, I. Zyma<sup>3</sup>, Y. Havrylets<sup>4</sup>, V. Rizun<sup>4</sup>, O. Lysenko<sup>5</sup>, S. Fedorchuk<sup>5</sup>

<sup>1</sup> *National Taras Shevchenko University of Kyiv, Department of Social Communication- Department of Physiology of Brain and Psychophysiology, Kiev, Ukraine;* <sup>2</sup> *National Aviation University, Aviation psychology department, Kiev, Ukraine;* <sup>3</sup> *National Taras Shevchenko University of Kyiv, Department of Physiology of Brain and Psychophysiology, Kiev, Ukraine;* <sup>4</sup> *National Taras Shevchenko University of Kyiv, Department of Social Communication, Kiev, Ukraine;* <sup>5</sup> *National University of Physical Education and Sports of Ukraine, Laboratory on Theory and Method of Sport Preparation and Reserve Capabilities of Athletes, Kiev, Ukraine*

\* Corresponding author.

The problem of stress in sports psychology is considered primarily in terms of intensity of the competition situation. It is known that psychological individual characteristics are correlated with the formation of the athlete's resistance to stress while training loads and

competition. Athletes engaged in such high risk sports confront to significantly higher levels of stress. The aim of our study was to detect the individual psychological characteristics that determine stress resistance in high-risk sportsmen. 60 climbers Kiev branch of the Federation of Mountaineering and Climbing and some other sections (26 women and 34 men, aged 18 to 30 years old,  $M_{age} = 24$ ,  $SD = 1.57$ ) participated in this study. We used the following tests: Cattell's Sixteen Personality Factor Questionnaire, EPI Test (by H. Eysenck), Diagnostics of Stress-Resistance Level ("Prediction"). Statistical processing of the obtained data was performed using the Pearson rank correlation and multiple linear regression analysis. The high and average level of stress resistance was detected in 42 high-risk sportsmen (70%). It was shown that the climbers perceived a large circle of situations as threatening and responded by anxiety (the self-preservation instinct). High psychological variability and adaptability to external conditions caused by the low levels of neuroticism, high stability and lability. Stress resistance boosted by increasing self-esteem of athletes. This allows us to conclude that the structure of stress resistance of high-risk sportsmen is balanced and defined by systemic volitional powers (strength, stability), self-control behavior (self-esteem) and features of the nervous system that characterize susceptibility to external events (neurotism).

### Treatment Resistance in first episode psychosis – Prevalence and predictors

T. Abreu<sup>1</sup>, G. Oliveira

Centro Hospitalar do Tâmega e Sousa, Psychiatry and Mental Health Department, Penafiel, Portugal

\* Corresponding author.

*Introduction.*– According to National Institute for Health and Care Excellence criteria, patients with Schizophrenia who do not respond to two sequential antipsychotic trials are classified as 'treatment resistant' (TRS). This corresponds to around 30% of patients.

Several studies proposed that neurotoxicity of psychotic episodes and chronic exposure to medication are the main possible causes of TRS, leading to the belief that this mostly occurs in chronic patients. However, more recent studies point out the existence of patients that are resistant to treatment since the first episode of psychosis (FEP), suggesting a neurodevelopmental etiology.

*Objectives.*– Gather information about the prevalence and predictors of resistance to treatment in FEP.

*Methods.*– The authors conducted a literature review on PubMed database for publications on TRS e FEP in adult population. No date of publication limit was established.

*Results.*– The most recent studies indicate that 70 to 80% of resistance to treatment occurs in FEP. Different factors have been associated with treatment resistance, mainly, early age of onset, severity of negative symptoms, worse premorbid functioning and longer duration of untreated disease. Other factors will also be discussed.

*Conclusions.*– It is important to notice that the majority of treatment resistance occurs since FEP. Adequate treatment should be initiated without delays.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Avolition and structural connectivity in schizophrenia: evidence of reduced white matter integrity between amygdala and insular cortex

A. Amodio<sup>1\*</sup>, M. Quarantelli<sup>2</sup>, A. Mucci<sup>1</sup>, A. Vignapiano<sup>1</sup>, G.M. Giordano<sup>1</sup>, A. Nicita<sup>1</sup>, P. Bucci<sup>1</sup>, S. Galderisi<sup>1</sup>

<sup>1</sup> University of Campania "Luigi Vanvitelli", Psychiatry, Naples, Italy;

<sup>2</sup> National Research Council, Biostructure and Bioimaging Institute, Naples, Italy

\* Corresponding author.

*Introduction.*– In patients with schizophrenia (SCZ), an association has been reported between the avolition/apathy domain of negative symptoms and a dysfunction within key regions of the reward system. Structural and functional abnormalities have been reported in several brain areas, including ventral-tegmental area (VTA), nucleus accumbens (NAcc), orbito-frontal cortex (OFC) as well as amygdala (AMY) and insular cortex (IC).

*Objectives.*– We investigated the white matter integrity of pathways connecting the above-mentioned regions in SCZ and healthy controls (HC), and their associations with clinical indices in patients.

*Methods.*– Diffusion tensor imaging data of 30 male SCZ and 17 male HC were investigated. Pathways connecting AMY and NAcc with OFC and IC were explored. Clinical evaluation included the Schedule for Deficit Syndrome (SDS), Positive and Negative Syndrome Scale (PANSS) and the MATRICS consensus cognitive battery (MCCB).

*Results.*– Reduced fractional anisotropy (FA) was observed in left AMY-ventral anterior IC connections, in SCZ compared to HC. This abnormality was negatively correlated with avolition/apathy, but not with the expressive deficit scores. SCZ also showed reduced connectivity indices (% of the probabilistic streamlines originating from a region that reach a second one) between right NAcc and medial OFC with respect to HC. The left NAcc-dorsal anterior IC connectivity index was negatively correlated with working memory.

*Conclusions.*– According to our findings, the avolition/apathy but not the expressive deficit domain is related to the reward system dysfunction. Distinct alterations seem to underlie cognitive impairment and avolition/apathy.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Particularities of the ability to identify emotions in individuals diagnosed with schizoaffective disorder

C. Bredicean<sup>1\*</sup>, I. Papava<sup>1</sup>, C. Giurgi -Oncu<sup>1</sup>, A. Jurma<sup>1</sup>, L. Hoge<sup>1</sup>, M. Frandes<sup>2</sup>, C. Homorogan<sup>3</sup>

<sup>1</sup> "Victor Babes" University of Medicine and Pharmacy, Neuroscience, Timisoara, Romania; <sup>2</sup> "Victor Babes" University of Medicine and Pharmacy, Biostatistics and Medical Informatics, Timisoara, Romania;

<sup>3</sup> Clinical Hospital Psychiatry, psychiatry, Timisoara, Romania

\* Corresponding author.

*Introduction.*– Schizoaffective disorder is a controversial pathology, both in terms of diagnosis and longitudinal evolution. The ability to identify emotions is part of social cognition and has an important role in the social functioning of people with a psychotic pathology. *Objectives.*– To assess the ability to identify emotions in the eyes, in a group of subjects with a diagnosis of schizoaffective disorder

**Method.**– We analyzed a group of 18 subjects with a diagnosis of schizoaffective disorder (according to the WHO ICD 10). The analyzed parameters were: socio-demographic (gender, level of education, profession and marital status), clinical (onset age, years of illness evolution, number of episodes) and the ability to identify emotions in the eyes (Reading the Mind in the Eyes test). Subsequently, the identified emotions were grouped according to the six basic emotions.

**Results.**– All individuals included in this study showed a decreased ability to identify emotions in the gaze. The study also showed that a higher educational level was directly correlated to an increase in the ability to correctly identify more emotions (Spearman  $R=0.638$ ,  $P<0.01$ ). Additionally, these individuals seemed to identify emotions such as “love” (Spearman  $R=0.542$ ,  $P<0.05$ ), “sadness” (Spearman  $R=0.491$ ,  $P<0.05$ ), “distrust” (Spearman  $R=0.597$ ,  $P<0.01$ ) better than others. There was no statistically significant correlation found in terms of the number of years of illness evolution.

**Conclusion.**– The level of education seems to be directly correlated with the ability to identify emotions in the eyes.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Course of negative symptoms sudomanins in schizophrenia: A one year follow-up study

O.O. Capatina\*, I. Miclutia

Iuliu Hatieganu University of Medicine and Pharmacy, Neuroscience, Cluj-Napoca, Romania

\* Corresponding author.

**Background.**– Negative symptoms are considered to be a separable domain of pathology from other symptoms of schizophrenia and the new perspective on these symptoms suggests that they encompass actually 2 separable domains: Diminished Expression(DE) and Avolition-Apathy(AA).

**Aims.**– The aim of this study was to examine the course of negative symptoms domains and their stability over a period of one year in patients with schizophrenia and to assess the relevance of this factor structure with external validators such as: sociodemographic characteristics, global functioning, and treatment.

**Methods.**– A sample of 95 subjects whom met the criteria for schizophrenia and were stable from the point of view of the symptoms for at least 3 month and had primary negative symptoms were included in our study. The patients were evaluated using the Positive and Negative Symptoms Scale (PANSS), Negative Symptoms Assessment-16 items (NSA-16), Global Assessment of Functioning (GAF), Calgary Depression Scale for Schizophrenia (CDSS), Simpson-Angus Extrapyramidal Side Effects Scale and were interviewed to assess sociodemographic characteristics. Principal component analyses (PCA) was conducted to establish the factor structure of the negative symptoms and the analyses of variance was used for to assess the stability of the symptomatology.

**Results.**– The PCA analyses established the two factor structure of negative symptomatology, explaining 79% of the variance. There was no significant effect for time in the negative symptomatology ( $P=0.38$ ,  $P=0.49$ ) and the AA domain is associated with poorer functioning ( $P=0.01$ ) and with higher doses of treatment ( $P=0.01$ ).

**Conclusions.**– AA and DE domains remained stable at one year follow-up, therefore they should be analyzed separately in terms of cause, predictive outcome and treatment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparison of neurocognition and social cognition between schizophrenia and bipolar disorder

G. Mihajlovic<sup>1</sup>, D. Pavlovic<sup>2</sup>, M. Zivanovic<sup>3</sup>, J. Djordjevic<sup>4</sup>

<sup>1</sup> Psychiatric Clinic, Clinical Center, University of Kragujevac, Affective Disorder Department, Kragujevac, Serbia; <sup>2</sup> Faculty for Special Education and Rehabilitation, University of Belgrade, Neuropsychology Department, Belgrade, Serbia; <sup>3</sup> Faculty of Philosophy, University of Belgrade, Psychology Department, Belgrade, Serbia; <sup>4</sup> Clinic for Psychiatric Disorders “Dr Laza Lazarevic”, Belgrade, Emergency Department, Belgrade, Serbia

\* Corresponding author.

Cognitive impairment is a key feature of both schizophrenia (Sch) and bipolar affective disorder (BD).

The aim of this study is to evaluate the neuropsychological deficits in patients diagnosed with Sch and BD and the corresponding clinical feature-deficits correlations.

The study included 60 outpatients from the Psychiatric Clinic “Dr Laza Lazarevic” in remission (30 Sch, 30 BD), and 30 healthy subjects. Clinical symptoms were assessed using PANSS in Sch, and YMRS and HAM-D in BD group. Subjects’ neuropsychological deficits were assessed using Mini-Mental State Examination (MMSE), Trail Making Test B (TMT-B) and Go/no-go, while sociocognitive deficits were assessed using Faux pas (FP) and the Reading the minds in the eyes test (RMET).

Sch patients demonstrated significant attention and short-term verbal memory deficits compared to BD ( $U=321.0$ ,  $P<.05$ ;  $U=317.0$ ,  $P<.05$ ). Both clinical groups achieved lower scores on RMET [ $\chi^2(2)=13.467$ ,  $P<.01$ ] and FP [ $\chi^2(2)=21.339$ ,  $P<.01$ ] compared to controls, whereas no difference between Sch and BD has been observed. Additionally, in Sch group negative, rather than positive symptoms were associated with poor performance on all neurocognitive and social cognitive measures used, whereas in BD group depressive symptomatology accounted for poor performance on TMT-B and RMET, while manic accounted for MMSE and RMET.

Similar neurocognitive and social cognitive impairment profiles have been reported in both schizophrenia and BD. Subclinical pathology in patients in remission is associated with the cognitive performance deficit severity.

### Efficacy of integrated community club care and community-based psychosocial rehabilitation on social cognitive processing in schizophrenia

S. Endre<sup>1</sup>, T. Bugya<sup>2</sup>, R. Herold<sup>1</sup>, T. Tényi<sup>1</sup>, V. Eszter<sup>1\*</sup><sup>1</sup> University of Pecs, Psychiatry and Psychotherapy, Pécs, Hungary;<sup>2</sup> University of Pecs, Department of Geoinformatics, Pécs, Hungary

\* Corresponding author.

**Introduction.**– Psychosocial rehabilitation aims to recover social functioning for mentally ill individuals. Community Psychiatric Institute (Pécs, Hungary) provides two types of psychosocial rehabilitation programs for schizophrenic patients to help improve their

social cognition. One is community-based psychosocial rehabilitation (CPR), the other is Integrated Community Club (ICC).

**Objectives.**– Our aim was to examine the efficacy of CPR and ICC on improving social cognition in schizophrenia.

**Methods.**– A total of 86 schizophrenic patients participated either in CPR, ICC or treatment as usual (TU). Both CPR and ICC received pharmacotherapy and took part in a 6-month program including trainings, such as communication and assertiveness trainings. In addition, ICC provided group therapeutic treatments four times a week and a continuously available day care where patients had the possibility to participate in various social interactions. TU group received only pharmacotherapy. Social cognitive domains were assessed in the three groups at baseline and post-treatment with a self-developed psychometric software including a battery of questionnaires that examined affective face perception, affective prosody perception, pragmatic language and mentalizing functions.

Kruskal-Wallis one-way analysis of variance by ranks and Wilcoxon Signed-Rank Test were performed to analyse data.

**Results.**– Social processing improved significantly both in CPR and ICC between baseline and post-treatment. After the Bonferroni correction ( $P < 0.01$ ), both ICC and CPR improved their performance in irony tasks ( $P < 0.001$ ;  $P = 0.001$ ) and CPR also improved performance in prosody tasks ( $P = 0.001$ ). However, TU group impairments of mentalizing progressed significantly ( $P < 0.001$ ).

**Conclusion.**– Results showed that CPR and ICC are effective psychosocial rehabilitation programs for patients to improve social processing.

**Disclosure of interest.**– This research was supported by the National Brain Research Program Grant No. NAP KTIA NAP-A-II/12.

### **Social cognition deficit related to reduced frontal gray matter volume as markers of psychosis proneness in 22q11.2 deletion syndrome**

M. Frascarelli<sup>1</sup>\*, A. Buzzanca<sup>2</sup>, E. Fontana<sup>2</sup>, T. Accinni<sup>2</sup>, C. Colonnese<sup>2</sup>, F. Di Fabio<sup>2</sup>, M. Biondi<sup>2</sup>

<sup>1</sup> Sapienza University Roma, Neurology And Psychiatry Department, Rome, Italy; <sup>2</sup> Sapienza University Roma, Neurology And Psychiatry, Rome, Italy

\* Corresponding author.

**Introduction.**– 22q11.2 Deletion Syndrome (22q11.2 DS) patients have 25% risk of psychosis onset. Social cognition deficits and brain abnormalities are supposed to be endophenotypes of schizophrenia.

**Objectives.**– The study assess the hypothesis that social cognition deficit is similar in 22q11.2 DS and schizophrenia. The second aim is to investigate associations between social cognition impairment and grey matter volume reduction.

**Methods.**– The sample consist of three groups: 13 22q11.2 DS non psychotic subjects (DEL), 25 schizophrenic patients (SCZ) and 10 healthy controls (HC). They have been assessed by TASIT (The awareness of social inference test), a social cognition task. All subjects performed a brain MRI scan; grey matter volume was examined whole-brain through Voxel Based Morphometry.

**Results.**– SCZ showed a significantly worse performance in “simple sarcasm” item respect to HC ( $P = 0.044$ ). Both SCZ and DEL revealed significant impairments in “paradoxical sarcasm” item compared to HC (respectively  $P = 0.007$  and  $P = 0.002$ ). Clinical groups showed significantly worse “basic social inference” scale results compared to HC (HC vs DEL  $P = 0.001$ ; HC vs SCZ  $P = 0.002$ ). The “paradoxical sarcasm” performance showed a positive correlation with the volume of left frontal medial gyrus ( $P < 0.001$ ), which showed

reduction in DEL compared to HC ( $P = 0.009$ ). The variable “basic social inference” positively correlated with the volume of the left intermediate frontal gyrus ( $P < 0.001$ ), which showed a reduction in both in SCZ ( $P < 0.001$ ) and DEL ( $P < 0.001$ ) respect to HC.

**Conclusions.**– Present results allow to presume that vulnerability to schizophrenia for 22q11.2 DS patients has a neurobiological ground related to the social cognition impairment.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Effectiveness of coordinated specialty care for early psychosis**

B. Galling<sup>1,2,3\*</sup>, C.U. Correll<sup>1,2,3</sup>

<sup>1</sup> Charité Universitätsmedizin, Child and Adolescent Psychiatry, Berlin, Germany; <sup>2</sup> Hofstra Northwell School of Medicine, Psychiatry and Molecular Medicine, Hempstead, USA; <sup>3</sup> The Zucker Hillside Hospital, Psychiatry Research, Glen Oaks, USA

\* Corresponding author.

**Introduction.**– Outcomes in people with schizophrenia-spectrum disorders have remained suboptimal. Several research programs for early psychosis yielded promising results for team-based, multi-element coordinated specialty care (CSC).

**Objectives.**– To meta-analytically compare CSC with Treatment as Usual (TAU).

**Methods.**– Systematic literature search of PubMed/PsycInfo/Embase/clinicaltrials.gov without language restrictions until 06/06/2017 for randomized trials comparing CSC versus TAU in early psychosis. Random effects meta-analysis of  $\geq 2$  studies with data, calculating standardized mean differences (SMDs) and risk ratios (RRs) for continuous and categorical outcomes.

**Results.**– Across 10 trials ( $n = 2176$ ; age =  $27.5 \pm 4.6$  years; male = 62.3%; trial duration =  $16.2 \pm 7.4$  (range = 9–24 months), CSC outperformed TAU at the end of treatment regarding all meta-analyzable outcomes. This included all-cause discontinuation (studies = 10,  $n = 2173$ , RR = 0.70, 95% confidence interval (CI) = 0.61–0.80,  $P < 0.001$ ; number-needed-to-treat (NNT) = 12.4),  $\geq 1$  hospitalization (studies = 10,  $n = 2105$ , RR = 0.74, 95% CI = 0.61–0.90,  $P = 0.003$ ; NNT = 10.1), total symptom severity (studies = 8,  $n = 1179$ , SMD =  $-0.32$ , 95% CI =  $-0.47$ ,  $-0.17$ ,  $P < 0.001$ ), positive symptoms (studies = 10,  $n = 1532$ , SMD =  $-0.22$ , 95% CI =  $-0.32$ ,  $-0.13$ ,  $P < 0.001$ ), negative symptoms (studies = 10,  $n = 1432$ , SMD =  $-0.28$ , 95% CI =  $-0.42$ ,  $-0.14$ ,  $P < 0.001$ ), general symptoms (studies = 8,  $n = 1118$ , SMD =  $-0.30$ , 95% CI =  $-0.47$ ,  $-0.13$ ,  $P = 0.001$ ), depressive symptoms (studies = 5,  $n = 874$ , SMD =  $-0.19$ , 95% CI =  $-0.35$ ,  $-0.03$ ,  $P = 0.017$ ), functioning (studies = 7,  $n = 1005$ , SMD = 0.21, 95% CI = 0.09–0.34,  $P = 0.001$ ), involvement in school/work (studies = 6,  $n = 1743$ , RR = 1.13, 95% CI = 1.03–1.24,  $P = 0.012$ ; NNT = 17.8), and quality of life (studies = 4,  $n = 505$ , SMD = 0.23, 95% CI = 0.004–0.456,  $P = 0.046$ ). Superiority of CSC regarding all outcomes was also evident at 6, 9–12, and 18–24 months of treatment (except general symptoms and depression at 18–24 months).

**Conclusion.**– In early psychosis, CSC is superior to TAU across all meta-analyzable, highly relevant outcomes with small-to-medium effect sizes. These results support the need for funding and utilization of CSC in patients with early-phase psychosis.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### White matter structure abnormalities in the deficit subtype of schizophrenia. A DTI study

G.M. Giordano<sup>1\*</sup>, M. Quarantelli<sup>2</sup>, A. Mucci<sup>1</sup>, A. Amodio<sup>1</sup>, A. Vignapiano<sup>1</sup>, A. Nicita<sup>1</sup>, P. Bucci<sup>1</sup>, S. Galderisi<sup>1</sup>

<sup>1</sup> University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy; <sup>2</sup> Biostructure and Bioimaging Institute, National Research Council, Via T. De Amicis 95, Naples, Italy

\* Corresponding author.

**Introduction.**– Deficit schizophrenia (DS) has been proposed as a separate disorder with respect to non-deficit schizophrenia (ND). It is characterized by the presence of primary, enduring negative symptoms and by different course, risk factors and clinical features. **Objectives.**– We investigated differences of white matter connectivity within several brain areas in subjects with DS compared to ND and healthy controls (HC), using probabilistic analysis of diffusion tensor imaging data.

**Methods.**– Forty-six subjects with chronic schizophrenia (SCZ) and 35 age- and gender-matched HC were included. Nine patients were classified as DS, and 37 as ND using the Schedule for the Deficit Syndrome. Psychopathology was assessed with the Positive and Negative Syndrome Scale, and neurocognition with the MATRICS Consensus Cognitive Battery. Connectivity index [CI] (% of the probabilistic streamlines originating from a region that reach a second one) and Fractional Anisotropy (FA) of pathways connecting dorso-lateral prefrontal cortex (DLPFC), nucleus accumbens (NAcc), amygdala (AMY) and insular cortex (IC) were examined.

**Results.**– CI between right AMY and DLPFC was reduced in SCZ compared to HC, but didn't differ between DS and ND. DS showed an increased CI from right AMY to dorsal-anterior IC compared to ND. In SCZ, PANSS disorganization was associated to the FA of right NAcc-DLPFC connections.

**Conclusions.**– Our data confirm previous evidences of distinct neurobiological alterations underpinning different symptom dimensions and clinical subtypes of SCZ. Abnormal connectivity patterns of brain regions involved in guiding goal-directed behavior based on experienced value seem to be related to primary and persistent negative symptoms.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Introduction and objectives.**– The aim of our work is to review the existing literature published on Post-Psychotic Depression (PPD) and to point out its relevance both as a comorbidity and as a distinct entity. A historical review of the term was carried out with a valid definition of PPD.

**Material and methods.**– A systematic literature search was conducted according to the guidelines for Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). A comprehensive search of Web of Science and PubMed was performed until February 1st, 2017

**Results.**– A total of 60 papers were found in the primary search. We excluded those papers written in languages other than Spanish or

English, duplicates or those that did not fit the search terms. The final number of studies included in this review was thirteen.

To the light of the results obtained in our review, we can state that despite the high prevalence of PPD (around 30% in different samples) there is a paucity of literature on the PPD.

**Conclusions.**– There is sufficient data to consider PPD as a distinct nosological entity, different from the secondary effect of antipsychotic medication, negative symptoms of psychosis, bipolar disorder, schizoaffective disorder or depression with psychotic symptoms. It also has differential characteristics with respect to the rest of depressions.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Prodromal phase of psychosis and drug consumption in emergency services

B. Girela Serrano<sup>1\*</sup>, M. Guerrero Jiménez<sup>2</sup>, C.M. Carrillo de Albornoz Calahorra<sup>3</sup>

<sup>1</sup> Hospital Santa Ana Motril, Psiquiatría, Motril, Granada, Spain;

<sup>2</sup> Complejo Hospitalario de Granada, Granada, Spain; <sup>3</sup> Hospital de Baza, Granada, Spain

\* Corresponding author.

**Background.**– 21% of women with first episode of Psychosis in the South-Granada between 2008 and 2014 went to hospital emergency during the duration of untreated psychosis (DUP) aiming a gynaecological consultation caused by psychotic symptoms. Only one in five was referred to mental health.

**Aims.**– To improve difficulties detecting cases during the prodromal phase, we aim to analyse the patient's profile, cannabis and other drugs consumption, reasons for consultation and study whether there are variables that facilitate referral to specialist intervention. **Methods.**– A retrospective clinical-cases review of medical histories was made searching for sociodemographic variables, drug consumption, emergency services consultations and psychotic prodromal outcomes.

**Results.**– They were single women between 18–32 years. 60% reported cannabis consumption. All of them live with family. 80% were studying or unemployed. Three types of emergency consultations were reported with a similar incidences: Order the emergency-contraception-pill, a pregnancy test or "a scan to check virginity/a non-consensual relationship". During the initial exploration about 40% were under the influence of drugs.

**Discussion.**– According to these results, the most important variables are to analyse any drug consumption and the reason for consultation. Moreover if substance abuse and a combination of prodromal symptoms including positive and other nonspecific are detected. Furthermore, at the profile with possible demands, we believe is appropriate not to delay mental health assessment after making the appropriate intervention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Obsessive compulsive symptoms in patients with schizophrenia: Prevalence and relation with clinical features of schizophrenia

A. Hakiri<sup>\*</sup>, A. Aissa, H. Ben Ammar, Z. ElHechmi Razi hospital, F, Manouba, Tunisia

\* Corresponding author.

**Introduction.**– Schizophrenia is a chronic, severe and heterogenous mental disorder. It has a various dimensions of symptoms including positive, negative, cognitive, affective and disorganised symptoms. A number of studies suggested a frequent additional occurrence of obsessive compulsive symptoms (OCS) in schizophrenia.

**Objectives.**– We aim to identify the prevalence of OCS in schizophrenia and to correlate it to other clinical dimensions of schizophrenia.

**Methods.**– A retrospective study nearby 30 patients with schizophrenia who are followed up at the outpatient unit. The participants fulfilled the diagnosis of schizophrenia as per the DSM-V diagnostic criteria. We used the obsessive compulsive inventory (OCI), the positive and negative syndrome scale (PANSS) and a semi-structured questionnaire to determine the premorbid personality, the family history, the age of onset, the duration of untreated psychosis, the number of relapses and the last prescribed treatment. The version 22 of SPSS was used for statistical analysis.

**Results.**– All patients are male. The average age is 37.33 years. 80% are single and live with their families. One-third of patients have a psychiatric family history (mood disorder or psychosis). 33% of the sample have obsessive compulsive symptoms. The most frequent obsession/compulsion is cleaning/washing. The presence of obsessive-compulsive symptoms is associated with an early age of onset and a longer duration of untreated psychosis. Patients who were treated with atypical antipsychotics had more OCS, and especially risperidone.

**Conclusion.**– The prevalence of OCS is higher in patients with schizophrenia than in general population. It is possible that these symptoms are induced by atypical antipsychotics.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Quality clozapine care (QC2): Using the patient journey to understand the lived experience of taking clozapine, to improve value-based person-centered care**

M.C. Hanlon<sup>1\*</sup>, A.P. O'Brien<sup>2</sup>, P. MacIsaac<sup>3</sup>, M. Fogarty<sup>4</sup>, C. Bjorksten<sup>5</sup>, M. Hunt<sup>4</sup>, D. Coates<sup>6</sup>, V. Drinkwater<sup>4</sup>, T. Gordon<sup>4</sup>, C. Matthew<sup>4</sup>, T. Parkin<sup>4</sup>, S. Tirupati<sup>4</sup>

<sup>1</sup> University of Newcastle, School of Medicine & Public Health, Newcastle, Australia; <sup>2</sup> University of Newcastle, School of Nursing & Midwifery, Newcastle, Australia; <sup>3</sup> Hunter Medical Research Institute, CREdITS, Newcastle, Australia; <sup>4</sup> Hunter New England Local Health District, Mental Health, Newcastle, Australia; <sup>5</sup> Hunter New England Local Health District, Mental Health Pharmacy, Newcastle, Australia; <sup>6</sup> Central Coast Mental Health Service, Translational Research, Gosford, Australia

\* Corresponding author.

**Introduction.**– Clozapine is an effective, but possibly-hazardous treatment for intractable psychosis<sup>1,2</sup>, with potentially-lethal side effects (e.g. metabolic syndrome, agranulocytosis, depression and suicide, cardiovascular disease and death), requiring mandatory monitoring<sup>3-6</sup>. Community management is now encouraged because of its potential to reduce stigma and improve access to care<sup>7-9</sup>, but it remains unclear how various models impact on patient safety and quality of life.

Hunter New England Mental Health (HNEMH) has developed a collaborative community care model. HNEMH clinicians enter patient records into ClopineCentral™, including patient details/demographics, blood group and test results, dates commenced/ceased, therapy interruptions/events, and current doses/quantity dispensed against each blood test, which are available to relevant local district clinicians.

**Objectives.**– We will determine how well the HNEMH model matches the HNEMH Care Guidelines (13\_05) for Clozapine Initiation, Monitoring, Management and Cessation, which encompass national & state policy directives.

**Methods.**– We will use a mixed-methods approach, with clozapine recipients, their carers, and relevant clinical staff, including semi-structured qualitative interviews and a quality of life survey for recipients<sup>10-12</sup>.

**Results.**– Thematic analysis will describe the pathways, barriers and enablers to quality clozapine care in a community context.

**Conclusions.**– By documenting the shared-care pathway between the hospital/HNEMH Community Mental Health Teams, and other service providers, the existing “HealthPathway” will be enhanced, enabling HNEMH to better-support person-centric care, through remodelling, service redesign and provision of excellent care every time – focusing on making the program more service user sensitive by identifying points at which quality assurance and further research attention are necessary.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Horrobin's membrane phospholipid theory of schizophrenia: The relationship between the Niacin Skin Flush Test, levels of GPR120 receptor and dietary fat intake**

H. Karakula-Juchnowicz<sup>1\*</sup>, J. Rog<sup>2</sup>, P. Wolszczak<sup>3</sup>, E. Stelmach<sup>4</sup>, M. Dzikowski<sup>2</sup>, J. Moryłowska-Topolska<sup>5</sup>, D. Juchnowicz<sup>6</sup>, P. Krukow<sup>5</sup>, J. Gałaszkiwicz<sup>2</sup>, J. Tomaka<sup>2</sup>, M. Koziol<sup>7</sup>

<sup>1</sup> Medical University, I Department of Psychiatry, Psychotherapy and Early Intervention, Department of Clinical Neuropsychiatry, Lublin, Poland; <sup>2</sup> Medical University of Lublin, I Department of Psychiatry, Psychotherapy and Early Intervention, Lublin, Poland; <sup>3</sup> Lublin University of Technology, Department of Automation, Mechanical Faculty, Lublin, Poland; <sup>4</sup> Medical University of Lublin, II Department of Psychiatry and Psychiatric Rehabilitation, Lublin, Poland; <sup>5</sup> Medical University of Lublin, Department of Clinical Neuropsychiatry, Lublin, Poland; <sup>6</sup> Medical University of Lublin, Department of Psychiatric Nursing, Lublin, Poland; <sup>7</sup> Medical University of Lublin, Department of Clinical Microbiology, Lublin, Poland

\* Corresponding author.

**Introduction.**– According to Horrobin's theory of schizophrenia, the biochemical basis of the illness is lipid metabolism disruption caused by hyperactivity of phospholipase A2 (PLA2). The niacin skin flush test reflects an activity of PLA2 and could assess lipid metabolism abnormalities. Activated by essential fatty acids (EFAs) GPR120 receptor mediates stimulation of PLA2. The role of GPR120 in the positive effect of EFAs omega-3 supplementation in schizophrenic patients remains unclear.

**Objectives.**– The aim of this study was to determine the relationship between the flush response to niacin, serum levels of GPR120 and fat intake among patients with schizophrenia and healthy controls.

**Methods.**– We performed the niacin skin flush test, measured GPR120 serum level and estimated fat intake in 49 patients diagnosed with schizophrenia and 27 healthy volunteers. PANSS scale were used to determine psychopathological symptoms in the patients group.

**Results.**– Flush response to niacin was lower in the patients group compared to the healthy controls ( $P < 0.05$ ) despite no difference in GPR120 serum levels and fat intake between groups. In the patients group there was a positive association between GPR120 and fatty acid intake ( $P < 0.05$ ) and a negative association with psychopatho-

logical symptoms. There was no link between GPR120 and fat intake in the control group ( $P < 0.05$ ).

**Conclusions.**– The results suggest differences in lipid metabolism in the patients group compared to the control group and confirming Horrobin's theory.

**Keywords:** Schizophrenia; Membrane phospholipid theory; Niacin skin flush test; GPR120

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Should patients with schizophrenia be put on a gluten-free diet? An association between markers of intestinal permeability, inflammation and gluten sensitivity in patients with schizophrenia**

H. Karakula-Juchnowicz<sup>1\*</sup>, M. Dzikowski<sup>2</sup>, J. Rog<sup>2</sup>, M. Koziol<sup>2</sup>, J. Moryłowska-Topolska<sup>3</sup>, A. Makarewicz<sup>4</sup>, M. Flis<sup>2</sup>, D. Juchnowicz<sup>5</sup>  
<sup>1</sup> Medical University, I Department of Psychiatry, Psychotherapy and Early Intervention- Department of Clinical Neuropsychiatry, Lublin, Poland; <sup>2</sup> Medical University of Lublin, I Department of Psychiatry, Psychotherapy and Early Intervention, Lublin, Poland; <sup>3</sup> Medical University of Lublin, Department of Clinical Neuropsychiatry, Lublin, Poland; <sup>4</sup> Medical University of Lublin, I Department of Psychiatry, Psychotherapy and Early Intervention, Lublin, Poland; <sup>5</sup> Medical University of Lublin, Department of Psychiatric Nursing, Lublin, Poland

\* Corresponding author.

**Introduction.**– One possible explanation for the schizophrenia development is low-grade inflammation, the source of which may be pathological processes in the gastrointestinal tract related to leaky gut and IgA and IgG-dependent food hypersensitivity.

**Objectives.**– To compare levels of markers of: intestinal permeability, inflammation, and gluten sensitivity between schizophrenic patients (SCHI) and controls (C).

**Methods.**– The total sample comprised 162 individuals (102 SCHI + 60C). Besides a nutritional test for all the participants and PANSS for SCHI, the battery of laboratory tests was administered, including: inflammatory markers (hsCRP, IL6); markers of intestinal permeability (sCD14, ASCA); markers of gluten sensitivity (anti-gliadin antibodies AGA IgA and AGA IgG); markers of coeliac disease (anti-tissue transglutaminase IgA antibodies and IgG antibodies against deamidated gliadin).

**Results.**– (1) Significant differences were observed between SCHI and C groups in the markers of intestinal permeability, markers of gluten sensitivity and the inflammatory markers. (2) Suspected celiac disease was found in 8.33% of SCHI versus 1.67% of C group. (3) Gluten sensitivity was noted in 25.5% of SCHI versus 10% of C (AGA-IgG) and in 19.6% of SCHI versus 6.67% of C (AGA-IgA). (4) Associations between intestinal permeability, gluten sensitivity and inflammation were noted in SCHI. (5) No correlations were found between AGA-IgA and AGA-IgG and gluten-intake.

**Conclusions.**– The study results suggest the role of inflammatory processes related to gluten sensitivity in the etiopathogenesis of schizophrenia, which may give grounds for including individual dietary interventions based on results of laboratory tests in the therapy of schizophrenic patients.

**Keywords:** Schizophrenia; Gluten sensitivity; Leaky gut syndrome

### **Serum levels of selected hormones and cognitive functions in schizophrenic female patients – Preliminary results**

K. Krysta<sup>\*</sup>, A. Bratek

Medical University of Silesia, Department of Psychiatry and Psychotherapy, Katowice, Poland

\* Corresponding author.

**Introduction.**– Sex steroid hormones play an important role in the development and clinical features of schizophrenia.

**Objectives.**– To find correlation between serum levels of selected hormones and cognitive functions.

**Methods.**– In the study group there were 28 women diagnosed with schizophrenia: 18 in reproductive age and 10 post-menopausal females. The control group consisted of 40 healthy female volunteers, 25 of them were in reproductive age and 15 after menopause. All participants underwent the following procedures: assessment of serum hormone levels (TSH, testosterone, estradiol, FSH, LH, prolactin and progesterone) and examination with neuropsychological tests: TMT; Stroop Test, Verbal Fluency Test.

**Results.**– We compared serum levels of hormones separately for women after menopause and in child bearing age. The most prominent differences in both groups pertained to significantly higher level of testosterone and prolactin, as well as lower of estradiol in the index group. Women suffering from schizophrenia performed worse in all neuropsychological tests. In the group of post-menopausal females, we found statistically significant correlations only in healthy controls – between prolactin and semantic fluency. In females in reproductive age different cognitive domains were affected in control and index groups. In the group of healthy controls we reported the following correlations: TMT A – TSH and estradiol; TMT B – estradiol; Stroop Task 2 – TSH, estradiol, while in the index group: TMT B – TSH; verbal fluency – TSH, FSH; semantic fluency – estradiol.

**Conclusions.**– We treat our study results as a voice in the discussion on this interesting and important problem.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0872

### **Family history and DUP: A retrospective study in first-episode psychosis at CHPL**

I. Pinto<sup>\*</sup>, S. Garcia, M.J. Avelino, T. Filipe, T. Teodoro, R. Mateiro, M. Martins, C. Ferreira, S. Alves, J. Salgado, F. Gomes, B. Neves  
 Centro Hospitalar Psiquiátrico de Lisboa, Clínica 1, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– It is well known that the duration of untreated psychosis (DUP) influences the prognosis of people with a first-episode psychosis (FEP). What it is still to clarify is how some factors affect DUP, like family history and consequently the familiarity with mental illness. Previous research obtained contradictory results for this relation.

**Objectives.**– Characterize DUP and a positive family history of psychiatric illness, namely psychosis in patients hospitalized for the first-episode psychosis and analyze if there is any relationship between them.

**Methods.**– A database with clinical information and family history of all patients hospitalized for the first-episode psychosis (FEP) in 2016 in the Treatment and Stabilization of Adolescents and Young Adults Service (SETA) of the Psychiatric Hospital Center of Lisbon (CHPL) was used in our study.

**Results.**– From the analysis of the database we obtained 52 patients hospitalized for FEP. The DUP had an average of 42 weeks, with a median of 12 weeks. Relatively to family history we divided the patients in groups: 9 people had family history of psychosis, 14 mental illness in first degree relative, 31 mental illness in the family and 14 no history. The mean values of DUP in each group were 32, 38, 47 and 52 respectively.

**Conclusions.**– Our results may suggest a decrease in DUP with a family history when compared with no history and even less delay on initiating the treatments when it is a first degree relative or one with psychotic illness. This is concordant with some of the preexisting data.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### **Time perception of patients with schizophrenia and bipolar disorder in the range of sub- and suprasedonds**

I. Szendi\*, S. Szalóki

University of Szeged, Psychiatry, Szeged, Hungary

\* Corresponding author.

**Introduction.**– Dysfunction in processing temporal intervals can be detected in numerous psychiatric and neurological disorders. Tracing this phenomena can help us better understand the experience of time in the patients' subjective experiences.

**Objectives.**– We have compared people with schizophrenia and bipolar disorder regarding time perception, which engages different brain areas during perception in the range of subseconds and suprasedonds.

**Participants.**–  $n = 11$  patients with schizophrenia,  $n = 6$  patients with bipolar affective disorder and  $n = 10$  healthy volunteers participated in the study.

**Methods.**– We used interval discrimination (perception task) and a multiple interval tapping (production task) to examine temporal disturbances. The tasks involved time intervals in both subsecond and suprasedond ranges.

**Results.**– Our results show that patients with schizophrenia show deficits both in temporal discrimination and in the multiple interval production task across suprasedond as well as subsecond ranges. Due to these deficits their performance compared to both patients with bipolar disorder and healthy controls was significantly reduced. In comparison, the performance of patients with bipolar disorder was similar to healthy controls and close to objective time intervals during both perception and production tasks.

**Conclusions.**– Our findings are consistent with previous results suggesting that patients with schizophrenia suffer from a general timing dysfunction rather than a localized temporal deficit. We have also found that regarding time perception, it is possible to differentiate not only between healthy controls and people with schizophrenia but also between people with schizophrenia and bipolar disorder.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0874

### **An audit of quality of assessment of side-effects in patients prescribed depot anti-psychotics in community mental health service**

H. Tahseen

Park Lodge Resource Centre, Community Mental Health Services, Northwich, United Kingdom

\* Corresponding author.

**Introduction.**– According to NICE 2009 standards, People receiving depot antipsychotic preparations should be maintained under regular clinical review, particularly in relation to risks and benefits of the medication.

**Objectives.**– Aim of the audit is to ensure that all patients on long acting depot antipsychotics should have standard review at least once a year.

**Method.**– 50 male and 50 female patients under two responsible clinicians in a Community Mental Health Service were randomly selected using prescribing data from the pharmacy department from March 2016 till March 2017 and we examined their medical notes about diagnosis, type and dose of depot anti-psychotic and documentation of annual reviews of side effects. It was also useful to consider whether there was a record for weight gain, movement disorders, sexual side effects and menstrual abnormalities. If patients were experiencing side effects, it was noted whether appropriate action was taken (e.g. blood test for Prolactin level, consideration of medication for extra-pyramidal side effects). The percentage of patients with an enquiry relating to side effects was also calculated.

**Results.**– 33% didn't have any documentation of side effects. 29% had a documented physical examination specifically to assess side effects. 35% had a documented movement disorder. No documentation on sexual side effects was present.

**Conclusions.**– There was a clear requirement for improvement in the assessment of side effects and their documentation. A physical health-check form should be devised for such patients with clear sections on sexual side effects, movement disorders and menstrual abnormalities. Community nurses should initiate annual physical checks.

**Disclosure of interest.**– The author has not supplied a conflict of interest statement.

PW0875

### **Perinatal stress and psychosis onset: Results from the Bologna first episode psychosis incidence study**

I. Tarricone<sup>1\*</sup>, L. Negrelli<sup>2</sup>, G. Pollutri<sup>3</sup>, M.G. Nanni<sup>2</sup>, D. Berardi<sup>4</sup>

<sup>1</sup> Alma Mater Studiorum Università di Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; <sup>2</sup> Università di Ferrara, Clinica Psichiatrica, Ferrara, Italy; <sup>3</sup> Università di Modena e Reggio Emilia, Dipartimento di Medicina Diagnostica, Clinica e di Sanità Pubblica, Modena, Italy; <sup>4</sup> Università di Bologna, Dipartimento di Scienze Mediche e Chirurgiche, Bologna, Italy

\* Corresponding author.

**Background and aims.**– The pathogenesis of psychosis relies on a constellation of causal factors according to the gene-environment interaction model. Perinatal stress represents an important risk factor for the development of psychosis because it could interfere with neurodevelopment. However, there are few studies that simultaneously investigated the effects of exposure to risk factors in conception, pregnancy and birth. We aim to investigate the frequency of and correlation with psychotic onset of pre, peri and post-natal risk factors.

**Methods.**– Case-control – incidence study. Patients (and their mothers) were eligible if they presented for the first time with first episode psychosis at the Bo West CMHC between 2002 and 2012. The Bo West CMHC serves a catchment area of about 200,000 people. The controls were recruited in the same catchment area and study period [1].

**Results.**– 42 patients and 26 controls and their mothers were included. Adjusted logistic regression showed that psychosis onset was significantly associated with: stressful situations during pregnancy; lower level of maternal physical health before or during

pregnancy; use of anti-inflammatory drugs during pregnancy; low level of maternal education.

**Conclusions.**– The results of our study suggest that stress during pre- and perinatal periods increases the risk of developing psychosis. More attention should be given to the containment of preinatal stress and the prevention of its adverse effects on mother and child mental health.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Comparison of facial expressions between the patient with schizophrenia and healthy control, utilizing the human facial modelling lab – Pilot study

K.M. Wilczynski<sup>1\*</sup>, A. Dudek<sup>2</sup>, K. Krysta<sup>2</sup>, D. Pęszor<sup>3</sup>, E. Martyniak<sup>2</sup>, M. Wojciechowska<sup>3</sup>, M. Krzystanek<sup>2</sup>, K. Wojciechowski<sup>3</sup>, M. Janas-Kozik<sup>1</sup>

<sup>1</sup> Medical University of Silesia, Department of Psychiatry and Psychotherapy of Developmental Age, Katowice, Poland; <sup>2</sup> Medical University of Silesia, Department of Psychiatric Rehabilitation, Katowice, Poland; <sup>3</sup> Polish-Japanese Academy of Information Technology, Human Facial Modelling Lab, Bytom, Poland

\* Corresponding author.

**Introduction.**– Aggravated social competencies, caused by deficits in area of communication, may have prominent, adverse impact on quality of life of individuals suffering from psychiatric disorders. Inability to properly exhibit and interpret facial expressions (FE), may lead to social exclusion, unemployment and deterioration of family life, what may significantly affect outcomes of the treatment. Aim of our study was to compare intensity of facial expressions in the individual with schizophrenia and in healthy control.

**Methods.**– 47-year-old patient suffering from schizophrenia, and 36-year-old healthy individual were presented with two video materials. First one contained different FE, presented by an actress, which they had to imitate. Second one consisted of a short comedy show which was intended to elicit spontaneous FE. Acquisition of FE was conducted with marker-based technology of human facial modelling. Obtained data was analyzed using Microsoft Excel and Mokka Software.

**Results.**– An overall range of FE, in the patient with schizophrenia, equaled 5.38 mm in case of the first video material and 2.10 mm in case of the second. In the healthy control values equaled respectively 6.41 mm and 7.66 mm.

**Conclusions.**– An overall FE intensity, measured as average distance covered by all markers during shifts from neutral position was significantly higher in case of the healthy participant. Utilization of marker-based methods in analysis of human FE seem to be reliable and remarkably accurate methodology.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Validation of the Illness Perception Questionnaire for schizophrenia in Chinese patients with schizophrenia

C. Zhou<sup>1</sup>, Z. Li

Peking Union Medical College, School of Nursing, Beijing, China

\* Corresponding author.

**Introduction.**– Nonadherence has contributed to outcome variations related to symptoms and social function in patients with schizophrenia. Studies show that illness perceptions have been associated with patients' reactions to health threats such as adherence and further have influenced health outcomes. The Illness Perception Questionnaire for Schizophrenia (IPQS) was developed to explore illness perceptions in patients with schizophrenia.

**Objectives.**– The aim of the study was to test the psychometric properties of the Chinese version of IPQS.

**Methods.**– Participants were 200 community patients with schizophrenia. Demographics, IPQS and the Knowledge About Schizophrenia Test were collected. The psychometric properties, including internal consistency, test-retest reliability, concurrent validity and known-groups validity were analyzed.

**Results.**– Except personal control subscale, other subscales were internally reliable. Most of the subscales, apart from personal control and personal blame subscales, were proven to be reliable over four weeks. Correlations with knowledge about schizophrenia denoted the good concurrent validity of IPQS. Besides, the subscale scores among patients of various educational levels, occupational status and monthly income were significantly different ( $P < 0.05$ ), indicating the known-groups validity of IPQS.

**Conclusions.**– The Chinese version of IPQS is a reliable and valid measure of illness perceptions about schizophrenia for patients. This may provide empirical evidence for its generalizability and possibility to bring insight into Chinese patients' illness perceptions about schizophrenia.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Iatrogenic psychosis

I. Lokmić-Pekić<sup>1\*</sup>, S. Bise<sup>2</sup>, H. Amra<sup>2</sup>, A. Muhamed<sup>3</sup>

<sup>1</sup> Psychiatric hospital of Canton Sarajevo, Bosnia and Herzegovina, Intensive care, Sarajevo, Bosnia, Herzegovina; <sup>2</sup> Psychiatric hospital of Canton Sarajevo, Bosnia and Herzegovina, Women department, Sarajevo, Bosnia, Herzegovina; <sup>3</sup> Psychiatric hospital of Canton Sarajevo, Bosnia and Herzegovina, man department, Sarajevo, Bosnia, Herzegovina

\* Corresponding author.

**Introduction.**– Medication acts as dopamine agonist in correction of pituitary disorders and treatment of pituitary tumor, prolaktinoma (pituitary tumor that increases secretions of prolactin). Adverse reactions to medication can present itself as confusion, psychomotor agitation, and hallucinations.

**Case report.**– 37 yo patient who was placed at the psychiatric unit 13 years ago. After 5 years of ambulatory treatment medication was discontinued and patient was in steady remission for next 7 years. Patient was hospitalized again due to the return of psychological symptoms. CT scan of the brain had shown tumor at the base of the skull. Patient was taken to neurosurgery and afterwards treated by endocrinologist due to increased prolactin. At the end of the treatment patient still presented symptoms and was admitted to psychiatric hospital. Symptoms of agitation, hallucinations, and disorganized behavior were possibly brought on by implementation of Cabergoline, agonist of dopamine, so

the medication was discontinued. Patient then was treated with antipsychotic medication haloperidol, aripiprazol and anxiolytic. Due to unsatisfactory results and presented signs of EPS, clozapine is introduced during hospitalization multiple consultations were done by endocrinologist and neurosurgeon and treatment with cabergoline was implemented again. Patient was discharged after 31 days absent of psychological symptoms.

*Conclusion.*– Recognition and treatment of patients with prolactin and psychiatric symptoms is difficult because treatment of one disorder can have negative effects on the other disorder. Joint efforts from multidisciplinary teams are necessary during treatment.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

## Depression - Part III

### Theory of mind and social cognition in major depression: Results of an observational analytic study

E. Albuquerque\*, A. Filipe, A. Machado, C. Coelho, J. Cerejeira  
Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

\* Corresponding author.

*Objective.*– To evaluate the relationship between executive deficits, depressive symptoms and changes in the theory of mind in a sample of patients diagnosed with major depression, using a control group of healthy individuals

*Methods.*– Female patients diagnosed with major depression, admitted to the psychiatric ward of our hospital institution were included in the study. Patients were excluded if there was a history of neurologic disease, substance use or brain injury. The presence of another psychiatric comorbidity was also considered a criterion of exclusion. A comparison with a group of healthy controls was also performed. The evaluation consisted in the application of the test Reading the mind in the eyes. Besides that, it also included sociodemographic variables, characterization of the current depressive episode and some cognitive tests (Moca, Trail Making Test, Verbal fluence tests and Stroop). Statistical analysis was performed using the SPSS V. 21.

*Results.*– Preliminary results suggest that social cognitive performance is impaired in depressed patients. The results also suggest a relationship between executive function and theory of mind deficits, which highlights the importance of the frontal lobe in this process.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Comparison of emotional distress in renal disease patients undergoing hemodialysis and patients with kidney transplantation in Cyprus

K. Argyropoulos<sup>1</sup>, G. Charalambous<sup>2</sup>, P. Faidonos<sup>2</sup>, A. Aresti<sup>2</sup>, A. Argyropoulou<sup>3</sup>, P. Gourzis<sup>4</sup>, G. Gastouniotis<sup>5</sup>, D. Avramidis<sup>1\*</sup>, E. Jelastopulu<sup>1</sup>

<sup>1</sup> Medical School, University of Patras, Public Health, Patras, Greece;

<sup>2</sup> Frederick University, Postgraduate Program Health Management, Nicosia, Cyprus; <sup>3</sup> Health Centre, General Practice, Andravida, Greece;

<sup>4</sup> University Hospital of Patras, Psychiatry, Patras, Greece; <sup>5</sup> General Hospital of Athens "Hippocratio", Emergency, Athens, Greece

\* Corresponding author.

*Introduction.*– Populations facing chronic illnesses have been reported to have poorer quality of life and of mental health.

*Purpose.*– The purpose of the study was to estimate differences referring in the presence of emotional distress in two groups of renal disease patients. Moreover, to investigate the relationship of sociodemographic variables to mental health.

*Material and method.*– A sample of 230 patients were recruited, consisting of 130 patients undergoing hemodialysis (HD) and 100 patients with successful kidney transplantation (KT). The instrument used to assess the emotional distress was the Greek version of the Hospital Anxiety and Depression Scale (HADS).

*Results.*– Patients with HD scored overall higher on the HADS compared to patients with KT (13.52 vs 10.30). Both patient groups showed higher mean scores in depression (HD: 8.85; KT: 6.20) than in anxiety (HD: 4.67; KT: 4.10). We observed statistically significant differences in the mean values for the overall HADS score ( $t = 3.12$ ,  $P = 0.002$ ) between HD patients and transplanted patients. Female patients scored overall higher compared to males in both groups (HT: 6.10 vs 11.91; KT: 11.20 vs 9.70), being significantly associated only in HT patients. In patients with KT older ages, lower educational level, being divorced or widowed and being retired scored significantly higher, whereas in HT patients only educational level and marital status play a significant role.

*Conclusions.*– In the present study, the overall HADS score was higher in HT patients, indicating thus the higher psychological discomfort in these patients. Furthermore, depression was associated with demographic parameters such as gender, age, educational level, marital and occupational status.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Depression of women during pregnancy: Results of a cross-sectional study

I. Bouzouita<sup>1\*</sup>, F. Ellouze<sup>2</sup>, H. El Kefi<sup>1</sup>, A. Baatout<sup>1</sup>, M.W. Krir<sup>1</sup>, C. Ben Cheikh<sup>1</sup>, S. Eddhif<sup>1</sup>, B. Bouguerra<sup>3</sup>, A.A. Oumaya<sup>1</sup>

<sup>1</sup> Hôpital militaire principal d'instruction de Tunis, Psychiatry, Tunisia;

<sup>2</sup> Razi Hospital, Ibn Jazar, Manouba, Tunisia; <sup>3</sup> Charles Nicolle Hospital, Gynecology B, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Pregnancy is an important period in the life of women. It contains many physical and mental changes. These changes may be important and induce symptoms of depression which can affect the well-being during this period.

*Objectifs.*– The purpose of this study is to research the prevalence and symptoms of depression of pregnant women.

*Methods.*– We conducted a cross-sectional study which concerns 100 Tunisian pregnant women. We used a questionnaire to investi-

gate demographic data. The prevalence and symptoms of depression were investigated by Edinburg Post-natal Depression Scale (EPDS). **Results.**– The mean age of participant women was  $29.4 \pm 5.6$  years. 62% of the sample were housewives and 25% had primary school education. 73% were of medium socioeconomic status and 2% were of low one. The mean pregnancy term was 25 gestational weeks  $\pm 9$  weeks. 42% of the pregnant women were in their third trimester. 60% of the participants noted that they were satisfied and enjoyed their pregnancy.

The mean score of Edinburg Post natal Depression Scale (EPDS) was  $8.7 \pm 5.4$ . We noted depressive symptoms in 28% of the sample.

**Conclusions.**– Depression during pregnancy is frequent and may be ignored by women and the healthcare professionals. The variation of the mood can affect the well-being of the women and even the couple. A systematic detection of depression during pregnancy can be useful to enhance the health care of pregnant women.

### Suicide in Huntington disease: Case report

C.A. Crisan<sup>1\*</sup>, R. Moldovan<sup>2</sup>, R. Popp<sup>3</sup>, V. Tibre<sup>1</sup>

<sup>1</sup> Iuliu Hatieganu University of Medicine and Pharmacy Cluj-Napoca, Neurosciences, Cluj-Napoca, Romania; <sup>2</sup> Babes-Bolyai University, Psychology, Romania; <sup>3</sup> Molecular Sciences, Romania

\* Corresponding author.

**Introduction.**– Huntington disease has traditionally been considered a movement disorder, but psychiatric symptoms as depression are one of the most common symptoms in HD, with a prevalence highest in manifest disease during stage 2, but it is also present during the illness prodrome.

**Objectives.**– The aim of this paper is to highlight the importance of an accurate evaluation of psychiatric symptoms, especially depression in Huntington disease patients, taking into account the major risk of suicide.

**Methods.**– The case of Mrs KDG, 49-year-old diagnosed with HD is presented. She was admitted in the Psychiatric Clinic I of the Emergency County Hospital Cluj-Napoca for negative hyperthymia, loss of interest and enjoyment, anxiety, anhedonia, reduced concentration, bleak and pessimistic view of the future, Beck triade with worthlessness, helplessness, hopelessness, diminished appetite, disturbed sleep, severe impairment in functionality due to motor symptoms (chorea, dystonia, impaired walking).

**Results.**– The psychological evaluation revealed an IQ of 110 points, MADRS score = 36 points, Beck inventory = 16 points, STAI-X1 = 58 points, STAI-X2 = 37 points, SCID-II revealed introvert and anankast traits. The neurological evaluation revealed chorea in distal, proximal and axial extremities and in facial musculature. A treatment with an SSRI antidepressant (Escitalopram 15 mg/day), a benzodiazepine (Clonazepam 2 mg/day) and a hypnotic (Zolpidem 10 mg/day) was initiated. The patient was very compliant with treatment, unfortunately, two months after discharge, she committed suicide.

**Conclusions.**– Identification and treatment of depression in individuals with the HD mutation is an essential part of clinical management in this population, especially owing to the high risk of suicide.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Positive psychology for management of suicidal patients: A controlled trial

D. Dassa<sup>1\*</sup>, E. Olie<sup>2</sup>, P. Courtet<sup>2</sup>, D. Ducasse<sup>2</sup>

<sup>1</sup> CHU Lapeyronie, Urgence post urgence Psychiatrique, Montpellier, France; <sup>2</sup> CHU Lapeyronie, Urgence Post-Urgence Psychiatrie, Montpellier, France

\* Corresponding author.

**Introduction.**– Gratitude is based on the ability to focus our attention in a different way towards daily life events, to fit into the present moment with attention and openness, in order to have a meaningful life. Gratitude includes mindfulness skills. Both gratitude and mindfulness have been shown their efficacy in reducing depressive symptomatology and suicidal ideation (Lambert, Fincham et al., 2012; Proyer, Gander et al., 2014). Recently Huffman et al. (2014) demonstrated the feasibility of an intervention based on positive psychology in suicidal inpatients. Patients performed daily positive psychological exercises during 7 days. Exercises including gratitude were associated with increased optimism and reduced hopelessness, which are dimensions linked with suicide.

**Objective.**– To compare the effectiveness (decreased psychological pain) of add-on positive psychology vs. control exercise in suicidal inpatients. We will present the results of a randomized controlled trial comparing the effectiveness of gratitude diary (vs. food diary) as an add-on to the usual management in 206 hospitalized patients with suicidal ideation or suicide attempt. We have assessed change of psychological pain, suicidal ideation, hopelessness and optimism between pre and post-intervention.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Investigation of the effects of recurrent transcranial magnetic stimulation (rTMS) therapy on taste and smell sensations in depression diagnosed patients

H. Kullakcı<sup>1</sup>, İ. Gündoğmuş<sup>1\*</sup>, M. Karaoğlan<sup>2</sup>, A. Algül<sup>1</sup>

<sup>1</sup> GATA Haydarpaşa Training Hospital, Psychiatry, Istanbul, Turkey;

<sup>2</sup> GATA Haydarpaşa Training Hospital, Neurology, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– In patients with Major Depressive Disorder (MDD), it is noteworthy that smell and taste sensations deteriorate compared to healthy volunteers. In this thesis study, it is aimed to investigate the effects of 15 sessions of rTMS therapy on smell and taste sensations in MDD patients.

**Method.**– In this prospective original study; Sociodemographic and clinical data of 30 cases of MDD with a decrease in smell and/or taste sensations and with an indication for rTMS were investigated. Hamilton Depression Scale (HAM-D) was used for severity of depression, while “Sniffin Stix” smell test was used for smell test and “Taste Strips” smell test was used for taste test.

**Result.**– It was determined that the taste and smell test results after rTMS treatment were statistically improved significantly compared to the pretreatment. rTMS treatment resulted in a decrease in HAM-D scores while also improving smell and taste test scores.

**Conclusion.**– It is important to be the first study to investigate the effects of rTMS treatment on smell and taste sensations in MDD cases. Our study showed a positive effect of rTMS treatment on smell and taste sensations even in patients who did not achieve adequate reduction in HAM-D scores. The same positive effect has been observed in both drug users and non-drug users. Thus, independent from depression scores, rTMS treatment will again have

its deserved place in terms of positive value added to the quality of life.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

<sup>3</sup> University of Peloponnese, Social and Educational Policy, Corinth, Greece;

<sup>4</sup> Hellenic Open University, School of Social Sciences, Patras, Greece

\* Corresponding author.

*Introduction.*– Depression is a chronic disease frequently encountered in patients seeking primary care, especially since the advent of the economic crisis. For the evaluation of depression in primary health validated tools are often used. The Zung Self-Rating Depression Scale (SDS) has been studied in a variety of populations. Till now, the Greek version has been validated only in a psychiatric setting.

*Objectives.*– To further validate the Greek version of the SDS in a patient sample of Greek primary health care units.

*Methods.*– A representative sample of 612 patients from six health centers and six rural practices in Greece took part in the study. All participating patients were randomly split into two equal groups and exploratory factor analysis was conducted initially on the first group to create multi-item scales. Confirmatory factor analysis was then performed on the second group to assess the model fit.

*Results.*– The questionnaire showed an excellent overall internal consistency (Cronbach's alpha = 0.942). A three-scale model (I: cognitive factor, II: somatic factor, III: restlessness) was extracted from the exploratory factor analysis. The confirmatory factor analysis indicated an acceptable model fit.

*Conclusions.*– The findings suggest that the Greek version of the SDS has good psychometric properties and can be used in primary healthcare settings.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### **Screening of depression in primary healthcare with the Zung Self-rating Depression Scale: Detection of the optimal cut-off point**

G. Tsiros<sup>1</sup>, E. Jelastopulu<sup>2\*</sup>, P. Sarafis<sup>3</sup>, P. Voila<sup>4</sup>, A. Tsirou<sup>1</sup>, M. Malliarou<sup>4</sup>, P.R. Domeyer<sup>4</sup>

<sup>1</sup> Health Center of Gastouni, General Medicine, Gastouni, Greece;

<sup>2</sup> Medical School, University of Patras, Public Health, Patras, Greece;

<sup>3</sup> Cyprus University of Technology, Nursing, School of Health Sciences, Limassol, Cyprus; <sup>4</sup> Hellenic Open University, School of Social Sciences, Patras, Greece

\* Corresponding author.

*Introduction.*– The Zung Self-Rating Depression Scale (SDS) is a validated tool for the assessment of depression. However, considerable ambiguity exists regarding its optimal cut-off point for the screening of depression.

*Objectives.*– The aim of our study was to assess the optimal cut-off point of the Greek SDS for the screening of depression in primary care.

*Methods.*– A total of 612 patients from six healthcare centers and six rural practices in Greece were clinically examined for depression and screened for depressive disorder using the SDS and the EQ-15D instruments. A ROC analysis was conducted on the SDS to detect the optimal cut-off value for the screening of depression.

*Results.*– The prevalence of major depression was 23.7% (145/612 patients). The ROC analysis on the SDS indicated that the area under the ROC curve was 0.901 and that the optimal cut-off value for screening of depression was 48 (sensitivity = 77.9%, specificity = 86.3%, correctly classified = 84.3%). The SDS score was highly correlated with the EQ-15D depression subscale ( $r = 0.818$ ,  $P < 0.0001$ ).

*Conclusions.*– The Greek version of the SDS is a valid tool to detect depression in primary care, indicating a score of 48 as an optimal cut-off-point.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

PW0887

### **Childhood trauma and big five personality traits: Comparative analysis of depressed and non-depressed population in Pakistan**

M. Wajid<sup>1</sup>, N. Husain<sup>2</sup>, T. Kiran<sup>1\*</sup>, N. Chaudhry<sup>1</sup>, M. Alvi<sup>1</sup>, F. Zulqarnain<sup>3</sup>, S. Farooque<sup>1</sup>, M. Husain<sup>1</sup>, M. Husain<sup>4</sup>

<sup>1</sup> Pakistan Institute of Living and Learning, Research, Karachi, Pakistan; <sup>2</sup> University of Manchester, Division of Psychology and Mental Health, Manchester, United Kingdom; <sup>3</sup> Potohar Mental Health Association, Research, Islamabad, Pakistan; <sup>4</sup> Harvey House Social Enterprises, Harvey House Social Enterprise, Lancashire, United Kingdom

\* Corresponding author.

*Background.*– Depression is a serious public health concern in the developing world and predicted to become the most common cause of disability by the year 2020. There is a well-established link between depression, personality traits and childhood trauma. The prevalence of depression is high in Pakistan but there is limited evidence on relationship of other psychological factors with depression.

*Objectives.*– To compare depressed and non-depressed population on childhood trauma and big five personality traits.

*Methods.*– This was a cross sectional survey of 455 participants, conducted in a tertiary care hospital in Karachi Pakistan. Structured Clinical Interview for DSM-IV was used to confirm the diagnosis of depression. Big five personality traits were assessed by using NEO-PI(R). Retrospective reports of childhood trauma were collected using the Childhood Trauma Questionnaire (CTQ). A comparable sample of non-depressed individuals was taken from same hospital.

*Results.*– Depressed group had significantly higher scores on all the 5 domains of CTQ (emotional abuse, physical abuse, sexual abuse, emotional neglect, physical neglect) as compared to non-depressed. Depressed group scored significantly higher on neuroticism as compared to non-depressed group. However, there was no significant difference between two groups on extraversion, openness, agreeableness, conscientiousness.

*Conclusion.*– Understanding of personality traits, early recognition of childhood trauma and appropriate intervention may play an important role in the prevention of depressive disorders throughout the life span. Long term cohort research is needed to further explore any probable associations.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Negative life events, social support and depression

N. Chaudhry<sup>1</sup>, I. Husain<sup>2</sup>, T. kiran<sup>1\*</sup>, M. Wajid<sup>1</sup>, R. Sattar<sup>1</sup>, F. Zulqarnain<sup>3</sup>, M. Husain<sup>4</sup>

<sup>1</sup> Pakistan Institute of Living and Learning, Research, Karachi, Pakistan; <sup>2</sup> Camden and Islington NHS Foundation Trust, Camden and Islington NHS Foundation Trust, London, United Kingdom;

<sup>3</sup> Potohar Mental Health Association, Research, Karachi, Pakistan;

<sup>4</sup> Harvey House Social Enterprises, Harvey House Social Enterprises, Lancashire, United Kingdom

\* Corresponding author.

*Background.*– Depression is a serious public health concern in low income countries and is predicted to become the most common cause of disability by the year 2020. Depression is associated with increased mortality and contributes to the disability of comorbid physical diseases. Several systematic reviews from both high and low income countries supported that social factors like lack of support play an important role in etiology of common mental disorders like depression. Moreover, experience of negative life events is also a well-established risk factor for development of depressive symptoms.

*Objectives.*– To compare frequency of negative life events as well as degree and source of social support between depressed and non-depressed individuals.

*Methods.*– A total of 455 participants were recruited for a cross sectional survey from psychiatry department of a public hospital in Karachi, Pakistan. Social support was assessed using Multidimensional Scale for Perceived Social Support (MSPSS). Burgha's Recent Life Event Questionnaire was used to identify negative life events. Non depressed participants were recruited from same hospital.

*Results.*– There was a significant difference between depressed and non-depressed groups on all three domains of perceived social support (friends, family, and significant other). Depressed group reported significantly more recent negative events as compared to non-depressed group.

*Conclusion.*– These results suggested that negative life events and lack of social support can be potential risk factors for depression. These findings provides useful information for developing psychosocial interventions for depression.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### St. John'S Wort and single compounds attenuate gene expression in neuronal cells after dexamethasone induced stress

S. Verjee<sup>1</sup>, A. Weston<sup>2</sup>, C. Kolb<sup>3\*</sup>, H. Abdel-Aziz<sup>3</sup>, V. Butterweck<sup>1</sup>

<sup>1</sup> Institute for Pharma Technology, School of Life Sciences, University of Applied Sciences Northwestern Switzerland, Muttenz, Switzerland;

<sup>2</sup> Institute for Chemistry and Bioanalytics, School of Life Sciences, University of Applied Sciences Northwestern Switzerland, Muttenz, Switzerland;

<sup>3</sup> Steigerwald Arzneimittelwerk GmbH, Medical and clinical affairs, Phytomedicines Supply and Development Center, Darmstadt, Germany

\* Corresponding author.

*Background.*– It is well known that dysregulation of the HPA axis plays an important part in the development and maintenance of depressive symptoms. Glucocorticoids affect cellular and molecu-

lar events in brains by modulating the expression of many genes during stress. In the present study we evaluated the effects of a St. John's wort extract (STW3-VI), hyperforin, miquelianin and the SSRI citalopram on the expression of genes relevant to HPA axis function in human neuronal cells.

*Methods.*– SH-SY5Y cells were treated with STW3-VI (20 µg/mL), hyperforin (10 µM), miquelianin (10 µM) or citalopram (10 µM) in the presence or absence of the glucocorticoid receptor agonist dexamethasone (DEX, 10 µM) for 6 h and 48 h, respectively. Quantitative real time PCR was used to determine the expression of FKBP5, CREB, GRIK4, VEGF, NET, and ARRB, which have been shown to be meaningful biomarkers in the treatment response for depression.

*Results.*– Using DEX to mimic stress conditions, we were able to show the responsiveness of the selected genes. It was shown that the gene expression pattern of FKBP5, CREB, GRIK4, VEGF, NET, and ARRB2 in SH-SY5Y neuronal cells is time and treatment dependent. Most pronounced effects were observed for FKBP5, which was upregulated after 6 h (1.3 fold) but an even stronger increase in mRNA expression was observed after 48 h (1.8 fold). While after 6 h of co-incubation only STW3-VI could reverse the dexamethasone induced increase in FKBP5 expression, after 48 h citalopram, miquelianin and hyperforin also reversed the glucocorticoid induced increase in FKBP5 mRNA expression.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Depression in the elderly: Diagnosis and treatment

N. Halouani, I. Lajmi\*, S. Ellouze, R. Naoui, J. Aloulou, O. Amami Hedi Chaker Hospital, psychiatry, Sfax, Tunisia

\* Corresponding author.

*Introduction.*– Depression is a major problem of public health especially in elderly. It is necessary to propose appropriate therapeutic management that must take into account the specificities of use of antidepressants and the psychotherapeutic strategies specific to the elderly.

*Objectif.*– Determine the semiological and therapeutic characteristics of the depression on elderly.

*Methods.*– A descriptive study, conducted in the psychiatric department in the Hedi Chaker hospital, Sfax, Including 30 patients with a major depressive episode according to the DSM IV during a period of 16 years (from 2000 to 2015).

*Results.*– Sex ratio (M/F) was 0.66. The mean age was 69 years and 8 months. The reason of hospitalisation was almost sadness and psychomotor instability. 86.7% of patients were hospitalized under constraints (compulsory hospitalization (23.3%), at the request of one third (60%)).

Major depressive episode occurs in in unipolar depression (45%), bipolar disorder (24%), pseudo-dementia depression (17%), post-psychotic depression (10%) and depression due to a general medical condition (4%).

Most patients (93.3%) were on antidepressant therapy, which was fluoxetine in 50%, sertraline in 16.7% and clomipramine in 16.7%. An adjuvant treatment with neuroleptic or anxiolytic was associated in 93.3% of the cases.

*Conclusions.*– Masked depression in elderly is frequent and has in common an absence of expressed sadness, even a denial of feelings of depression. Therapeutic response to antidepressants is delayed and globally worse, with more resistant forms and residual symptomatology. Despite this finding, very few therapeutic trials have been specifically dedicated to the depressed elderly.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### About the effectiveness of low-frequency repetitive transcranial magnetic stimulation (LF-rTMS) in the treatment of moderate to severe recurrent depressive disorder

F. Lasters<sup>1</sup>, I. Mestdagh<sup>1</sup>, B. Chris<sup>2</sup>, G. Hans<sup>3</sup>, P. Van de Heyning<sup>4</sup>, F. Van Den Eede<sup>1</sup>

<sup>1</sup> University Hospital Antwerp, Psychiatry, Antwerp, Edegem, Belgium; <sup>2</sup> University Hospital Ghent, Psychiatry, Ghent, Belgium;

<sup>3</sup> University Hospital Antwerp, Anesthesia, Antwerp, Edegem, Belgium; <sup>4</sup> University Hospital Antwerp, otorhinolaryngology, Antwerp, Edegem, Belgium

\* Corresponding author.

**Introduction.**– As a biological treatment modality for depressive disorders, low-frequency repetitive transcranial magnetic stimulation (LF-rTMS) at the dorsolateral prefrontal cortex has been shown to be effective. However, there is no consensus about the treatment protocol and clear predictors of treatment response are as yet lacking.

**Objectives.**– The primary objective of the present study was to determine whether a 5-week, 3-times a week LF-rTMS augmentation protocol is effective in treating moderate to severe recurrent unipolar depressive disorder. The secondary objective was to investigate which subdomains of the Beck Depression Index-II-Dutch (BDI-II-NI) predict treatment outcome best.

**Method.**– A retrospective, uncontrolled, open-label study including 20 consecutive patients. In the analysis, the last-observation-carried-forward approach was adopted. Response was defined as a 50% decrease in BDI-II-NI scores, with items being clustered into a cognitive, an affective and a somatic domain.

**Results.**– A significant post-treatment decrease in BDI-II-NI scores ( $P=0.003$ ) was observed in 40% of the patients. The reductions in the cognitive ( $P=0.016$ ), affective ( $P=0.001$ ) and somatic ( $P=0.002$ ) domains were all statistically significant. The somatic domain was the strongest predictor ( $P=0.005$ ;  $R^2=0.540$ ).

**Conclusion.**– The proposed LF-rTMS protocol is effective in the treatment of moderate to severe unipolar depressive disorders, with the somatic domain of the BDI-II-NI being the most predictive of treatment success.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

PW0892

### Incidence of treatment-resistant depression in a cohort of patients with major depressive episode

S. Maroua<sup>1</sup>, R. Jomli<sup>1</sup>, U. Ouali<sup>1</sup>, Y. Zgueb<sup>1</sup>, S. Ouanes<sup>2</sup>, F. Nacef<sup>1</sup>

<sup>1</sup> Razi Hospital, psychiatry A, Mannouba, Tunisia; <sup>2</sup> CHUV, psychiatry, Lausanne, Swaziland

\* Corresponding author.

**Introduction.**– Depression is a common, and disabling disorder with serious individual and collective consequences. This highlights the need to individualize and scrutinize the concept of resistant depression in order to adapt the therapeutic strategies.

**Objectives.**– To estimate the incidence of treatment-resistant depression in patients with a first major depressive episode, and to examine the sociodemographic and clinical factors associated with resistance.

**Methods.**– A descriptive prospective longitudinal study of outpatients with a first major depressive episode, was conducted. Patients with bipolar disorder, or having had a positive score in the Hypomanic Check List 32 were excluded. Eligible patients were

put on a selective serotonin reuptake inhibitor, either fluoxetine or sertraline. Participants were followed regularly until they had a therapeutic response or until they met the criteria for resistant depression.

**Results.**– The study involved 82 adults, with a mean age of  $44.5 \pm 11.1$  years and a sex ratio of 0.46. The incidence of treatment-resistant depression was 19.4% 95% CI=[5.5–33.3]. Among the sociodemographic and clinical factors, family history of psychosis ( $P=0.038$ ) and chronic respiratory comorbidities ( $P=0.016$ ) were associated with treatment-resistance.

**Conclusion.**– In this study, the incidence of treatment resistant depression is at the lower limit of the figures reported in the literature. Identifying clinical factors predictive of resistance can certainly help clinicians to recognize cases of resistant depression promptly. Genotypic analysis which will probably become more widespread in the clinical practice, will likely lead to an even earlier prediction to treatment response.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Efficacy of music therapy interventions in the treatment of mood disorders: A systematic review

G. Panciroli<sup>1</sup>, M. Marchi<sup>1</sup>, G. Mattei<sup>2</sup>, G.M. Galeazzi<sup>1</sup>, S. Ferrari<sup>1</sup>

<sup>1</sup> University of Modena and Reggio Emilia, Department of Diagnostics, Clinical and Public Health Medicine, Section of Psychiatry, Modena, Italy; <sup>2</sup> University of Modena and Reggio Emilia, Department of

Diagnostics, Clinical and Public Health Medicine, Section of Psychiatry, “Marco Biagi” Department of Economics, Modena, Italy

\* Corresponding author.

**Introduction.**– In the treatment of mood disorders, especially of depressive disorders, different psychotherapeutic techniques, such as cognitive-behavioral therapy and interpersonal therapy, play a significant role, alongside drug therapy. In this context, music therapy may contribute to the treatment of depressive disorders and bipolar disorders. Music therapy intervention techniques can be either active or receptive and performed in either individual or group sessions.

**Objectives.**– This study aims to investigate the effectiveness of music therapy interventions in the treatment of mood disorders by means of systematic review of the scientific literature.

**Methods.**– A bibliographic research was performed within the scientific databases “Web of Science” and “Scopus”. The article’s selection was made using the criteria of the PRISMA guidelines.

**Results.**– Of the 1420 records identified through database searching, only 12 randomized controlled trials on depressive disorders met the inclusion criteria required by this review and no study was found on bipolar disorders. Ten studies found a statistically significant decrease in depression levels with music therapy compared to control groups. One study showed positive changes with music therapy but it did not reach statistical significance. One study underlined that music therapy could have an impact in the cortical activity of depression, recorded via EEG. Due to marked heterogeneity of interventions, populations and outcome measures, no data synthesis or meta-analysis were possible.

**Conclusions.**– Findings from individual studies suggest that music therapy on patients suffering from mood disorders is a feasible treatment and support the need for further research on this subject.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Shaken baby syndrome as a consequence of depression in young fathers

K. Pushkarev<sup>1\*</sup>, T. Assimova<sup>2</sup>, G. Kausova<sup>1</sup>, A. Kudaibergenova<sup>3</sup>  
<sup>1</sup> Kazakhstan School of Public Health "KSPH", Public Health, Almaty, Kazakhstan; <sup>2</sup> Kazakh-Russian Medical University, Department of psychiatry, narcology with the course of neurology- medical and general psychology and pedagogy, Almaty, Kazakhstan; <sup>3</sup> Republican Coordination Center for Stroke Problems, Republican Coordination Center for Stroke Problems, Almaty, Kazakhstan

\* Corresponding author.

According to the statistics of the World Health Organization, during the first year of life of the child 20% of mothers and 14% of fathers become victims of postpartum depression.

A psychological survey was conducted during the reception of a neurologist and psychologist of married couples with babies who had been diagnosed with Shaken Baby Syndrome(SBS).

The aim of the study was to find out the effect of the postpartum depression of both spouses and the development of the child's shake syndrome in the child as a result of aggressive acts against his parents.

There were 104 cases analyzed. The fathers experiencing a depressive condition were 69.2% (72), which is 2.2 times more plague of mothers 30.7% (32). According to the duration of 70.8% of fathers (51) at the time of development of SBS, depression lasted for 3–4 months, and in 29.2% (21) in 4–6 months.

In 76.4% (55) of cases, men noted the development of depression as a consequence of their unreadiness for changes in life after child-birth, 56% (40), the increased requirements of the wife in 51.4% (37), the difference in expectation and reality were noted (37), fatigue in 47.2% (34), lack of female attention in 44.4% (32). An anxiety-depressive disorder was found in 41.7% of fathers (30), hysterico-depressive in 22.2% (16), asthenia-depressive 19.4% (14), melancholic in 16.7% (12).

Thus, depression in young fathers is not currently a rarity and requires careful further study and understanding of the problem. It can also be said that in the implementation of the SBS, young fathers are 2.2 times more likely to blame than the mother.

### Patterns of antenatal and postnatal depressed mood on child health at five years postpartum

M.J. Rotheram-Borus<sup>1\*</sup>, M. Tomlinson<sup>2</sup>, T. Weichle<sup>3</sup>  
<sup>1</sup> Semel Institute for Neuroscience and Human Behavior at UCLA, Psychiatry, Los Angeles, USA; <sup>2</sup> Stellenbosch University, Department of Psychology, Stellenbosch, South Africa; <sup>3</sup> Semel Institute for Neuroscience and Human Behavior at UCLA, Department of Psychiatry, Los Angeles, USA

\* Corresponding author.

*Introduction.*– The negative consequences of maternal depressed mood have been well-established both in high income and low and middle income countries. Most studies, even those examining longitudinal outcomes, only assess depression at one point. This study examines the consequences of maternal depressed mood on child outcomes over the first 5 years of life.

*Methods.*– Pregnant women in 24 peri-urban township neighborhoods in Cape Town, South Africa ( $n=1238$  mothers) were randomized by neighborhood to a home visiting intervention or a standard care condition and 92% were followed repeatedly at two

weeks post-birth, 87% at 6 months, 91% at 18 months and 85% at 36 months, and 83% at 60 months post-birth. Regressions were conducted to examine how the pattern of depressed mood over time impacted child outcomes at 60 months.

*Results.*– Mothers were categorized as: (1) never depressed ( $n=451$ , 40.6%), (2) antenatally depressed only ( $n=144$ , 13%); (3) postnatally depressed only ( $n=290$ , 26.1%); or (4) both antenatally and postnatally depressed ( $n=226$ ; 20.3%). Similar across intervention conditions, depressed mothers were significantly less educated, and had less electricity and income and more likely to have problematic drinking, food insecurity, be HIV seropositive, and experience intimate partner violence at 60 months, the pattern of maternal depressed mood was significantly associated with compromised physical growth, child behavior problems, and reduced executive functioning.

*Conclusions.*– Patterns of maternal depressed mood over time differentially influence child outcomes over their first five years. More proximal, post-natal depressed mood appears to have a larger influence on child outcomes, compared to antenatal depressed mood.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

\* Corresponding author.

*Background.*– There is increasing interest in investigated the possible influence of non-pharmacological interventions among patients with hypertension (HT), along with depression and anxiety. Here, investigated, if and to what extent deep breathing exercises over a time period of eight weeks, compared to a control condition.

*Methods.*– A total of 60 patients (mean age: 58 years) suffering from hypertension, depression and anxiety took part in the study. They were randomly assigned either to the intervention (deep breathing exercises (DBE)) or the control condition (leisure time activity (LTA)). They completed questionnaires on depression and anxiety. Blood pressure was assessed twice. DBE consisted of group sessions of 60–90 min once the week and exercising at home. LTA consisted of group sessions of handy crafting and outdoor activities at the same duration, intensity and frequency as the DBE condition. The intervention lasted for 8 weeks; further 8 weeks later, follow-up was performed.

*Results.*– Hypertension, and symptoms of depression and anxiety decreased significantly over time, but more so in the DBE, compared to the LTA condition. After study completion and 8 weeks later (follow-up), the effect of DBE remained stable.

*Discussion.*– Deep breathing exercises have the potential positively impact on hypertension, depression and anxiety. Further, the technique is easy to learn, easy to apply and easy to install during everyday life.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

### Prevalence of depression and anxiety in patients with multiple sclerosis

N. Smaoui<sup>1\*</sup>, N. Halouani<sup>1</sup>, S. Daoud<sup>2</sup>, M. Damak<sup>2</sup>, S. Ellouze<sup>1</sup>, R. Naoui<sup>1</sup>, J. Aloulou<sup>1</sup>, C. Mhiri<sup>2</sup>, O. Amami<sup>1</sup>

<sup>1</sup> Hedi Chaker University Hospital, Department of Psychiatry B, Hedi Chaker University Hospital, Sfax, Tunisia, sfax, Tunisia; <sup>2</sup> Habib Bourguiba University Hospital, Department of Neurology, Habib Bourguiba University Hospital, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Depression and anxiety are the most common psychiatric disorders in patients with multiple sclerosis (MS) and contribute to reducing the quality of life of such patients.

**Objectives.**– To assess the prevalence of depression and anxiety in patients with MS and their correlation with clinical factors.

**Methods.**– This was a cross-sectional, descriptive and analytical study of 42 patients with MS, carried out in the neurology department at Habib Bourguiba Hospital in Sfax, Tunisia, from January to June 2017. The evaluation of anxiety and depression was done by the Hospital Anxiety and Depression Scale (HADS) and the level of disability by the Expanded Disability Status Scale (EDSS).

**Results.**– The mean age of the patients surveyed was  $36.9 \pm 9.6$  years and the sex ratio was 0.9. The mean duration of MS was  $8.4 \pm 5.2$  years. Relapsing-remitting MS occurred in 88.1% of cases. The mean EDSS score was  $2.8 \pm 2.1$ . According to the HADS, 38.1% of patients had depressive symptoms and 54.8% had anxious symptoms. Statistical analysis showed that high scores for depression were correlated with high EDSS scores ( $P=0.047$ ,  $r=0.296$ ). On the other hand, there was no correlation between depression or anxiety and the form of MS, duration of disease and the number of relapses.

**Conclusions.**– The results of our study emphasize the high frequency of anxiety and depression and their relation to the degree of disability in patients with MS. It seems necessary to pay particular attention to these disorders for better management.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Acceptability, attitudes and representations of general population and medical doctors towards computerized cognitive behavior therapies (CCBT) for depression in France

B. Tommy<sup>1,2,3\*</sup>, I. Galina<sup>3</sup>, G. Bruno<sup>1</sup>, B. Michel<sup>1,3</sup>

<sup>1</sup> CHU Pasteur 2, Psychiatrie, NICE, France; <sup>2</sup> Centre Hospitalier Princesse Grace, Psychiatrie, Monaco, Monaco; <sup>3</sup> LAPCOS, Psychologie, Nice, France

\* Corresponding author.

**Introduction.**– In some countries, the CCBT are considered as full fledged therapies scientifically validated in the treatment of depression.

**Objectives.**– Our aim was to establish an overview of the practices in psychotherapy and to assess the social acceptability, attitudes and representations of patients and medical doctors towards CCBT in French population.

**Methodology.**– Three surveys were sent online to voluntary subjects (VS) and to medical doctors (GPs and psychiatrists).

**Results.**– The results show a general concern on the accessibility, availability and the effective use of CBT. For the VS the main explanations of this phenomenon lie in the fear of being stigmatized, in personal time constraints, in an insufficient frequency of therapy sessions and in an apprehension of face to face. For the psychi-

atrists and the GPs, the main causes are the cost of the therapy and the too long waiting period to have appointments with therapists. The results on the acceptability of CCBT show a clear positive result from VS, psychiatrists and GPs. The benefits of CCBT perceived by the medical doctors and VS are the cost, better flexibility and a loss of the fear of being stigmatized. The respondents raised concerns over the possibility that CCBT may reinforce the loneliness of patients. Given the absence of face to face contact with therapist in the implementation of the treatment, some respondent perceive this therapy as being inadequate in helping patients to understand their medical condition, to integrate the core concepts of CBT and therefore maintaining them involved in the treatment. As a result, the long term efficiency of this treatment raises concern from medical doctors and voluntary subjects.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

### Albumin binding-site alteration in melancholic depression under pharmacotherapy

M. Uzbekov<sup>1\*</sup>, T. Syrejschchikova<sup>2</sup>, N. Smolina<sup>1</sup>, V. Brilliantova<sup>1</sup>, G. Dobreteov<sup>3</sup>, V. Krjukov<sup>4</sup>, V. Krasnov<sup>5</sup>

<sup>1</sup> Moscow Research Institute of Psychiatry, Brain Pathology, Moscow, Russia; <sup>2</sup> Lebedev Physical Institute, High energy electrons, Moscow, Russia; <sup>3</sup> Research and Clinical Center of Physical-Chemical Medicine, Department of Photonics, Moscow, Russia; <sup>4</sup> Moscow Research Institute of Psychiatry, Department of Affective Disorders, Moscow, Russia; <sup>5</sup> Moscow Research Institute of Psychiatry, Department of Affective Disorders, Moscow, Russia

\* Corresponding author.

**Introduction.**– Depression is one of most frequent and severe mental disorders. There are no objective laboratory indices that can help to assess the severity of condition and efficacy of pharmacotherapy. Disturbances in molecular processes in pathological conditions can be connected with conformational changes in protein (albumin) structure.

**Objectives.**– Investigation of blood albumin conformation in patients with melancholic depression under pharmacotherapy.

**Methods.**– 22 patients with melancholic depression were examined before and after 30 days of treatment with Venlafaxin (150 mg/day). Control group consisted of 54 volunteers. Fluorescence decay of CAPIDAN fluorescent probe bound to serum albumin was measured in nano- and picosecond ranges using laser device. Samples were excited by rapid laser flash ( $7 \times 10^{-10}$  s).

**Results.**– There were revealed 3 binding sites in albumin molecule with fluorescent decay time of 1, 3 and 9 nanoseconds (A1, A3 and A9 sites, respectively) in healthy volunteers. Analysis of fluorescence decay parameters of CAPIDAN probe in serum samples of controls and patients before treatment showed that the mean amplitudes A1, A2, and A3 in sera of patients were significantly higher than in controls ( $P=0.025$ ). In course of treatment with Venlafaxin (30 days), fluorescence intensity of CAPIDAN probe decreases and approaches the fluorescence of controls. The relative changes of all three amplitudes during treatment were practically the same.

**Conclusions.**– Melancholic depression is followed by disturbances in albumin conformation. Studied parameters can serve as potential biomarkers for evaluation of efficacy of pharmacotherapy.

**Disclosure of interest.**– The authors have not supplied a conflict of interest statement.

**Metacognitive therapy for depression:  
A feasibility study in Germany**L. Winter<sup>1\*</sup>, U. Schweiger<sup>2</sup>, A. Wells<sup>3</sup>, K.G. Kahl<sup>1</sup><sup>1</sup> Hannover Medical School, Psychiatry, Hannover, Germany;<sup>2</sup> University of Luebeck, Department of Psychiatry, Luebeck, Germany; <sup>3</sup> University of Manchester, Division of Psychology and Mental Health, Manchester, United Kingdom

\* Corresponding author.

*Background.*– Metacognitive therapy (MCT) is a recent development with demonstrated efficacy in current major depressive disorder (MDD). The treatment aims to modify thinking styles like rumination and worry and their underlying metacognitions, which have both been shown to be involved in the initiation and perpetuation

of MDD. Wells has published a treatment manual in English which has been translated into German in 2010. With our study we investigated whether this treatment manual leads to similar treatment effects when used in the German version.

*Methods.*– 20 depressed patients were included. They all received metacognitive therapy by certified therapists on an outpatient basis.

*Results.*– We found significant improvement of depression symptoms measured with the BDI ( $d > 0.8$ ). A further indicator for excellent feasibility is the fact that no drop outs were observed.

*Conclusions.*– The German version of the treatment manual is feasible for the treatment of depression. The treatment was well accepted and response, remission and recovery rates were high.

*Disclosure of interest.*– The authors have not supplied a conflict of interest statement.

#### Cultural reflections in practicing cognitive-behavioural therapy for social phobia

R. Aly

Egyptian Association of Cognitive Behavior Therapy, President, Cairo, Egypt

Evidence-based practice of cognitive behaviour therapy has long been adopted as an effective therapy for treating anxiety disorders including social anxiety disorder. In many situations it is the chosen therapy for such a debilitating disease. Due to its proven efficacy & readiness applicability it has proven to be the 1st choice of therapy for social anxiety across different life spans from adolescents to geriatrics. Yet, cross-cultural differences have seldom been considered in the approach towards managing social anxiety. Many differences lie between populations & countries in defining what is accepted & what is not with regard to social interactions. Even across the one country many differences may color the perception of appropriate social communication. Hence no one-size-fits all can be adopted here. Thus, during the application of cognitive behavioural therapy, effectual therapist should modify his conceptual framework of action while still trying to abide with the fundamental notion of CBT of exposure experiments. In doing this many therapists may be challenged in their work. While still lacking a strong body of research, clinical experience can provide us with some helpful innovations for successful practice. Our aim is to provide therapists & psychiatrists across the Arab world with tools for applying successful CBT for social anxiety. A series of case studies are discussed to present some innovations in applying CBT for patients suffering from social inhibitions. Moreover, essentials of past research are reviewed & needs for further research directions in the field are discussed.

#### Razi psychiatric hospital staff concerns during disasters: Content analysis

N. Amanat<sup>1\*</sup>, S.H. Hosseini<sup>1</sup>, H.R. Khankeh<sup>2</sup>, S. Bahrampouri<sup>1</sup>

<sup>1</sup> University of Social Welfare and Rehabilitation Sciences, Health in Emergency and Disaster, Tehran, Iran;

<sup>2</sup> Karolinska Institute, Department of Clinical Science and Education, Stockholm, Sweden

\* Corresponding author.

*Introduction.*– The idea for this study was inspired by the participation of staff to hospital disaster preparedness workshop. Hospital staffs are count on and expected to fulfill responsible roles during disaster situations. Most of the earlier studies focused on health care workers willingness to attend in outbreaks, bioterrorism and pandemic agents. However, there is little research that specifically explores the concerning of psychiatric hospital staff to attend work in disasters.

*Objectives.*– At this study, we focused on Razi psychological Hospital staff concerns during disasters.

*Method.*– The study was performed in 2016, and conducted using qualitative content analysis methods. Twenty-three participants were selected purposefully and data were collected through interviews, focus group, and observation. Data saturation was a criterion for sampling.

*Results.*– “Disaster based resiliency” was the main theme. Three main categories include “Ignoring the basic human needs” and “lack of disaster-based organization” and “emotional response”. And we found 10 sub-categories, and 71 codes. Most of staff concern about their family in time of disaster.

*Conclusion.*– It seems for appropriate and effective response during disaster, need to resolve main concerns of hospital staff, and improve resiliency of hospital, for effective response and prevent loss in disaster.

### Burki's Index of Dhant

M. Bhadar<sup>1\*</sup>, Z. Mukhtar<sup>2</sup>, S. Asghar<sup>3</sup><sup>1</sup> *Sexual Health Institute Pakistan, Psychiatry, Lahore, Pakistan;*<sup>2</sup> *AZM Center, Psychology, Sargodha, Pakistan;*<sup>3</sup> *Sexual Health Institute Pakistan, Psychology, Lahore, Pakistan*

\* Corresponding author.

**Aims.**– Dhant is highly prevalent disease in subcontinent. Symptoms are vague and multiple. Careful study of symptoms reveals it is mixture of psychological, somatic, inflammatory, urinary and symptoms of allergy. Attempt is made to quantify severity of disease for its gradation. Tool is developed for gradation of disease and to monitor treatment response.

**Method.**– Classical symptoms of dhant were studied from Hakims books of Tibay Unani. Symptom checks list of dhant was developed. It was administered to population of dhant patients. Symptoms having significant statistical value were sorted. Symptoms were phrased in Urdu language by a team of Hakims and experts of Urdu language.

**Results.**– Questionnaire consisting of 27 questions were developed. Index has been divided into different domains including anxiety, depression, somatic urinary, sexual, inflammatory and allergy symptoms. Every symptom was graded on five response option.

**Discussion.**– Burki's Index of Dhant is based on medical interpretation of dhant phenomenon. It meets criteria of test and retest reliability, standardization, validity and practicality. Anxiety and depression domains explain psychological state. Allergy and inflammatory domain reflects level of sickness. Urinary symptom reveals urinary tract involvement. Somatic domain level reveal extend of somatization phenomenon very common in subcontinent. Sexual symptoms revolve around sexual functions like changes in libido, erectile IVLT, frequency of nocturnal emission, function of the

patients. Scores has been used to compute treatment response of treatment regimens. In order to evaluate norms larger population studies are required.

**Conclusion.**– Burki, index of dhant help evaluate and design treatment according to differential domain score and compute response.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Problematic masturbation multifaceted phenomenon

M. Bhadar<sup>1\*</sup>, S. Asghar<sup>1</sup>, Z. Mukhtar<sup>2</sup><sup>1</sup> *Sexual health institute of Pakistan, Psychiatry, Lahore, Pakistan;*<sup>2</sup> *AZM center, psychology, Sargodha, Pakistan*

\* Corresponding author.

**Introduction.**– Masturbation is a universal practice done, medically healthy activity. When it is done in hard way or at a frequency that is causing impairment in social, occupational and other area of functioning it become problematic. Attempt to control or reduce it gets repetitively failed. This can cause urethral inflammation and genital lesions like Pyronie's disease. How and why this healthy activity becomes unhealthy?

**Method.**– Internet search was made at various websites like psych info science direct pub med using key words masturbation, compulsion, addiction, impulsive, etc.

**Result.**– Compulsive masturbation is part of hyper-sexuality disorder. Because of inconsistency in defining criterion, there is no authentic epidemiological study of subject.

**Discussion.**– Excessive masturbation can be understood as spectrum of compulsivity, impulsivity and addiction. As a compulsive act it can be considered as self-treatment for depression anxiety or frustration. Masturbation can be an attempt to neutralize recurring obsessions. Compulsive masturbation is followed by guilt feeling and is ego dystonic. In impulsive masturbation there are irresistible urges and impulses to act out. Impulsive masturbation occur secondary to mood changes or occurrence of stress. Excessive masturbation do follow pattern of addiction as well. There is continued engagement despite adverse physical and psychological consequences, loss of control and. Neuro-plastic changes in amygdla and neuclus accumbency necessitate greater frequency of masturbation to counter dysphoria. Due to neuroplastic change in glutamergic transmission subject becomes cue sensitive. Treatment with SSRIs anti glutamergic have shown promising result.

**Conclusion.**– Psychiatrist should give due consideration to problematic masturbation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0006

### Can doctors apply treatment strategies for patients with bodily distress syndrome

A. Dybdal

*Medical Student, Aarhus University, Aabyhoej, Denmark*

**Introduction.**– Patients with bodily distress syndrome (BDS) with multiple unexplainable somatic symptoms are prevalent in all medical settings and challenge the health care system in time and economically aspects. Despite that documented effective treatment for this patient group is available, doctors appear to struggle to apply these strategies both in primary and secondary care. For the individual doctor, it is essential to know and manage the patient

related as well as the doctor related factors that could prevent proper treatment for this patient group.

**Objectives.**– This case report presents a 65-year-old man with multiple unexplainable symptoms, which have caused substantial consequences for the patient and for the health care system. We identify which factors related to the patient, the doctor and health care system that lead to this man's intensified condition of BDS. Furthermore, we discuss whether the involved doctors were able to follow the common treatment strategy.

**Conclusions.**– Discussion and conclusion is available after the research work.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0007

### **Determination of the temperament characteristics to the levels of stress and discomfort in patients with premenstrual dysphoric disorder**

G. Erzin<sup>1</sup>, H. Kilic<sup>2</sup>, S. Bayram<sup>3</sup>, E. Goka<sup>3</sup>, K. Ozdel<sup>1</sup>

<sup>1</sup> Diskapı Yıldırım Beyazıt Education and Research Hospital, Psychiatry, Ankara, Turkey;

<sup>2</sup> Zonguldak, Psychiatry, Zonguldak, Turkey;

<sup>3</sup> Ankara Numune Training and Research Hospital, Psychiatry, Ankara, Turkey

\* Corresponding author.

**Introduction.**– Although the premenstrual dysphoric disorder is common in women between 18 and 45 years of age, it has not received much attention as a research topic in psychiatry.

**Objective.**– Determining the temperament characteristics, distress and discomfort resistance of premenstrual dysphoric disorder patients and contributing to the diagnosis of the disease.

**Method.**– Participants of the study were given sociodemographic data form, scan scale for pre-menstrual symptoms, distress resistance scales, and discomfort resistance scale.

**Results.**– There were 43 participants. The average age of the participants was  $27.56 \pm 8.4$ . The average duration of the menstrual cycle was  $27.50 \pm 3.22$  days. The average age of menarche was  $13.21 \pm 1.27$  years and the average duration of the menstrual cycle was  $5.54 \pm 1.34$  days. A total of 18.6% ( $n=8$ ) of them were learned to have psychiatric disease history in their families and 16.3% ( $n=7$ ) of them had psychiatric treatment before. Only 11.6% of the participants were pre-diagnosed as premenstrual dysphoric disorder.

**Conclusion.**– Better recognition of premenstrual dysphoric disorder and determination of temperament, distress and discomfort resistance levels of women with this disorder may reduce the disruptions in certain areas and minimize the loss of labor force.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Broken heart disease and psychiatric pathology: A case report**

F.J. Gómez Beteta\*, M. Villanueva Gallego, J. Peman Rodriguez, J. Ibañez Vizoso, M. Perez Lombardo, V. Crossley López, F. Garcia-Escribano Martín, L.M. Chiva San Roman, C. Carrascosa Carrascosa

Hospital Clinico San Carlos, Instituto de Psiquiatria y Salud Mental, Madrid, Spain

\* Corresponding author.

**Objective.**– Highlight the importance of performing an organic screening before diagnosing panic attacks, especially in the cases of refractoriness.

**Material and methods.**– The case of a 58-year-old woman diagnosed with anxiety-depressive disorder, refractory to antidepressant and anxiolytic treatment was presented. In the Emergency Service, it was detected that elevated numbers of myocardial damaging enzymes and echocardiographic alterations existed which were studied in the Department of Cardiology and diagnosed as Takotsubo Syndrome. During follow-ups at a Psychiatry clinic, it was observed that the symptoms of anxiety persist such as nausea, tachycardia, sweating, and dizziness, which do not subside with prescribed pharmacological treatment. After the following studies significant findings of elevation of metanephrines in blood and urine, and images of abdominal ultrasound and scintigraphy with MIBG compatible with paraganglioma at the left intrarenal location were found. It required surgical intervention with the paraganglioma being extirpated resulting in improvements of her anxious disorder, but the depressive symptoms persist.

**Conclusions.**– Although Tako-Tsubo cardiomyopathy secondary to pheochromocytoma is a very rare entity, it should be taken into account in the differential diagnosis of anxiety disorders that do not respond to usual treatment, especially in postmenopausal women. It is estimated that about 47% of the patients with this pathology present a previous story of psychiatric or neurological pathology and that 17.1% were medicated with one or more antidepressants. The case is representative of the psychiatric aspects of the organic disease and the diagnostic and therapeutic problems that arise when these are the form of onset of the disease.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0009

### **Obsessive-compulsive disorder with obsessive-compulsive personality disorder – A case report**

A. Gudi

Singapore General Hospital, Psychiatry, Singapore, Singapore

**Introduction.**– Obsessive-compulsive disorder along with anankastic personality is a diagnostic challenge for the experienced clinician too [1]. Untreated OCD and OCPD are risk factors to develop in other psychiatric problems pushing the patient to seek treatment. They do exist together and must be carefully diagnosed and appropriately treated. Here, I present a case report of such an unusual case and its treatment.

**Objectives.**– To highlight that OCD and OCPD can co-exist and needs to be carefully teased out and a need for appropriate treatment.

**Results.**– The patient's diagnosis was carefully done and patient was successfully treated [2] with antidepressants and low-dose anti-psychotic, along with behavioural therapy to address both OCD and OCPD.

**Conclusions.**– Obsessive-compulsive disorder should be carefully teased out from Obsessive-compulsive personality so appropriate treatment can be administered.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Released-active drugs as a modern tool of psychiatric and neurological diseases therapy

G. Khakimova<sup>1\*</sup>, E. Kardash<sup>2</sup>, V. Fateeva<sup>1</sup>, E. Gorbunov<sup>1</sup>, S. Tarasov<sup>1</sup>

<sup>1</sup> OOO "NPF Materia Medica Holding", Research & Analytical Department, Moscow, Russia;

<sup>2</sup> OOO "NPF Materia Medica Holding", FSBSI Institute of general pathology and pathophysiology, Research & Analytical Department, Moscow, Russia

\* Corresponding author.

To date, there are many modern drugs for psychiatric and neurological diseases treatment. However, almost all of them have different side effects that limit their use in ambulatory practice. Moreover, uncontrolled long-term use of such drugs creates a high risk of mental and physical dependence.

The alternative is to use innovative released-active drugs presented on the Russian and CIS pharmaceutical markets, for example, Tenoten, Divaza, Brizantin, Kolofort and Proproten-100. The peculiarity of these drugs is that due to special manufacturing process – the consecutive reduction of the concentration of initial drug substance (different antibodies), new structures emerge in the solution. These new structures are derivatives of the initial antibodies, but possess a different type of the activity: they retain specificity of action, however, do not neutralize their target, but modify it. This activity has been named released-activity, and the derivatives of the antibodies – released-active form of antibodies. Released-activity allows to biochemical correct the violations of integrative activity of the brain. The spectrum of pharmacological activity of the released-active drugs has been shown in the numerous experimental and clinical studies conducted in the leading research centers of Russia and Europe. For example, it was proved that released-active form of antibodies to S100 protein has anxiolytic, antidepressant, anti-stress, anti-aggressive, nootropic (anti-amnesic, neuro-protective) and neuro-trophic activities without sedative and muscle relaxant effects and any type of dependence.

Thus, application of innovative market-proven released-active drugs could be considered as a modern effective and safe tool of psychiatric and neurological diseases pharmacotherapy.

### Stress and medically unexplained symptoms: Voice of Pakistani patients

N. Chaudhry<sup>1</sup>, M. Husain<sup>1</sup>, S. Tofique<sup>1</sup>, T. Kiran<sup>1\*</sup>, N. Gire<sup>2</sup>, C. Furber<sup>3</sup>, A. Husain<sup>2</sup>, H. Nusrat<sup>2</sup>

<sup>1</sup> Pakistan Institute of Living and Learning, Research, Karachi, Pakistan;

<sup>2</sup> University of Manchester, Division of psychology and mental health, Manchester, United Kingdom;

<sup>3</sup> University of Manchester, Division of Nursing Midwifery and social work, Manchester, United Kingdom

\* Corresponding author.

*Background.* – Patients presenting to primary care and medical outpatient units frequently express physical complaints that may be unrelated to any organic disease. Such medically unexplained symptoms (MUS) are commonly attributed to psychological or emotional problems. MUS are disabling, and are associated with significant costs to the individual and the health system.

*Objectives.* – To explore the phenomenon of medically unexplained symptoms and participants explanations of their symptoms, causes/triggers and impact on their lives.

*Methods.* – Semi-structured interviews were conducted with a total of 20 participants with an established history of physical symptoms unexplained by an organic/physical cause, recruited from medical outpatient units of a public hospital in Karachi, Pakistan. Participants scoring 9 or above on Patient Health Questionnaire-15 (PHQ-15) were considered eligible. All interviews were digitally recorded and transcribed verbatim.

*Results.* – We used framework analysis to analyze the data. Following 5 themes were emerged (i) physical symptoms included headache/body pain, heaviness, numbness, gastric problems, and dizziness (ii) feelings experienced by the participants included loneliness, depressed mood, hopelessness and anxiety (iii) triggers for symptoms included relationship difficulties, stress related to children, poverty and supernatural beliefs (iv) coping strategies included rationalization and distraction (v) impact on participants' lives included being unable to function as normal, denial of psychological challenge, and impact on family.

*Conclusion.* – Primary care physicians should be trained in understanding the psychological manifestations of MUS so they are better equipped in their management. There may also be a role of psychological interventions in low resource settings like Pakistan.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

It was inspected 136 patients with anxiety disorders (AD). The inspected were divided into 3 groups according to heading of ICD-10: 35 patients with panic disorder (PD) (episodic paroxysmal disorder (EPD)), 34 patients with generalised anxiety disorder (of GAD) and 67 patients with the mixed anxiously-depressed disorder (of MADD). For EPD pathognomyc is predominance of paroxysmal somatic-vegetative and emotional violations on a background the high indexes of personality anxiety and in relation to the normal indexes of reactive alarm. For GAD more inherent connections of permanent and paroxysmal somatic-vegetative and emotional violations are on a background the high indexes of reactive alarm and in relation to normal-personality anxiety. For MADD inherent interference connection of both clinical and pathopsychological displays. From data of methodology of Spilberger scale in most patients there was a high level of reactive alarm in all three groups. From data, got by methodology of K. Leongard, considerable predominance of anxious type was determined for all patients. On the basis the got results, by us reasonable and worked out system of psychotherapy and psychocorrection of sick EPD, GAD and MADD, built on the systems and multilevel principles. The base method of realization of medic-psychologic rehabilitation of sick GAD and MADD, was group psychotherapy. The decline of general level of anxiety, internal anxiety was attained in most patients. On the whole considerable improvement it was attained in 72% patients of I group, in 68% patients of II group and in 78% patients of III group.

### **Body-centric healing of extreme trauma**

R.H. Kurz\*, D. Howard

*Outstanding Achievements, Research, Long Ditton, United Kingdom*

\* Corresponding author.

*Introduction.*– The Extreme Abuse Survey report on endritual-abuse.org (run by US Clinical Psychologist Dr Ellen Lacter) outlines numerous extreme offences and complex trauma symptoms. Traditional Psychiatry and Psychology, often failing to acknowledge the formation of dissociative disorders by neglect and abuse in early childhood, have little to offer. Energy oriented approaches (e.g. Kurz & Fecht, 2016) provide an alternative. Drawing on the unique experiences of a survivor of extreme abuse, this paper outlines a body-centric healing method.

*Objectives.*– The presentation provides a personal perspective on abuse and symptoms experienced as well as healing.

*Aims.*– The aim of this presentation is to disseminate information about the impact of extreme offending on mental health and survivor-informed techniques for healing.

*Methods.*– Release of traumatic memories triggered a period of self-reflection and self-healing that resulted in a technique that could potentially benefit others.

*Results.*– The method consists of focusing one's awareness on the physical body, and from there locating and healing wounds in the energy body until the energy body is repaired, and health is restored. There are seven umbrella elements: self-care, self-monitoring and recording, caring for your word, caring for your actions, a strong intention for self-healing, arranging your life so that you can heal, and persistence. There are seven detailed stages of the process.

*Conclusion.*– This self-healing approach was an isolated individual's solution for dealing with the debilitating somatoform dissociation caused by trauma. It is referenced with published literature, other survivors' accounts, and catalogues anomalous autobiographical phenomenological experiences.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The prevalence of adult separation anxiety disorder in outpatient clinic in Egypt**

A. Meshref\*, M. Abouzed

*Al-Azhar University, Faculty of Medicine, Psychiatry, Cairo, Egypt*

\* Corresponding author.

*Background.*– Prevalence of adult separation anxiety disorder (ASAD) is still under estimated, and its risk factor is unclear.

*Aim of the work.*– This study aimed to assess the prevalence and risk factor associated with ASAD in psychiatric outpatient clinic.

*Methods.*– Four hundred and ten patients diagnosed with any anxiety disorders according to DSM-V. We assess their sociodemographic data, Hamilton for depression, Hamilton for anxiety and the Separation Anxiety Symptom Inventory).

*Results.*– Patients with social phobia show higher prevalence of ASAD and this co-morbid was elevated in female than male. Early separation anxiety scores but this association was unique in females only. ASAD was also co-morbid with depression and low educational level.

*Conclusions.*– Prevalence of ASAD is under estimated and clinicians diagnose it as another anxiety disorder especially social anxiety or depression.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Acting upon misperceptions of one's own body**

V. Pitron

*Psychiatrie, Hôpital Européen Georges-Pompidou, Paris, France*

One may believe the perception of one's own body to be trustworthy, or even immune to errors, since it is about "the same old body always there", as William James (1890) put it. However, bodily awareness can be impaired in several psychiatric conditions. Patients with body hallucinations, for instance, misperceive their own body. They feel their organs rot in the Cotard syndrome, and during Alice in Wonderland hallucinations they sometimes even perceive and see their body parts changing shape (Todd, 1955). Impaired body perceptions also occur during the phantom limb phenomenon, among patients with somatic symptom disorders when they report sensations that are inconsistent with their objective physical lesions, and in anorexia nervosa. Those symptoms may be influenced by how patients act with their body, insofar as actions influence body perceptions and vice versa (Pitron and de Vignemont, 2017). One major question then arises: to which extent can actions help to reverse impaired body sensations in psychiatric conditions? Interestingly, it is possible to mimic psychiatric bodily symptoms in healthy volunteers with the rubber hand illusion paradigm that makes participants perceive their own body part with another shape or in a different position (Botvinick and Cohen, 1998; Van der Hoort et al., 2011). After describing how actions can reshape body perceptions during the rubber hand illusion, I shall discuss the circumstances under which action-oriented treatments may offer good opportunities for bodily symptoms of psychiatric patients.

*Background.*– Marriage satisfaction and the quality of partnership play an important role in the occurrence of psychiatric disorders. Anxiety disorders affect the family everyday functioning, require greater demands for adaptation and re-evaluation of the existing habits of family members and consequently may result in family dysfunction due to anxiety disorders, especially in marital relationship or partnership.

*Method.*– The relevant studies were identified through the Web of Science, Pub Med, and Scopus databases, within the period 1990–2017.

*Results.*– Dissatisfaction in a relationship can act as a trigger for the development of anxiety disorders and could also be responsible for the modulation and maintenance of these disorders. However, this dissatisfaction may also be the consequence of manifestation of the anxiety disorders. The individuals with the anxiety may feel guilty about their partners because of the tolerance and help (does not matter what kind and quality of the help he/she provides), sometimes they are submissively grateful because of the support, they may feel inferior, tend to serve him/her. On the other hand, he/she begins to rebuke partner's supposed negative attitudes; the patient may start to use his psychological problems as an excuse and expect others to help him and solve the situation. Consequently, he/she starts to check and criticize the partner and this tense situation may lead to problems in marriage and disturbs family functioning.

*Introduction.*– In many cases problems of rehabilitation of mental patients are connected with their attitude towards the process of the therapy that conditions its inconsistency and fragmentariness. *Objective.*– To study efficiency and specifics of rehabilitation of patients with non-psychotic mental disorders at the stage of the therapy and after discharge from hospital.

*Methods.*– Clinical-psychopathological, clinical-dynamic, clinical-follow-up, immunological, psychological, statistical. Sixty patients of non-psychotic level – with adjustment disorders, somatoform and organic mental disorders were examined.

*Results.*– The examination and therapeutic-preventive activities were carried out. In the process of the therapy all patients showed significant improvement of their state, however, gradual worsening of their overall health was noted, 10 months after discharge from hospital in 38 cases (63.3%), the patients needed additional courses of treatment. In most cases the therapeutic-preventive activities were canceled earlier than needed or were carried out fragmentarily. Only 13 patients (21.67%) passed fully the recommended course of pharmacotherapy and two patients (3.33%) continued psychotherapy after discharge. About 30% of patients of all groups preferred not to continue the course of the treatment but its repetition next year. Hospital (therapeutic) social environment and appropriate social-medical activities were perceived as socially accepted ways of avoidance from social risks and manipulation of the surrounding people.

*Conclusions.*– Existing model of specialized assistance to patients with non-psychotic mental disorders needs enforcement of its social and educational components as well as psychotherapeutic and psychocorrective component.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The comparison of anxiety disorders prevalence in 8–12 years old children in only child families and families with several children. Gorgan, 2017**

P. Sayyah Ensan<sup>1\*</sup>, F. Derakhshanpour<sup>2</sup>, N. Erfanian Khadivi<sup>3</sup>

<sup>1</sup> Medical Student, Golestan University of Medical Sciences, Ramsar, Iran;

<sup>2</sup> Medical Doctor, Golestan University of Medical Sciences, Gorgan, Iran;

<sup>3</sup> Medical Student, Golestan University of Medical Sciences, Gorgan, Iran

\* Corresponding author.

*Introduction.*– Anxiety disorders with a prevalence of 5 to 17 percent are one of the most commonly diagnosed psychiatric disorders in childhood. Considering the high prevalence in the community, on the one hand, and increasing the tendency of the family to have a maximum of one or two children, on the other hand, the need for further research projects Determine the effect of this procedure on the behaviour of children.

*Materials and methods.*– A questionnaire including questions about sex, age, mother's occupation, mother's education level and number of children's children, screening of emotional disturbances associated with childhood anxiety (Spence) is being used. This questionnaire was completed by children aged 12-8 years old who referred to Taleghani Hospital's non-psychiatric clinics and pediatricians' offices.

**Results.**– The results of the study showed that in all subgroups of anxiety other than general anxiety ( $P=0.084$ ), mean scores were significantly higher in children of multi-child families, and this statistically significant increase was observed ( $P<0.003$ ), and in 49 (34.3%) children of single-child families and 94 (65.7%) of children in multi-child families, there was anxiety disorder and this result was statistically significant. Severity has been significant ( $P=0.001$ ).  
**Conclusion.**– It can be concluded that the prevalence of anxiety disorder among children with siblings is higher than that of single children and among single children in girls. The idea that single children have better family conditions and care more will be raised.

### **Asthma and panic disorder: Two conditions, one presentation**

F. da Silva<sup>1</sup>, P. Amadeu Almeida, N. Oliveira

Hospital de Magalhães Lemos, Internamento C, Porto, Portugal

\* Corresponding author.

**Introduction.**– Panic disorder and asthma frequently co-occur.

**Objectives.**– The aim of this study is to review the current literature about the co-occurrence of asthma and panic disorder.

**Methods.**– We conducted a literature review searching the terms “asthma” AND “panic” in Pub Med. The search strategy was limited to articles written in English and that used adult human samples. Bibliographic references of the identified articles were also included.

**Results.**– Asthma increases the risk of developing anxiety disorders, including panic disorder. Several factors may explain this phenomenon. Medications typically used in asthma management, such as adrenergic agonists, theophylline and steroid medications have anxiogenic properties. In anxiety prone patients, the frightening experience of having repeated asthma attacks may precipitate a panic disorder, with typical cognitive distortions. On the other hand, anxiety can impact asthma-related outcomes. In patients with asthma, anxiety-related hyperventilation can lead to hypocapnia, which in turn induces bronchoconstriction and asthma symptoms worsening. Interventions based on cognitive-behavioural techniques and respiratory rehabilitation has been proposed to treat patients with both conditions.

**Conclusions.**– The recognition of symptom overlap between asthma and panic attacks is important for the differential diagnosis and the identification of comorbidity. The understanding of underlying mechanisms is important for treatment success.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Comparison of SSRIs and SNRIs in Generalized Anxiety Disorder (GAD)**

G. Sulejmanpasic<sup>1\*</sup>, S. Bise<sup>2</sup>

<sup>1</sup> Neuropsychiatrist, Psychiatric Clinic, Sarajevo, Bosnia, Herzegovina;

<sup>2</sup> Neuropsychiatrist, Cantonal Psychiatric Hospital “Jagomir”,

Sarajevo, Bosnia, Herzegovina

\* Corresponding author.

**Introduction.**– Generalized anxiety disorder (GAD) often leads to physiologic symptoms, including fatigue, muscle tension, restlessness, and other somatic complaints. Women are almost twice diagnosed over their lifetime. Antidepressants, selective sero-

tonin reuptake inhibitor (SSRI) and serotonin norepinephrine reuptake inhibitor (SNRI) classes, are the first-line medication treatments. Escitalopram as SSRIs increases intrasynaptic levels of the neurotransmitter serotonin by blocking the reuptake of the neurotransmitter into the presynaptic neuron. Duloxetine as SNRIs inhibits the reuptake of serotonin and norepinephrine (NE) in the central nervous system and increases dopamine (DA) specifically in the prefrontal cortex.

**Objective.**– Compare clinical efficacy, safety and tolerability of escitalopram and duloxetine in patients with generalized anxiety disorder (GAD).

**Methods.**– 8-week, fixed-dose, parallel-group design. A total of 10 outpatients (mean age = 38.8 years, all women) with a ICD-10 criteria-defined GAD diagnosis received escitalopram 20 mg/day ( $N=5$ ) and duloxetine 60 mg/day ( $N=5$ ). The primary efficacy measures were the HAM-A and CGI-I.

**Results.**– Duloxetine was more effective after the first month of treatment and had greater functional improvement in all of five patients. The mean change represents 49% decrease in HAM-A total score from baseline for duloxetine-treated patients and had significantly greater improvement ratings at endpoint on the CGI-I. Safety and tolerability of both medications were equal.

**Conclusion.**– These data suggested that a connection between early improvement of duloxetine, endpoint response and remission status, can be used to guide clinical decision-making. The findings support the inclusion of duloxetine as an empirically validated pharmacologic intervention for GAD as well.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Bipolar disorders**

### **Co-existence of bipolar disorder and OCD: A case study**

R. Abubaker

Atlanta VA Medical Center, Psychiatry, Atlanta, USA

Bipolar disorder is considered a serious life long mental illness and often with other comorbidities like Anxiety disorder, substance use disorder and OCD (Obsessive-compulsive Disorder) OCD, which was grouped under Anxiety disorder in DSM IV, has become a separate disorder with several underlying disorders. This case report will present a case of a patient seen in outpatient setting with a diagnosis of Bipolar disorder and who also displayed symptoms of Obsessive-compulsive disorder. We will present the likelihood of having both these disorders at the same time, how do they present clinically and their treatment options. We will also discuss the fact that often when the bipolar disorder symptoms like mania or depression are controlled with treatment including the use of medications the OCD symptoms still persist. Will also outline the new advances in diagnostic imaging for OCD and what different treatments can be available for these patients in future.

\* Corresponding author.

**Introduction.**– Twitter is a social media platform with growing activity and impact on public opinion. Major mental disorders seem to be a frequent topic of interest in Tweets during the recent years.

**Objective.**– To analyze Tweets referring to bipolar disorder from the Twitter accounts of prominent US mass media outlets.

**Methods.**– A qualitative analysis of Tweets selected among a representative sample of American communication media outlets in Twitter. We selected the 15 accounts with the highest number of followers. Tweets were selected if they made any reference to Bipolar disorder. This study focused on the Tweets from 2007–2016.

**Results.**– Eighty-two Tweets were selected and divided into three categories. 66% were testimonies from patients (“Carrie Fisher’s openness about her bipolar disorder motivated me to talk about mine”, “Catherine Zeta-Jones talks about her struggle with bipolar disorder”), 30% focused on medical advancements or epidemiological facts (“HEALTH: Study: Breast Cancer Drug May Treat Bipolar Disorder”) and a minority had a condescending tone towards these disorder. Tweets referred to personal testimonies had the highest number of retweets. Peaks in the number of tweets have been observed when celebrities were subjects of the news.

**Conclusions.**– Bipolar disorder has been the topic of a variety of Tweets among US mass media Twitter accounts, reflecting a social interest on this disorder, most especially when testimonies and news are related to celebrities.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Assessment of the psychosocial adjustment in bipolar patients in remission**C. Ati<sup>\*</sup>, W. Homri, R. Zeramdini, N. Bram, I. Ben Romdhane, R. Labbane*Hospital Razi, Psychiatry C, Tunis, Tunisia*

\* Corresponding author.

**Introduction.**– Bipolar disorder is a chronic and disabling mental disorder associated with reduced quality of life, impaired functioning and significant burden for families and society.

**Objectives.**– To assess the psychosocial adjustment in patients with bipolar disorder in remitted state, and to identify the socio-demographic and clinical features interfering with this adjustment.

**Methods.**– This is a cross-sectional, descriptive and analytic study involving 60 patients diagnosed with bipolar disorder type I, according to DSM IV-R criteria, in clinical remission for at least three months. Psychosocial adjustment was assessed with The Social Adjustment Scale by Weissman.

**Results.**– Of the 60 bipolar patients recruited in the study, 18.3% were unemployed. One third of employed subjects had moderate or severe occupational functioning impairment. 20% were divorced or separated. 45% were married. 32% of married patients had moderate or severe marital dysfunction, significantly influenced by having children, a criminal record, a poor insight or comorbid personality disorders. 30% of patients had moderate or severe family maladjustment. More than a half had a moderate or severe social

impairment, significantly influenced by family history of mood disorder, frequency of relapse and the total follow-up duration. 55% of bipolar patients had moderate or severe general psychosocial maladjustment and was associated with psychiatric family history, depressive episodes as well as severe manic episodes with psychotic features.

**Conclusion.**– Our study underlines the importance of both pharmacological and psychotherapeutic interventions aiming to improve psychosocial adjustment and occupational functioning in patients suffering from bipolar disorder.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Partial empty Sella syndrome and bipolar affective disorder: Two case reports**E. Başar<sup>\*</sup>, Y. Görgülü, R.K. Çınar, M.B. Sönmez  
*Trakya University School of Medicine, Psychiatry Department, Edirne, Turkey*

\* Corresponding author.

Empty sella syndrome is an illness characterized by filling of cerebrospinal fluid in the pituitary fossa. Due to reduction of pituitary gland, hypopituitarism may occur 20% to 50% of patients. There is a case report in the literature of a patient had manic attack due to hyponatremia according to syndrome of inappropriate anti-diuretic hormone (SIADH). Beside that another case report had been published of a patient had bipolar disorder and the empty sella syndrome incidentally.

Here we present two cases that have been treated in our inpatient clinic for manic phase of bipolar disorder, diagnosed for partial empty syndrome. During the investigations to rule out the organic cranial pathology, partial empty sella appearance has been noticed. There was no neurologic, visual dysfunction or laboratory abnormality in both patients. Thyroid dysfunction was ruled out. Patients should be investigated further for hypopituitarism. Patients have remitted less than 4 weeks of treatment with valproic acid and atypical antipsychotics.

Empty sella syndrome coexisting with bipolar disorder is a very occasional condition. Our knowledge is not enough to claim that the empty sella syndrome is a cause of bipolar disorder. But we should investigate patients with bipolar disorder carefully for organic pathology.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0026

**Validation of the Arabic version of the Bipolar Prodrome Symptom Scale –Prospective (BPSS-P) in Tunisian adolescents and young adults**A. Ben Dhia<sup>\*</sup>, A. Braham, A. Souilem, J. Sehli, A.S. Bannour, S. Ben Nasr, B. Ben Hadj Ali*CHU Farhat Hached, psychiatry department, Sousse, Tunisia*

\* Corresponding author.

**Aim.**– The study aimed to examine whether the Arabic version of the Bipolar Prodrome Symptom Scale–Prospective (BPSS-P) has good construct, concurrent validity and reliability.

**Methods.**– Validity was established on a sample of 78 Tunisian subjects aged between 14 and 30 years. These subjects were divided into 3 groups according to the BPSS-P scores: BPSS (–) ( $n=31$ ), ARMS: at risk of mania syndrome ( $n=21$ ), bipolar NOS ( $n=10$ ), POBS

[presence of bipolar syndrome: bipolar 1 and 2 ( $n = 16$ )]. For construct validity, we used the convergent validity. We used Young Mania Rating Scale (YMRS) and Montgomery-Asberg depression rating scale with the BPSS-P. For concurrent validity, we studied the correlation between symptoms of the BPSS-P and their equivalents in the YMRS and MADRS. The BPSS-P reliability was conducted by studying the Interrater reliability.

**Results.**– The ARMS group was shown with intermediate scores of YMRS, MADRS between the groups BPSS-P (–) and POBS. That confirms a good construct validity of the Arabic BPSS-P. We noted a correlation between the scores in mania and depressive sections measured by the BPSS-P and their corresponding level of the YMRS and MADRS. These results show that the BPSS-P has a good concurrent validity. For the reliability study, we noted a good correlation between the two raters with a Pearson coefficient ranging from 0.66 to 0.8.

**Conclusion.**– Analysis of the results of construct validity, concurrent validity and reliability of the BPSS-P indicates that this version translated into Arabic is valid and reliable.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0027

### **Linguistic validation of the Arabic version of the Bipolar Prodrome Symptom Scale – Prospective (BPSS-P)**

A. Ben Dhia\*, A. Souilem, A. Braham, A.S. Bannour, S. Ben Nasr, B. Ben Hadj Ali

CHU Farhat Hached, psychiatry department, Sousse, Tunisia

\* Corresponding author.

**Introduction.**– The relevance of the identification of prodromal symptoms reside in its involvement in the management and prognosis of bipolar disorders and in the eventuality of identifying these subjects before the outbreak of the disorder that usually begins in adolescence.

**Aim.**– The aim of this work is to translate the BPSS-P scale into literary Arabic and to verify its validity.

**Methods.**– We translated the BPSS-FP into literary Arabic using the translation and retro-translation method with direct translation, retro-translation and a comparison between source scale and retro-translated scale. The validity of content was done through the pre-test and expert opinion.

**Results.**– A first comparison of the two versions, source and retro-translated, made it possible to detect certain discrepancies, some of which were related to translation and others to retro-translation. Then a verification of the Arabic literary version was carried out. Subsequently, a second retro-translation was made. Once these steps were completed, we proceeded to the steps of validity of the content. Remarks made during the pre-test concerned either the vocabulary used, or the grammatical and syntactical construction of items. No problems with ethical or cultural considerations have been reported. The experts' opinion made it possible to detect items deemed linguistically inappropriate to measure the concept. Alternatives to certain terms deemed complicated have been proposed. According to this step, the quality of the items in the BPSS-P was very satisfactory overall.

**Conclusion.**– It emerges from this work that the quality of the items in the BPSS-P has proved satisfactory overall. However, further validation of the BPSS-FP is necessary.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0028

### **Early-onset bipolar disorder: descriptive study among 48 bipolar patients**

A. Ben Haouala<sup>1</sup>\*, B. Amamou<sup>2</sup>, A. Mhalla<sup>1</sup>, L. Gaha<sup>1</sup>

<sup>1</sup> Fattouma Bourguiba University Hospital, psychiatry, Monastir, Tunisia;

<sup>2</sup> University hospital of Monastir, research laboratory vulnerability to psychosis, faculty of medicine of Monastir, university of Monastir, Tunisia, psychiatry, Monastir, Tunisia

\* Corresponding author.

**Introduction.**– Bipolar disorder is a mood disorder. Symptoms of mania and depression in adolescents may manifest themselves through a variety of different behaviours.

**Objective.**– To study different characteristics of early onset bipolar disorder.

**Methodology.**– It was a descriptive retrospective study of all bipolar patients with early onset hospitalized between January 2008 and December 2016 in the psychiatry department in Monastir and had a minimum follow-up of six months

**Results.**– The study was involved 48 patients with 28 men. The average age was 33.75 years. The mean age of onset of the disease in our study population was 16.1 years with extremes ranging from 13 to 18 years. A stressor preceding the first episode was present in 41.7%. These were mostly family conflicts (14.6%). The average number of years of study was 8.9. 79.1% were single and 4.2% were divorced. The family history of mood disorder was found in 50% of patients and schizophrenia in 29.2. 22.9% of the patients had a criminal record as well as addiction to a substance in 31.3%. The nature of the first episode was predominantly manic in 81.2%. The delay between the 1st episode and the 1st relapse had a median = 12 months. The average number of access per year was 0.54. We found a higher frequency of manic episodes with a mean of  $5.1 \pm 3.6$ . A dominant polarity of the manic type was found in 97.9% and 72.9% had psychotic symptoms in their relapses.

**Conclusion.**– Our study suggests that early onset bipolar disorder presents some differences in clinical expression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0029

### **Age and delayed diagnosis of early-onset bipolar disorder**

I. Berrahal\*, R. Damak, H. Maatallah, Y. Abid, M. Cheour

Razi Hospital, Psychiatry Ward "Ibn Omrane", Mannouba, Tunisia

\* Corresponding author.

**Introduction and objective.**– Our aim was to examine the influence of the age at onset of the illness and the delay of diagnosis of the early-onset Bipolar disorder (EOBD).

**Methods.**– Fifty-five patients, aged between 18 and 22 years, diagnosed with EOBD according to DSM-V criteria and followed up for at least one year were included. Twenty-five subjects were diagnosed after a delay of one year of follow up. The level of significance was fixed at a probability  $P < 0.05$ .

**Results.**– We collected 55 patients, all single, with an average age of 20.4 years and a standard deviation of 1.4 and a sex ratio equal to 1.5. Forty-five percent were diagnosed after a delay of one year of follow up. A statistically significant difference ( $P = 0.018$ ) was observed in relation to age of first hospitalization: Those diagnosed late with an EOBD were younger than those diagnosed early ( $19.92 \pm 1.35$  years vs.  $Z 20.83 \pm 1.41$  years). The average delay between the onset of the illness and the diagnosis was 14.4 months (SD: 16.2 months). The delay was correlated inversely with age at

onset of illness ( $r = -0.192$ ). Independently, delay to diagnosis was associated with more depressive symptoms ( $P = 0.03$ ) and anxiety ( $P = 0.05$ ).

**Conclusion.**– These data converge with other evidence that early onset of bipolar disorder is associated with a long delay to diagnosis and to first pharmacologic treatment. To reduce complications related to this delay, the recognition and diagnosis of EOBBD needs to be improved.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The coexistence of arachnoid cyst with bipolar disorder: A case report

L. Castanheira<sup>1\*</sup>, C. Ferreira<sup>1</sup>, L. Ferreira<sup>2</sup>, E. Fernandes<sup>1</sup>, I. Silva<sup>1</sup>, J. Jerónimo<sup>1</sup>, E. Reis<sup>1</sup>, R. Santos<sup>1</sup>, A. Guerra<sup>3</sup>, M. Carvalho<sup>1</sup>, J.M. Pereira<sup>1</sup>

<sup>1</sup> Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Psychiatry, Lisboa, Portugal;

<sup>2</sup> Hospital Distrital de Santarém, Psychiatry, Santarém, Portugal;

<sup>3</sup> Hospital Espírito Santo, Psychiatry, Évora, Portugal

\* Corresponding author.

**Introduction.**– It has been reported that AC occurred in about 1% of the general population and even more prevalent in psychiatric patients.

**Objectives.**– To present a clinical case illustrative of the relationship between the presence of an arachnoid cyst (AC) and psychiatric symptoms.

**Methods.**– We used a multidisciplinary approach to the patient and reviewed the literature about the theme.

**Results.**– Male 57-year-old, with previous psychiatric disorders and a history of AC and hepatitis C, was admitted at the emergency department with grandiose delusions, insomnia, increased activity, social disinhibition, behavioural disorganization and heteroaggressiveness, that begun three months ago. A cranial computer tomography (CT) revealed the presence of the already documented AC in the left frontal lobe. After consultation with Neurosurgery, conservative management was proposed. He was admitted into the Psychiatric Service and started in sodium valproate, olanzapine and diazepam. During his stay at the hospital, the patient's psychotic symptoms persisted with frequent periods of mental confusion and behavioural disorganization. He repeated the cranial CT that show no new changes and did an electroencephalogram with normal result. The treatment was adjusted and the patient was discharged after two months of hospitalization with mild improvement in symptomatology. We started a follow-up outpatient care, including psychiatric and neurosurgical appointments.

**Conclusions.**– Some articles suggest that there is an etiologic relationship between AC and psychiatric disorders, however it is difficult to be absolutely certain whether the lesion had influence on the patient's psychiatric symptoms or not. More research is necessary to establish the relationship between cyst lesions and psychiatric symptoms in bipolar patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### May serum uric acid levels help us distinguish between bipolar and unipolar depression? – An exploratory study

P. Oliveira, M. Coroa<sup>\*</sup>, J. Ribeiro, N. Madeira  
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Recent studies have found a correlation between serum uric acid (UA) levels and the mood disorder diagnosed, with lower UA levels found in unipolar disorder and higher levels in bipolar disorder (BD).

**Objectives.**– Assess if serum UA levels in patients admitted for unipolar depression can predict later evolution to BD.

**Methods.**– We retrospectively analysed UA levels in patients hospitalized in our Psychiatry Department with a diagnosis of depressive disorder over a 3-year period (June/2006 to June/2009), including all patients who had an UA measurement. Patients above 40 years old, with conditions and taking medications that alter UA levels were excluded. We subsequently identified the patients who received the diagnosis of BD later on.

**Results.**– Overall, 1074 patients were hospitalized with a diagnosis of depression within the stated time interval. 72 met inclusion criteria. 60 (83,3%) had the diagnosis of unipolar depression and 12 (16,7%) the diagnosis of BD. We found a positive correlation between UA levels and diagnosis with higher UA in patients who were later diagnosed with BD. In multivariate analysis, a positive correlation with statistical significance was also found.

**Conclusions.**– We found a positive correlation in inpatients with unipolar depression between serum uric acid levels and later diagnostic conversion, with higher levels of uric acid in patients later diagnosed with BD. Our results suggest UA as a possible risk biomarker for BD in patients with unipolar depression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

**Introduction.**– There is increasing evidence of an overlap (biological, genetic and phenomenological) between the chronic psychosis spectrum disorders, including bipolar disorder (BD), schizoaffective disorder (SA) and schizophrenia (SCZ), thus bringing into question the "traditional" dichotomy between schizophrenia and bipolar disorder.

**Objectives.**– To comparatively assess patients with "stable" BD, "stable" SA, patients who have shifted from BD to SCZ (BD-SCZ) and patients who have shifted from SCZ to BD (SCZ-BD).

**Methods.**– Thirty-three inpatients with BD, 32 inpatients with SA, 31 inpatients with BD-SCZ and 31 inpatients with SCZ-BD, hospitalized in the Timisoara Psychiatric Clinic between 2014 and 2017 were included in our study. All patients were diagnosed in accordance with ICD-10 criteria. We used the MINI Interview and the BPRS to assess all patient groups.

**Results.**– We found statistically significant differences in our 4 patient groups regarding: educational level (SCZ-BD and BD-SCZ patients had higher educational levels than BD and SA patients); a positive family history for chronic alcohol consumption (higher for BD and BD-SCZ patients); alcohol abuse (higher in BD and SCZ-BD patients); supportive social network (lower quality in SCZ-BD patients); intrafamilial violence (highest in BD and BD-SCZ patients); age at onset (BD patients had a higher age at onset than the other patient groups); number of episodes (patients with SCZ-BD had a significantly higher number of episodes than SA and BD-SCZ patients).

**Conclusions.**– The identified parameters might have partial predictive value in regards to the outcome of patients with psychotic spectrum disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Isoniazid: Prophylaxis treatment of tuberculosis. Does it increase the risk of psychosis? Case report**

P. del Sol Calderón<sup>1</sup>\*, A. Izquierdo de la Puente<sup>1</sup>, S. Boi<sup>2</sup>

<sup>1</sup> Hospital universitario puerta de hierro, psychiatry, Madrid, Spain;

<sup>2</sup> Hospital universitario puerta de hierro, psychiatry, Madrid, Spain

\* Corresponding author.

Isoniazid is a drug related to psychiatric symptoms such as mania or psychosis, being these infrequent, appearing sometimes prodromes of anxiety and emotional lability. Its etiology is unknown, believing the relation between isoniazid and deprivation of vitamin B as a possible cause. The main action is to withdraw isoniazid along with antipsychotic treatment. It's important to rule out any causal relationship despite the patient's antecedents towards to a more specific therapeutic approach

The aim of this case is to show the possible relation between isoniazid and psychotic symptoms in a patient with bipolar disorder. Its a 36 year old male with bipolar disorder and B27 + ankylosing spondylitis with axial and peripheral involvement who enters into psychiatry unit for manic decompensation with psychotic symptoms. Usual treatment: lithium 1800 mg, isoniazid 300 mg, calcium foliate, methotrexate and certolizumab. The patient takes isoniazid for 3 months as a prophylactic treatment after the finding of positive Mantoux test with negative chest radiograph prior to starting certolizumab. Lythimia before the entry: 1.01. The patient suffers insomnia, delirious ideation of megalomaniac content as well as phenomenon of telepathy with famous people. Starts treatment with dispersal in increasing dose until 12 mg, being insufficient to control the symptoms. Thus rheumatology is consulted, which after a negative quantiferon test discard the presence of a latent tuberculosis suspending isoniazid. After it, starts treatment with 400 mg of valproic acid as a second mood stabilizer. Progressively the remission of symptoms occurs along with the euthemia of the patient

### **Social cognition and predominant polarity in euthemic bipolar disorder**

P. Ferentinos<sup>1</sup>, K. Dafnas, K. Kampouris, E. Porichi, A. Zika, A. Kyriazis, Z. Alevrogianni, A. Douzenis

Attikon University Hospital, 2nd Department of Psychiatry, University of Athens, Athens, Greece

\* Corresponding author.

**Introduction.**– Deficits in social cognition (theory of mind and emotion recognition) have been detected in manic, depressed and euthemic bipolar subjects. The effect of clinical variables other than mood ratings (especially manic symptoms) on social cognitive performance of bipolar patients is understudied.

**Objectives.**– We investigated whether predominant polarity (PP) affects social cognitive performance of euthemic bipolar patients.

**Methods.**– We compared 36 healthy controls (HC) with no family history of major psychiatric disorder in their first-degree relatives and 54 euthemic (Hamilton depression and Young mania scores  $\leq 7$ ) bipolar I or II patients (30 with depressive PP, PP-D; 24 with manic PP, PP-M) on two social cognition tasks: Faux-Pas Recognition Task and Reading the mind in the Eyes.

**Results.**– There were not significant differences in gender, age, and education among the three groups or in CGI severity, Hamilton depression and Young mania scores among the two patient groups. Significant differences among the three groups were detected on Faux-Pas detection score (ANOVA,  $P=0.027$ ,  $\eta^2=0.08$ ). In specific, PP-M performed significantly worse than PP-D (post-hoc Bonferroni  $P=0.028$ ) but neither patient group differed significantly from HC. No significant differences were recorded on Eyes.

**Conclusions.**– Euthemic bipolar subjects with manic PP display worse theory of mind performance compared to those with depressive PP. Further research is warranted to investigate whether this is the result of a distinct temperament profile or of the cumulative effect of manic/hypomanic episodes.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Patients with bipolar disorder referred to a consultation-liaison psychiatry service**

A. Giménez Palomo<sup>1</sup>\*, L. Pintor<sup>1</sup>, S. Herranz<sup>1</sup>, R. Sánchez<sup>2</sup>, G.

Annella<sup>1</sup>, J.E. Pinzón<sup>1</sup>, S.P. Gomes<sup>1</sup>

<sup>1</sup> Hospital Clinic, Psychiatry, Barcelona, Spain;

<sup>2</sup> Parc de Salut Mar, Psychiatry, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Consultation-liaison psychiatry (CLP) is required when inpatients with medical or surgical processes need psychiatric evaluation or treatment. More studies about the approach of bipolar patients in these settings are needed.

**Objectives.**– To describe the main clinical features of bipolar patients according to DSM-IV-TR criteria attended by a CLP service in a general hospital.

**Methods.**– Retrospective analysis of clinical records of patients treated by CLP service of Hospital Clinic of Barcelona over a 10-year period (from January 2005 to December 2014).

**Results.**– Over a 10-year period, 187 bipolar patients were asked for consultation and 51,3% were men. On average, they were aged  $56.5 \pm 15.1$  years old. 78.1% of them had psychiatric history of bipolar disorder, and 25.7% of patients were referred from a General Medicine service. The most common physical problems were intoxications or poisonings (16.6%), infections (10.7%) and fractures (9.1%). Some of the reasons for referral were suicide attempt or

risk (13.4%), anxiety (2.7%), depression (2.7%), psychosis (3.7%) and treatment adjustment or mental state examination (62%). Regarding the main pharmacological treatment, 39% received mood stabilizers, 8.5% antidepressants and 41.1% antipsychotics. At discharge, 69.5% were linked to a mental health consultation and 13.4% were admitted to the psychiatric department.

**Conclusions.**– According to previous data, 21.9% of patients were diagnosed of bipolar disorder by our CLP service. Suicide attempt or risk assessment is a frequent reason for referral in a CLP service, being the main reason in 13.4% of bipolar patients. In 13.4% of cases from our sample an admission to a psychiatric department was needed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **PDW and RDW are new parameters for bipolar subtypes and unipolar depression**

İ. Gündoğmuş\*, A. Algul, M. Kıyanççek

GATA Haydarpaşa Training Hospital, Psychiatry, Istanbul, Turkey

\* Corresponding author.

**Introduction.**– Although bipolar disorder and unipolar depression are complex and multifactorial mental disorders characterized by mood swings, disability and impaired quality of life, pathophysiologies of both disorders are not fully understood and without an adequate biological explanation. In this context, interest in the etiology of these disorders has been increasing.

**Methods.**– Between January 2016 and January 2017, in our study a 69 patients with manic episodes of bipolar disorder, 60 patients euthymic episodes of bipolar disorder, 70 patients with unipolar depression and 60 sex-matched healthy volunteers (control group) were retrospectively analysed. PDW, RDW and platelets levels were measured in four groups.

**Results.**– In our study, 199 patients and 60-control group were included. There were no differences between the patients and the healthy control group participants in terms of age and sex. Bipolar subtypes and unipolar depression patient group was statistically significantly different from the healthy control on RDW, PLT and PDW.

**Conclusion.**– Our study is the first in the literature in terms of comparing the measure of blood PDW, RDW and platelet levels in bipolar subtypes, unipolar depression and healthy control groups. We believe that levels of PDW, RDW and platelet can be used as a novel marker for bipolar subtypes and unipolar depression. With it, advanced, detailed and larger prospective clinical studies are required to confirm these findings.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Association of multiple sclerosis and bipolar disorder: A case report**

A. Hakiri\*, H. Ben Ammar, A. Tounsi, S. Ben Fadhel, Z. El Hechmi

Razi hospital, F, Manouba, Tunisia

\* Corresponding author.

**Introduction.**– Multiple sclerosis (MS) is an autoimmune condition, which affects central nervous system causing neural demyelination and degeneration. It causes impairments in sensation, motor function, and cognition. Patients with MS develop neuropsychiatric symptoms during the course of the disease such as: depression,

anxiety, apathie, disinhibition, hallucinations, euphoria and bipolar disorder (BD).

**Objectives.**– We aim to illustrate the comorbidity of multiple sclerosis with bipolar disorder.

**Methods.**– A case report and a review of literature.

**Results.**– Mrs A.B.H is 29 years old. The patient was diagnosed with multiple sclerosis in her remitting-relapsing form, at the age of 20. She was treated with interferon (beta 1a). Two years after the diagnosis of MS, the patient was hospitalized in psychiatry department for the first time, for a manic episode with psychotic features, that occurred simultaneously with a relapse of her immune disease. She was treated with haloperidol and valproate. The patient was hospitalized 6 times for manic relapses always following the cessation of her treatment. the prevalence of bipolar disorder in multiple sclerosis at the time of diagnosis and across time was estimated to 16%. BD is twice as common in MS. It can be explained by a biological and inflammatory mechanism and also by emotional distress from being diagnosed or living with a chronic medical condition.

**Conclusion.**– Among individuals with multiple sclerosis (MS), mental health comorbidities damage the quality of life and play a significant role in contributing to secondary disability.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0038

### **Memory evaluation in bipolar disorder patients**

G. Hamdi\*, H. Ben Ammar, R. Nefzi, Z. El Hechmi

Razi Hospital, F, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Memory plays a very important role in cognition and is often equated with it. The memory impairment during the symptomatic phase of bipolar disorder is well documented e but few studies that have an interest in mood stabilization. The goal of this study was to assess memory function in euthymic bipolar patients s comparing with controls.

**Subjects and methods.**– A cross sectional study case-control, conducted among 50 bipolar patients and 50 euthymic subjects healthy volunteers matched *selon l'âge*, sex and educational level. The evaluation of the memory is based on e 3 validated scales: Hopkins verbal Learning Test (HVLT) of the e Span test figures and e test categorical semantic verbal fluency.

**Results.**– The evaluation by HVLT showed a mean score of the total immediate recall chez bipolar patients significantly lower than in controls (6.80 vs. 21.98 + 23.82 + 3.707, P=0.048). The average score of the span direct numbers of patients and the control subjects were comparable (4.78 ± 1.18 vs. 4.80 + 1.01, P=0.66). The evaluation of memory testing by efluence verbal categorical semantics showed an average of better words generated significantly in control subjects (P = 0.004).

**Conclusion.**– This work has shown impairment of memory function in bipolar patients even if PHA mood stabilization. The presence of these residual cognitive impairment is associated with a lower level of functioning and then with a poor prognosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0039

### C-reactive protein level in tunisian bipolar patients

G. Hamdi, H. Ben Ammar, R. Nefzi, N. Smari, Z. El Hechmi  
Razi Hospital, F, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– Studies exploring the relationship between serum levels of CRPus and bipolar disorder (TB) are few and inconclusive.

*Objective.*– This study was to evaluate serum levels of CRPus in 50 euthemic bipolar patients compared to a control group.

*Subjects and methods.*– This is a cross-sectional study among 50 bipolar patients and euthemic 50 witnesses volunteers and healthy subjects matched for age and sex. The assessment is made using a questionnaire exploring the socio-demographic and clinical data and ladders psychomé internationally validated cudgels.

*Results.*– The average rate of the CRP us in bipolar patients was  $2.82 + 3.04$  mg/l (0.53 to 9.66) versus  $1.63 \pm 2.22$  mg/l (0.61 to 7.20) in controls ( $P=0.03$ ). The rate of CRPus did not seem to be affected by the age of disease onset ( $P=0.31$ ), disease duration ( $P=0.45$ ), the type of mood stabilizer ( $P=0.17$ ) or the mean dose of antipsychotics ( $P=0.36$ ). We have no significant correlation between the average rate of CRPus and the average scores of various psychometric tests used in the clinical evaluation.

*Conclusion.*– Our study showed that the rate of CRPus Significant, is higher in euthemic bipolar and does not vary with socio-demographic and clinical parameters which means it is a parameter of the disease.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### The art of wellness

K. Hines

The Kevin & Margaret Hines Foundation, Brain Health & Wellness,  
Alpharetta, USA

Kevin shares his story of hope and celebration of life. Kevin Hines is a mental health advocate, global speaker, best-selling author, documentary filmmaker and entrepreneur who reaches audiences all over the world with his story of an unlikely survival and his strong will to live. Two years after he was diagnosed with bipolar disorder (at 19 years of age), he attempted to take his own life by jumping from the Golden Gate Bridge. He is one of only thirty-four (less than 1%) to survive the fall and he is the only Golden Gate Bridge jump survivor who is actively spreading the message of living mentally healthy around the globe.

Kevin discusses his evidence informed recovery toolkit which plays a crucial role in his recovery. He shares his process for wellness, resilience and recovery. In order to be self-aware and cognizant of his mental wellness, Kevin has developed a 10 step regimen to stay on track and monitor the signs of falling off track. Clinical studies are discussed that prove why these are important to maintain wellness for everyone, not just those with a diagnosed mental illness. Audiences come away with a knowledge of how to build their own toolkit for maintaining their mental wellness, as well as the wellness of their loved ones.

### The effectiveness of attention process training on sustained attention deficit in partially or remitted patients with bipolar mood disorder

H. Jamilian<sup>1\*</sup>, M. Nokani<sup>1</sup>, S. Sharifi<sup>2</sup>

<sup>1</sup> School of Medicine, Arak University of Medical Sciences, Psychiatry, Arak, Iran;

<sup>2</sup> Azad University of Arak, Psychology, Arak, Iran

\* Corresponding author.

*Introduction.*– Impaired sustained attention is a robust feature of the manic and depressive state and sustained attention deficit persists during the euthemic phase of bipolar mood disorder and disrupting the patients' function.

*Objectives.*– The aim of present study was to investigate the effectiveness of attention process training on deficits in sustained attention in bipolar patients.

*Methods.*– The participants of this study were six bipolar patients which were treated with mood stabilizers in Amirkabir hospital, Arak, Iran. Participants were assessed at baseline, during treatment, and 1 month follow-up. Participants after various baseline spots (3,5, and 7 spots) were randomly arrived to attention process training program, that consisted of 15 20-minute sessions twice a week. Sustained attention was measured by continues performance test. Data were analysed based on recovery percentage and visual inspection.

*Results.*– All participants showed fewer Omission and Commission errors after intervention. Percentage of Non-overlapping Data (PND) for all cases was above 76%. All participants showed better performance in reaction time. Percentage of Non-overlapping Data (PND) for all cases was above 66%.

*Conclusion.*– It seems that attention process training can be an effective supplementary treatment for improving sustained attention deficit in patients with bipolar mood disorder.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0042

### Bipolar Mood Disorder (BMD) is the result of ambiguity between master and slave circadian oscillator

K. Khodabakhshi Pirkalani<sup>1\*</sup>, Z. Talaeerad<sup>1</sup>, R. Khodabakhshi Pirkalani<sup>2</sup>

<sup>1</sup> Mehr Medical Group, Internal Medicine/Gynecology, Tehran, Iran;

<sup>2</sup> Mehr Medical Group, Internal Medicine/Clinical Psychology, Tehran, Iran

\* Corresponding author.

*Introduction.*– Circadian system derangement is generally accepted as pathogenesis of BMD without clear mechanism.

*Objectives.*– Here we present an elegant illustrative algebraic model that incorporates multiple genes (multiple oscillators that prevent chaos) in the pathogenesis of BMD.

*Methods.*– The circadian genes CLOCK/BMAL1 heterodimer within the suprachiasmatic nucleus is regarded as the master oscillator with a nearly curve of  $y = a \sin x + b$ . Light/darkness from ganglion retinal cells affects it as noise (<5%) without changing periodicity; hence  $y = \Omega (ne^x + b) + a \sin x$ . Superimposition oscillating functions can change the pattern of periodicity and even abolish or negate periodicity of others. The master oscillator has suppressing effect on 3 slave oscillators. We suggest that alternating reigning of the master and slave oscillators can cause a dying curve in the form of  $Y = f(e^t)g(\sin 1/t) + \zeta(b)$  where  $t$  is time and  $f$  and  $g$  are two functions typical for master and slave oscillator and  $\zeta(b)$  the effect of

light/darkness which in contrast to the previous situation is not negligible. This causes the disease course unpredictable. Alternate reigning of master and slave oscillators is due to:

- mutation in the master with longer periodicity;
- mutation in the master with no suppressing effect on slaves;
- mutation in the slave with less sensitivity to the suppressing effect of the master;
- mutation in the slave with shorter periodicity than the master.

*Results.*– Disease course and subtypes can be predicted by the curve behaviour.

*Conclusions.*– Based on the above, mathematical biology can find relevance in treatment strategies.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0043

### **Bipolar Mood Disorder (BMD) can be classified into 4–5 broad molecular categories based on parametric oscillation theory and signs and symptoms**

K. Khodabakhshi Pirkalani\*, Z. Talaerad, R. Khodabakhshi Pirkalani

*Mehr Medical Group, Internal Medicine/Gynecology, Tehran, Iran*

\* Corresponding author.

*Introduction.*– Correlation of molecular basis of multiple oscillators with different clinicopathologic presentation of BMD spectrum is lacking.

*Objectives.*– We present an elegant illustrative algebraic model that incorporates multiple genes (multiple oscillators that prevent chaos) in the pathogenesis of BMD.

*Methods.*– Based on 73 patients literature review we have differentiated 4–5 disease activity patterns. A divergent model of one master circadian oscillator in the suprachiasmatic nucleus (CLOCK and BAML1 heterodimer) + at least 4 slave oscillators (neuronal PAS domain protein 2, Rora, Rev-erb, and CSNK1E) and the downstream effector genes PER1, PER2, PER3, CRY1, CRY2, Teneurin 4, NCAN (Neurocan), GSK3-b and casein kinase I epsilon were designed to highlight both heterogeneity in regard to genetics and presentation.

*Results.*– Five patterns of disease activity curves with the appropriate molecular explanations:

- Master oscillator mutation (below 75% activity): One attack, rare exacerbations, near normal inter interval mental social functioning.
- Major mutation of the master oscillator and ambiguity between master and slave oscillator: Frequent attacks with inter interval derangements.
- Hyperactive mutant of slave oscillators and suppression of the master oscillator: One major attack and no apparent remission with a wide range of signs (even contradictory) alternating in prominence.
- Master oscillator mutant with higher activity: Change of the innate frequency.

Mutation in one or two downstream genes (i.e. GSK3-b, Per, CRY, NCAN: A diagnostic dilemma, mild continuous signs and symptoms without attacks; overlap with borderline or schizotypal personality disorder or transient simple schizophrenia disorders.

*Conclusions.*– Finding molecular correlation with disease subtypes and activities is possible.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0044

### **General results of personality scores of bipolar patients studied by MCMI-III during inter-attack periods and relevance to clinical course**

K. Khodabakhshi Pirkalani\*, Z. Talaerad, R. Khodabakhshi Pirkalani

*Mehr Medical Group, Internal Medicine/Gynecology, Tehran, Iran*

\* Corresponding author.

*Introduction.*– The global functioning of bipolar patients between attacks is not fully delineated.

*Objectives.*– Evaluation of relevance of personality tests for BMD and finding correlations in addition to risk factors.

*Methods.*– Thirty three patients during inter attack interval and 45 normal volunteers were evaluated by way of the MCMI-III. All of them were under treatment with Lithium.

*Results.*–

- There were overall higher scores in schizotypal, borderline, narcissistic, histrionic and self-destructive personalities among BMD patients compared to the control group.  $P < 0.03$ .
- With the BR score of 72, all (33 out of 33) patients fulfilled the diagnosis of at least one of the personality disorders.  $P < 0.04$ .
- Borderline personality had the highest correlation with BMD and after scheduled interview 22 of 33 patients fulfilled the criteria for it.  $P < 0.1$ .
- Presence of high scores in apparently contradicting personalities such as Obsessive-compulsive and histrionic or narcissistic and dependent or avoidant and histrionic were also encountered.  $P < 0.02$ .

*Conclusions.*– Although many patients with BMD show normal functioning during inter attack intervals they fulfill the criteria of some personality disorders. This is in concordance with our idea that BMD spectrum has correlation with personality disorders in a subgroup that has mutations in the downstream genes (glycogen synthase kinase3-b (GSK3-b), casein kinase I epsilon, NCAN, PER1, 2, 3 or CRY1, 2 . . .) rather than master circadian oscillators (CLOCK/BMAL1). They do not show full blown symptoms but remain aberrant with subclinical attack like fluctuations. Besides, presence of criteria of apparently contradicting personalities might also be a sign of ambivalent “Weltanschauung”.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Clinical differences between bipolar disorders I and II**

L. Asensio Aguerri<sup>1</sup>, L. Nuevo Fernández<sup>2</sup>, C. Rodríguez<sup>2</sup>, V. Muñoz Martínez<sup>2</sup>, L. Beato Fernández<sup>2</sup>, B. Mata Saenz<sup>2</sup>, E. Segura Escobar<sup>2</sup>

<sup>1</sup> Psychiatrist, Hospital General de Ciudad Real, Sevilla, Spain;

<sup>2</sup> Psychiatrist, Hospital General de Ciudad Real, Ciudad Real, Spain

\* Corresponding author.

*Introduction.*– The Bipolar disorder (BD) is a chronic mental disorder, which have highly incapacity and negative consequences on the patient. The main clinic is based on severe mood changes. The manic or hypomanic episodes are the ones that determine the diagnosis, which will be interspersed by depressive episodes. In the case of BD I we will observe manic episodes, and in BD II, hypomanic episodes.

*Objectives.*– The objective is to provide a bibliographic review of the clinical differences between bipolar disorders types.

*Methods.*– A systematic review from the literature has been carried out by Pub Med/Medline (keywords bipolar disorders, subtypes, clinical).

**Results.**– DBI: Patients present at least one episode of mania and may have a depressive episode. The prevalence is 0.6%. We can observe psychotic symptoms. They have more severe episodes, but longer interval between episodes, so the quality of life is better. The age of onset of the symptomatology is earlier.

**DBII.**– Patients present episodes of hypomania, and depressive episodes. The prevalence is 0.4%. There are more susceptible to sub-depressive states, to chronic depression and the interval between episodes is usually lower. There is increased comorbidity with alcohol abuse and other mental disorders, such as personality disorder. here is more genetic influence in type I than in type II.

**Conclusions.**– There are important differences between the I and II, which must be known to perform a correct diagnosis and approach of the patient. Type II is not a “light version” of TB I. Both are chronic pathologies, and in most cases incapacitating.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Automated analysis of verbal fluency performance in patients with bipolar disorder

G.F. Lima<sup>1\*</sup>, L. Weiner<sup>2</sup>, N. Vanello<sup>3</sup>, N. Doignon-Camus<sup>4</sup>, G. Bertschy<sup>2</sup>, A. Giersch<sup>2</sup>

<sup>1</sup> None, None, Palmer, USA;

<sup>2</sup> INSERM, 1114, University Hospital of Strasbourg, Strasbourg, France;

<sup>3</sup> University of Pisa, Dipartimento di Ingegneria dell'Informazione, Pisa, Italy;

<sup>4</sup> University of Strasbourg, University of Strasbourg, Strasbourg, France

\* Corresponding author.

**Introduction.**– Verbal fluency tasks (VFT) are a widely used neuropsychological tool for assessing spontaneous word production under restricted rules—usually starting with a given letter or semantic category. Although only the number of words is usually considered, VFT are thought to tap at least two cognitive components: lexiEVsemantic processing and executive function. Both are reportedly impaired in bipolar disorder (BD). Automated techniques have been increasingly used to assess semantic organization of verbal performance. However, to our knowledge, such techniques have never been applied to VFT in BD across different mood episodes.

**Methods.**– Overall, 83 patients with BD – 25 manic, 12 mixed manic, 19 mixed depressed, 17 depressed, and 20 euthemic – and 31 controls were recruited. Participants were administered clinical questionnaires, and the letter and semantic VFT. Performance on VFT was analysed using clustering algorithms which incorporated Latent Semantic Analysis (LSA) – a computational technique in natural language processing—to quantify semantic similarity.

**Results.**– The number of clusters in both VFT conditions differed significantly among groups. Post-hoc Tukey analyses showed that depressed and mixed manic patients produced fewer clusters than controls in the semantic task and letter task, respectively. Correlations between two human-scored clusters and automated clusters were high ( $r > .70$ ), suggesting good face validity.

**Discussion.**– Preliminary results show promising evidence that automated analyses of verbal performance can differentiate states in BD, and also give insights into the relationship between semantic anomalies and clinical symptoms.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0047

### Typical and atypical antipsychotics in acute mania: Comparison of effectiveness

C.R. Medici<sup>1,2\*</sup>, L.M. Kai<sup>1,2</sup>, S.B. Kristensen<sup>3</sup>, C. Kirkedal<sup>1,2</sup>, P. Munk-Jørgensen<sup>4</sup>, S.P.V. Straszek<sup>1</sup>

<sup>1</sup> Aarhus University Hospital, Department of Affective Disorders Q, Århus C, Denmark;

<sup>2</sup> Aarhus University Hospital, Psychiatric Research Academy, Aarhus, Denmark;

<sup>3</sup> Aarhus University, Section of Biostatistics, Aarhus, Denmark;

<sup>4</sup> Odense University Hospital, Psychiatric Department, Odense, Denmark

\* Corresponding author.

**Introduction.**– Mania is challenging to treat. Typical antipsychotics may be more efficient compared with atypical antipsychotics, however, with unfavorable side effects.

**Objectives.**– To investigate the course of acute manic episodes and the correlation between change in severity of mania by type of antipsychotic treatment.

**Methods.**– This retrospective case record study included patients admitted with mania (International Classification of Diseases 10<sup>th</sup> revision code F30, F31.0, F31.1, F31.2 or F31.6) at the Department of Affective Disorders, Aarhus University Hospital from 2013–2016. The dose of typical and atypical antipsychotics was standardized as defined daily dose according to the World Health Organization's guidelines. The severity of mania was measured daily with the Modified Bech-Rafaelsen Mania Scale (MAS-M). We applied a linear regression in a mixed model.

**Results.**– We included 56 admissions. MAS-M varied between patients—both daily variation and change over time. Patients receiving typical antipsychotics had a higher baseline MAS-M, more recent admissions, more mechanical constraint and higher dose of antipsychotics. The daily change in MAS-M score was -0.18 points/day for typical antipsychotics and -0.22 points/day for atypical antipsychotics. Thus, the MAS-M reduction-rate was 0.04 (95% CI 0.02; 0.06) points/day higher in the group receiving atypical antipsychotics only (adjusted for age, gender, mechanical constraint and dosage of antipsychotics).

**Conclusions.**– The improvement-rate of mania was similar in the two groups which supports a preference for atypical antipsychotics to reduce risk of severe side effects. The results may reflect confounding by indication.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Bipolar disorder and behavioral addictions

H. Nafaa<sup>1\*</sup>, L. Benchikhi<sup>2</sup>, A. ouanass<sup>3</sup>

<sup>1</sup> Mohammed V university, faculty of medicine and pharmacy, Arrazi psychiatric hospital, Sale, Morocco;

<sup>2</sup> Mohammed V university, faculty of medicine and pharmacy of Rabat, psychology, Rabat, Morocco;

<sup>3</sup> Mohammed V university, faculty of medicine and pharmacy of Rabat, Arrazi psychiatric hospital, Salé, Morocco

\* Corresponding author.

**Background.**– Behavioral (or non-chemical) addictions can be explained as disorders characterized by repetitive behaviours beyond the control of the person. Few studies have looked for the potential association of behavioural addictions and emotional disorders. Behavioral addictions can be explained as disorders characterized by repetitive behaviours beyond the control of the person.

Few studies have looked for the potential association of behavioural addictions and emotional disorders.

**Aims.**– To study the sociodemographic characteristics among patients with bipolar disorder comorbid to any kind of behavioural addictions and set up then a profile of these patients.

**Methods.**– The sample is made of 100 patients with behavioural addiction in at least one field. These patients are consultants (outpatients) or are hospitalized (inpatients) at Arrazi psychiatric Hospital. We did a symptoms screening of mood disorders in these patients. Screening instrument: MINI (Mini International Psychiatric Interview) These patients have been compared to a control group.

**Results.**– About 80% of patients with behavioural addiction have been diagnosed with a bipolar disorder, especially manic episode. Behavioral addictions are more frequent in bipolar patients than in controls. This association can be explained by high levels of impulsivity and individual and social immaturity.

**Conclusion.**– Bipolar disorder poses a risk to the individual's physical and emotional well-being. Those afflicted with bipolar disorder have a higher rate of relationship problems, economic instability, accidental injuries and suicide than the general population. They are also significantly more likely to develop a behavioural addiction as well as to drugs or alcohol.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### A gender perspective in bipolar disorder

R. Navarro Pablo<sup>1\*</sup>, B.O. Plasencia Garcia de Diego<sup>2</sup>, S.L. Romero Guillena<sup>3</sup>, F. Gotor Sanchez-Luengo<sup>4</sup>, O. Santamaría Gómez<sup>4</sup>

<sup>1</sup> Nuestra Señora de Valme Hospital, Department Of Psychiatry, Sevilla, Spain;

<sup>2</sup> De la Merced Osuna Hospital, Department of Psychiatry, Seville, Spain;

<sup>3</sup> U.G.C Salud Mental Virgen Macarena Hospital, Department of Psychiatry, Seville, Spain;

<sup>4</sup> Nuestra Señora de Valme Hospital, Department of Psychiatry, Seville, Spain

\* Corresponding author.

**Introduction.**– In connection with Bipolar Disorder, some gender differences are known. Evidence has reported an increased risk of type II Bipolar Disorder in women. There are also differences in associated diagnoses, so alcohol abuse is more frequently present in men and anxiety disorders in women. No differences were found in prevalence, incidence, age of onset, severity of symptoms or suicidal behaviour.

**Objective.**– To study whether there are differences in relation to diagnosis, age, number of admissions, average hospital stays or toxic consumption between women and men with Bipolar Affective Disorder.

**Methods.**– Descriptive, epidemiological and retrospective study that analysed the medical histories of all hospitalized patients with a diagnosis of type I and II Bipolar Disorder, Schizoaffective Disorder and Bipolar Disorder induced by substance or medical condition in the Hospitalization Mental Health Unit of Seville (between January 2013 And December 2016). Variables collected: age, sex, residence (urban or rural), number of admissions, mean hospital stay and toxic consumption. SPSS was used for statistical analysis.

**Results.**– Out of a total of 2953 admissions, 88% had one of the referral diagnostics. 56,5% were female and 43,5% were male. There were no statistically significant differences in relation to age, diagnosis, residence, number of admissions or length of hospital stay. There was statistically significant difference ( $p < 0.05$ ) in relation to

toxic consumption, finding that the percentage of toxic-consuming patients is higher in males.

**Conclusions.**– We could observe variations in each gender that should be taken in account when addressing the Bipolar Condition holistically, so further studies on gender in Bipolar Disorder are necessary.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Mania with psychotic symptoms after malaria prophylaxis with atovaquine-proguanil

A.M. Franco<sup>1</sup>, J. Nogueira<sup>2\*</sup>, G. Jesus<sup>3</sup>, M. Salta<sup>1</sup>, R. Sousa<sup>1</sup>, B.

Barata<sup>1</sup>, J. Vieira<sup>1</sup>, M.J. Freire<sup>1</sup>, I. Fonseca<sup>1</sup>, N. Ribeiro<sup>1</sup>, A. Gamito<sup>1</sup>

<sup>1</sup> Hospital de Setúbal, Departamento de Psiquiatria, Setúbal, Portugal;

<sup>2</sup> Centro Hospitalar de Setúbal, Psiquiatria e Saúde Mental Unidade de Internamento de Doentes Agudos, Setúbal, Portugal;

<sup>3</sup> Faculdade de Medicina de Lisboa, Clinica Universitaria Psiquiatrica, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Although rare, psychiatric symptoms have been associated with the use of antimalarial drugs, mainly with quinolones. Mood disorders and acute psychosis can occur. Newer antimalarial classes are less known to cause psychiatric adverse effects. The association of Atovaquine and Proguanil (Malarone<sup>®</sup>) is currently widely used, but published reports on its psychiatric side effects are scarce.

**Objectives.**– Case report of a manic episode with psychotic symptoms following malaria prophylaxis with Atovaquine-Proguanil, with complete remission of symptoms after the interruption of the drug association. Literature review about the clinical case.

**Methods.**– Case report was prepared with data obtained from clinical files. Literature review was made using Pub med database. Specific terms were searched: Atovaquine/Proguanil Hydrochloride; antimalarial; neurotoxicity; mania.

**Results.**– A 27-year-old woman, without previous psychiatric history, was prescribed Atovaquine-proguanil as malaria prophylaxis five days before she presented to the psychiatry emergency room with a clinical picture compatible with mania with psychotic symptoms. She was given haloperidol 5 mg IM and she was discharged with a prescription for haloperidol 3id and indication for suspension of the antimalarial therapy. She suspended haloperidol the next day. On the second day after the visit to the ER there was a complete resolution of all symptomatology.

**Conclusions.**– This clinical report calls the attention of clinical teams to a still unknown and rare association between psychiatric symptoms and malaria prophylaxis with Atovaquine-proguanil. The complete resolution in few days without a sustained antipsychotic therapy strongly suggests that the clinical picture was an adverse effect of the drug and not a primary psychiatric disease.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

The psychiatric emergency is an important clinical practice, it is necessary to know what are the most frequency pathologies that visit us to improve our attention and to avoid this kind of attention and also the ingress.

*Methods.*– We analysed all the patients that visit to emergency in our hospital, first of all we build a data base and then we analysed these data with SPSS program.

*Results.*– In this year 1143 patients have been attended in our emergency (95,25 patients/month). We choose a random month (January), in this month 52% were people between 30–49 years old, 44% were women. Years. One of the most important and frequent reasons for visiting an emergency room (and even precipitating hospitalization) is that the patients leave the treatment and that precipitates decompensation of the underlying pathology. In the case of bipolar disorder it is not an exception

*Conclusions.*– After having analysed this population of bipolar disorder we concluded that we need treatments than improve the adherence (like injectable antipsychotics), decrease secondary effects and improve quality of live, and secondary decrease the need to go to emergency.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

<sup>5</sup> University Hospital Puerta del Mar, Psychiatry, Cádiz, Spain

\* Corresponding author.

We present the case of a 45-year-old female patient diagnosed with type I bipolar disorder, who entered psychiatry due to behavioural disturbance, disorientation and possible psychopathological decompensation. She was diagnosed with bipolar disorder since 2012, type II diabetes, dyslipidemia and hypertension. She had been hyperthymic, irritable, insomnia, very disorganized and incoherent language. During admission with the readjustment of psychopharmacological treatment, there is evidence of an improvement in clinical status; but abruptly it begins again with symptoms of disorientation, including memory loss, requiring consultation by Neurology. Cranial Magnetic Resonance showed small ischemic subcortical lesions dispersed by supratentorial white matter. Given the history of cardiovascular risk and the persistence of disorientation intermittently, a neurological study of the patient was necessary, demonstrating the existence of brain lesions. Numer-

ous psychiatric symptoms are common in patients with lesions in the Central Nervous System, so it is important to carry out the differential diagnosis, since the symptoms of psychopathological decompensation can mask the physical condition. In this case it could be epileptic seizures, cerebrovascular disease or drug abuse, concomitantly with the manic episode. Finally, with the complementary tests and the neurological study performed, it was determined that they were transient ischemic accidents. In this case we chose to use asenapine, because of its intermediate risk of metabolic syndrome, unlike other antipsychotics, and due to the intolerance to extrapyramidal effects risperidone that she had previously experienced.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0053

### Verbal fluency in patients with bipolar I disorder

J. Oueslati<sup>\*</sup>, O. Moula, S. Chebli, S. Khanfir, R. Triki, R. Ghachem Razi Hospital, Pinel adult psychiatry ward, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Cognitive deficits are present in bipolar I disorder (BDI) during the acute phase of illness and euthymic Areas such as attention, memory and executive function are involved. Verbal fluency (VF) tasks afford rapid and reliable assessment of both verbal ability and executive functions. Studies using these tasks have however yielded discrepant results.

*Objectives.*– Determine the extent of the VF impairment in euthymic BDI patients. Explore the effect of clinical and treatment-related parameters on VF.

*Methods.*– Twenty five euthymic patients with BDI were matched to 25 healthy community controls. Demographics, clinical characteristics and current treatment were collected. Letter and category tasks have been applied. VF was assessed in BDI patients and compared with healthy individuals.

*Results.*– BDI patients were male in 60% of cases. The mean age was 40 ± 8 years. Forty eight per cent of the patients were single. Among our cohort, 16% had university level and 28% had stable professional activities. The mean age at onset was 22 years and the mean length of illness was of 14 years. The number of hospitalizations had a median value of 4. Twenty four patients received mood stabilizer and 20 patients received antipsychotics. As compared to the control group, BDI patients reached significantly lower scores in both letter ( $p = 0.003$ ) and category tasks ( $p < 0.001$ ). We didn't found any significant relation between clinical and therapeutic features and cognitive deficits in BDI patients.

*Conclusion.*– VF impairments are observed in BDI and seem to be independent of clinical and therapeutic factors.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Psychoeducation in bipolar disorder: A case study

A. Özoğul<sup>1\*</sup>, B. Özkan<sup>2</sup>

<sup>1</sup> Psychiatric Nursing, Ankara, Turkey;

<sup>2</sup> Psychiatric Nursing, Ankara, Turkey

\* Corresponding author.

*Introduction.*– Bipolar disorder is a chronic, recurrent, life-long disease that requires treatment. Because individual and social adjustment is difficult, and morbidity and suicidal risk are high, careful consideration of the patient and family is required. It

is stated in the literature that the application of psychoeducation besides the medication applied to the patient improves the adaptation process of the patient and the number of recurrent hospitalizations decreases.

**Objectives.**– This study was conducted to evaluate the efficacy of psychoeducation applied to the patient in the manic period who uses her drugs irregularly, spends her money uncontrollably, needs to newly recognized people easily, needs to travel frequently, and is hospitalized recurrently.

**Methods.**– 10 sessions of psychoeducation were applied to the patient once a week and 'Young Mani Assessment Scale' was used to evaluate the manic condition of each patient. In the psychoeducation, information about the biological nature of the patient's illness was assessed, the patient's stratification was assessed, the natural coping mechanisms of the patient were defined, the existing support mechanisms were actuated, the family process was assessed, and the contents were regulated according to the patient's individual characteristics and disease findings.

**Results.**– The awareness of compliance with the drug use, belief in healing, and illness symptoms has increased after the psychoeducation. Recurrence was not observed in the patient after discharge.

**Conclusion.**– It has been observed that adaptation to the illness has increased and psychoeducation practice is recommended together with drug treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0055

### **Use of benzodiazepines and hypnotics in maintenance phase of patients with bipolar disorder in an outpatient setting**

A. Peh

Changi General Hospital, Dept of Psychological Medicine, Singapore, Singapore

**Background and aims.**– Guidelines for the maintenance treatment of bipolar disorder generally do not include the use of hypnotics, in particular benzodiazepines. In the acute phase of mania, benzodiazepines are useful for anxiety, agitation and insomnia. The aim is to describe the use of hypnotics in patients with bipolar disorder in remission seen at an outpatient clinic in Singapore.

**Method.**– The case notes of patients with bipolar disorder in remission, seen by a single psychiatrist (author) in an outpatient bipolar disorder clinic in a general hospital unit from Dec 2014 to Mar 2015 were studied. Data describing the age, sex, type of bipolar disorder and psychotropic medications prescribed, was obtained.

**Results.**– Overall, 42 patients were included, of which 13 (31%) were male and 29 (69%) were female. The age ranged from 23 to 82, with mean age of 47 years. Of these 17 (40%) had Bipolar I and 25 (60%) had Bipolar II. There were a total of 12 patients on long-term use of hypnotics (28.6%). Of these 4 were Bipolar I and 8 were Bipolar II. There were 6 patients on benzodiazepines; 1 on zolpidem; 1 on hydroxyzine; 1 on both benzodiazepines and zolpidem; 2 on both benzodiazepine and hydroxyzine; 1 on zolpidem, benzodiazepines and hydroxyzine. There was no pattern of escalating usage of hypnotics in all of them.

**Conclusion.**– About one third of the patients were prescribed hypnotics as adjunctive medication for maintenance treatment, mostly on benzodiazepines.

**Keywords:** Bipolar disorder; Maintenance treatment; Benzodiazepines and hypnotics

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

<sup>4</sup> Faculty of Social Science and Health Care, Constantine the Philosopher University in Nitra, Slovak Republic, Department of Psychology Sciences, Nitra, Slovak Republic

\* Corresponding author.

**Objective.**– The internet is an important source of information and exchange for patients and can exert considerable influence on their health-related behaviours and decisions. Internet-based therapy typically involves the interaction between a consumer and therapist via the Internet and incorporates the use of a structured Web-based treatment program for consumers to access in conjunction with therapist assistance (usually by email). Over the past decade, Internet-based treatments have been found effective for a variety of physical health conditions and mental health disorders, such as headache, encopresis, tinnitus, depression, panic disorder, social phobia, GAD and posttraumatic stress disorder.

**Aims.**– The purpose of this open study will be to test the efficacy of therapist-assisted internet 12 module 4 month long self-help program based on cognitive behavioural approach (IB-CBT) with the treatment as usual (TAU) for bipolar affective disorder patients who are medicated with thymostabilisers.

**Method.**– Participants who recruit from the patients of the Psychiatric clinic Olomouc at time of start the maintenance pharmacological phase of the treatment of bipolar affective disorder will be randomized to the TAU (treatment as usual) and IB-CBT (12 modules of internet based CBT+ TAU). All participants will complete a clinical diagnostic interview, and a set of questionnaires to assess affective symptoms at four time periods (start of the maintenance treatment period and at follow up: 6 month, 12 month and 24 month). The study will be done in open conditions.

**Results.**– The results from the start of the maintenance treatment period will be present.

**Disclosure of interest.**– Supported by grant IGA MZ ČR NT11047.

EV0057

### **Diagnosis of late-onset bipolar disorder in a patient with history of lacunar thalamic stroke**

N.F. Ribeiro\*, I. Fonseca, A.M. Romão Franco, R. Ribeiro  
Centro Hospitalar de Setúbal, Psiquiatria, Setúbal, Portugal

\* Corresponding author.

**Introduction.**– Bipolar disorder (BD) is an affective disorder. Although sparse, published information regarding BD following stroke is increasing in recent years. A few cases of late onset bipolar disease have been described as a consequence of lacunar ischemic lesions, specifically those affecting the basal ganglia and the thalamus. Recent studies have also implied that intrinsic brain functional connectivity may play a role in bipolar disorder pathophysiology.

**Objectives.**– We aim to present a clinical case of secondary BD following stroke, which represents a possible link with Default Mode Network.

**Methods.**– A literature review was made using Pub Med and Clinical key databases.

**Results.**– A 55-year-old Caucasian woman with no previous psychiatric history complained to her Family Doctor about depressive mood, hypersomnia and anhedonia. Symptoms appeared one year after a stroke with a lacunar lesion involving the thalamus and the posterior arm of the right internal capsule. She was prescribed Paroxetine 20 mg with improvement. Four years later she displayed hypomanic symptoms and was medicated accordingly, with non-compliance to treatment. After three years, she was admitted to a Psychiatric Unit with dysphoric mood, pressure of talk, increased energy, flight of ideas, grandiose and mystical delusions and lack of insight.

**Conclusions.**– This case suggests a significant role of stroke-associated lacunar thalamic lesions in late-onset bipolar disorder, underlining the importance of searching for brain injury in such patients. The findings of this case are coincident with the most recent evidence regarding brain function connectivity in mood disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0058

### Possible predictors for suicide attempts in mood disorders

A.M. Romosan<sup>1\*</sup>, L. Dehelean<sup>2</sup>, M.M. Minciuna<sup>3</sup>, A. Olteanu<sup>3</sup>, S. Milos<sup>3</sup>, R. Balint<sup>3</sup>, R.S. Romosan<sup>2</sup>

<sup>2</sup> University of Medicine and Pharmacy “Victor Babes”, Neurosciences, Timisoara, Romania;

<sup>3</sup> Timisoara Psychiatric Clinic, Psychiatry, 1st year resident, Timisoara, Romania

\* Corresponding author.

**Introduction.**– Bipolar, schizoaffective and recurrent depressive patients have a high risk for suicide attempts, especially during the acute episodes. Discovering possible early predictors is essential for preventing suicide attempts.

**Objectives.**– To compare the patient groups and identify early predictors for suicide behaviour.

**Methods.**– 69 patients diagnosed with recurrent depressive disorder, 59 patients diagnosed with bipolar affective disorder and 64 patients diagnosed with schizoaffective disorder, according to ICD-10 diagnostic criteria, admitted in the Timisoara Psychiatric Clinic between 2009 and 2017 for depressive episodes were selected for this study. Patients were assessed with the MINI Interview, HAM-D-17 Scale, and the SCL-90.

**Results.**– The highest suicide attempt rate was found in the bipolar group. The schizoaffective group as well as the bipolar group showed positive correlations between suicide attempts and disorder duration and between suicide attempts and the “interpersonal sensitivity” item of the SCL-90, while in the recurrent depressive group we found a positive correlation between suicide attempts and the “anxiety” item of the HAM-D scale, which may indicate that higher anxiety could lead to more frequent suicide attempts.

**Conclusions.**– Bipolar affective disorder and recurrent depressive disorder patients are at a high risk for suicide. Early and efficient treatment coupled with identifying predictors for suicide may reduce suicidal behaviour.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0059

### MHPG as a biomarker for bipolar disorder

H. Saiz Garcia<sup>1\*</sup>, V. Pereira Sánchez<sup>2</sup>, M.Á. Álvarez de Mon<sup>2</sup>, Á.S. Rosero<sup>1</sup>, L. Montes<sup>1</sup>, E. Mancha<sup>1</sup>

<sup>1</sup> Complejo Hospitalario Navarra, Psychiatry, Pamplona, Spain;

<sup>2</sup> Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

\* Corresponding author.

**Introduction.**– The lifetime prevalence of bipolar disorder is about 4%. Bipolar disorder has many clinical implications, such as high rates of suicide. Using blood levels of a biomarker should be a very useful tool in clinical practice to know if a patient is in remission or not. Several biomarkers have been studied among the past decade. 3-methoxy-4-hydroxyphenylglycol (MHPG) is a metabolite of noradrenaline. This metabolite is reduced in plasma levels after treatment with antipsychotic drugs.

**Methodology.**– A review was conducted aiming to clarify the relationship between MHPG and affective disorders, including depressive and manic disorders. The literature search was conducted in Pub Med data reviewing articles dating between 2009 and 2015.

**Results.**– 1. MHPG levels in plasma are related with noradrenaline levels in the brain. 2. Higher levels of MHPG are related with manic states. 3. Low levels of MHPG are associated with higher rates of depression. It could also be related with higher rates of suicide.

**Conclusions.**– The MHPG level is likely to reflect the clinical characteristics of the switch process in bipolar disorder, and has prognostic significance for the treatment of manic and depressive states. The MHPG level is associated with the severity of the illness. The MHPG level can vary from one individual to another, it is important to know each patient’s levels from one to another state. There are no studies with high evidence on this relationship, but it could be an useful marker with a significant clinical correlate.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0060

### Measurement and dimensionality of subjective well-being in bipolar disorder

O. Santamaria<sup>1\*</sup>, S.L. Romero<sup>2</sup>, F. Gotor<sup>1</sup>, R. Navarro<sup>1</sup>, B.O. Plasencia<sup>3</sup>

<sup>1</sup> Nuestra Señora de Valme University Hospital, Psychiatry, Seville, Spain;

<sup>2</sup> Virgen Macarena University Hospital, Psychiatry, Sevilla, Spain;

<sup>3</sup> La Merced Hospital, Psychiatry, Osuna Seville, Spain

\* Corresponding author.

**Introduction.**– In bipolar disorder (BD), affective status is significantly associated with subjective well-being. That relationship is particularly significant for depressive symptoms. However, a “good” subjective well-being in manic patients mirrors the pathological euphoric mood.

**Objective.**– Analyze whether it is appropriate the use of the Subjective Well-Being under Neuroleptic Scale (SWN-K) among patients with BD.

**Method.**– Forty-nine outpatients were recruited. Subjective well-being was evaluated using the SWN-K. Current symptomology was rated using the Hamilton Depression Rating Scale (HAM-D) and the Young Mania Rating Scale (YMRS).

**Results.**– In our sample, there is a strong inversely correlation ( $|r| > 0.7$ ,  $p < 0.01$ ) between the score on the HAM-D and the total score on the SWN-K. HAM-D and SWK are linearly related and that relationship is inverse, declining an average of 2.46 points on the

SWN-K, for each point increase on the HAM-D. There is a modest direct correlation ( $0,30 \leq r \leq 0,70$ ,  $p < 0,01$ ) between the total score on the YMRS with the total score on the SWN-K. Both variables are linearly related and this relationship is direct, increasing an average of 0.94 points in the mental function subscale, for each point increase in the YMRS. In each subscale of the SWN-K is detected this relationship with the YMRS, and in all of them the relation is moderated and direct.

**Conclusions.**– Affective status is associated with subjective well-being in bipolar patients and that relationship is particular significant for depressive symptom. Further investigations are necessary to assess subjective well-being in acute mania, to determine whether SWN-K is a good tool for it.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0061

### **Introjections, projection and disintegration of the ego in paranoid paroxysms**

S. Trifu<sup>1\*</sup>, A.I. Trifu<sup>2</sup>, A.C. Trifu<sup>2</sup>, A.M. Dragoi<sup>3</sup>

<sup>1</sup> UMF Carol Davila, Psychiatry, Bucharest, Romania;

<sup>2</sup> Medical Military Institute, Medicine, Bucharest, Romania;

<sup>3</sup> Hospital for Psychiatry, Psychiatry, Sapunari, Romania

\* Corresponding author.

Bipolar affective disorder is expressed differently according to the premorbid personality, which will also influence the evolution of the first axis disorder in terms of establishing the therapeutic alliance, compliance with treatment and social functioning.

**Objective.**– This case consider a bipolar affective disorder characterized by severe manic episodes with psychotic phenomena, alternating with moderate depression. I<sup>th</sup> axis disease overlaps with a paranoid personality, which imparts a particular function of the patient, both in illness and in remissions. The paranoid personality determines the legal-medical complications of the case more than its manic episodes, and the psychotic phenomena overlapped with severe mania are also the transition from paranoid to paranoid functioning, which requires a detailed differential diagnosis with delusional disorder.

**Methods.**– Hospitalization in a psychiatric service, study of legal documents, repeated psychiatric assessments for legal medical expertise, psychological examination, follow-up of psychotropic treatment, monitoring of therapeutic alliances and tremendous feelings in counter-transfer.

**Results.**– The patient presents a predominantly defined symptomatology at the level of thinking, affectivity and attitudinal behavioural sphere. The absence of phenomenology in the perceptual area and its translation to the thinking plane implies paranoid character. The function of the patient is dominated by delirious interpretations, tangentiality, multiple words meaning, denial and projection mechanisms, dysphoria, raptus potential, pulse fixations in pathological jealousy spectrum.

**Conclusion.**– The legal-medical complications of the case are mainly determined by its paranoid side and by the inability to disinvest what he loved, the manic episode giving him the power to act and to behave violently.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0062

### **Mania secondary to HIV: A case report**

I. Zabaleta Andreu<sup>1\*</sup>, C. Aguilar Romero<sup>1</sup>, C. Sanahuja Muñoz<sup>1</sup>, I. García Hoyos<sup>1</sup>, J. Klotz<sup>2</sup>

<sup>1</sup> Hospital Universitario de Fuenlabrada, Psychiatry, Fuenlabrada, Spain;

<sup>2</sup> New York State Psychiatric Institute-Columbia University, Division of Child and Adolescent Psychiatry, New York, USA

\* Corresponding author.

**Introduction.**– The World Health Organization (WHO) estimates that 37 million people were living with human immunodeficiency virus (HIV) at the end of 2016. HIV is a multisystem illness related to profound immune dysregulation, but it can also cause several neuropsychiatric disorders, such as cognitive impairment, behavioural difficulties or other psychiatric symptoms. Mania is an uncommon clinical presentation, but can complicate any stage of the infection and it has prognostic implications.

**Objectives.**– Clinical description of an acute mania episode secondary to HIV infection and description of the appropriate treatment used.

**Methods.**– Case report of a patient admitted in our Short-Term Hospitalization Unit.

**Results.**– Our patient was a 44-year-old, with 3-year history of HIV infection, admitted to our Unit due to an agitation episode and delusions. He had no prior history of psychiatric illness. The family reported he experienced progressive impairment during the last year. Psychiatric evaluation revealed religious and grandiose delusions, inappropriate affect and accelerated thinking and speech. It is diagnosed as a maniac episode and antipsychotic treatment (Haloperidol) is initiated, but due to extrapyramidal symptoms it is changed to Olanzapine 30 mg/24 h. Valproic acid 1500 mg/24 h was used as a mood stabilizer. He was discharged from the hospital on this treatment and on antiretroviral therapy and he continued follow-up.

**Conclusions.**– This condition is often undiagnosed because of its low prevalence. Early psychopharmacological treatment can improve the quality of life for these patients, due to enhanced adherence to antiretroviral treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0063

### **Screening for psychiatric disorders with self-administered questionnaires**

M. Zimmerman

Rhode Island Hospital/Brown University, Psychiatry and Human Behavior, Providence, USA

\* Corresponding author.

**Introduction.**– To improve diagnostic recognition, self-administered screening scales have been recommended. A problem with much of the research effort on screening scales is the confusion between diagnostic testing and screening. It is important for a screening test to have high sensitivity because the more time intensive/expensive follow-up diagnostic inquiry will presumably only occur in patients who are positive on the initial screen.

**Objectives.**– Investigators vary in how they analyze their data in determining the recommended cutoff score on a self-administered screening questionnaire. To illustrate this, in the present report we examined how often each of the different approaches towards determining a cutoff score on bipolar disorder screening scales were used.

**Methods.**– We reviewed 68 reports of the performance of the 3 most commonly researched bipolar disorder screening scales to determine how the recommended cutoff on the scale was derived. **Results.**– Most studies recommended a cutoff point on the screening scale that optimized the level of agreement with the diagnostic gold standard. Only 11 (16.2%) studies recommended a cutoff that prioritized the scale's sensitivity.

**Conclusions.**– It is important for clinicians to understand the difference between screening and diagnostic tests. The results of the present study indicate that most studies of the performance of the 3 most commonly studied bipolar disorder screening measures have taken the wrong approach in deriving the cutoff score on the scale for the purpose of screening.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Eating the teddy bear: A pica case report

C. Aguilar Romero<sup>1\*</sup>, I. Zabaleta Andreu<sup>1</sup>, G. Ruiz Lobera<sup>2</sup>, I. García Hoyos<sup>1</sup>

<sup>1</sup> Hospital de Fuenlabrada, Psychiatry Department, Madrid, Spain;

<sup>2</sup> Hospital de Fuenlabrada, Child and Adolescents Psychology Department, Madrid, Spain

\* Corresponding author.

**Introduction.**– Pica is defined as the persistent eating of non-nutritive substances for at least one month. It occurs particularly in children and pregnant women. Pica has been associated with iron deficiency or serious affective deprivation.

**Objectives.**– We report a case of an 8-year-old girl with pica for foam rubber.

**Results.**– An 8-year-old girl was referred to child and adolescent mental health consultations after being treated in the hospital emergency department for abdominal pain and vomiting in which foam rubber content was detected. The patient admitted to having ingested part of a stuffed toy in the context of anxiety after receiving a reprimand from her parents for bad grades. The pica disorder as reported by parents starts at age 3 but they had not previously consulted. As a medical history the patient was born with intestinal malrotation that required surgical intervention. She also presented low levels of ferritin (7 ng/mL) and iron supplements were prescribed. The mother refers to difficulties in parenting and depressive symptoms during the first two years of life. The mother had an anxious bond with the girl with overprotection and guilt. These difficulties in relation to attachment and the anxious component of the mother may be influencing the child to eat the stuffed toys. Due to the anxiety component of the symptom, relaxation therapy and psychotherapeutic support consultations were recommended.

**Conclusion.**– Pica is probably a pattern of behaviour that responds to multiple factors. Many treatments have been described with varying responses. It is important to be aware of this common but often overlooked disorder.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Introduction.**– Autism spectrum disorder (ASD) is a complex neurodevelopmental disorder with unknown etiology. Several studies have reported some environmental factors associated with developing ASD. However, there are only few studies addressing that in Saudi Arabia.

**Objective.**– To assess some of the environmental factors associated with ASD.

**Methods.**– Case control observational study ( $n=293$ , ratio = 1:1.5). ASD cases ( $n=115$ ) were approached through autism schools in Riyadh. Age and gender matched controls ( $n=178$ ) were obtained from primary and intermediate schools. Data was collected through an Arabic questionnaire filled by the parents. It contains several questions addressing demographics and evaluating potential risk factors in both, child and parents.

**Results.**– Presence of psychiatric disorders in the parents or their families were reported more in ASD group compared to controls with highly significant statistical difference. For instance, 10.4% ( $N=12$ ) of ASD group mothers had psychiatric disorder with only 1.0% ( $N=2$ ) in control group ( $OR=10.303$ ,  $p<0.0001$ ). Moreover, 23.5% ( $N=27$ ) of the ASD group father's family has a psychiatric disorder compared to only 2.2% ( $N=4$ ) in control group ( $OR=13.4224$ ,  $p<0.0001$ ). However, consanguinity marriage and parents mean age at time of child delivery was not statistically significant compared to controls. Complications during pregnancy of ASD group mothers were reported significantly higher (37.9%) compared to control group (10.7%) ( $OR=4.9978$ ,  $P<0.0001$ ). For example, 26 mothers (22.6%) in ASD group had gestational diabetes mellitus compared to 10 mother (5.6%) in control group.

**Conclusion.**– ASD was associated with some environmental factors. Such as, family history of psychiatric disorders and pregnancy complications.

<sup>2</sup> Hospital Clinic San Carlos, Madrid, Spain;

<sup>3</sup> Complejo Hospitalario de Navarra, Pamplona, Spain;

<sup>4</sup> Universidad de Alcala, Madrid, Spain

\* Corresponding author.

**Introduction.**– Information on health and disease is one of the priority interests of people in countries with high economic development. Increasingly, patients and their families seek information about it on the internet and on social networks.

**Objective.**– To conduct a qualitative analysis on the Tweets that refer to ADHD from the Twitter accounts of prominent US mass media outlets.

**Methods.**– Fifteen US news media outlets were selected and analysed. These outlets were chosen based on the number of followers

on their Twitter accounts and were narrowed down to those with the most followers. The Tweets were selected if they made any reference to ADHD (ex. ADHD from @nytimes). This study focused on the Tweets from 2007–2016.

**Results.**– Overall, 208 Tweets were selected and divided into four categories. 50 focused on general interest (“Common symptoms of women with ADHD”), 92 were testimonies from patients (“Simone Biles proudly opens up about having ADHD”), 38 revolved around scientific advancements (“Research shows Omega-3 fatty acids helped improve attention spans of boys with or without ADHD”) and 28 had a condescending tone towards these disorders

**Conclusions.**– The rise in ADHD diagnosis has been one of the most controversial issues in psychiatry in the past ten years. Twitter perfectly reflects this truth by presenting both sides of the argument. On one hand, users turn to Twitter to reinforce the existence of ADHD by giving personal testimonies and statements. Conversely, doubters use Twitter to not only express their disbelief in the disorder, but also attack both doctors and patients.

<sup>5</sup> Psychiatric Hospital of Thessaloniki, Psychiatric, Thessaloniki, Greece;

<sup>6</sup> General Hospital Of Kymi, anesthesiology, Kymi, Greece;

<sup>7</sup> General Hospital of Corfu, Psychiatric, Leivadia, Greece

\* Corresponding author.

**Introduction.**– Alzheimer disease (AD) is the most common type of dementia. The memory loss and the cognitive decline usually starts slowly and worsen over time. As a neurodegenerative affects people over 65–70 years old, and only rarely onset begins earlier of the fifth decade of life. Depression is a symptom of dementia or it's often met as a prodromal stage of AD.

**Objectives.**– Herein we present a case old a 58year-old man who get the diagnosis of depression instead of AD.

**Methods.**– A 58year-old man, owner of a security company referred to a psychiatry due to “forgetfulness” and behavioural changes. His wife mentioned that he became anxious with sleep disturbances and also jealous. He admitted to have difficulties in many daily activities. He was diagnosed with depression and got a prescription for SSRIs. The next ten months he deteriorated and he was almost unable to work, to drive home alone, to pay the bills or to remember his appointments. The neurological examination with Mini Mental test and MoCa test, the CFS examination and brain MRI established the diagnosis of AD, excluding other causes of dementia. Cholinesterase inhibitors were prescribed.

**Results.**– This case although the patient's family remarked the memory decline the physician overlooked it and didn't include at the differential diagnosis dementia.

**Conclusions.**– Dementia has an insidious onset and psychiatric disorders, like depression, are a part of dementia's spectrum. Physicians should keep a high level of suspicion of AD to figure out if psychiatric symptoms are part of dementia or are isolated disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **BMI reduction observed with outpatient use of clozapine, General Hospital of Santorini**

P. Argitis<sup>1</sup>\*, A. Karampas<sup>2</sup>, S. Skopelitou<sup>1</sup>, P. Platari<sup>2</sup>, M. Poulou<sup>3</sup>, K. Paschalidis<sup>4</sup>, K. Mpaklori<sup>5</sup>

<sup>1</sup> General Hospital of Santorini, Psychiatric, Santorini, Greece;

<sup>2</sup> University Hospital of Ioannina, Psychiatric, Ioannina, Greece;

<sup>3</sup> General Hospital of Santorini, Anesthesiology, Santorini, Greece;

<sup>4</sup> Psychiatric Hospital of Thessaloniki, Psychiatric, Thessaloniki, Greece;

<sup>5</sup> General Hospital of Santorini, Nutrition and Dietetics, Santorini, Greece

\* Corresponding author.

**Background.**– The use of Clozapine, is widely linked in literature with an increase in BMI1 and consequent negative metabolic changes2. The protocol of outpatient initiation of Clozapine followed by the psychiatric department of our hospital allowed the observation of patients at their usual non-restrictive environment.

**Objective.**– To observe whether outpatients' BMI, starting on clozapine, would be affected by their treatment.

**Method-Material** To achieve this, an interview with the clinical dietitian was performed at the date of Clozapine initiation followed by monthly observations. The procedure was the same each time: BMI measurements were taken and the same sets of questions were asked about habitual nutrition, in the form of a food frequency questionnaire, appetite changes and physical activity routine. Data collected from 9 patients with treatment resistant schizophrenia. All were on depot treatment (thus excluding unsatisfactory response due to non-compliance) at the minute of initiation. They were observed for 6 months, by when the dose of clozapine had been fully adjusted by the psychiatrist.

**Results.**– An overall initial raise in BMI appeared at the first month, which declined the following months and then stabilized during the last month. By the end of the 6 month period, 7 patients' BMI was below their initial BMI. All patients mentioned raised appetites and physical activity that did not exceed the one before their treatment with Clozapine. No relation was observed between BMI reduction and PANSS score.

**Conclusions.**– Further research is needed to explain the unexpected BMI reduction at 6 months while appetite for food was being increased and physical activity remained unchanged

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Peculiarities of child-parent relations in Tuvinian families with children and adolescents suffering from behavioral disorders**

M. Belokrylova<sup>1</sup>\*, A. Sandyy-ool<sup>2</sup>

<sup>1</sup> Mental Health Research Institute- Tomsk National Research Medical Center- Russian Academy of Sciences, Borderline States Department, Tomsk, Russia;

<sup>2</sup> Republican Psychiatric Hospital, Children' Department, Kyzyl, Russia

\* Corresponding author.

**Introduction.**– Various factors influencing on formation of personality abnormalities in children include life style of parents and their

attitude toward their educative functions. Purpose of this investigation is study of peculiarities of child-parent relations in families with children and adolescents suffering from behavioural disorders.

**Methods.**– We have examined 76 boys and 18 girls at the age of 6–17 years, under counseling observation at dispensary unit of Republican Psychiatric Hospital of Republic of Tyva for hyperkinetic disorders (F 90–47.9% of cases) and behavioural disorders (F 91–52.1%). Verification of psychopathological disorders was carried out according to diagnostic criteria of ICD-10. Out of 94 patients–64 children lived in families, 30–at a boarding school, child home. We used clinical-psychopathological, psychological methods of investigation. With questionnaire PARI we have performed evaluation of educative style of mothers of 50 patients suffering from hyperkinetic disorders (28) and behavioural disorders (22).

**Results.**– Out of 23 analysed aspects-signs we have distinguished on both groups signs predominating according to scored evaluation, and namely: “Irritability”, “Suppression of aggressiveness of the child”, “Avoidance of communication with the child”, “Excessive restraint”, “Indifference of the husband”, “Dependence of the mother”. In addition, mothers of patients with hyperkinetic disorders had higher scores according to severity of such signs as “Excessive care”, “Sense of self-sacrifice”, “Dissatisfaction with the role of housewife”.

**Conclusions.**– Obtained results may be used as stimulus material during psychodiagnostic and psychocorrective work oriented at preventive rehabilitation of children and adolescents with emotional and behavioural disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

<sup>4</sup> Sant'Andrea Hospital, Psychiatry Unit, Rome, Italy;

<sup>5</sup> Sapienza University of Rome, NESMOS Department, Rome, Italy

\* Corresponding author.

**Introduction.**– Rorschach Perceptual and Thinking Index (PTI) has been proved effective in differentiating adolescents at clinical high risk for psychosis from non-psychotic patients, evaluated with the Structured Interview for Prodromal/Psychosis-risk Symptoms (SIPS). However, the relationships between SIPS and PTI criteria have not been explored.

**Objectives.**– The aims of this study were to investigate the relationships between the five PTI criteria, their main variables (X-%; WSum6; M-) and the SIPS subscales (Positive, Negative, Disorganization and General Symptoms).

**Methods.**– A sample of 117 help seeking adolescents, 68% females, aged 14–19 years, with anxiety, mood and bipolar spectrum disorders were included in the study. All were recruited at the first visit and evaluated with the Rorschach (according to the standard

Comprehensive System Method) and the Structured Interview for Prodromal Symptoms (SIPS).

**Results.**– PTI Total score and PTI1 significantly correlated with SIPS negative, disorganization and general subscales ( $r_s 0,2-0,4$ ;  $p < 0,05$ ); PTI2 with disorganization and general subscales ( $r_s 0,2-0,4$ ;  $p < 0,05$ ); PTI3 with positive subscale ( $r_s = 0,22$ ;  $p = 0,02$ ); PTI4 with positive, negative and disorganization subscales ( $r_s 0,2-0,4$ ;  $p = 0,02$ ) and PTI5 with disorganization and general subscales ( $r_s = 0,2$ ;  $p < 0,02$ ). WSum6 significantly correlated with positive and disorganization subscales ( $r_s = 0,2-0,3$ ;  $p < 0,01$ ); X- with disorganization and general subscales ( $r_s 0,2-0,3$ ;  $p < 0,02$ ) and M- with disorganization subscale ( $r_s = 0,2$ ;  $p = 0,02$ ).

**Conclusions.**– Rorschach PTI criteria and their main variables (X-%; WSum6; M-) show a mild to moderate correlation with specific SIPS subscales and might be helpful in identifying adolescents at risk for psychosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Alexithymia in a Tunisian adolescent population

W. Bouattour\*, R. Sellami, I. Baati, A. Feki, I. Feki, J. Masmoudi  
University hospital center Hedi Chaker, Department of Psychiatry “A”, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Alexithymia is not a diagnostic category included in any mental disorder but a multifaceted personality construct associated with various somatic or psychiatric disorders as well as non-clinical populations. This personality construct is characterized by four main features: 1) difficulty identifying and distinguishing emotions from bodily sensations; 2) difficulty describing and verbalizing emotions; 3) poverty of fantasy life; 4) externally oriented thinking. Alexithymia has been widely studied in adult populations. Although, research with adolescents is relatively limited.

**Objectives.**– To assess the prevalence of alexithymia in a population of adolescents and to determine some associated factors

**Methods.**– A cross-sectional study including 237 randomly recruited adolescents. Alexithymia was diagnosed using the twenty-item Toronto Alexithymia Scale (TAS-20).

**Results.**– The average age of participants was 14.77 and the sex ratio (M/F) was 0.96. The prevalence of alexithymia was 35.86%. The average score of TAS-20 was significantly higher in adolescents practicing sport (58.2 versus 54.76), using drugs (68.66 versus 56.39) and those who were dissatisfied with their body image (61.1 versus 55.8). Alexithymia was also correlated to younger age (age < 16 years).

**Conclusion.**– Our study has just shown that alexithymia is common among adolescents in our country and is a predisposing factor in the use of toxic substances. These results underline the need for screening and early management of alexithymia in our adolescents in order to protect them from involvement in conduct disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Impulsivity in adolescents: What associated factors

W. Bouattour\*, R. Sellami, I. Baati, A. Feki, I. Feki, J. Masmoudi  
University Hospital Center Hedi Chaker, Department of Psychiatry “A”, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Impulsivity is a key concept for psychopathological states, especially among teenagers. Indeed, several problematic behaviours that arise during this period are associated with higher levels of impulsivity.

**Objectives.**– To assess the prevalence of impulsivity in a population of adolescents and to determine some associated factors.

**Methods.**– A cross-sectional study including 237 randomly recruited adolescents. Trait impulsivity was measured using the Barratt Impulsiveness Scale-11 (BIS-11).

**Results.**– The average age of participants was 14.77 and 51.1% of them were female. Thirteen adolescents participated in gambling. Of the participants, 93 (39.2%) had impulsivity-trait (score  $\geq 72$ ). The average BARRATT score was significantly higher in smoking adolescents (72.46 versus 67.83 in non-smoking;  $P=0.03$ ) and in gamblers adolescents (76.54 versus 67.91 in non-players;  $P=0.008$ ). The BIS-11's dimension "Cognitive Impulsivity" was also correlated to alcohol consumption ( $P=0.013$ ) and conflictual family environment ( $P=0.035$ ). There was no correlation between impulsivity and socio-demographic factors.

**Conclusion.**– The current study indicates that impulsivity, present in more than a third of our adolescents, constitutes a risk factor for using toxic substances and gambling.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0073

### **Anxiety and depression in adolescence**

W. Bouattour\*, R. Sellami, I. Baati, A. Feki, I. Feki, J. Masmoudi  
University hospital center Hedi Chaker, Department of Psychiatry A, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Anxiety and depression are often dismissed as developmentally normal components of a teenager's life. This perception may explain the lack of existing research on sub-clinical emotional difficulties in adolescence. They often occur and their comorbidity is common in children and adolescents.

**Objectives.**– To assess the prevalence and the comorbidity of anxiety and depression in a population of adolescents and to determine some associated factors.

**Methods.**– A cross-sectional study including 237 randomly recruited adolescents (age between 13 and 18 years). Depression and anxiety symptoms were assessed by the Hospital Anxiety and Depression Scale.

**Results.**– The average age of participants was 14.77. More than one-third of adolescents (39.24%) had a depressive symptomatology of which 14.8% had certain depression. More than half of adolescents (54.43%) had an anxiety symptomatology, of which 27.8% had a certain anxiety state. Comorbid certain anxiety and depression was observed in 8% of cases while anxiety and depressive symptomatology coexisted in 26.6% of cases. The average HAD-A score was significantly higher in younger ( $P=0.041$ ) girls ( $P=0.000$ ) which parents were divorced ( $P=0.001$ ). The average HAD-D score was significantly higher in adolescents with conflictual family environment ( $P=0.008$ ), divorced parents ( $P=0.000$ ), using tobacco ( $P=0.000$ ), alcohol ( $P=0.046$ ) and practicing gambling ( $P=0.02$ ).

**Conclusion.**– Our study showed that anxiety and depression are common in our adolescent population and each is associated with substantial functional impairment and future mental health problems. Depression symptomatology constitutes a risk factor for addiction.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0074

### **What about masturbation among Tunisian adolescents? Cultural influences**

S. Bourgou\*, R. Khemekhem, A. Belhadj  
CHU Mongi SLIM, Child Psychiatry Department, La Marsa, Tunisia

\* Corresponding author.

**Introduction.**– Sexuality remains till now for Tunisian teenager a 'taboo' subject, despite the society emancipation and development.

**Objective.**– The objective was to study masturbation practice and knowledge among Tunisian adolescents.

**Methodology.**– A cross-sectional study was conducted on 77 adolescent (43 ♀, 34 ♂) attending a high school in Essalama City, Tunisia. They completed a questionnaire exploring different items: demographic data, knowledge about masturbation and possible masturbation activities.

**Results.**– The mean age was 13.8 years. Five girls and 19 boys tried masturbation at least once. The average starting age was 12.8 years for boys and 12.2 years for girls. Concomitant pornography viewing was founded for 6 boys. The non-practice of masturbation reasons' were: religious forbidden ("hram"; 86%), masturbation ignorance (66%), losing virginity fear (42%) and venereal diseases fear (37%). For half of girls and 44% of boys, masturbation was a "dirty" act. 67% of girls and 18% of boys believed that people who masturbate to be "mentally ill". For 56% of girls and 44% of boys, masturbation could damage the genital tract and compromise fertility. Eleven adolescent believed that masturbation is a criminal act punishable by law. Nine girls thought that masturbation could make them pregnant.

**Conclusion.**– Sexual education is a necessity among Tunisian children and teenager. It will help to bring down the cultural taboos and provide clear information adapted to each age and life period.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0075

### **The impact of the smartphone use in Tunisians adolescents: What do parents think?**

S. Bourgou\*, S. Jelili, A. Belhadj  
CHU Mongi SLIM, Child Psychiatry Department, La Marsa, Tunisia

\* Corresponding author.

**Introduction.**– Recently, smartphone has become an important tool for accessing information, interaction, and entertainment in modern society. However, the impact of smartphone use on individuals, especially among adolescents, has become a great concern.

**Objectives.**– Describe the perception of Tunisian parents of the impact of the smartphone use on their adolescents.

**Methods.**– Cross-sectional study by the team of the Child Psychiatry department, in the Mongi Slim Hospital (Tunis, Tunisia) during September 2017. An anonymous questionnaire was published on social networks for parents concerning the use of smartphones by their adolescents aged between 12 and 18 and its repercussions.

**Results.**– Overall, 185 mothers and 67 fathers replied to the questionnaire. The mean age of their adolescents was 14.3 years and the sex ratio was 0.94. The mean age of smartphone acquisition was 11.9 years. According to 34.6% of the parents, teenagers spent 3 to 6 hours per day using the smartphone. The main uses reported were: Facebook (66.7%), playing games (60.2%) and taking photos (49.6%). As per parents, the use of smartphones by their children had an impact on their sleep (43, 1%), their family relationships (55.3%), their friend relationships (23,7%) and their school performance (44.6%). 45, 9% of parents reported at least 3 consequences

of the smartphone use. More than half of the sample thought that their children were addicted to the smartphone.

**Conclusions.**– It seems important to understand adolescent smartphone use patterns and their associated risks. The role of parent is important in order to control use and to detect any abuse.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0076

### **Effects of gender differences on smartphone use according to parents: A Tunisian study**

S. Bourgou\*, S. Jelili, A. Belhadj

CHU Mongi SLIM, Child Psychiatry Department, La Marsa, Tunisia

\* Corresponding author.

**Introduction.**– Smartphone have become increasingly popular in recent years among teenagers. However, the role of individual characteristics in the smartphone use is far from clear.

**Objectives.**– Examining the effect of gender differences on smartphone use according to tunisian parents.

**Methods.**– Cross-sectional study by the team of the department of child Psychiatry, in the Mongi Slim Hospital (Tunis) during September 2017. An anonymous questionnaire was published on social networks for parents concerning the use of smartphones by their adolescents aged between 12 and 18 years. A comparison between genders was made, using Pearson's chi-squared test.

**Results.**– A total of 255 responses were retained. 73.4% of them were from mothers. The sex ratio was 0.94 and the mean age of adolescents was 14,3 years. The mean age of smartphone acquisition was 12 years for girls and 11, 8 years for boys. According to the parents, teenagers would spend 3 to 6 hours per day using the smartphone (34.6%). No significant difference between gender on duration of smartphone use has been found ( $P=0,757$ ). Taking photos for girls and playing games for boys were statistically the main uses reported by parents. No gender differences were found in the control exercised by the parents. 53% of boy's parents and 60% of girl's parents felt that their children were addicted to the smartphone ( $P=0,288$ ).

**Conclusion.**– Teenagers, both boys and girls, seem to use their smartphone in a similar way according to their parents. A direct survey will confirm or deny this parental observation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0077

### **“Conditio sine qua non” for anorexia of female adolescents: different blood types mother/daughter with traumatic contact between mother/daughter blood during pregnancy and/or birth**

L. Bracco

Medical Doctor, Specialist in Psychiatry, Psychotherapist, Medical Clinic address: corso Marconi 37, 10125 Turin, Italy

\* Corresponding author.

**Introduction.**– My new theory is that Anorexia of the Female Adolescent, in addition to the girl's psychological causes, needs a necessary but not sufficient condition: Different mother/daughter blood types (O, A, B, AB) and traumatic contact between the two blood types during pregnancy and/or birth.

**Objectives.**– Reducing the mortality rate and the consequences of anorexia by providing a theory that allows us to have early and predictive diagnosis.

**Methods.**– Twenty-four years ago, in a purely casual way, I found the blood type difference between an anorexic patient and her mother. Pregnancy had been with placental detachment and birth was traumatic, presumed cause of a mother/daughter blood contact. From that day on, I checked, in the case of female adolescent anorexia, the anorexic and her mother's blood types.

**Results.**– In my collection of data (more than 100 cases in 24 years): only the girls who have a different blood type (O, A, B, AB) from the mother are anorexic and from the patient's history we could think of a mother/daughter blood contact. There are no exceptions in my data.

**Conclusions.**– Female adolescent anorexia recognizes some psychological causes of the girl and her family, but requires a “sine qua non conditio”. Recognizing this condition allows us an early diagnosis, a predictive hypothesis and a right view of mother/daughter relationship, that is not conflicting but is simply disturbed by an immunological alarm.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0078

### **The problem of child's rehabilitation under conditions of disease of unclear etiology, pathogenesis and prognosis**

N. Burlakova\*, Y. Fedorova

Lomonosov Moscow State University, Faculty of Psychology, Department of Neuro- and Pathopsychology, Moscow, Russia

\* Corresponding author.

Causes, treatments and prognosis for opsoclonus myoclonus syndrome (OMS) remain unexplored that determines difficulties in social and psychological rehabilitation of the children with OMS. The research was conducted in the group of 21 OMS-children and included both them and their families.

Our aim was to explore systematically the connection between hypothetical disease etiology and course of disease (severity, treatment and prognosis), on the one hand, and mental development of children, their emotional state and relationship in “mother-child” dyad, on the other hand.

The following methods were used: observation of a) patient's development, b) state dynamics in hospital, c) relationship in “mother-child” dyad; analysis of parent-child relationship based on semi-structured interviews with mothers; assessment of psychoverbal and intellectual development and its psychological features.

Conducted research demonstrates heterogeneity within the group: children differ drastically in severity of the disease as well as treatment methods differ. The medical prognosis is indefinite as well as the parents' attitude toward the child's future. The influence of psychological and social factors on course of disease and prognosis was underestimated. The potential of psychosocial rehabilitation almost was not used in treatment.

In treatment planning for idiopathic diseases and its prognosis, not only biological, but also psychosocial approach seems important. Rehabilitation of patients should be based on the psychological knowledge and understanding of curing features possessed by psychological intervention. It is possible and necessary to involve both children suffering from such diseases and their parents into psycho-preventive and socio-psychological rehabilitation programs constructively using the biopsychosocial model of disease and its treatment.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0079

### **Influence of disease onset time on mental development of children with opsoclonus myoclonus syndrome**

N. Burlakova<sup>1</sup>\*, Y. Fedorova<sup>1</sup>, Y. Mikadze<sup>1</sup>, R. Bembeeva<sup>2</sup>, E. Ilyina<sup>3</sup>, N. Zavadenko<sup>2</sup>

<sup>1</sup> Lomonosov Moscow State University, Faculty of Psychology, Department of Neuro, and Pathopsychology, Moscow, Russia;

<sup>2</sup> Russian National Research Medical University named after N.I. Pirogov, Department of Neurology, Neurosurgery and Medical Genetics, Faculty of Pediatrics, Moscow, Russia;

<sup>3</sup> Russian Children's Clinical Hospital, Psychoneurology Department, Moscow, Russia

\* Corresponding author.

Opsoclonus myoclonus syndrome (OMS) is a rare disease understudied from clinical-psychological perspective. The disease onset time should be considered in psychological analysis; achieved data could help in organization of psychocorrectional work.

The aim of the research was to explore the dependence of cognitive and psychological development on disease onset time. The research included 21 children with OMS aged from 2,5 years to 10,5 years. The following methods were used: analysis of patient's development and medical record, psychological interview with parents, neurological state assessment and pathopsychological assessment. Patients were divided into three groups according to disease onset time: 1) disease onset before the age of 1 year ( $n=3$ ), 2) disease onset of 1–3 ( $n=15$ ), 3) disease onset at the age 3–5 ( $n=3$ ). The developmental delay was discovered in most cases ( $n=12$ ), several children were diagnosed with intellectual disability ( $n=5$ ). Intellectual retardation depends on early disease onset time (before the age of 1 year,  $n=2$ ), number of disease recurrences (more than 5 times) and their severity. Normal intelligence level was diagnosed in 4 cases: with late disease onset (at the age 3–5,  $n=3$ ), mild severity ( $n=1$ ), without disease recurrence ( $n=1$ ). The normal intelligence level was diagnosed in 1 case with early onset of the disease (aged 1 year).

The developmental delay is connected with early disease onset, but not directly. Other factors such as treatment duration and quality, time from disease onset to diagnosis should be analysed more carefully to understand their role in mental development of the children with OMS.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

<sup>2</sup> Universidade Federal de Alagoas, Programa de Pós-graduação em Ciências da Saúde, Maceió, Brazil

\* Corresponding author.

*Introduction.*– The regions in Brazil present economic and social discrepancies. In the southeast, there are higher income rates and better index of social development, whereas the northeast shows

lower development indexes and more poverty indicators. In this context, it is important to understand how the executive functions (EF) profile, as an important cognitive ability to manage self-control, is associated to regional differences.

*Objective.*– Compare executive functions indicators of school children from two regions of Brazil. Methods: Descriptive study involving children (6 and 7 years-old) enrolled in the first year of primary education in two public schools from Maceió (north-east) [ $n=69$ ; 45 male and 24 female], and one private school from São Paulo (southeaster) [ $n=43$ ; 23 male and 20 female]. Different dominium of EF were assessed using WISC-IV (working memory index), trial making test, and a questionnaire answered by the teachers about difficulties in EF (Work Memory–WM; Inhibitory Control–IC; Flexibility - FL; Aversion to Delay - AD and Regulation–RG).

*Results.*– *T* tests indicated significant difference between all indexes (Table 1), with the best results pointing to the schools in the south-easter.

*Conclusions.*– Children from schools in the southeaster of Brazil presented better performance in EF tasks and on teachers' reports if compared to children from the northeast. Considering that superior performance on EF is a predictor of better mental health, it is necessary the improvement of EF training programs at schools to reach a greater number of children.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Association of cyberspace/digital games related factors with psychopathology and cyber issues in adolescents: A preliminary report**

F.H. Çetin<sup>\*</sup>, S.A. Ersoy, K. Durmuş, H.A. Güler, S. Türkoğlu

Selçuk University Medical Faculty, child and adolescent psychiatry, Konya, Turkey

\* Corresponding author.

*Intoduction/objective.*– However studies suggest that internet addiction and digital gaming addiction (as a form of internet addiction) may cause psychopathologies and cyber issues, the factors playing role under these conditions have not been clear yet. In this study, we aimed to define these factors and to guide the clinicians improve preventive basic interventions.

*Method.*– For this preliminary report, 47 adolescents aged from 12 to 18 years were analysed. All cases were assessed with Revised Children's Anxiety and Depression Scale (RCADS), Internet Addiction Scale (IAS), Digital Game Addiction Scale (DGAS), Cyber-Bullying Scale, Cyber-Victimization Scale, Sensivity to Cyber-Bullying Scale, Connors'-Wells' Adolescent Self-Report Scale Short (CASS:S). Children's parents were assessed with Eysenck's Personality Inventory (EPI). All cases were evaluated for psychiatric diagnosis with Schedule for Affective Disorders and Schizophrenia for School-Age Children–Present and Lifetime Version (K-SADS-PL) and clinical evaluation.

*Results.*– There was a significant positive correlation between IAS scoring, and RCADS total anxiety subscore, RCADS total anxiety-depression subscore, CASS:S scores, Cyber-Bullying Scale scores, Cyber-Victimization Scale scores ( $r=0.522$ ,  $P<0.001$ ;  $r=0.468$ ,  $P=0.001$ ;  $r=0.500$ ,  $P<0.001$ ;  $\rho=0.398$ ,  $P<0.05$ ;  $\rho=0.353$ ,  $P<0.05$ ). Likewise there was a significant positive correlation between DGAS scoring and the same scales ( $\rho=0.357$ ,  $P<0.05$ ;  $\rho=0.309$ ,  $P<0.05$ ;  $\rho=0.295$ ,  $P<0.05$ ;  $\rho=0.341$ ,  $P<0.05$ ;  $\rho=0.353$ ,  $P<0.05$ ).

*Conclusions.*– Internet and gaming addiction correlated with anxiety, depression and ADHD. As the level of Internet and gaming

addiction increases, being cyber bullying and victimization levels are also increasing. The study sample will be expanded to illuminate sociodemographic variables and the research will continue.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Prevalence of posttraumatic stress disorder in student whose school burned down**

C. Charnsil<sup>1</sup>, A. Nakpanpong<sup>2</sup>

<sup>1</sup> ChiangMai University, Psychiatry, Chiang Mai, Thailand;

<sup>2</sup> Chiangmai University, Psychiatry, Chiangmai, Thailand

\* Corresponding author.

*Aims.*– To examine prevalence of posttraumatic stress disorder (PTSD) and its related factors in student whose school burn down.

*Methods.*– Student in 1-6 grade were screen PTSD by using UCLA PTSD Reaction Index (DSM-5 Version) with permission from parents at 1 month and 6 months after school burn down. Diagnosis was confirmed by child psychiatrist interview. Percentage and logistic regression were use as statistic evaluation.

*Results.*– Five of fifty-six students (8.9%) had PTSD at one month after incidence. Two of them symptoms recovered after six months. There are six of fifty six students (10.7%) had PTSD at six months after incidence. Female:male ratio was 2:3. Student who live in dorm while it burned down had significantly had PTSD more than those who did not live  $P < 0.01$ ,  $RR = 5.16$  (4.04-6.6).

*Conclusions.*– PTSD is common disorder in children after disaster. Although the symptoms can recovered shortly after incidence but there are some children had symptoms after one month of incidence.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Parenting styles and social skills of school-aged children with Attention-Deficit Hyperactivity Disorder (ADHD)**

W. Charoenwongsak\*, K. Wangtrakul, K. Luangbumroong, C. Kwunrod, P. Promchuay

Southern Institute of Child and Adolescent Mental Health, Southern Institute of Child and Adolescent Mental Health, Surat Thani, Thailand

\* Corresponding author.

*Background.*– Social impairment is not part of diagnostic criteria of attention-deficit hyper activity disorder (ADHD), but is strongly associated with the condition and still often persists after treatment of primary symptoms through medication and behavioural therapy. Interactions between parents and child, particularly parenting styles, have been found to be associated with wide-range of outcomes in child's life, but very few studies have been conducted in investigating its association with child's social impairment.

*Objective.*– To examine the association between parenting styles of primary caregivers and social skills of children with ADHD.

*Methods.*– We investigated the association in a sample of children (6-12 years of age), who were diagnosed with ADHD and have received treatment at Southern Institute of Child and Adolescent Mental Health in Surat Thani, Thailand, through questionnaires. Cross-sectional statistical analyses, including Pearson correlation, were used to examine the association between parenting styles and social skills of children with ADHD.

*Results.*– Total of 221 participants were analysed; There are a negative correlation between neglectful parenting style and participant's self-control, problem-solving skill, and conflict resolution skill ( $P < 0.05$ ) and a positive correlation between authoritative parenting style and participant's self-confidence ( $P < 0.05$ ) while controlling for primary caregiver sociodemographic factors (marital status, education level, and income), participant's length of received treatment, and medication adherence.

*Conclusions.*– Neglectful parenting style has been found to be negatively associated with participant's self-control, problem-solving skill, and conflict resolution skill, while authoritative parenting style has been found to be positively associated with participant's self-confidence.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **View of rural parent's medical activity**

B. Dashieva<sup>1</sup>, S. Tyulyupo<sup>2</sup>

<sup>1</sup> Mental Health Research Institute, Tomsk National Research Medical Center, Russia, Borderline States Department, Tomsk, Russia;

<sup>2</sup> Tomsk State University, Department of Genetic and Clinical Psychology, Tomsk, Russia

\* Corresponding author.

*Introduction.*– The level of child's satisfaction in medical care depends on parent's attitudes to apply the available medical service effectively.

*Purpose.*– We focus on rural parents' behaviour as medical services users, based on analysis of 153 Cards of Individual Development (COID) of children aged 7-18. The data was obtained in a course of mediEVpsychological counseling in one of the comprehensive schools in the Tomsk Region.

*Methods.*– We chose to study the cases of children with residual effects of perinatal brain damage (PBD). The empirical basis of the research was obtained from deconstruction of COID and clinical data in them with a pattern of a child's medical supervision as a primary unit of analysis.

*Results.*– There were few reasons of parents' initial visit to the doctor. That were need of vaccination or going to kindergarten; acute illnesses, when the period visits to the doctor was extremely short; the routine of establishing and maintaining of disability status and parents' sought for medical attention on children's deviant behaviour. We distinguish the following characteristics of rural parents' behaviour: (a) the narrowing range of the active complaints, (b) the incomplete execution of medical prescriptions, and (c) formal adherence to medical procedures if parents are claiming for social benefits. Parents complained only in cases of severe, socially observable symptoms. Only a few parents used opportunities of medical services systematically and consistently.

*Conclusion.*– In rural area, the improvement of children's health implies persistent social efforts to evolve parents' culture of interaction with health care system.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0085

### Treatment of psychotic features in suicidal adolescents with complex psychopathology in an ASS crisis intervention unit

C. de Blecourt<sup>1\*</sup>, M. van der Reijden<sup>2</sup>, C. Laumen<sup>2</sup>, A. de Blecourt<sup>3</sup><sup>1</sup> Dr Leo Kanner Huis, CIBA, Oosterbeek, The Netherlands;<sup>2</sup> Dr Leo Kannerhuis, Ciba, Oosterbeek, The Netherlands;<sup>3</sup> Retired, None, Etten Leur, The Netherlands

\* Corresponding author.

**Objectives.**– To propose a transdiagnostic treatment approach in adolescents with complex ASS.

**Background and aims.**– We were impressed by the complexity of comorbid clinical features in adolescents with ASS who had imperative hallucinations to suicide and marked traits of Anorexia Nervosa. These combinations made it virtually impossible to start treatment of ASS. A sense of urgency was felt to prioritize treatment focus in order to prevent detrimental impact on Team cohesion.

**Materials and methods.**– Patients were mainly under the age of 18. Signs that might be interpreted as obsessive thoughts, presumably connected to autistic thinking, were treated as imperative hallucinations, monitoring plasma levels of antipsychotics for dose adjustment. In the selection procedure, as a pilot study, patients were visited in their referring clinic to give advice concerning treatment of psychotic features in relation to suicidality. Disturbances in behaviour were scrutinized for the possibility of another explanation than ASS.

**Results.**– In two patients a marked improvement occurred using haloperidol and a combination of aripiprazole and pimozide, respectively. In a third patient frequent outbursts of rage were seen as possible indication for Intermittent Explosive Disorder and treated with Lithium with good result. In a fourth patient with comorbid Reactive Attachment Disorder interactions with group members were conceived as paranoid and treated successfully with a low dose of pimozide. Patients with severe eating disorders were further excluded from admission.

**Conclusions.**– Eventually the specific climate designed for ASS patients might be used with more specific benefit by ASS patients in which comorbidity in the sense of transdiagnostic psychiatry is treated as much as possible, in advance.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Emotional experience of parents in a situation of child's hospitalization in a psychiatric hospital

D. Dovbysh<sup>1,2\*</sup>, M. Bechuk<sup>2</sup>, A. Iliina<sup>2</sup>, N. Bytchkova<sup>2</sup>, E. Podurova<sup>2</sup><sup>1</sup> Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation., Department of Pedagogy and Medical Psychology, Faculty of Higher Nursing Education and Psycho Social Work, Moscow, Russia;<sup>2</sup> Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Moscow Department of Health Care, Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Moscow Department of Health Care, Moscow, Russia

\* Corresponding author.

**Introduction.**– Hospitalization of the child in psychiatric clinic often appears for parents tough decision. Understanding of this by experts is an important factor of successful cooperation

**Objectives.**– To determine the parents' most popular strategies for emotional regulation and to evaluate their effectiveness at the time of hospitalization of their child in psychiatric clinic.

**Methods.**– A total of 89 parents have participated in a research. Research techniques: The Beck depression questionnaire; Test "Study of anxiety"; Questionnaire of cognitive regulation of emotions.

**Results.**– Parents demonstrate high rates of situational and personal anxiety (64% and 53%); 46% of them have symptoms of depression. The most popular (an average rank 7,3 and 6,7) were "Positive revision" and "Planning" strategy. However neither they, nor any other strategy were connected with decrease in level of anxiety and a depression. The positive correlation of symptoms of a depression and such strategy as "Rumination" and "Katastrofization" ( $r=0,538$  и  $r=0,498$ ,  $P=0,01$ ); signs of situational anxiety and strategy "Acceptance", "Rumination" and "Katastrofization" ( $r=0,419$ ,  $r=0,484$ ,  $r=0,487$ ,  $P=0,01$ ) is noted. There are no differences in symptoms of emotional trouble and in the patterns of regulation in mothers and fathers and also at those whose child is hospitalized for the first time and repeatedly.

**Conclusions.**– Expression of symptoms of a depression and anxiety demonstrate that hospitalization is stressful for all family. The lack of effective regulation strategy in this situation sets for experts a separate task of helping not only to the child, but also to all his family.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### What does the Internet do for the Indian adolescent?

S. Dutta<sup>1\*</sup>, D. Prasad<sup>2</sup>, A. Gupta<sup>3</sup>, H. Naidu<sup>4</sup><sup>1</sup> Nur Manzil Psychiatric Centre-Lucknow-India, Department of Psychiatry, Lucknow, India;<sup>2</sup> Nur Manzil Psychiatric Centre-Lucknow-India, Child and Adolescent Guidance Clinic, Lucknow, India;<sup>3</sup> Nur Manzil Psychiatric Centre-Lucknow-India, Department of Clinical Psychology, Lucknow, India;<sup>4</sup> Nur Manzil Psychiatric Centre-Lucknow-India, Department of Psychiatry, Lucknow, India

\* Corresponding author.

**Background.**– Adolescents, particularly students form a growing chunk of the Internet user base in India. Online activities largely comprise of internet gaming and social media use. Clinicians are increasingly encountering problematic internet use as a presenting feature of mental disorders among teenagers.

**Aim and objective.**– The authors attempted a detailed evaluation of the determinants of internet overuse in a small group of adolescents.

**Method.**– We examined five individuals with excessive internet use. Apart from psychopathology, patterns of emotional regulation, social behaviours, family dynamics and the pressing need and gratifications derived from the internet were explored in detail.

**Results.**– The patients were diagnosed with Obsessive-compulsive disorder, Anorexia Nervosa, Paranoid schizophrenia (prodrome), Somatoform Pain disorder and Major depressive disorder. Borderline personality traits and passive aggression were dominant in most individuals. Loneliness, low self-esteem, impulsivity, body image issues, parental discord and peer influences were important triggers. Need for affiliation, conflict resolution, a virtual yet heightened sense of achievement, distraction from real life stressful situations and instant appraisal were some of the observed gratifications.

**Conclusion.**– It is apparent that internet has taken precedence over live interaction and recreational activities and may assume problematic proportions. Intervention need not be restricted to diagnosis alone but also exploration of psychodynamic underpinnings. Gradual withdrawal and substitution with adaptive emotional release mechanisms should be a focal point of therapy.  
**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The impact of parenting style, perfectionism and self-efficacy on children anxiety symptoms: A pilot study**

A. Keshavarz<sup>1</sup>, M. Erfanian<sup>2\*</sup>, S. Khaleghi<sup>1</sup><sup>1</sup> Azad University, Department of Psychology, Torbat-e-Jam, Iran;<sup>2</sup> Maastricht University, Faculty of Psychology and Neuroscience, Maastricht, The Netherlands

\* Corresponding author.

Understanding the contributing factors of anxiety disorders in children has always been a controversy in the child and adolescent psychiatric community. The results of several studies suggest the contribution of various parent-related factors as an important component in mental health of children. Therefore, the aim of this study is to investigate the causal relationship between parenting styles, perfectionism and self-efficacy of mothers' with children's anxiety symptoms. The current research is a descriptive study with 157 female parents who were selected by random sampling method. The participants were evaluated with parenting self-efficacy styles questionnaire, and multi-dimensional Frost perfectionism scale. The data were analysed with multiple regression. The results indicate that parenting styles, maternal perfectionism, and self-efficacy significantly predict anxiety symptoms in children. The findings of this study are consistent with prior literature suggesting that children's anxiety symptoms are associated with some of the parents' characteristics. The role of family, especially the mothers imply the formation and the continuation of anxiety disorders in their children. Therefore, it is worth considering the maternal variables in the provision of educational and preventive programs and in the treatment of children with anxiety disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0089

### **Neurodevelopmental and childhood-onset schizophrenia in an adolescent presenting inherited 10q26.3 duplication**

A. Fernandez<sup>1\*</sup>, B. Bardoni<sup>2</sup>, E. Dor<sup>1</sup>, A. Florence<sup>1</sup>, S. Thummler<sup>1</sup><sup>1</sup> Lenval CHU, child and Adolescent Psychiatry, Nice, France;<sup>2</sup> IPMC, Institute of Biological Sciences, Valbonne, France

\* Corresponding author.

**Introduction.**– Childhood-Onset Schizophrenia (COS) is defined by an onset of schizophrenia positive symptoms (delusions, hallucinations, disorganized speech or behaviour) before age 13. A higher rate of neurodevelopmental and cytogenetics abnormalities is observed in COS compared to adult onset schizophrenia. The exact pathogenic mechanism remains unknown.

**Case description.**– We describe a 17-year old girl without ante- or perinatal history despite uncomplicated caesarian section. The family history was marked by the violent father's death in early patient's childhood. The developmental history revealed

delayed motor milestones, communication, intellectual (IQ=74) and learning impairments. She presented tantrums and poor social interactions since the age of 7 and delusion and visual hallucinations at age of 12, and was diagnosed with COS. EEG, cerebral MRI, standard blood analysis and metabolic screenings were normal. A chromosomal microarray analysis revealed interstitial 324 kb duplication (10q26.3). Familial segregation revealed the presence of this microduplication in both patient and her mother, associated with schizophrenia spectrum disorders, and the absence in the asymptomatic 22-year old sister.

**Conclusion.**– Our report is the first description of an association of 10q26.3 duplication, so far described in autism, with Childhood-Onset Schizophrenia. The mother's psychotic disorder evolved since adolescence (15 years) while her daughter presented an early and neurodevelopmental form of schizophrenia. This case argues in favor of the schizophrenia "two-hit hypothesis" where the second hit, an early childhood psychotrauma, might explain the early neurodevelopmental clinical presentation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0090

### **A qualitative study of how legal guardians experience deliberate self-harm among adolescents under their custody**

R. Galea<sup>\*</sup>, M. Galea

University of Malta, Faculty of Health Sciences, Msida, Malta

\* Corresponding author.

This study was conducted in partial fulfillment of a master's degree at the University of Malta.

**Background.**– Deliberate Self-Harm is the intentional act of causing harm to oneself in the absence of suicidal intentionality, however it's repetitive nature increases the risk of fatality having severe repercussions on global public health. The overall aim was to explore the lived experience of legal guardians of adolescents who deliberately self-harm.

**Method.**– Heideggerian Hermeneutic Phenomenology underpinned the study while Interpretative Phenomenological Analysis guided the extrapolation and interpretation of results. Four participants and one pilot study were recruited, consisting of mothers in care of adolescents who received care from the Child Guidance Unit and engaged in Deliberate Self-Harm in the past year. In-depth semi-structured interviews were carried out and transcripts were produced. These were analysed and themes were extrapolated through abstraction.

**Results.**– Results demonstrated the anguish and distress experienced by legal guardians due to social, financial and familial circumstances faced. Guilt and feelings of defenselessness and helplessness were reported as devastating while trying to cope and maintain an adequate level of function-ability.

**Discussion.**– The background of these individuals and socio-economic factors hugely impact the development of their circumstances, however the dedication of these legal guardians assisted them in enduring their difficult familial stresses.

**Conclusion.**– Further support and education for the legal guardians should be provided from the psychiatric services. Studies recruiting adolescents coming from different cultural backgrounds and investigating any possible discrepancies and a longitudinal study exploring the skills learned and satisfaction gained from services utilized should be conducted.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Underage admissions to a brief psychiatric hospitalization unit

H. De la Red Gallego<sup>1</sup>, M. De Lorenzo Calzón<sup>1</sup>, A. Álvarez Astorga<sup>1</sup>, A. Alonso Sánchez<sup>1</sup>, Y. González Silva<sup>2</sup>, S. Gómez Sánchez<sup>1</sup>, I. Sevillano Benito<sup>1</sup>, V. Mercedes<sup>1</sup>, V. Martín Arranz<sup>1</sup>, S. Geijo Uribe<sup>1</sup>, F. De Uribe Ladrón de Cegama<sup>1</sup>

<sup>1</sup> Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain;

<sup>2</sup> Gerencia de Atención Primaria de Salamanca, Primary Care, Salamanca, Spain

\* Corresponding author.

**Introduction.**– At least 20% of children and adolescents have some mental disorder. When they require admission, there is usually a greater impact on family, social and school functioning.

**Objectives.**– To know the epidemiological characteristics of the children inpatients.

**Methods.**– A cross-sectional study on the prevalence of psychiatric disorders in a Brief Hospitalization Unit. Description of the sample. Inclusion criteria: younger than eighteen years admitted between May 2007 and May 2017. Variables: age, sex, health care district, days of stay, diagnosis. Quantitative variables are described with averages and standard deviation, and qualitative variables with percentages.

**Results.**– Patients admitted: 1006. Average age: 13.7 (14.2). Gender: female: 521 (52%), male: 485 (48%). Average age according to gender: woman: (14.2), male: (13.3). Prevalence of diagnosis by gender: Psychotic disorders: female: 35.23%, male: 64.77%. Eating Disorders (ED): female: 83.60%, male 16.40%. Autism spectrum disorder: female: 13.43%, male: 86.57%. ADHD: woman: 29.73%, male: 70.27%. Other diagnoses: female: 54.28%, male: 45.72%. Ávila 56 (6%), León: 95 (9%), El Bierzo: 74 (7%), Salamanca: 66 (7%), Valladolid West: 124 (12% Valladolid Este: 294 42 (4%), Burgos: 82 (8%), Palencia: 85 (9%), Segovia: 33 (3%). Days of average stay: overall: 23.87. ED: 39.68. Rest of diagnoses: 20, 14.

**Conclusions.**– The most frequent causes of admission were ED, anxiety disorders, ADHD, psychotic and affective disorders. Males were admitted more frequently, except in cases of ED. The mean age was lower in males. The mean stay was higher in cases of ED. Admissions were greater in our health care district.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Optimize clinical drug performance for the treatment of ADHD using response surface analysis

R. Gomeni<sup>1</sup>\*, B.G. Francoise<sup>2</sup>

<sup>1</sup> Pharmacometrica, Reseach and Development, Buzet sur Tarn, France;

<sup>2</sup> Pharmacometrica, Reseach and Development, Buzet sur Tarn, France

\* Corresponding author.

The objective of this paper was to develop a novel model-based methodology utilizing the response surface analysis and a non-linear optimizer algorithm to maximize the clinical benefit of drug treatments. The response to a treatment was described by a drug-disease model accounting for multiple components such as the dosage regimen, the pharmacokinetic characteristics of a drug (including the mechanism and the rate of drug delivery), and the exposure-response relationship. A convolution-based approach was used to characterize the pharmacokinetics of the drugs used

and an indirect-response modeling approach was used to link the drug exposure with the clinical response.

A case study is presented to illustrate how the performances of drug treating the attention deficit hyperactivity disorder (ADHD) can be improved. The results of the analysis indicated that a substantial improvement in clinical benefit was expected when optimal strategies were deployed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0093

### Inflammation and its part on treating non-responders in schizophrenia

D. Gorgoli

Consultant Psychiatrist, Psychiatric Department of “Konstantopouleio” General Hospital of N. Ionia, Athens, Athens, Greece

\* Corresponding author.

Inflammation has been playing an important part in our understanding of psychiatric disorders, for at least a decade now.

In this oral presentation, we are trying to achieve an understanding of how anti-inflammatory drugs can reduce psychotic symptoms in schizophrenic patients, who are not responding to antipsychotic treatment.

In order to do so, we have overviewed all publications of the last 5 years of research, that contain the words “inflammation” and “Schizophrenia”.

The aim is to outline the fact that (and explain how) most non-responders, have a lot of specific inflammatory cytokines on circuit and that this blocks most antipsychotics.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Improvement of Autism Diagnostic Observation Schedule (ADOS) Scores after comprehensive intensive early interventions in a clinical setting

N. Haglund<sup>1</sup>\*, S. Dahlgren<sup>2</sup>, M. Råstam<sup>3</sup>, P. Gustafsson<sup>4</sup>, K. Källén<sup>5</sup>

<sup>1</sup> Lund University, Dept. of Clinical Sciences, Lund Child and Adolescent Psychiatry, Lund, Sweden;

<sup>2</sup> University of Gothenburg, Department of Psychology, Gothenburg, Sweden;

<sup>3</sup> Institution for Clinical Science, Lund University, Child and Adolescent Psychiatry, Lund, Sweden;

<sup>4</sup> Institution for Clinical Science, Child and Adolescent Psychiatry, Lund University, Lund, Sweden;

<sup>5</sup> Institution for Clinical Science- Lund university, Obstetrics and Gynecology, Lund, Sweden

\* Corresponding author.

**Introduction.**– Pre-school children with autism in southern Sweden are offered to participate in a Comprehensive Intensive Early Intervention (CIEI) program.

**Objectives.**– The primary aim of the study was to evaluate the ongoing CIEI-program.

**Methods.**– The improvement of the Autism Diagnostic Observation Schedule (ADOS) test results between baseline and evaluation among children participating in the CIEI-program ( $n = 67$ ) was compared to children in a comparison group (receiving traditional habilitation services only,  $n = 27$ ). The difference between the study groups regarding change of ADOS-scores (total, and calibrated severity scores, respectively) were estimated using ANCOVA.

**Results.**– Children in the CIEI-group improved their ADOS-total scores between baseline and evaluation (-0.8 scores per year; 95%CI: -1.2 to -0.4), whereas no such improvement was detected in the comparison group (+0.1 scores per year; 95%CI: -0.7 to +0.9). The change difference (change among children in the CIEI-group vs change in the comparison group) was statistically significant, both crude and after adjusting for possible confounders (-1.1; 95%CI -1.9 to -0.4). Children in the CIEI-group also significantly improved their ADOS-severity scores, but not significantly differently so from the comparison group.

**Conclusions.**– The results from the current study must be interpreted cautiously, but they do support earlier studies reporting on improvement of autism symptoms after early intensive interventions. This naturalistic study indicate that children with autism benefit from participating in early comprehensive intensive programs, and that investments in these programs may be highly justifiable, and may be of immediate importance to health care organizations when allocating the already strained resources to different patient groups.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Childhood subclinical characteristics in schizophrenia – Toward the early screening for the risk of schizophrenia

Y. Hamasaki<sup>1\*</sup>, T. Nakayama<sup>1</sup>, T. Hikida<sup>2</sup>

<sup>1</sup> Kyoto women's university, Faculty for the study of contemporary society, Kyoto, Japan;

<sup>2</sup> Institute for Protein Research, Osaka University, Laboratory for Advanced Brain Functions, Osaka, Japan

\* Corresponding author.

**Background and aims.**– The subclinical behavioural and psychological characteristics of schizophrenic children have not been sufficiently investigated to present specific evidences. This study is a retrospective report of childhood neurobehavioural assessment in adult patients with schizophrenia and healthy controls using the CBCL to elucidate the subclinical characteristics of schizophrenic children and to find out indicators which predict later development of schizophrenia.

**Method.**– Schizophrenia outpatients in his/her twenties who fulfill DSM-IV-TR criteria and who present now mainly negative symptoms after passing an acute stage were investigated. Normal healthy subjects were also examined as sex- and age-matched controls. By modified use of the CBCL as a retrospective assessment questionnaire, the parents of the patients and of control subjects rated their childhood (aged 6-8 years) behaviours.

**Results.**– A logistic regression using the eight CBCL syndrome subscale T-scores adequately classified 85.8% of the population. Among the eight subscale T-scores, those of Withdrawn, Thought problems and Aggressive behaviour were significantly associated with risk of schizophrenia, although any of these mean scores were not in clinical range. Concerning Aggressive behaviour, patients showed a significantly lower score than controls.

**Conclusion.**– The results suggest that subclinical neurobehavioural characteristics of schizophrenia already exist in the patients' childhood. The combination pattern of these subclinical characteristics would predict later development of schizophrenia. Quite early screening for risk of schizophrenia could be possible with some instrument using obtained logistic regression model.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Perceptions of parents having child with thalassemia

H. Heidari<sup>1\*</sup>, A. Ahmadi<sup>2</sup>, K. Solati<sup>3</sup>

<sup>1</sup> Shahrekord Medical University of Science, Nursing Faculty, Shahrekord, Iran;

<sup>2</sup> Shahrekord Medical University of Science, Health Faculty, Shahrekord, Iran;

<sup>3</sup> Shahrekord Medical University of Science, Psychiatry Faculty, Shahrekord, Iran

\* Corresponding author.

**Background.**– Patients with thalassemia need to inject blood repeatedly and need to be treated with chelating. Thalassemia like any other chronic disease affects different aspect of person's life and despite of therapeutic measure, the patient is faced with several physical and psychological problems. Therefore the purpose of this study was exploring perceptions of parents having child with thalassemia.

**Methods.**– The method applied in this study is content analysis. 10 participants was selected purposely in this study. Data collection was done deep, semi-structured, face to face and individual interviews.

**Findings.**– Ten participants including 5 mothers, 1 grandmother, 2 fathers and 2 nurses participated in the study. The average age of mother was 33 years old and the average age of father was 44, the grandmother was 50, the average age of nurses was 45, the average work experience of nurses was 20 and the average work experience in thalassemia department was 4 years. Having analysed data, the three following categories were specified: rejection of child's disease, parents' psychological problems, and psychological problems of family members.

**Conclusion.**– The results of present study revealed that parents of child with thalassemia experience several psychological problems and they need to support from health system. It is also necessary that health authorities establish consulting nurses for parent with child having thalassemia to provide them with necessary consulting services.

**Keywords:** Parent; Thalassemia; Content analysis

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Introduction.**– Dissocial disorder is one of the most controversial entities in Psychiatry. It is a persistent set of behaviours that evolve over time. It is characterized by destructive behaviours against society, which violate other people's rights, norms and use deception to achieve their goals. These manifestations are linked to a series of familiar, social and school situations that can initiate or maintain them.

**Methodology.**– A 13-year-old woman, Mapuche, who lives with her mother and her partner. She had no psychiatric history until two months ago, when she consulted Psychiatry, at the initiative of the mother, due to behavioural alterations and inappropriate and aggressive behaviour in school and at her home. Brought to the ER because he had tried to kill a classmate. Excessive interest in the violent manga, (creepypasta).

**Results.**– In the EPP it stands out: Avoidance and facial expressionlessness. Stereotyped phrases. Inappropriate affection. Cold attitude. Unyielding and magical thinking. Search for eccentric behaviours. Non-compliance with standards. He reacts with excessive anxiety and anxiety when he breaks the pre-established idea that he has of any situation. We maintain delayed diagnosis. It presents schizotypal, autistic spectrum and compatible dysocial traits, of which we will explain the differential diagnosis.

**Conclusion.**– Psychopathy is a form of mania without deficit in cognitive faculties, but with a severe damage in the affective capacity. Dissocial disorder before age 15 is a diagnostic criterion in adults. Importance of focusing on sensitive stages of development. Non-solvent methodological studies that demonstrate the efficacy of treatments for psychopathy: unfavorable results in general.

### Family aggregation in ADHD and other pathologies of the child and adolescent. About a case

G. Hernandez Santillan\*, A. Huertas-Paton  
Hospital Universitario Príncipe de Asturias, Alcala de Henares,  
Madrid, Psychiatry, Madrid, Spain

\* Corresponding author.

Family studies implicate share genetic risk between attention deficit hyperactivity disorder (ADHD) and bipolar disorder, schizophrenia, major depression and autism. The influence of the emotional expression of caregivers on children and onset disorders in childhood has also been described. Nevertheless, in clinical practice sometimes the relation between members of a family is obviated.

**Objectives.**– Describe the psychopathology between the siblings of a family and their influence on the evolution of each one.

**Methods.**– Presentation of a case.

**Results.**– A 16-year-old male has been in follow-up for Mental Health for three years due to behavioural disturbance, social isolation and low academic performance. He is the youngest of four siblings. The older brother, with no diagnosed pathology, was characterized by violent behaviour, fits of anger and intimidation of the parents. The sister attended with anorexia nervosa and self-harm, in addition to consuming THC with the patient, with whom she had a fusional relationship for a year, which she abandoned for her work. The younger brother is diagnosed with autism spectrum disorder (ASD), under treatment. Apparently healthy parents. The patient was taking prolonged-release methylphenidate with partial adherence to treatment for one year, in addition to cognitive-behavioural therapy and family intervention; with improvement results. He is currently undertaking vocational training and has started a relationship.

**Conclusions.**– It is important to carry out a family approach for the treatment of ADHD, as well as to study the case of siblings, considering the probable vulnerability to develop other pathologies in them, as much for sharing genetic

as environmental factors and breeding styles. (Figure 1)

### Examining the relation among the methods of parenting and creativity of high school girls students on Sari city

S. Heydari<sup>1</sup>, M. Shafiei Amiri<sup>2</sup>

<sup>1</sup> Islamic Azad University, Clinical Psychology, Qazvin, Iran;

<sup>2</sup> Islamicazad University Sari Branch, Psychology, Sari, Iran

\* Corresponding author.

**Introduction.**– The parenting style is a combination of parental behaviours that occur in a wide range of situations and create a barren parenting environment.

**Objective.**– Current study has been done for examining the relation among the methods of parenting and creativity of high school girl's students on sari city.

**Aim.**– Studying the relationship between the methods of parenting and creativity of high school girl's students on sari city

**Method.**– This study is of descriptive type and the method of study is correlation one. Statistical society of study includes all girls' students of high school degree on sari city in which includes about 1400 persons.

**Result.**– Sampling has been done by the aid of kerjtis- Morgan table and about 203 persons has been selected by method of random-categorical method. Gathering standard questionnaire instrument of Bamrind parenting practices methods includes 30 questions and also Abedi creativity questionnaire includes 60 questions has been used and parenting practices, creativity method questionnaire stability has been examined through Cronbach's alpha and its amount (8.86-0.83) has been calculated, respectively. In order to analyze data, we have used of Pearson correlation test by the aid of SPSS software.

**Conclusion.**– The result of study has shown there is relation among the methods of parenting practices and creativity of students. Easy parenting practices, autocratic parenting and authoritarian parenting respectively are the strongest anticipating the amount of students' creativity.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Parental attitude and beliefs to children with mental and behavioral disorders

M. Ivanov

Federal State Budgetary Scientific Institution "Mental Health Research Center", Department of Child Psychiatry, Moscow, Russia

\* Corresponding author.

**Introduction.**– The presence of mental and behavioural disorders in a child is a heavy burden for the whole family.

**Objectives.**– To reveal the features of the parental attitude to children with mental and behavioural disorders.

**Methods.**– Questionnaire for parents "parental attitude to children's illnesses"; the Plutchik's Life Style Index (Russian version); The Clinical Global Impressions–Severity scale (CGI-S) and Statistical methods.

**Sampling.**– Parents of 80 children aged from 2 to 7 (mean 4,6): 20–mental retardation (F80–82–ICD-10), 40–autism spectrum disorder (ASD; F84), 20–intellectual disabilities (F70–79).

**Results & conclusions.**– Parents of children with developmental disabilities often do not realize the morbid nature of changes in the behaviour of children and interpret it as spontaneity, pamperedness or even giftedness. Most parents of children from all groups underestimated the doctor's recommendations for compliance with the regime (treatment and upbringing). The parents of children with intellectual disabilities and autism spectrum disorder use the following defense mechanisms–denial, reaction formation and intellectualization. The awareness of illness is connected with age of a child and the severity of disorder (CGI-S) in mental retardation and intellectual disabilities, but not in ASD. The parents of children with ASD quite often explain the state of their child as giftedness, that cannot be evaluated by other people. Parents' beliefs concern social assessment of the prospects for its development. This study should contribute to the development of support programs to families with children with mental disorders. It is aimed at increasing compliance and reducing family tensions.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Depression, anxiety and eating disorders: Prevalence and association among adolescents studying in public schools of Delhi

P. Khanna\*, B. Aeri

Institute Of Home Economics, University Of Delhi, Food & Nutrition, New Delhi, India

\* Corresponding author.

**Introduction.**– Data on prevalence of mental health disorders indicates that 4.5% and 3% of the Indian population is suffering from depression and anxiety respectively. Depression is ranked by WHO (2015) as the single largest contributor to global disability, therefore there is a need to investigate the maturation patterns (gender specific) & its relationship with psychosocial & nutritional factors which impact overall health of an adolescent.

**Objectives.**– The present research was designed to study the prevalence & association of depression & anxiety with eating disorders & BMI among adolescent boys & girls (aged 13–16 years) studying in public schools of Delhi.

**Method.**– Three hundred adolescents participated in this cross-sectional study. For the assessment of depression and anxiety & eating disorders Child Behavior Checklist (CBCL; administered to the parents) and Three Factor Eating Questionnaire (TFEQ; admin-

istered to the subjects) were used respectively. Data were also collected on socio demographic profile, physical activity, dietary practices & consumption pattern, food intake (24hr recall, Food Frequency Questionnaire), body image perception, locus of control & anthropometric (Weight, Height, BMI, Body fat %) profiles.

**Results.**– Prevalence of depression & anxiety is 37.5% and eating disorders (restrained, uncontrolled & emotional) is 18% respectively. Anthropometric data revealed that 18.3%, 7% and 20% of the subjects are underweight, overweight and obese respectively. 58% of the malnourished subjects are suffering from depression & anxiety.

**Conclusion.**– This study highlights the association of mental health with eating disorders & nutritional status of adolescents. It will also serve as a strategic tool for mental health prevention & management policies designed for adolescents.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Child mental health and juvenile delinquency

D. Kim<sup>1</sup>, S. Kim<sup>2</sup>

<sup>1</sup> Korea Development Institute, Public Finance and Social Policy, Sejong, Republic of Korea;

<sup>2</sup> Ajou University Hospital, Psychiatry & Behavioral Sciences, Suwon, Republic of Korea

\* Corresponding author.

Using a nationally representative survey on U.S. children and young adults, we examine the consequences of mental health problems in childhood (age 4–12) on subsequent delinquency measured by lifetime criminal activities and illicit drug use by age 18. After controlling for family-specific unobserved factors as well as child-specific observed factors, we find that antisocial scores in childhood are strongly associated with lifetime arrest, probation, and incarceration as well as lifetime illicit drug use in adolescence. We also find that symptom scores for ADHD are associated with lifetime victimization in physical attack and rape, but not with criminal activities or illicit drug use. Our results are robust in a model that allows comorbidity. Gender differences are inconspicuous in general although we find that anxious/depressed symptoms are often positively associated with delinquent outcomes only among females.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Weakness in holistic processing in children with specific language impairments

S. Kiselev

Ural Federal University, Clinical Psychology, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– Children with specific language impairments (SLI) have deficit in producing and understanding language (Bishop, 1997). The nature of this developmental disorder is still not understood. We have shown that children with SLI at the age of 6–7 have weakness in holistic processing (Kiselev et al., 2017). The goal of this research was to examine the hypothesis that children with SLI at the age of 4–5 have also deficit in brain holistic mechanism.

**Method.**– Experimental group included 17 Russian-speaking children with SLI at the age of 4–5. The control group consisted of 17 children. The children from experimental and control group were matched for IQ, gender and age. We used the Rey-Osterrieth Com-

plex Figure Test to assess the brain holistic mechanism in children. It was proposed that part-oriented strategy in copying Complex Figure is related to weakness in holistic processing (Luria, 1973).

**Results.**– In comparison to children from control group the majority of children with SLI (63%) had immature (part-oriented) strategy in copying Complex Figure. In view of the obtained results it can be assumed that preschool children with specific language impairment have deficit in the specific brain mechanism responsible for holistic processing. We hope that our results will help to elucidate the nature of impaired mechanism in specific language impairment in children.

**Funding.**– The research was supported by Act 211 Government of the Russian Federation, agreement 02.A03.21.0006

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0104

### **Deficit of memory in delayed recall condition in preschool children with ADHD**

S. Kiselev

Ural Federal University, Clinical Psychology, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– It was shown that children with ADHD have deficit in prefrontal cortex function including deficit in working memory (Martinussen et al., 2012). In our previous research we have revealed that ADHD children at the age 8–9-years have deficit in memory in delayed recall condition (Kiselev et al., 2017). The goal of this research was to examine the hypothesis that preschool children with ADHD have the same deficit in memory in delayed recall condition as children at the age 8–9-years.

**Method and participants.**– The experimental group included 13 children with ADHD at the age 5–6-years. The control group included 13 typically developing children. The children from experimental and control group were matched for IQ, gender and age. Children from both groups were assessed with visual memory subtest from Luria's neuropsychological assessment battery. This subtest is designed to assess the ability to perform visual memory for objects in immediate and delayed conditions. Two-way ANOVA was used to reveal group differences in reproducing the objects in two conditions.

**Results.**– We have not revealed significant differences between children from experimental and control group in the reproducing the objects in immediate condition. However, the interaction of condition type and group was significant ( $p \leq 0,05$ ). ADHD children were less successful in reproducing the objects in delayed condition. In view of the obtained results, it can be assumed that preschool children with ADHD have specific deficit in memory in delayed recall condition.

**Funding.**– The research was supported by Russian Foundation for Basic Research, grant No. 15-06-06491A.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Characteristics of psychological development of toddlers with congenital heart disease subjected to heart surgery**

M. Kiseleva

Bakoulev Center for Cardiovascular Surgery, Rehabilitation Center for children with Congenital Heart Disease, Moscow, Russia

\* Corresponding author.

The situation of pediatric heart surgery is a major psychological stress for toddler with congenital heart disease (CHD) and his family, connected with a long stay in a hospital, pain, early separation from mother, movements and play limits. Much attention is now being placed on the psychological and social outcomes of these children.

The participants of our research were 84 diads: toddlers with severe CHD subjected to heart surgery and their mothers. Mean age:  $14,52 \pm 1,50$  months old, 43,50% - girls. Center for Epidemiologic Studies Depression Scale was used to measure depression rate in the mothers. State-Trait Anxiety Inventory–for anxiety rate in the mothers. The level of psychological development and functioning of the toddlers was measured two days before the surgery by The Diagnosis of Neuro-Psychological Development of Infants (DNPDI) designed by Pantuhina G.V., Pechora K.L., Fruht E.L.

We've found out that 34,8% of the infants with CHD had 1 epicrisis period delay in their psychological development; 43,5% - had 2 epicrisis period delay. Among the mothers–40,1% had heightened level of state anxiety, 26,6% had high level of state anxiety. 65,2% of the mothers reported depressive symptomology. We've shown that the higher level of depressive symptoms in the mothers from the study group correlated with bigger delay in the psychological development of toddlers with CHD subjected to heart surgery ( $R = 0,835$ ,  $p = 0,000$ ).

The further research in this field suggests the search for techniques helping to improve the mothers' psychological functioning as it plays a great role in toddlers development.

### **Impact of motor sequencing training on executive and motor abilities in children with ADHD**

N. Kiseleva\*, S. Kiselev

Ural Federal University, Laboratory for brain and neurocognitive development, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– It is known that children with ADHD have deficit in executive and motor abilities. It is of great significance to receive the evidence for efficiency of different training programmes that are aimed to help children with ADHD. The goal of this study was to assess the impact of 12 weeks of motor sequencing training on the executive and motor abilities in children with ADHD.

**Participants and methods.**– The participants were 24 children aged 5–6 years (mean age = 5.1) with ADHD. Children were randomly assigned to the intervention and comparison group. Children from intervention group participated in 12 weeks of motor sequencing training. This programme trains the child to plan, sequence and process information more effectively through repetition of goal-directed movements. This programme is built on the conceptual framework derived from the work of Luria's theory of restoration of neurocognitive functions (Luria, 1963, 1974). The Luria's child neuropsychological assessment battery was administered before and after the intervention period.

**Results.**– Analysis of covariance tested the effect of motor training programme on four scales of the Luria's child neuropsychological assessment battery: Executive scale; Motor scale; Visuo-spatial scale; Memory scale. Group differences ( $p < .05$ ) were found for the Executive scale and Motor scale. Posttest mean for the intervention group were significantly ( $p < .05$ ) greater than the control group.

**Conclusion.**– Motor sequencing training in children with ADHD benefits both motor abilities and executive functions.

**Funding.**– The research was supported by Act 211 Government of the Russian Federation, agreement no. 02.A03.21.0006.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0107

### **Impact of visuospatial training on language abilities in children with SLI**

N. Kiseleva\*, S. Kiselev

Ural Federal University, Laboratory for brain and neurocognitive development, Ekaterinburg, Russia

\* Corresponding author.

**Background.**– It was shown that children with specific language impairments (SLI) have deficits not only in producing and understanding language but also in visuospatial abilities (Kiselev et al., 2016). We assume that training programmes that are aimed to develop the visuospatial abilities can help children with SLI. The goal of this study was to assess the impact of visuospatial training on the language abilities in children with SLI.

**Participants and methods.**– The participants were 28 children aged 6–7 years (mean age=6.8) with SLI. Children were randomly assigned to the intervention and comparison group. Children from intervention group participated in 36 weeks of visuospatial training. This programme trains the child to do different visuospatial exercises both on motor and cognitive level. This programme is built on the conceptual framework derived from the work of Luria's theory of restoration of neurocognitive functions (Luria, 1963, 1974). We used the subtests from Luria's child neuropsychological assessment battery to assess language abilities in children before and after the intervention period.

**Results.**– Analysis of covariance tested the effect of visuospatial training programme on five language subtest from Luria's child neuropsychological assessment battery. Group differences ( $p < .05$ ) were found for subtest that assess understanding prepositions that describe the spatial relations between objects. Posttest mean for the intervention group were significantly ( $p < .05$ ) greater than the control group.

**Conclusion.**– Visuospatial training in children with SLI benefits specific language abilities for understanding sentences with spatial prepositions.

**Funding.**– The research was supported by Act 211 Government of the Russian Federation, agreement no. 02.A03.21.0006.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0108

### **A novel way of analyzing facial emotions processing in children with Autism spectrum disorders**

L. Kobylinska<sup>1,2\*</sup>, C. Anghel<sup>3</sup>, F. Rad<sup>3</sup>, I. Mihailescu<sup>3</sup>, I. Dobrescu<sup>3</sup>

<sup>1</sup> Titan Psychiatry Hospital "Dr. Constantin Gorgos", Child and Adolescent Mental Health Center, Bucharest, Romania;

<sup>2</sup> "Carol Davila" University of Medicine and Pharmacy, Physiology and Fundamental Neuroscience, Bucharest, Romania;

<sup>3</sup> "Prof. Dr. Al. Obregia" Clinical Psychiatry Hospital, Child and Adolescent Psychiatry, Bucharest, Romania

\* Corresponding author.

Emotion perception in autism spectrum disorders is one of the most researched topics of the past decade, being extremely important for monitoring the therapy progress. Facial emotions processing can be done using eye-tracking devices. However, these can sometimes be hard to wear for the child. Stating from this observation, it becomes

important to device other ways of studying facial emotions processing in autism spectrum disorders

The aim was to develop a program that will help identify the pattern in which image processing occurs.

Eighteen children (8 neurotypical) were included in this study, based on informed consent. They were asked to press on some images displaying facial emotions and the order in which they touched the different features of the faces in the photos was quantified and then analysed.

The data was analysed using Spss 22.0 and non-parametric testing was employed for non-continuous variables.

There were differences between the two groups for the emotion of "surprise"  $p$  Wilcoxon  $< 0.05$ . The children in the control group also had significant differences from one press to another on the same picture, for the emotion of surprise ( $\chi^2(8,3) = 9.18, P = 0.02$ ). In the group on children with autism spectrum disorders, this trend of difference was observed for the emotion of "fear" ( $\chi^2(10,3) = 7.92, P = 0.04$ )

These results suggest that the test of showing children facial emotions might be an efficient manner of analyzing emotional processing in children with developmental disorders. Another important conclusion is that not all emotions are processed in the same way in both typical and non-typical children.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0109

### **Cohort study of gaze following ability in preterm infants**

A. Kotyusov<sup>1\*</sup>, N. Pavlova<sup>1</sup>, K. Kunnikova<sup>1</sup>, T. Gliga<sup>2</sup>

<sup>1</sup> Ural federal university, Laboratory for brain and neurocognitive

development, Екатеринбург, Russia; <sup>2</sup> Birkbeck, University of London, Centre for Brain and Cognitive Development, London, United Kingdom

\* Corresponding author.

**Background.**– The aim of the current study was to investigate the influence of prematurity on development of gaze following behaviour.

**Participants and methods.**– Our study consists of two birth cohort: 10 month cohort consists of 7 preterm infants with mean corrected age 9.71(1.17), mean gestation age 35.29 (17.50) and 10 full-term infants with mean age 10.42 (1.19); 14 month cohort consists of 8 preterm infants with mean corrected age 14.06(1.64), mean gestation age 32.37(16.71) and 10 full-term infants with mean age 10.42(63). The infants from both cohorts were matched for gender and age. Each trial was divided in four phases: 1- the model sits, looking down; 2- the model is looking straight ahead; 3- the model is shifting her gaze to the toy; 4- the residual time. The percentage of performed trials, fixation duration (ms) on relevant and irrelevant stimulus were analysed.

**Results.**– We have not revealed the significant ( $P \leq 0.05$ ) differences between groups from 10 month cohort. Statistically significant ( $P \leq 0.05$ ) differences were found between groups from 14 month cohort: difference in the number of performed trials (full-term. 85 (22) and preterm. 44 (36),  $F = 8.747, P = 0.015$ ); fixation duration on relevant stimulus in the 4<sup>th</sup> phase (full-term 5.389 (2.207)s and preterm 2.307(1.716)s,  $F = 10.474, P = 0.005$ ).

**Conclusion.**– Premature infants have shown lower level of gaze following behaviour in 14 month in comparison to infants from control group. It can be assumed that prematurity has influence on the development of communication skills related to gaze following behaviour in infants at 14 month of age. This work was supported by grant Russian Science Foundation 17-15-01144

### **The use of oxytocin in autism spectrum disorder: A literature review**

G. Kudva Kundadak

National University Hospital, Department of Psychological Medicine, Singapore, Singapore

\* Corresponding author.

*Objective.*– Autism Spectrum Disorder (ASD) is a neuro-developmental disorder that affects 1% of the general population and involves persistent deficits in social communication. It is also characterized by the presence of repetitive behaviours, restricted interests and inflexible adherence to routines. One possible treatment for the social communication deficits observed in Autism involves the use of Oxytocin.

*Method.*– Our literature review shall involve a comprehensive look at published data on the use of Oxytocin in individuals for the amelioration of social cognitive deficits, and we shall review the mode of administration, doses and treatment regimens used for this purpose, and suggest a possible treatment plan involving oxytocin for patients who have ASD, and what the expected responses to such a treatment regimen might be.

*Result.*– Once daily usage of Intranasal Oxytocin, at 24 International Units (IU) may help with social cognitive deficits, although the magnitude of this effect is small. There is little evidence on whether this effect persists after cessation of Oxytocin.

*Conclusion.*– Oxytocin may be a useful adjunct to social skills training and early intervention strategies for individuals with Autism and Social Cognitive Deficits.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0111

### **Trauma-based mind control and Istanbul protocol for torture diagnosis**

R.H. Kurz

Outstanding Achievements, Research, Long Ditton, United Kingdom

\* Corresponding author.

*Introduction.*– This paper reviews the applicability of the Istanbul Protocol for Torture Diagnosis to extreme child abuse cases as outlined on the website [traumabasedmindcontrol.com](http://traumabasedmindcontrol.com).

*Objectives.*– The presentation outlines the difficulty of tackling a suspected Organised Ritualised Crime Network (ORCAN) with conventional Psychiatry and Psychology skills and offers alternatives from torture research.

*Aims.*– This presentation aims to explore research based alternatives to the ‘Discourse of Disbelief’ where allegations of extreme abuse and authority compromise are simply denied.

*Methods.*– Document reviews yielded a disturbing picture of an extreme abuse network comparable to the Marc Dutroux case in Belgium and promising diagnostic methods that could be deployed to properly investigate allegations.

*Results.*– A small child showed flashbacks and signs of dissociation after repeated contact visits to his biological father. Review of case materials suggested the operation of a high-level extreme abuse ring involving prominent mental health professionals, business leaders and politicians. Child disclosures covered bizarre as well as sexually exploitative abuse acts that a child would be rather unlikely to come up with without corresponding experiences. Authority representatives alleged that the mother was mentally

unwell and took the child into care without proper examinations. The detailed guidelines contained in the Istanbul Protocol for Torture Diagnosis could probably lead to the identification of suitable proof to prosecute suspected offenders.

*Conclusions.*– Extreme abuse torture of small children appears to be met with denial when actually workable diagnostic approaches are available.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0112

### **Potential barriers in the therapeutic relationship in unaccompanied refugee minors in mental health**

P. Majumder<sup>1</sup>, P. Vostanis<sup>2</sup>, K. Karim<sup>2</sup>, M. O'Reilly<sup>2</sup><sup>1</sup> University of Nottingham, Medicine and Health Sciences,

Nottingham, United Kingdom; <sup>2</sup> University of Leicester, Psychology, Leicester, United Kingdom

\* Corresponding author.

*Introduction.*– Even though refugee children, particularly unaccompanied refugee minors, present with disproportionately high prevalence of emotional and psychological morbidities, this group of vulnerable but marginalized young people's access to utilize mental health service has been consistently shown to be significantly poorer than the general population. However, so far there has not been much research to explore the possible underlying reasons or barriers for them to access mental health service in their host countries.

*Objectives.*– This research aims to understand unaccompanied refugee minors' barriers to access and utilize specialist mental health services and to explore any specific issues that are perceived to be related to this poor engagement with the services.

*Methods.*– The study was conducted by using semi-structured interviews with fifteen unaccompanied refugee young persons and their carers to elicit their views, perceptions and beliefs based on their experience of receiving treatment from a specialist mental health service in the UK.

*Results.*– Thematic analysis was used to analyze the interview transcripts. After analyzing the interview data, main findings were categorised into two broad themes, the participants' perceptions of the intervention received, and the professionals involved. The different elements and pertinent issues within these two broad areas were discussed.

*Conclusions.*– The findings will help stimulate further research into gaining better understanding of the barriers for these young people to access help, and contribute in developing services that are more efficient in engaging this vulnerable group and suitable to meet their specific needs.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Body dissatisfaction, depression and self-esteem in obese Tunisian adolescents**

R. Masmoudi<sup>1</sup>, D. Trigui<sup>1</sup>, F. Hadj Kacem<sup>2</sup>, R. Feki<sup>1</sup>, I. Feki<sup>1</sup>, M. Abid<sup>2</sup>, J. Masmoudi<sup>1</sup><sup>1</sup> Hédi Chaker University Hospital, Psychiatry “A”, Sfax, Tunisia; <sup>2</sup>

Hédi Chaker University Hospital, Endocrinology, Sfax, Tunisia

\* Corresponding author.

**Objective.**– The aim of this work was to examine the relation between body dissatisfaction, depression and self esteem in adolescents with obesity.

**Methods.**– The patient group included 30 participants (18 girls, Mean age = 15.27 years  $\pm$  3.59) who were diagnosed as having obesity at Endocrinology service of University Hospital Hédi Chaker, Sfax and the control group consisted of 30 non obese participants (25 girls, Mean age = 16.53 years  $\pm$  1.85). Socio-demographic and clinical data related to obesity were collected using a self-reporting questionnaire. We used the Bruchon-Schweitzer's Body image questionnaire (QIC) to measure body image dissatisfaction, the Rosenberg Self-Esteem Scale to evaluate the self-esteem and the CES-D (Center for Epidemiologic Studies - Depression) to detect depression.

**Results.**– In this study, the patient group stated that they are highly dissatisfied with their bodies compared to the control group ( $P=0.005$ ). Obese adolescents demonstrated more depression ( $P=0.009$ ) than normal weight peers. We did not find any significant difference in mean scores for self-esteem between the two groups. The obese children with body dissatisfaction had significantly lower self-esteem and higher levels of depressive symptoms than the obese children without body dissatisfaction.

**Conclusion.**– Our findings suggest that obesity may be linked to body dissatisfaction which was also associated with low self-esteem and high levels of depressive symptoms. These psychological consequences of obesity, associated with somatic complications could further darken the prognosis in this young population. A multidisciplinary approach including psychotherapeutic treatment is essential to optimize the quality of the care provided.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Relaxation kinetics in the study of neurobiological processes using functional magnetic resonance imaging and spectroscopy

M. Ublinskiy, N. Semenova, T. Akhadov, P. Menshchikov\*, A. Manzhurtsev, I. Melnikov

Clinical and Research Institute of Emergency Pediatric Surgery and Trauma, Radiology, Moscow, Russia

\* Corresponding author.

Biochemical reactions in normal living cells are multistage chemical processes that take place in a stable steady state. Study of the dynamic system behaviour and kinetics of system return to the initial stable steady state provides ample information on the process mechanism. The aim of this study is to combine the method of localization dynamic spectroscopy we developed with relaxation kinetics techniques using MRI methods (fMRI and NMR).

Nine mentally and neurologically unimpaired men comprised test group (mean age was 22.1  $\pm$  1.9).

MRI data were performed on Achieva Philips 3.0 T scanner. The fMRI audio-stimuli (tone, 1 kHz frequency, 70–80 dB) were presented to the test subjects. The test subjects were instructed to press a special button with the right hand index finger upon the stimulus presentation. The paradigm of the study consisted of 210 dynamics, the number of target stimuli was 30. A spectroscopic voxel measuring 20'10'15 mm<sup>3</sup> was placed in the activation area.

Statistical analysis demonstrated that without a load all measured values are constant. The load effect is observed for two parameters: [Hb]/[dHb] (BOLD) and NAA. For [Hb] we observed three kinetically discriminable processes involving at least four kinetic stages. The variation of the NAA concentration follows similar kinetics.

Analysis has revealed six kinetically discriminable stages. The oxygen consumption activation processes are kinetically related to the concentration dynamics of the NAA as a neuronal marker. The developed approach reveals the multi-substrate character of the process and makes it possible to formulate hypotheses of the molecular response mechanisms. (Figures 1, 2, 3)

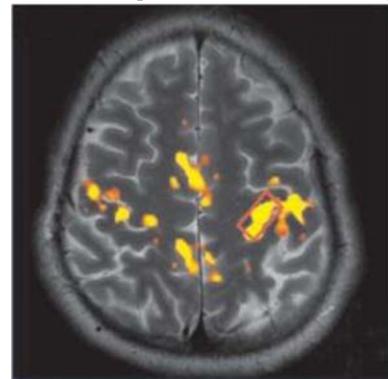

Fig 1 Position of the spectroscopic voxel in the axial T2-weighted brain images

### **New paradigms in child and adolescent psychodermatology: A case series from India**

D.K. Mohinder Singh<sup>1\*</sup>, R. Kalra<sup>2</sup>, R. Ghildiyal<sup>2</sup>

<sup>1</sup> Mahatma Gandhi Missions Medical College, Navi Mumbai, India, Department of Psychiatry, Mumbai, India; <sup>2</sup> Mahatma Gandhi Missions Medical College, Navi Mumbai, India, Department of Psychiatry, Navi Mumbai, India

\* Corresponding author.

**Introduction.**– There is sparse literature available in context of Child and Adolescent Psychiatry and Dermatology from India.

**Objectives.**– To report an interesting case series on Child and Adolescent Psycho-dermatology where patients were referred from Dermatology to Psychiatry.

**Methodology.**– Case Series. Case 1 was a 7 year old boy with Trichotillomania referred for further management. Case 2 was a 3 year old boy with Neurofibromatosis referred for developmental problems. Case 3 was a 4 year old girl with Tuberous Sclerosis referred for developmental problems. Case 4 was a 14 year old boy with Systemic Lupus Erythematosus referred for fearfulness. Case 5 was a 12 year old boy with Alopecia Totalis referred for counseling.

**Results.**– All the five cases were clinically diagnosed by the Consultant In charge in Child and Adolescent Psychiatry and advised further appropriate psychological assessments, referrals, treatment settings, pharmacotherapy and psychotherapy. Case 1 was diagnosed with Depressive Episode (Moderate with somatic syndrome) and received Syrup Fluoxetine 5 ml od and CBT. Case 2 was diagnosed with Autism with Self Injurious Behavior and received Syrup Risperidone 0.25 mg hsod and Autism Training. Case 3 was diagnosed with Global Developmental delay and advised Child Occupational Therapy. Case 4 was diagnosed with Organic Psychosis and advised Tablet Olanzapine titrated to 7.5 mg daily. Case 5 was diagnosed with Severe Depression without psychosis and advised Tablet Escitalopram (10 mg) and CBT.

**Conclusion.**– We perceive that child and adolescent psychodermatology is a fascinating new area of clinical research and recommend further original research with better methodology.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Alice in Wonderland syndrome. Case report**

R. Molina Cambra<sup>\*</sup>, A. Muñoz Domenjó, M. García-Poggio Fernández-Renau, J.F. Cruz Fourcade, S. Bravo Herrero, R. Martín Aragón, P. Muñoz-Calero Franco, M. Eliche Moreno, Á. Martínez Fernández, E. Ramos García

Hospital Universitario de Móstoles, Psiquiatría, Madrid, Spain

\* Corresponding author.

**Introduction.**– Alice in Wonderland Syndrome is a neurological disorder usually diagnosed in childhood. This syndrome is characterized by body-image distortion and disordered perception of distances, size, shape and spatial relationships between objects.

**Objectives.**– To know the different etiologies, clinical characteristics and outcome of the patients diagnosed with this syndrome.

**Methods.**– We review recent literature related to a clinical case admitted to our Psychiatric Emergency Service. A 14- year-old girl presented with a sense of strangeness consisting on changes in shapes and in spatial relation amongst objects, whilst being aware of the illusory nature of her perceptions. This picture appears in the context of a migraine in neurological follow-up. The patient had

psychological history and her neurologist appreciated that symptoms were stress-related.

**Results.**– After being evaluated by the Neuropaediatric Emergency Service, organic pathology is ruled out by EBV serological tests and imaging tests. Finally, Alice in Wonderland Syndrome was diagnosed in relation to migraine with atypical aura.

**Conclusion.** We should take into account the Alice in Wonderland Syndrome when patients present with the described symptomatology. This picture is unfrequent but alarming, with benign nature and spontaneous resolution in most cases.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The separation protocol during hospitalisation for suicidal behaviours in children and adolescents: A survey of French psychiatric practice**

M. Mourouvey Payet<sup>\*</sup>, L. Woestelandt, B. Golse Necker-Enfants malades Hospital, Child and Adolescent Psychiatry, Paris, France

\* Corresponding author.

**Objective.**– The study aimed to assess practices of French psychiatrists regarding the management of children and adolescents with suicidal behaviours, focusing on the use of the separation protocol. This framework, in which youth are separated from their relatives, appears to be a French practice, and is not formalized.

**Methods.**– We conducted an online survey. French psychiatrists caring for children and adolescents were asked to describe their practice of the separation protocol, via a questionnaire.

**Results.**– A total of 147 participants were enrolled in the study. Most of them worked in a university hospital. Children and adolescents who made a suicide attempt (SA) were systematically hospitalized in 61% of cases, compared to a rate of 20% in those presenting with suicidal ideations (SI). A separation protocol was set up systematically in 39% of cases, and on a case-by-case basis in 51%. The most common criteria cited were family relationship difficulties (78%). The mean age from which a separation protocol was indicated was 11.25 years. As for duration, 29% of participants reported a 24-48 hours period, and 21% a 48 hours period. Reasons given to justify use of the separation protocol were to allow a better clinical assessment (75%), and separate the child from a potentially harmful environment (57%). There were no significant differences between academic and non-academic practitioners regarding the characteristics of the separation protocol.

**Conclusion.**– This study confirms that the separation protocol is a widespread practice in France, despite the deprivation of liberty it implies. Studies need to be conducted to assess implications of this practice.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **“I am bigger than the sun”. Bipolar disorder in pediatric age**

V. Muñoz Martínez<sup>\*</sup>, C. Rodríguez Gomez-Carreño, E. Segura Escobar, B. Mata Saenz, L. Asensio Aguerri, L. Nuevo Fernández, G.A. Jimenez Londoño, L. Beato Fernandez Ciudad Real University Hospital, Psychiatry, Ciudad Real, Spain

\* Corresponding author.

With this case report we would like to make a review about pediatric bipolar disorder (BPD) and we want to describe the phe-

nomenclology and clinical characteristics of BPD in children. We present an 8 years old child who gets into our inpatient unit because of behavioural alterations.

**Methods.**– The parents describe symptoms like mood changes intense irritability and outbursts of anger. All of these symptoms are associated psychomotor restlessness and distractibility. He started to threaten his parents (“I’ll cut your head off”) and also verbalizes unusual contents, which impress of grandiloquence expressing their own omnipotence (“I am going to destroy the sun and the moon with spell”). Finally, the diagnose was an maniac episode in pediatric age.

**Results.**– Most DSM-5 symptoms of mania were common in the children and adolescents with BPD with the most common symptoms being increased energy, distractibility, and pressured speech. On average, four of five bipolar cases also showed threshold levels of irritable mood and grandiosity, and more than 70% of all cases showed elated/euphoric mood, decreased need for sleep, or racing thoughts. Roughly 69% of cases also showed poor judgment, whereas only half of bipolar cases demonstrated flight of ideas, and slightly more than one-third showed hypersexuality or psychotic features.

**Conclusions.**– The clinical picture that emerges is that of children or adolescents with periods of increased energy (mania or hypomania), accompanied by distractibility, pressured speech, irritability, grandiosity, racing thoughts, decreased need for sleep and euphoria/elation

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Psychotherapy integrative model of mental and behavior disorders children moved out of “anti-terrorist operation” zone**

B. Mykhaylov<sup>1\*</sup>, A. Kaafarani<sup>1</sup>, M. Vodka<sup>2</sup>, I. Vashkite<sup>2</sup>, T. Aliieva<sup>2</sup>

<sup>1</sup> Kharkiv medical academy of postgraduate education, Psychotherapy, Kharkiv, Ukraine; <sup>2</sup> International Charity Fund Alexander Feldman Fund, Psychotherapy, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**– Contemporary one of the most pressing problems in the Ukrainian health care is children’s mental health. The reason of this problem is the increasing number of extreme situations (military operations in the territory of Ukraine). Due to this we established the training model of specialists capable of carrying out psychosocial rehabilitation to victims of “anti-terrorist operation” (ATO).

**Objectives.**– The mental and behaviour disorders children affected of ATO. We studied 280 family: 110 adults and 170 children. The aim of the project was to optimize the provision of psychosocial support for children with problems of the psychic sphere by developing a system of psychotherapy adjustment and psychological education at the Centre for psychosocial rehabilitation of children. The basic component was the creation of the necessary conditions that expand the comfort and a safe space for the child to enhance positive impacts and mitigate negative impacts of the social environment.

**Methods.**– The leading role was played by a combination of three areas of work: psychotherapy (individual and family) psychocorrection (trainings, art-, hyppo-therapy) and social work.

**Results.**– In 86.5% of the children showed stabilization of mental and emotional state, reducing aggression, increasing motivation to social activity. In 58.0% of families - reducing conflict relations. **Conclusions.**– The non-standard integrative psychotherapy model, psycho-correction allowed organizing a fruitful and cre-

ative leisure. Provided of this model resulted in the reduction of aggression and anxiety, increased motivation for the successful development of new activities and problem-solving skills and conflict situations with peers and family members.

### **Use of asenapine in childhood, our experience**

L. Nuevo Fernández<sup>1\*</sup>, V. Muñoz<sup>2</sup>, L. Mella<sup>3</sup>, E. segura<sup>4</sup>, B. Mata<sup>5</sup>, L. Asensio<sup>4</sup>, P. Baos<sup>2</sup>

<sup>1</sup> Ciudad Real University Hospital, Psiquiatria Uhbij, Ciudad Real, Spain; <sup>2</sup> Hospital general Ciudad real, uhbij, ciudad real, Spain; <sup>3</sup> Hospital general Ciudad real, usmij, ciudad real, Spain; <sup>4</sup> Hospital general Ciudad real, uhb, ciudad real, Spain; <sup>5</sup> Hospital general Ciudad real, usm, ciudad real, Spain

\* Corresponding author.

**Introduction.**– In a childhood and adolescent inpatient unit, we could find different kind of pathologies (bipolar disorder, schizophrenia. . .) who need an hospitalization. In this study we are going to pay attention in those ones which we used asenapine like antipsychotic. In spite of the few studies presented to date, in our dairy practice we use them with efficacy and low secondary effects. Aim of the study: Analyze the use of asenapine in our unit.

**Methods.**– We analysed all the patients minors under 18 years old (N=1117) who were admitted in our inpatient unit a between 2009–June 2016. Our data were analysed with the SPSS program.

**Results.**– In the last 8 years (2009-2016), in our unit of hospitalization for children and adolescents (UHBIJ), 1711 children were evaluated in our emergency room (we do not include the patients in review or consultation). 1117 have been hospitalized with different pathologies. (aproximate 139 admissions per year). We have reported, in last three and a half years, 14 cases treated with asenapine. Their diagnoses were 71,4% bipolar disorder, 7,1% Attention deficit disorder and hyperactivity, 7,1% schizoaffective disorder, and 14,2% disrupt behaviour. We also analized other parameters like treatment dose (since 5 mg yo 10 mg), evolution, sex, age. . .

**Conclusion.**– The use of asenapine is a good treatment in patients who have mania and bipolar disorder but we find another uses (disrupt behaviour, schizoaffective disorder. . .) like others second-generation antipsychotic.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0121

### **Family functioning and socio-demographic features of children diagnosed with night terrors at a tertiary treatment center**

N. Özgedik<sup>1\*</sup>, A.E. Tufan<sup>2</sup>, M. Sari<sup>2</sup>

<sup>1</sup> Abant İzzet Baysal University, Faculty of Medicine, Psychiatry, Bolu, Turkey; <sup>2</sup> Abant İzzet Baysal University, Faculty of Medicine, Child and Adolescent Psychiatry, Bolu, Turkey

\* Corresponding author.

**Introduction.**– Besides the biological function of sleep is still largely unknown, sleep is seen as an important part of the healing process and is considered essential to life in the physical, neurological, and emotional areas.

**Methods.**– Records of patients evaluated in the past year (i.e. August 2016- August 2017) at the Department of Child and Adolescent Psychiatry of the Abant İzzet Baysal University Medical Faculty were

screened and those with a primary diagnosis of Sleep (Nigh) Terrors as per ICD-10 (F51.4) were recorded. The parents are contacted via telephone and General Functioning subscale of the Family Assessment Device (FAD) were completed. Data were entered into a database prepared via SPSS Version 20.0 (IBM Inc.) and descriptive statistics were used for analyses.

**Results.**– Within the study period 22 patients (59.1% female) with a mean age of 7.8 (S.D = 3.1) years were diagnosed with Sleep Terrors. Mean ages of mothers and fathers were found to be 36.1 (S.D = 6.7) and 38.3 (S.D = 6.9) years; respectively. Comorbidity with other psychopathology as well as family history of psychopathology were rare (9.1%; each). Mean score of FAD- General Functioning was found to be 1.6 (S.D = 0.6) and 72.7% of parents of children rated their family general functioning in the pathological range. Half of the children received symptomatic treatment (i.e. hydroxyzine) while others received psychoeducation and supportive therapy.

**Conclusion.**– Sleep terrors in school age children in our sample were mostly without comorbidity although symptoms were long-lasting and family functioning was poor.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0122

### **Retrospective follow-up data on the use of intramuscular paliperidone palmitate in adolescents and young adults**

V. Pereira Sánchez<sup>1\*</sup>, M. Arrieta<sup>1</sup>, N. Ferrer-Chinchilla<sup>1</sup>, M. Santos<sup>1</sup>, C. Llanes<sup>2</sup>, M.A. Alvarez de Mon<sup>1</sup>, P. de Castro-Manglano<sup>1</sup>  
<sup>1</sup> *Clinica Universidad de Navarra, Psychiatry and Medical Psychology, Pamplona, Spain*; <sup>2</sup> *Complejo Asistencial de Zamora, Servicio de Psiquiatría, Zamora, Spain*

\* Corresponding author.

**Introduction.**– Paliperidone palmitate, in its monthly and trimestral intramuscular administrations, has shown efficacy in the long-term treatment schizophrenia-spectrum disorders in adults. Data is scarce on off-label use in other disorders and in younger patients.

**Objective.**– To describe sociodemographic, clinical and follow-up data from adolescents and young adults in treatment with palmitate paliperidone.

**Methods.**– We conducted an observational retrospective follow-up collection of sociodemographic, clinical and outcome data from patients with ages ranging 15-30 years old and in treatment with monthly and trimestral palmitate paliperidone in our department of Psychiatry.

**Results.**– A total of 23 young patients received monthly or trimestral palmitate paliperidone. Most frequent primary diagnosis (61%) was oppositional defiant disorder (ODD); the rest where schizophrenia, bipolar disorder, substance abuse and others. Average age of patients was 21 years, and average duration of treatment was 8.9 months. Final dose widely varied from 50 to 150 mg/month. 87% of patients achieved antipsychotic monotherapy with this treatment. 77% required no psychiatric hospitalization after initiation of treatment; the rest were hospitalized once. 4% discontinued treatment due to adverse effects.

**Conclusion.**– Palmitate paliperidone has been safely used in adolescents and young adults in our clinical setting. The most associated diagnosis was ODD, and overall results suggest good tolerability and efficacy. More clinical trials with palmitate paliperidone and other long acting antipsychotic should be conducted in these populations in order to establish its clinical indications.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0123

### **An overview of recent findings on social anxiety disorder in adolescents and young adults at clinical high risk for psychosis**

M. Pontillo<sup>\*</sup>, S. Guerrero, O. Santonastaso, M. Tata, R. Averna, S. Vicari, M. Armando  
*Children Hospital Bambino Gesù, Neuroscience and Neurorehabilitation, Rome, Italy*

\* Corresponding author.

**Background.**– Some studies showed that anxiety is particularly frequent in the Clinical High Risk (CHR) for psychosis population. Notably, social anxiety disorder is identified as one of the most common anxiety disorder in CHR adolescents and young adults. Despite this, the frequency and the clinical significance of social anxiety in this population have been underestimated.

**Methods.**– A selective review of literature published between 2011 and 2017 on social anxiety disorder in CHR adolescents and young adults.

**Results.**– Five studies are included. In particular, three studies demonstrated that CHR adolescents and young adults have higher levels of anxiety compared to controls. Furthermore, anxiety, including social anxiety, is related to the severity of psychotic symptoms. The other studies included show inconsistent results regarding the possible relationship between social anxiety and social functioning.

**Conclusions.**– Social anxiety disorder was common in CHR adolescents and young adults and correlated with more severe attenuated psychotic symptoms (e.g. suspiciousness). Thus, assessment of social anxiety disorder, along with other anxiety disorders, should be standard for all CHR adolescents and young adults presenting for help. Future longitudinal studies on larger samples of CHR adolescents and young adults are essential to examine the relationship between anxiety disorder and transition to psychosis

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0124

### **Where is my home? Probe into adolescent attachment styles**

D. Prasad<sup>1\*</sup>, S. Dutta<sup>2</sup>, H. Naidu<sup>2</sup>

<sup>1</sup> *Nur Manzil Psychiatric Centre, Child and Adolescence Guidance Clinic, Lucknow, India*; <sup>2</sup> *Nur Manzil Psychiatric Centre, Department of Psychiatry, Lucknow, India*

\* Corresponding author.

**Introduction.**– Adolescence is considered as a transition period from childhood to adulthood. The duration of this stage is variable depending on biological, psychological and social stressors. Elements of attachment take their foundation early in life. Depending on the environment, the child will either become securely or insecurely attached. Aim: To examine the attachment patterns among adolescence and their later consequences.

**Method.**– We hereby present 5 case vignettes of adolescence with chief complaints of intense anger, self-harm, disordered eating and disobedience. Sessions primarily focused on ventilation with patient and parents. Information related to abuse, bullying at school, early childhood experiences and parental conflicts were explored.

**Results.**– It was found that adolescents failed to achieve a sense of security from the parental figure. Witness to abusive fights, strained home environment, emotional turmoil gathered a place in their minds. Resorting to harming oneself, extreme refusal of

food, pornography and gaming in excess and disobedience were manifested.

*Conclusion.*– Thus attachment holds a central place in the psychological journey of adolescence. Adulthood behaviour, coping mechanism, adaptive choices and development of mental health problems may be traced back to attachment styles.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0125

### Some questions of therapy of vegetative disorders in children and adolescents with depression

T. Proskurina<sup>1\*</sup>, E. Mykhailova<sup>1</sup>, T. Matkovska<sup>2</sup>, A. Goloborodko<sup>3</sup>

<sup>1</sup> SI Institute for Children and Adolescents Health Care of the Nat, psychiatry, Kharkov, Ukraine; <sup>2</sup> SI Institute for Children and Adolescents Health Care of the Nat2 V.N. Karazin Kharkiv National University, Ukraine, psychiatry, Kharkov, Ukraine; <sup>3</sup> V.N. Karazin Kharkiv National University, Ukraine, student 3rd year of education, Kharkov, Ukraine

\* Corresponding author.

*Background and aims.*– Vegetative dysfunction is one of the central manifestations of the affective pathology in children. Despite numerous studies concerning vegetative disorders treatment in children with depression, it remains a pressing problem at present.

*Materials and methods.*– A total of 120 children aged 12 - 14 with depression were involved in the study. Clinical psychopathological, somatic neurological, psychological (CDRS-R rating scale for depression in children, B. Mendelevych Test for the assessment of the neurotic status, scheme of investigation for recognizing the signs of vegetative disorders' by Vein AM, and neurophysiological methods (multidimensional linear and nonlinear investigation of brain dynamics -Kolmogorov-Sinai entropy (KSE)) have been used in the study.

*Results.*– It has been established that formation of clinical manifestations of vegetative dysfunction in children during puberty is based on emotional stress, imbalance of self-regulation processes, and depressive disorders somatization. The level of vegetative disorders, depression, asthenia and anxiety in adolescents corresponds to the criteria of the disease. A reduced adaptive capacity for loading (intellectual tests) has been diagnosed, which confirms a decrease in HRV parameters. The results obtained enable the authors to substantiate the strategy of intervention for correction of vegetative dysfunction in children with depression, precisely administration of neuropeptide (Semax, 0.1%) in combination with cognitive-behavioural therapy and low-power physiotherapy (electromagnetic radiation of millimeter range).

*Conclusion.*– The proposed complex provides regulation, anti-stress, vegetal stabilizing, adaptogenic, and neuroprotective effects in a very short time without pharmacobiologic load on the child's organism at puberty with preserving compliance and quality of life.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0126

### Description of neurodevelopment in children aged 0–5 years in child development centers

I. Ramos Vidal<sup>1\*</sup>, A.M. Romero Otalvaro<sup>2</sup>, M. Muñoz Argel<sup>2</sup>, A. Florez Rossi<sup>2</sup>, I. Villamil<sup>2</sup>

<sup>1</sup> Faculty of Psychology, Department of Social Psychology, Sevilla, Spain; <sup>2</sup> Universidad Pontificia Bolivariana, Psychology, Monteria, Colombia

\* Corresponding author.

*Introduction.*– Neurodevelopment is a dynamic process of interaction between the organism and the environment that results in the (a) organic and functional maturation of the nervous system, (b) the development of the psychic functions and (c) the structuring of the personality (Early Care White Paper, 2000). This process begins very early and continues several years after birth, with critical periods for normal brain development, the main ones being intrauterine life and the first year of life (Medina et al., 2015).

*Objectives.*– The study aimed to describe the characteristics of neurodevelopment in children 0-5 years old institutionalized in child development centers, the population is characterized by the presence of social variables such as extreme poverty and low educational level.

*Methods.*– The information was collected through the ASQ3 test administered to the parents of the children. The population consists of 213 participating mothers and/or parents.

*Results.*– The results show that 50.2% of the children are in a normal range of neurodevelopment measured by the scale; 26.2% at risk and 23.4% at low. The areas evaluated were communication, gross motor, fine motor, problem solving and socio-individual. The analysis by the areas shows that the fine motor skills present low performance compared to the other areas evaluated.

*Conclusions.*– The results of the study serve as a baseline to continue the path of diagnosis and early intervention

*Keywords:* Neurodevelopment; Child development and early intervention.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Anti-NMDAR encephalitis versus ADHD. Case report

N. Rodríguez Criado<sup>1\*</sup>, G.S. Fernando<sup>2</sup>, M.D. Andrea<sup>1</sup>, M.A. Ruben<sup>1</sup>, M.C.F. Paloma<sup>1</sup>, C.D.L. Nuria<sup>1</sup>, D.C.M. Ana<sup>1</sup>

<sup>1</sup> Hospital Universitario de Móstoles, Psychiatry, Móstoles, Spain; <sup>2</sup> Hospital Universitario de Móstoles, Psychiatry, Madrid, Spain

\* Corresponding author.

*Introduction.*– Isolated psychiatric episodes are infrequent but can occur as initial onset or relapse of anti-NMDAR encephalitis.

*Objectives.*– The aim of our study was to review the status of the issue by a case report.

*Methods.*– Literature research was carried out using Pub Med and Up-To-Date. Publication dates: 10 years. MeSH terms were “anti-NMDAR encephalitis” and “psychiatric episodes”.

*Results.*– A 15-year Caucasian male with progressive school failure, memory deficits and social isolation was referred to psychiatry. A.D.H.D study and neuropsychology tests were completed. Results were negative. 2 months later his condition worsened gradually. He was hospitalized because of neurological symptoms like hallucinations, delusions, disorganized thinking and insomnia. Screening for NMDAR antibodies was done because of decreased level of con-

consciousness and stupor with catatonic features. The results were positive and finally immunotherapy was successful.

**Conclusion.**– Patients with anti-N-methyl-D-aspartate receptor (NMDAR) encephalitis often develop prominent psychiatric manifestations. In patients with new-onset psychosis, having a history of encephalitis, subtle neurological symptoms, and/or abnormal results on supplementary tests should prompt screening for NMDAR antibodies. In summary, the results presented here suggest that little research has focused on. Recognition of these episodes is important because they respond to immunotherapy.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Serotonin syndrome in a 10 year old child: A case study**

D. Roy

*The Prince Charles Hospital Metro North Health Services, Acute Care Team, Dept. of Psychiatry, Chermside, Australia*

\* Corresponding author.

A 10-year-old Caucasian male who presented to the Emergency Department with worsening shortness of breath, malaise, and cough that were gradually worsening over the past 4 days. He had recently been seen by a private psychiatrist and commenced on Sertraline 2 weeks back at a dose of 25 mg mane and rapidly hiked to 150 mg within the fortnight!, In ED, patient was noted to be in distress with tachypnea and tachycardia. He was admitted with a diagnosis of possible pneumonia and was started on antibiotics. Within 24 hours of admission, patient went into respiratory distress with agitation, confusion and muscular rigidity. At this time, the possibility of serotonin syndrome was entertained.

Sertraline was ceased and general supportive treatment was provided. He showed rapid recovery after 5 days with follow-up.

**Discussion.**– This case displays a very typical presentation of serotonin (5-HT) syndrome (SS). The key learning point is the high index of suspicion to diagnose and treat this condition before it becomes fatal. SS is classically described by a triad of symptoms: mental status change, autonomic hyperactivity, and neuromuscular abnormality.

**Differential diagnosis.**– NMS, anti-cholinergic toxicity, malignant hyperthermia, meningitis. The key step towards diagnosis is a thorough history and physical examination. The most common clinical manifestations are neurological, autonomic, and neuro-muscular changes.

**Sternback/Hunter criteria.**– *Lab tests:* CPK or myoglobin levels can help in determining extent of muscle breakdown. *Management:* mostly supportive, cessation of any possible offending agents including SSRI, MOI inhibitors, antipsychotics,

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Psychoactive effects of nutmeg in an adolescent man: A case study**

D. Roy

*The Prince Charles Hospital Metro North Health Services, Acute Care Team- Dept. of Psychiatry, Chermside, Australia*

\* Corresponding author.

Mr. DB, a 14 year male who presented with a delirium like picture with extreme agitation, confusion and disorientation. He had a past diagnoses of ODD and polysubstance abuse (THC, ETOH etc). P/E and organic screen done showed no abnormality. A Urine Drug

Screen was not positive for any of the commonly used psychoactive substances.

On MSE, he displayed confusion and poor orientation to Time, Place and Person. His MMSE score was 24/30. At this stage, a detailed mental assessment was not possible, and so he was transferred to the Child and Adolescent Inpatient Unit. During the next day or so he was noted to be presenting with a fluctuating mental state and also seen to be responding to external stimuli which responded well to a trial of benzodiazepine (lorazepam 1–2 mg PRN to a max of 6 mg in 24 hrs).

He showed significant improvement in his mental state over the next 2 days and was discharged back home. On follow-up 2 weeks later he showed no features of a morbid mental state. However, he reported having used 5–6 crushed Nutmegs a day prior to hospitalization and that he had often done this with his friends in the past for the 'high' effects that it produced.

Nutmeg contains an active psychoactive compound called 'myristicin', belonging to the deliriant drug family. Effects can range from a mild high or 'stoned feeling' similar to THC to full-blown experience with auditory and visual hallucinations and shifts in perception.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Personal constructs of adoptive parents with the experience of care for children with significant developmental and emotional-behavioural disorders**

A. Ryzhov<sup>1</sup>, E.B. Zhuykova<sup>2</sup>, L.S. Pechnikova<sup>1</sup>, E.T. Sokolova<sup>1</sup>, M.A. Bebtshchuk<sup>3</sup>

<sup>1</sup> Lomonosov MSU, Faculty of psychology, Moscow, Russia; <sup>2</sup> Institute of Integrative Family Therapy, Department of developing family forms of care of children, Moscow, Russia; <sup>3</sup> G.E. Sukhareva Scientific and Practical Centre of Mental Health of Children and Adolescents, Director, Moscow, Russia

\* Corresponding author.

**Introduction.**– The current social policy in Russia actively encourages adoption and fostering of children with developmental abnormalities. The discrepancies between parental expectancies and attitudes with child's behaviour, disillusionment with their perceived ability to cope with problems arisen increases the risk of family crisis and eventual placement failure.

**Objective.**– To study how the experience of care for children with serious developmental disorders or mental illnesses is related to expectancies and parental attitudes.

**Methods.**– A modification of repertory grid technique was used, with parents ranking the pictures of supposedly parent-less children, as well as own family members. Quantitative indexes of construct differentiation and element distances, content-analysis of constructs and qualitative analysis of each grid were employed. Responses of parents of 16 families with adopted children with serious developmental and behavioural disorders (all resulting in stationary psychiatric care necessity) were compared to 12 control adoptive families and 20 families without adopted children.

**Results.**– No significant differences on single indexes between groups were found. The parents from under investigation group were both low and high scorers defined by interquartile range. Qualitative analysis permitted to describe some characteristic patterns of how the experience of care for difficult children influence construing: the simplified construing (with use of problematic children as reference element or stigmatizing), the monolithic con-

struing with fusion of images of self and adopted children, loosened construing with projection of idiosyncratic beliefs.

**Conclusions.**– The impact of experience of care for seriously disturbed children isn't unimodal. It is not determined by severity of child disturbances only.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Spiritual psychotherapy for adolescents with conduct disorder

M. Salmanian<sup>1\*</sup>, M. Mohammadi<sup>1</sup>, B. Ghobari-Bonab<sup>2</sup>, J. Bolhari<sup>3</sup>  
<sup>1</sup> Psychiatry and Psychology Research Center, Tehran University of Medical Sciences, Psychiatry and Psychology Research Center, Tehran University of Medical Sciences, Tehran, Iran; <sup>2</sup> Psychology and Education of Exceptional Children Department, University of Tehran, Psychology and Education of Exceptional Children Department, University of Tehran, Tehran, Iran; <sup>3</sup> School of Behavioral Sciences and Mental Health, Iran University of Medical Sciences, School of Behavioral Sciences and Mental Health, Iran University of Medical Sciences, Tehran, Iran

\* Corresponding author.

**Objective.**– The global burden of conduct disorder is considerable, especially in males. Majority of studies showed that spirituality has significant effect on delinquent and antisocial behaviours. we designed the Spiritual Psychotherapy Package for Adolescents with Conduct Disorder and executed it as a random clinical trial with control group.

**Method.**– Qualitative content analysis and focused sessions with experts were used to design the package and its validity was assessed by experts. The package was executed for 30 adolescents with conduct disorder aged 14 to 18 years in 4 experimental groups at Tehran reformatory as a random clinical trial. Aggression Questionnaire, and The Attachment to God Inventory were completed. Outcome measurements in experimental group were compared with control group who was 30 adolescents with conduct disorder in the same reformatory, in the pre-post package administration and after 6 month follow-up.

**Results.**– Four main themes were extracted from the data analysis: 1) Object relations based on insecurity and fear; 2) Object relations based on inability and abjection; 3) Object relations based on pessimism and mistrust; 4) Object relations based on non-maintenance of boundaries and limits. The findings of the clinical trial showed significant difference in avoidance attachment to God in experimental group as compared to control group. Also, we found significant decrease in anger measurements in experimental group at post-treatment and follow-up as compared to pre-treatment.

**Conclusion.**– The findings of this study indicated effectiveness of the Spiritual Psychotherapy Package for Adolescents with Conduct Disorder in reducing anger and avoidance attachment to God.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Study of the pattern of psychotropic medications prescribed for children referred to child psychiatry clinic, Mansoura University Hospital

A. Samy\*, M. El-wasify, M. El-Hadidy, S. Tobar  
 Mansoura university hospitals, Psychiatry, Mansoura, Egypt

\* Corresponding author.

**Introduction.**– The number of children diagnosed with psychiatric disorders as well as the use of psychotropic drugs in children has increased significantly in the past two decades. This situation is of concern because it is not clear that the benefits of many psychotropic medications exceed the potential harms in children. To the best of our knowledge there are no regional studies in Egypt that review and summarize the pattern of psychotropic prescriptions in children.

**Objectives.**– Degree of concordance between psychotropic medications prescribed for children referred to child psychiatry clinic, MUH and the Maudsely guidelines.

**Methods.**– All the enrolled patients were subjected to:

- clinical assessment using the Arabic version of MINI KID;
- the socio-economic status scale for health research in Egypt;
- the study population prescriptions were reviewed to assess those pattern versus the Maudsely guidelines, 12th edition.

**Results.**– (Table 3)

Table 3 Distribution of psychotropic drug prescription within the studied group.

Drug categories	No. (%)
Antipsychotics drugs	154 (56.6)
stimulants atomoxetine	27 (9.9)
anticonvulsants	94 (34.6)
behavioral therapy	42 (15.4)
antidepressants	
Mono-therapy	187 (67.3)
Combined therapy	89 (32.7)
	Median (Min.-Max.) for combined therapy 2 (2-5)

**Conclusions.**– The degree of concordance between psychotropic medications prescribed for children referred to child psychiatry clinic, MUH and the Maudsely guidelines was ordered as follow:

- 42.3% disagreed;
- 34.2% partially agreed;
- 23.5% totally agreed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### A case report of how abuse can spark mania in children

A. Seker\*, S. Ozmen

Erciyes University, Child and Adolescent Psychiatry, Kayseri, Turkey

\* Corresponding author.

**Introduction.**– According to a recent meta-analysis, the overall rate of Bipolar Disorder (BD) among youth aged 7-21, is 1.8%. It is also known that certain traumatic experiences such as abuse can trigger the symptoms.

**Objective.**– To emphasize that all forms of abuse need to be questioned, regardless of the provided reasons for the patient's referral.

**Aim.**– To provide an example of a complicated case of how abuse and trauma may end up in a chain of full-blown manic episodes (BD 1).

**Methods.**– Literature review in scientific database and case report presentation.

**Results.**– A 7-year-old girl was brought to our clinic with complaints about irritability, grandiose manners, attention problems, lack of sleep and increased talkativeness which were going on for the last 3 weeks with on-off periods. She had numerous relatives -including her father- who were suffering from psychosis/BD. No organic pathology could be detected through neurological testings (EEG, MRI) or blood tests. When further questioned, her mother told the girl had been molested by a man some weeks ago. These

mood swings had started right after this incident. She went through another manic episode until being stabilized by Aripiprazole.

**Conclusion.**– It can be difficult to suspect/question abuse when the child is admitted to the clinic with seemingly irrelevant complaints. Yet, it is of vital importance that a child psychiatrist keeps in mind that abuse might be the underlying reason for many cases of psychopathology.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0134

### **Suicidal risks in juvenile bipolar versus major depressive disorders: Systematic review and meta-analysis**

G. Serra<sup>1\*</sup>, F. De Crescenzo<sup>2</sup>, M.P. Casini<sup>1</sup>, R.J. Baldessarini<sup>3</sup>, S. Vicari<sup>1</sup>

<sup>1</sup> Pediatric Hospital Bambino Gesù, Department of Neuroscience, Roma, Italy; <sup>2</sup> Catholic University of the Sacred Heart, Institute of Psychiatry and Psychology, Roma, Italy; <sup>3</sup> McLean Hospital, Harvard Medical School, Department of Psychiatry, Belmont MA, USA

\* Corresponding author.

**Objective.**– Suicide attempts are prevalent in association with major mood disorders, and risk is greater with bipolar disorder (BD) than major depressive disorder (MDD) in adults. There may be similar relationships in juvenile mood disorders, but the evidence has not been compiled systematically and quantitatively.

**Method.**– We searched for reports of studies comparing rates of suicide attempts in children or adolescents diagnosed with BD or MDD, and applied random-effects meta-analysis.

**Results.**– In 6 reports from 1995 to 2017, with 2,303 participants diagnosed with mood disorder from the United States and South Korea, aged 3 to 18 years, rates of suicide attempts differed significantly by diagnosis: BD (31.5%) > MDD (20.5%) > hypomania or mania-only (8.49%). Risk of suicide attempts differed (BD > MDD) highly significantly by meta-analysis (OR = 1.71, CI = 1.33–2.20,  $p < 0.0001$ ), and was very similar if a study with attempts and suicidal ideation was excluded (OR = 1.64, CI = 1.26–2.14,  $p < 0.0001$ ).

**Conclusion.**– Risk of suicide attempts in juvenile mood disorder patients ranked: BD > MDD » hypomania or mania-only » juvenile general population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Emergency referrals to liaison psychiatry department in a busy Dublin Pediatric Hospital, with a focus on deliberate self harm presentations, 2011–2015; trends over time**

S. Sexton

Lucena Clinic, Child and Adolescent Psychiatry, Dublin, Ireland

\* Corresponding author.

**Introduction.**– The Paediatric Liaison Psychiatry Department in the Children's University Hospital (CUH) serves one of the busiest Emergency Departments in Europe for children under 16 years of age.

**Objectives.**– To analyse all referrals to the Paediatric Liaison Psychiatry Department in the Children's University Hospital (CUH) with a particular focus on deliberate self-harm (DSH) presentations. In terms of service need, demographic and clinical and characteristics and service use. To compare these DSH presentations in terms

of socio-demographic and clinical characteristics with a previously published cohort from this centre.

**Methods.**– Clinical database and chart reviews. Descriptive and analytical statistics using SPSS version 23

**Results.**– In terms of service need, there were 1256 presentations involving 1087 individuals who were referred for a psychiatric assessment to the Liaison Psychiatry Service. There has been a five-fold increase in DSH presentations compared with the earlier study. There was a high rate of non-school attendees (10%). The most common method of self-harm was an overdose with paracetamol. The rates of self-cutting which increased from 15% ( $n = 33$ ) in 2012 to 25% ( $n = 67$ ) in 2013. In terms of service use, the rate of admission to CUH for continuing care was 43% ( $n = 533$ ) over the five year period, and the average length of stay was 2.11 days.

**Conclusions.**– The majority of these cases were discharged to the community after a psychosocial and psychiatric assessment and those requiring admission were discharged in under 3 days reflecting the crisis nature of many of these presentations.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0136

### **Effectiveness of treatment for children with ADHD and autism with noofen**

M. Shahini\*, A. Ahmeti

University Clinical Center of Kosova, Child and Adolescent Psychiatry, Prishtina, Kosovo

\* Corresponding author.

Attention Deficit Hyperactivity Disorder (ADHD), especially when it is in comorbidity with autism, is a challenge in psychiatric treatment. Noofen has been found to have demonstrated a positive effect on ADHD children by improving cognitive, self-control, focus, attention distribution, and verbal memory. The purpose of this study was to assess the effectiveness of Noofen in the treatment of Hyperactivity and Autism in children ages 4–11. Participants were children who have sought medical help at the Mental Health Center for Children and Adolescents.

In this pilot study are included 12 children, and it was done during 2016, over a period of three months. 10 of the participants were male and two females. The average age of the participants was  $M = 7.08$  ( $SD = 2.46$ ). Children have been diagnosed with childhood psychiatric hyperactivity disorder and are treated with NOOFEN with an average dose of 250 mg to 500 mg. The NOOFEN Dosage was made according to a psychiatric preparedness scheme. The results showed that 11 children had improved symptoms of hyperactivity, while one of the children reported improvement, but was discontinued due to the anaesthetic effect (headache). Participants were also monitored through CBCL in improving the symptoms of hyperactivity as well as through direct interviews with parents.

This pilot study has shown that treating the symptoms of hyperactivity with attention deficit as well as some of the symptoms of autism is effective in the short term, especially in attention and language but we do not currently have the effects for a longer time.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## Autism spectrum disorder: Organization of treatment and parental perceptions

A. Subbotkina

Rehabilitation Center "Ogonek", Rehabilitation Department, Moscow, Russia

Despite there is no proof that most of medically induced methods of correction of ASD, arranging medical treatment of ASD is based on combination of various interferences.

Our experience of dealing with parents of children with ASD shows that in 95% of observations scientific substantiation of a stimulation method is not of priority importance.

Otherwise, when parents run across a new method for the first time, medical personnel was required to explain what therapy needed to be applied. However, the main reason, when making a decision, was interaction with other parents. In 3% of observations the decision was made by parents after their 5<sup>th</sup> visit.

The main motivation component in making the decision was visible reduction of certain symptoms in other children's cases.

Fifteen percent of parents after the first visit of trainings had questions about physiotherapy methods, dynamic proprioceptive correction and massage, though during the initial examination there was no misunderstanding on their part. After the second explanation of how the method works there were no more questions.

Such stimulation methods as transcranial direct current stimulation, lingual correction, sensory integration and behaviour therapy caused no questions from parents. Also there were no questions about the course duration and the timing of each stimulation.

## The association of sleep onset latency and sleep duration with psychologic problems according Strengths and Difficulties Questionnaire (SDQ) in Siberian adolescents: The school-based study

S. Tereshchenko\*, M. Shubina

Scientific research institute of medical problems of the North, Department of child's physical and mental health, Krasnoyarsk, Russia

\* Corresponding author.

The SDQ was developed by R. Goodman [J Child Psychol Psychiatry. 1997 Jul;38 (5):581-6] as a brief psychopathological screening tool that has been recommended for the detection and classification of psychosocial problems in adolescents. Data regarding the SDQ assessment in adolescent with sleep disturbances are limited.

*Materials and methods.* – A total of 481 urban Siberian (Krasnoyarsk) adolescents (aged 12-18; boys/girl ratio 213/268) were tested with self report version of SDQ questionnaire and sleep characteristics. Adolescents were asked "During the past month, how long (in minutes) has it usually taken you to fall asleep each night?" to estimate sleep onset latency. Bedtime and wake-up time on school days were assessed with the question: "At what times (hours:minutes) do you usually go to bed and wake up on school days?" Data are shown as median (25-75% quartiles). Kruskal-Wallis test was used.

*Results.* – Significant positive associations were detected between sleep onset latency and SDQ total difficulties score with more

remarkable progressive increasing in adolescents with emotional problems (Table 1). Hyperactivity score exhibited progressive association with sleep time reduction (mainly due to late time of "going to bed").

Table 1. Sleep onset latency in adolescents with different SDQ points subgroups (min).

Table (3): Distribution of psychotropic drug prescription within the studied group

Drug categories	No. (%)
Antipsychotics drugs Stimulants Atomoxetine Anticonvulsants	154 (56.6) 27 (9.9) 94 (34.6) 42 (15.4) 23 (8.5) 15 (5.5)
Behavioral therapy Antidepressants	
Mono-therapy	187 (67.3)
Combined therapy	89 (32.7) Median (Min.-Max.) for combined therapy 2 (2-5)

Table 2. Sleep duration in adolescents with different SDQ points subgroups (hours:minutes).

Table 1. Sleep onset latency in adolescents with different SDQ points subgroups (min).

SDQ scales	Self rated SDQ (points subgroups)			
	Average (unlikely to be clinically significant) n=314	Slightly raised (may reflect clinically significant problems) n=114	High (substantial risk of clinically significant problems) n=53	p
Total difficulties score	15,1 (14,3-16,0)	22,7 (19,4-25,9)	29,8 (24,6-34,9)	0,002
Conduct problems score	16,2 (15,2-17,2)	20,1 (18,0-22,2)	24,0 (19,2-28,9)	0,098
Emotional symptoms score	16,5 (15,5-17,6)	21,3 (16,3-26,3)	24,2 (20,9-27,4)	0,022
Hyperactivity score	16,9 (15,8-17,9)	21,6 (18,4-24,9)	19,6 (15,7-23,6)	0,075
Peer problem score	16,1 (15,0-17,2)	22,3 (19,7-24,8)	17,1 (15,1-19,1)	0,052

*Conclusion.* – Sleep onset latency increasing may be used as surrogate marker of psychosocial problems in adolescents, especially those with emotional problems (Table 2)

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0139

## Conduct disorder and ADHD in children with soiling and encopresis -- Albanian experience

S. Tomori\*, E. Dervishi, V. Velmishi, P. Cullufi

University Hospital Center "Mother Teresa", Pediatric Service, Tirana, Albania

\* Corresponding author.

*Objective.* – To evaluate the presence of mental health comorbidities in children suffering from fecal soiling or encopresis in gastroenterology-endocrinology-neurology unit of pediatric hospital.

*Materials and methods.* – A total of 22 children outpatients and inpatients, aged 4 to 13 years old, with fecal soiling, encopresis or functional constipation, were assessed for mental health diagnoses based on clinical evaluation and were diagnosed based on DSM-IV-R. Their parents completed the Albanian version parent report form of Strength and Difficulties Questionnaire (SDQ). SDQ is a screening instrument of emotional and behavioural problems in children and adolescents.

*Results.* – The overall frequency of any psychiatric symptom in the sample of children was 68.2 percent. Among the evaluated children the most prevalent symptoms were those of conduct disorder (68%), than peer problems (54%), emotional symptoms (45%), hyperactivity symptoms (41%). One in three children had also enuresis as a comorbidity and 40% had symptoms of separation anxiety disorder. There were not any statistically significant differences between sexes in the frequency of psychological disorders.

*Conclusions.* – Conduct disorder tends to be prominent in children with encopresis, it is evident that majority of them are prone of

stigma and this is associated with high levels of distress for both children and parents. Higher frequency of hyperactivity symptoms and ADHD and emotional symptoms warrants more specific evaluation of possible causes of these high frequency rates.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0140

### **Psychosocial aspects related to adolescent fatherhood: A systematic review**

E.R. Turato\*, F.G.C. Surita, J.V. Freitas-de-Jesus

Laboratory of Clinical-Qualitative Research–Department of Medical Psychology and Psychiatry, State University of Campinas, Brazil

\* Corresponding author.

*Introduction.*– The physical and psychosocial risks of teenage pregnancy have been described broadly, but studying the mental health and life experiences of adolescent fathers has been neglected. Researchers have shown some negative effects, like decreasing years of schooling, early marriage, and jeopardizing on labour market outcomes. A systematic review may contribute to add solid evidence about this issue.

*Objective.*– To understand the psychosocial issues related to adolescent fatherhood.

*Methods.*– Following the PRISMA Checklist, original articles were included. Participants were adolescent fathers between 10 and 19 years old. Psychosocial aspects were described as: negative emotional disorders, externalizing behaviours, self-esteem, meanings related to fatherhood, emotional experiences, interpersonal relationships, and social support. MEDLINE, EMBASE, PsycINFO, Web of Science, and CINAHL were accessed, using the terms: (paternity OR fatherhood) AND adolesc\*. Studies published from 2012 to 2016 were included. Two authors screened the titles and abstracts independently, as well as the full text. A senior author accessed disagreements.

*Results.*– In short, 536 records were identified, 99 full-text articles were assessed, and 16 studies were included. We provided a narrative synthesis and 8 categories emerged: (1) Fatherhood: role of provider, feelings, and expectation; (2) Contraception, love, and sex; (3) Family and social relationships; (4) Education: a look to the future; (5) Commitment and access to partner and baby; (6) Identity and gender role; (7) Mental health; and (8) Criminality and externalizing behaviour problems.

*Conclusions.*– Main results point out adolescents assume fatherhood as transformative, besides facing difficulty on becoming fathers, especially considering the role of provider.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0141

### **Psychological problem among children who are sexually abused**

M.M. Uddin Ahmed

Bandhu Social Welfare Society, Training Unit, Dhaka, Bangladesh

*Background and aims.*– Sexual abuse referred to as molestation is the forcing of undesired sexual behaviour by one person upon another. And child sexual abuse is a form of child abuse in which a child is abused for the sexual gratification of an adult or older adolescent. The aim of the study was to explore psychological problems among children who are sexually abused.

*Materials & method.*– Sample of the study comprised of 29 children who are sexually abused and got service from YVC center of

BSWS through peer education at cruising spot. The age range of the participants was between 12–18 years. Among these children male (MSM) child was 20 and TG children were 09. All the children were from lower social economic status. All the cases were referred from cruising spot. Qualitative study was used as a focus group discussion (FGD) and in-depth interview (IDI) design. To collect data, in depth interview and socio-demographic questionnaires were used. Content analysis was used to analyze qualitative data.

*Results.*– The major findings comprised of two sections. The first one describes the nature of child sexual abuse among the sample and the section two describes four major domains of psychological problems and behavioural problems.

*Conclusion.*– So at last it can be said that sexually abused children suffers from long term negative effects. It is likely that stigma and discrimination against these groups has had a number of negative consequences for this group, many of which are connected with increased long traumatic risk.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Problem behavior management through the use of informative material and shared reading stories among four-year olds in a Brazilian school**

A.P. Rodrigues, C. Varanda\*

Universidade Paulista, Institute of Human Sciences, Santos, Brazil

\* Corresponding author.

This study investigated and intervened in behavioural difficulties among 37 four-year-old children from a municipal school in Santos/SP, Brazil. The Inventory of Behaviors of Children and Adolescents - Report for Teachers (C-TRF) was used for behavioural assessment. Descriptive statistics showed a preponderance of externalizing behaviours, evidencing aggressive behaviour and attentional problems. Inferential analysis showed that aggressive behaviour and attentional problems were correlated, which was expected once both are classified as externalizing ones. The internalizing behaviour “withdrawn” was correlated to “attentional problems” and “aggressive behaviour” suggesting that once the child cannot keep his/her attentional focus to what is happening, he/she disconnect of the environment and withdraws. The externalizing behaviours were the most cited by the two teachers, perhaps because they are the most easily identifiable and those that cause the most need for management. Positive Behavior Support (PBS) was used focusing on the management of problem behaviours and on the promotion of prosocial behaviour. Teachers were instructed through printed material created by the second author based on the PBS model and also through the proposal of shared reading children’s books, highlighting sociocognitive aspects of the chosen stories. The effectiveness of the interventions was verified through a questionnaire answered by the teachers, which was qualitatively analysed. The results showed attentional improvement and a broader interest for shared reading. The need for more effective school administrative support for the teachers to use and develop those strategies was pointed out and should be addressed in future research.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Emotional dysregulation in our adolescents is it a risk of depression?

A. Vargas Castro\*, J. Servaye

Centre Hospitalier Jean-Martin Charcot, Pédopsychiatrie, Paris, France

\* Corresponding author.

The World Health Organization (WHO) has defined: Depressive disorder will be the main cause of incapacity for industrialized societies in the year 2020 (WHO,2001). In the same way, the WHO draws attention when describing that between 15% and 20% of Adolescents would have this kind of pathology in the course of their lives (Labelle et Bedwani, 2011).

Emotional dysregulation can be observed within the normal process of biopsychosocial neurodevelopment during childhood and specifically during adolescence (Mc. Elroy,2015). However, emotional dysfunctional dysregulation is a characteristic of many child & adolescents mental disorders. In fact, the emotional dysfunctional dysregulation could be found in depressive disorders, where the family dysfunction plays an important role (Bienvenu et Davydow,2011).

The objective of this article is to describe a clinical case in our practice and work in mental health with children and adolescents. We would like to identify the symptoms and signs of emotional dysfunctional dysregulation in an adolescent, a diagnostic hypothesis, a psychotherapeutic plan, the psychoeducation and the psychopharmacological option.

Finally, We would like to conclude as the emotional dysfunctional dysregulation in adolescents is obligatory study of comorbidity and specialized clinical approach to avoid the chronically irritability and the possible consequences both epigenetic and biopsychosocial.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0144

### Impulsivity, emotional dysregulation and bipolar spectrum in adolescents. Evolution and treatment in one adolescent with comorbidity between odd, ADHD, impulsivity, emotional dysregulation and bipolar spectrum

A. Vargas Castro\*, J. Servaye

Centre Hospitalier Jean Martin Charcot, Pédopsychiatrie, Île-de-France, Paris, France

\* Corresponding author.

**Introduction.**– The irritability and Emotional Dysregulation are causes of consulting that increase day by day in our services of Child & Adolescent Mental Health. This irritability and impulsivity dysfunctional in adolescents, must be studied in their overall states. **Background.**– There is a high comorbidity between the impulsivity, frequent irritability, outburst of anger, inattention, hyperactivity and greater degree of oppositional defiant behaviour seen in Externalizing disorders, and Bipolar Spectrum or Bipolar disorder(BD), being a challenge to diagnosis and treatment in adolescents. **Objective.**– Demonstrate by reviewing a case, the diagnostic comorbidity between Oppositional Defiant Disorder (ODD), Externalizing Disorders, Attention Deficit Disorder with Hyperactivity(ADHD), associated with a pattern of Bipolar Spectrum, its effective psychotherapeutic and psychopharmacological treatment.

**Methodology.**– A twelve-years-old adolescent,with a four year history of hypoprosexia, hyperactivity, inattention, and impulsivity in the context of family dysfunction. There was also occasional hyperphagia. He had received psychotherapeutic and psychopharmacological treatment to ODD, then to Attention Deficit Disorder with Hyperactivity and increased symptoms. We needed to change the psychopharmacological treatment, because still the sintomatology with irritability, distractibility, restlessness, anger outburst, hyperactivity, grandiosity and dysphoria. In the test of Young Mania Rating Scale and HCL-32,the results were compatible with BD. The new pharmacological treatment were with Antipsychotic. He had psychotherapeutic management-social skills- and family therapy. HAS (Haute Autorité de Santé). Now the prognosis is better(CHIP-AE),and there is absence of irritability.

**Conclusions.**– The irritability dysfunctional, emotional dysregulation and impulse control deficits, have a high etiopathogenic relationship with Bipolar disorder in Adolescents, where the same psychotherapeutic treatment could be effective. However, the psychopharmacological treatment is a challenge and should be monitoring step by step.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Physiological correlates of clinical symptoms in autism spectrum disorders

S. Velikova<sup>1\*</sup>, S. Polevaia<sup>1</sup>, V. Dvoryaninova<sup>2</sup>, S. Parin<sup>3</sup>, L. Savchuk<sup>1</sup>, A. Safonov<sup>3</sup>, K. Gromov<sup>3</sup>, A. Fedotchev<sup>4</sup>, O. Balandina<sup>2</sup>

<sup>1</sup> Nizhny Novgorod State Medical Academy, Central Scientific Research Laboratory, Nizhny Novgorod, Russia; <sup>2</sup> Institute of Pediatrics, PFMRC of Russian Ministry of Health, Nizhny Novgorod, Russia; <sup>3</sup> N.I. Lobachevsky State University of Nizhny Novgorod, Laboratory of Psychophysiology, Nizhny Novgorod, Russia; <sup>4</sup> Institute of Cell Biophysics, Russian Academy of Sciences, Pushchino, Russia

\* Corresponding author.

**Introduction.**– Autism spectrum disorders (ASD) display significant heterogeneity, therefore identification physiological correlates to the clinical symptoms is of practical importance for subtyping the cases, planning personalized treatment and assessment the pathophysiological dynamics.

**Objective.**– Searching for correlates to clinical symptoms (estimated in accordance with the Autism Diagnostic Observation Schedule-ADOS) in ASD, using electroencephalographic (EEG) and Heart rate variability (HRV)-based assessments.

**Methods.**– Seventeen children with ASD (5.4 ± 2.5 years) were recruited. EEG (19-channel) in parallel with HRV was recorded at rest with closed eyes. EEG functional connectivity (LORETA-based analysis of absolute phase) was assessed with Neuroguide software. Further, obtained data were subjected to correlation analysis (Spearman *r*) with ADOS evaluation data.

**Results.**– Z-score based EEG comparison with normative database, demonstrated significant differences in absolute phase between different Brodmann areas (BA) areas, but most prominent among the areas within somatosensory cortex (BA1,2,3), observed in all children. Partial correlation analysis (EVfactors age, gender) showed: a negative correlation between the stereotypic use of words/phrases and absolute phase between right BA1/BA3 and BA2/BA3 for beta bands; the quality of social reaction correlated negatively with the absolute phase between BA1/BA2 and BA1/BA3 for delta and theta in the left, and for beta in the right hemisphere; HRV-based index 'low versus high frequency', correlated positively with initiation of joint attention( $r=0.006$ ) and quantity of social initiatives ( $r=0.022$ ).

**Conclusions.**– Analysis of EEG functional connectivity can be useful for objective evaluation of ASD symptoms. HRV can be applied to distinguish the contribution of stress to the presented clinical symptoms in ASD.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Modular therapeutic interventions for maltreated children and young people: A focus on the mental health of refugee children on the move in Europe**

E. Vizard\*, J. Gray, M. von Werthen

UCL Great Ormond Street Hospital, Institute of Child Health, London, United Kingdom

\* Corresponding author.

**Introduction.**– Children and adolescents being forced to flee their homes in an attempt to escape war, persecution, organised violence, and political or religious unrest is a global issue (BBC Radio 4, 2016; UNHCR, 2014). Children on the move are subjected to a multitude of possible traumatic events including the witnessing, experiencing and forcible participation in extreme violence and killing, alongside losses of family, security, and property, and overall upheaval. Such cumulative traumas are extremely damaging to the mental health of these children, with notably high rates of PTSD, depression and anxiety disorders. As a result, they often show signs of biologically embedded 'toxic stress' due to extreme, prolonged exposure to unpredictable stressors. Research demonstrates the benefits of a modular approach, using 'common practice elements' with children who have experienced violence and related trauma.

**Objectives.**– Increased awareness of the mental health needs of refugee children on the move in Europe. Presentation of the HfCF guides for intervention with children who have suffered violence and related trauma.

**Methods.**– Findings from a review of the literature will be presented. Advice on using the intervention guides will be given.

**Results.**– The workshop conclusions will be submitted in a paper to European Psychiatry.

**Conclusion.**– Mental health treatment recommendations will be made for refugee children on the move in Europe.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0147

### **Resignation syndrome in refugee children in Sweden**

A.L. von Knorring<sup>1</sup>\*, E. Hultcrantz<sup>2</sup>

<sup>1</sup> Uppsala university, Dept. of Neuroscience- Child and adolescent psychiatry, Uppsala, Sweden; <sup>2</sup> Linköping university, Dept. of otolaryngology, Linköping, Sweden

\* Corresponding author.

**Introduction.**– Sweden has the highest rate of refugees per capita in Europe. Many traumatized refugee children have been affected by a longstanding disorder: "resignation syndrome" during the last two decades.

**Objectives.**– The aim is to describe the background, onset, course, and recovery of the disorder.

**Methods.**– A total of 50 children are examined and followed from onset and through recovery.

**Results.**– Most children come from ethnic minorities in the former Soviet Union or Balkan States. Flight from their homeland has been

due to severe trauma to family members which was witnessed or directly experienced by the later sick child. The first symptom is the child's resistance to eat and drink, and he/she becomes mute. General mobility is lost and so is sensibility for pain. The children usually come to the hospital in a stupor or catatonia-like state. After hydration, tube-feeding is initiated. When establishing a confidence that they are safe and secure, usually with a residency permit, which can take years, the children slowly begin to recover. The tube can usually be removed after 3 months and return to school after 6–12 months. Depressive symptoms are common long after "recovery".

**Conclusions.**– The acute threat of deportation back to a place where the children experienced a severe trauma re-activates their unbearable fear and stress and causing the catatonia-like condition. The onset can be acute in connection with a negative decision in their asylum process or as a result of a progressive depression during the long waiting time for a decision.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0148

### **Study of psychosocial profile and health related quality of life of sufferers of pediatric malignancies**

E. Zaky<sup>1</sup>\*, R. Elhossiny<sup>2</sup>, D. Elnasharty<sup>2</sup>

<sup>1</sup> Professor of Pediatrics and Head of Child Psychiatry Unit- Faculty of Medicine- Ain Shams University, Pediatrics, Cairo, Egypt; <sup>2</sup> Faculty of Medicine- Ain Shams University, Pediatrics, Cairo, Egypt

\* Corresponding author.

**Background.**– The great advances in early diagnosis and treatment of different malignant tumors have improved the overall health care of the sufferers and prolonged their life expectancy; a fact that made the improvement of the psychosocial status and the overall quality of life of cancer patients, a target and a necessity.

**Objectives.**– Evaluation of the psychosocial profile of an Egyptian sample of children suffering from different types of malignancies whether newly diagnosed or survivors compared to controls.

**Participants & methods.**– Twenty children with newly diagnosed malignancies (Group I), 20 cancer survivor children (Group II), and 20 healthy children of comparable age and sex to Group I & II as controls (Group III) were enrolled. Assessment of Health Related Quality of life (HRQOL), socioeconomic status, and psychological profile was carried out for all the participants.

**Results.**– Depression score was significantly higher in malignancy sufferers whether newly diagnosed or survivors compared to controls while mean values of Anxiety and Pediatric Symptom Checklist Scores were significantly higher only in newly diagnosed compared to controls. On the other hand, HRQOL; both total and all sub scores, were significantly lower in newly diagnosed malignancy patients compared to controls. In survivors; the total HRQOL was significantly lower compared to controls with the highest imprints on physical and social subcategories.

**Conclusion.**– The reported significant psychological burden and reduction of HRQOL highlight the importance of evaluation of such parameters as an integral part of the management plan of sufferers of pediatric malignancies whether newly diagnosed or survivors.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Towards depsychiatrisation of transgender identity: A French study for ICD-11

F. Askevis-Leherpeux<sup>1\*</sup>, A. Baleige<sup>2</sup>, S. Chouchane<sup>3</sup>, M. De la Chenelière<sup>2</sup>, P. Desmons<sup>4</sup>, R. Robles<sup>5</sup>, A. Fresan Orellana<sup>6</sup>, G. Reed<sup>7</sup>, J.L. Roelandt<sup>8</sup>

<sup>1</sup> WHOCC Lille, INSERM - Eceve, Lille, France; <sup>2</sup> WHOCC Lille, French WHOCC, Lille, France; <sup>3</sup> WHOCC Lille, Franch WHOCC, Lille, France; <sup>4</sup> WHOCC Lille, French WHO, Lille, France; <sup>5</sup> National Institute of Psychiatry "Ramón de la Fuente Muñiz", Psychiatry, Mexico, Mexico; <sup>6</sup> National Institute of Psychiatry "Ramón de la Fuente Muñiz", Psychiatry, Mexico City, Mexico; <sup>7</sup> World Mental Health Organization, Mental Health, Geneva, Switzerland; <sup>8</sup> WHOCC Lille, INSERM, Eceve, Lille, France

\* Corresponding author.

**Introduction.**– As a part of the development of ICD-11, WHO recommended to remove gender identity disorders from the chapter on mental and behavioural disorders to a non psychiatrising chapter. Current classifications consider that the presence of psychological distress and impairment are necessary and sufficient to consider transgender as a mental disorder. It implies that they are universally reported and determined by gender incongruence per se. A first study, conducted in Mexico showed that they are not always present and are predicted by experiences of social rejection

**Objective.**– The aim of this study was to replicate the Mexican study in a French context, assuming that distress and impairment will not be reported by everyone, and that they may have other determinants than gender incongruence.

**Method.**– A total of 72 transgender adults, mostly trans-women (60%), were asked to answer a questionnaire related to their experiences of gender incongruence, distress, functional impairment, social rejection and violence, during their adolescence.

**Results.**– As in Mexican study, most French participants reported having experienced psychological distress (88.4%) or functional impairment (85.5%). But both features were not reported by everyone. Moreover, distress was related to work and scholastic dysfunction, and participants who experienced dysfunction also reported more experiences of social rejection, particularly from schoolmate and/or coworkers.

**Conclusion.**– Results confirmed the overall pattern observed in Mexico and support the suggestion to classify transgender incongruence outside of the category of mental disorders in future ICD-11. This could improve access to treatment, and contribute to reduce stigmatisation and victimisation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### From pseudologia fantastica to psychogenic psychosis: A case report

N. Fernández Gómez<sup>1</sup>, A. Muñoz San José, J. Marín Lozano, B. Bardón Rivera, M.F. Bravo Ortiz

Hospital Universitario La Paz, Servicio de Psiquiatría y Salud Mental, Madrid, Spain

\* Corresponding author.

**Introduction.**– Both Pseudologia Fantastica (PF) and Psychogenic Psychosis (PP), are two entities described between late 19th century and early 20th. Their concepts have been poorly defined and understood.

**Objetives** We conduct a review of the literature about PF and PP in current classification systems, as well as the development of PP in patients with PF symptoms.

**Methods.**– We describe and analyse a clinical case of PF which developed PP, conducting a literature review of both disorders and their relationship.

**Results.**– PF is an entity that consists on a disproportionate falsification that may be extensive and complicated. Frequently, PF has its onset during the adolescence and presents over a period of years or even a lifetime. In current diagnostic systems, PF is included within Factitious Disorder. On the other hand, PP are the varied clinically independent psychoses, whose distinctive feature is that they are caused by psychic factors (psychic trauma). They typically have an acute onset and early remission. Currently, these psychotic episodes are diagnosed as “acute and transient psychotic disorders”. Certain individuals diagnosed of PF slowly develop delusional doubts (‘doutes délirantes’) and when a stressful event occurs, they suffer a PP episode.

**Conclusions.**– PP diagnosis has almost disappeared since the introduction of ICD-10 because of the elimination of aetiological factors in this classification. This diagnosis is now mainly subsumed under “acute and transient psychotic disorders”. Furthermore, more reviews and studies about PF diagnosis in current classifications, and its relationship with other disorders are required.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0151

### Ganser's syndrome. Classification challenges and differential diagnosis throughout a case

H. De la Red Gallego<sup>1\*</sup>, S. Cepedello Pérez, R. Hernández Antón, A. Alonso Sánchez, A. Álvarez Astorga, N. De Uribe Viloria, M. Gómez García, L. Rodríguez Andrés, F. De Uribe Ladrón de Cegama  
Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

\* Corresponding author.

**Introduction.**– Ganser's Syndrome (GS) is classified as dissociative disorder in CIE 10 and DSM 5. It was first described as a hysterical reaction, result of an unconscious effort to escape an intolerable situation. Differential diagnosis involves psychosis, factitious disorders and simulation.

**Objectives.**– To outline the persistence of controversies about Ganser's symptoms. To emphasize the role of cognitive impairment and organic disorders. Make differential diagnosis between GS, factitious disorders and simulation.

**Methods.**– A 50-years-old male, prison inmate, with personal history of HIV, HCV, cirrhosis, COPD, cognitive impairment. Former IVDU and alcoholic, he currently takes tobacco, cannabis and amphetamines. First admission to our unit with diagnosis of substance induced psychotic disorder, neuroleptic depot was prescribed. Second admission subsequent to agitation and disorganized language plenty of neologisms. After a few days he admitted simulation in order to achieve probation. At third admission he was agitated, provided approximated answers and behaviours.

**Results.**– Deterioration of somatic and neurological processes was not demonstrated by clinical examination, brain imaging and blood analysis. Drugs were not detected. Symptoms continued for weeks despite a cancelled trial that was supposed as a stressor.

**Discussion.**– Psychosis, SG and simulation can overlap. Relevance of organic pathology, especially neurological, in Ganser's symptoms, as described in most of the reviewed literature. Conceptualization of GS as a polymorphic clinical presentation with multiple causality, in which there is a difficulty in cognitive and emotional elaboration

of conflicts, under the confluence of personality factors, low IQ or cognitive impairment and organic damage.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0152

### **A surf through “mixed states” or “features” in mood disorders**

S. Maroua<sup>1</sup>, A. Aissa<sup>2</sup>, H. Maatallah<sup>3</sup>, Z. ElHechmi<sup>2</sup>

<sup>1</sup> Razi Hospital, psychiatry A, Mannouba, Tunisia; <sup>2</sup> Razi Hospital, psychiatry F, Mannouba, Tunisia; <sup>3</sup> Razi Hospital, psychiatry E, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– In spite of the progress in understanding their pathogenesis, “mixed states” remain challenging to recognize and to treat. In fact, The higher rates of misdiagnosis and therefore inadequate treatment in patients experiencing mixed symptoms are well documented. A better understanding of “mixed states”, through a literature review, is thus probably useful.

*Objective.*– To examine the different dimensional and nosological descriptions and classifications proposed to define the mixed symptoms in mood disorders.

*Methods.*– The literature attempting to describe or define the mixed states had been explored using the Medline database and the following keywords: “mixed states”, “mixed features”, “mixed episode”, “bipolar disorder”, “affective disorder”, “classification” and “nosology”. A bottom-up search from the articles obtained had been also pulled.

*Results.*– Pub Med research returned 252 results. The number of articles has remarkably increased in the last decade. Indeed, mixed symptoms have been described since the antiquity with Hippocrates and Aretaeus of Cappadocia. Then, Kraepelin succeeded with other authors shed light on this concept in the late eighteenth. In this era, the Kraepelinian model was the dominant one until the introduction of the DSM III in 1980. Finally, the DSM 5 introduced the new nosological entity, mixed features, and denied its pathognomonic character of bipolar disorder.

*Conclusion.*– While progress has been made in its neurobiological specification, the clinical diagnosis of mixed states didn’t stop evolving in order to be more adapted with the statistical findings and clinical presentations.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0153

### **Persistent complex bereavement disorder: A case report**

J. Oueslati, A. Maamri, S. Chebli, S. Khanfir, O. Meziou, H. Zalila  
Razi Hospital, outpatient ward, Tunis, Tunisia

\* Corresponding author.

*Background.*– Persistent complex bereavement disorder (PCBD), previously known as complicated grief disorder is a newly proposed diagnosis included in the DSM-5 as an invitation for further study and exploration. It’s a diagnosis assigned to individuals who experience an unusually disabling or prolonged response to bereavement and have shown persistent and severe grief symptoms during at least 6–12 months after the death of a loved one.

*Aim.*– Outline clinical features and treatment of PCBD.

*Methods.*– Our case study deals with a patient with PCBD who consulted and were followed in psychiatry outpatient ward.

*Results.*– Mr NH was a 38-year-old father who lost his child at the age of two by drowning seven years ago. Since the tragedy,

he was devastated, felt hopeless and experienced a deep yearning and longing for his kid. He started being disconnected from social life and accumulating absenteeism at work. He became irritable, anxious and started picturing his son and reviewing in his mind his laughs and attitudes. He also reported nightmares and his tries to avoid reminders that would trigger intense emotion or physical symptoms. He was often neglecting his diabetes medication knowing this could be dangerous. The prolonged symptoms were so unbearable that he made a suicidal attempt and was referred to our ward. Patient was treated with Paroxetine 20 mg/j and didn’t show an improvement yet (3 months).

*Conclusion.*– PCBD has been recently the focus of DSM-5 work groups as its symptoms, prognosis and treatment are specific. Further studies are needed to understand and well define this condition.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0154

### **Compulsory admission: The Portuguese protocol**

M. Pinheiro\*, J. Pais

Centro Hospitalar Tâmega e Sousa, Psychiatry, Souto, S. M. Feira, Portugal

\* Corresponding author.

*Introduction.*– Compulsory admission (CA) are necessary as a way of assuring psychiatric patients’ safety and those around him/her. Even though a CA in Portugal is mainly a clinical (ie, medical) decision, it requires judicial (ie, legal) authorization, because it clashes with the patient’s freedom and rights. Taking into account that there are no standardized European protocols for CA, we describe the Portuguese Protocol.

*Methods.*– Review of clinical and legal determinants that concern CA in Portugal. A patient shall have a CA if he/she has a serious psychiatric condition that: (1) Can create a dangerous situation of legal and/or of patrimonial value of a relevant item, personal or non-personal, and refuses to undergo the necessary medical treatment; (2) Circumvents the ability to discern consequences and the lack of medical treatment may accentuate that state.

*Results.*– CA are classified as “urgent” or “non-urgent”. Urgent CA, which are more frequent in our country, occur when the patient’s behaviour requires immediate evaluation in the Emergency Department. Non-urgent CA are initiated by law representatives after a complaint is made (ex: family). A reevaluation is obligatory by two other psychiatrists. Further details are available in The Constitution, namely in “Decreto-Lei no35/99. In: Diário da República (DR), I Série A–no30; 5/2/99” and in “Lei de Saúde Mental no36/98. In: DR, I Série A–no169; 24/7/98”. (Link: [www.dre.pt](http://www.dre.pt))

*Discussion.*– Psychiatric disorders are unique in their sometimes dramatically change in the patients wellbeing. Future research should try to standardize protocols for CA in Europe.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0155

### **A psychopathological evaluation of frequent attenders of acute psychiatric ward**

M. Preve\*, L. De Peri, E. Bolla, A.R. Moor, R.A. Colombo, R. Traber  
Sociopsychiatric Organization, Psychiatric Clinic, Mendrisio, Switzerland

\* Corresponding author.

**Introduction.**– The problems of admission and readmission is very current worldwide and is a problem that concern different level of care. A retrospective observational study was conducted in a psychiatric ward in Switzerland in a period of 4 years (2012–2016). The purpose of this study is to determine the clinical and psychopathological characteristics of the frequent attenders of psychiatric service during the period of 2012–2016. We propose a literature review.

**Method.**– We conducted a systematic retrospective study of the admissions in the psychiatric clinic in Ticino during the period of 2012–2016. We review the literature with the use of the principal database (Pub Med, Enbase, PsychInfo). We use the definition of frequent attenders that are used in literature.

**Results.**– Sociodemographic characteristics year by year are explained in the table. Frequent attenders are associated significantly with male gender ( $p < .001$ ), younger age ( $p < .001$ ), caucasian race ( $p < .001$ ), psychiatric diagnosis of schizophrenia ( $p < .001$ ) or bipolar disorder ( $p < .001$ ), dependence comorbidity for alcohol ( $p < .001$ ) or cocaine ( $p < .001$ ), high frequency of admission more of 8 admission/year ( $p < .001$ ).

**Discussion and conclusion.**– Frequent attenders are a problem of the psychiatric service [1,2]. Effects of the readmission determine an increase of health costs and force to consider in worldwide health care a resolution that is valid for the personal care and in terms of pharmaconomy. Further research is warranted to replicate our clinical and qualitative observations and, in general, quantitative studies in large samples followed up over time are needed. Methodological limitations are considered.

### **An exaggerated physical reaction in misophonia**

S. Tunç<sup>1</sup>\*, H.S. Basbug<sup>2</sup>

<sup>1</sup> Kafkas University, Department of Psychiatry, Kars, Turkey; <sup>2</sup> Kafkas University, Department of Cardiovascular Surgery, Kars, Turkey

\* Corresponding author.

Misophonia is described as a condition in which negative emotions and negative physical reactions are triggered by particular sounds. The patients with misophonia demonstrate hatred and extreme intolerance against specific non-dominant and repetitive sounds. It is a severe psychiatric disorder rather than a mere obsession. Its symptoms may vary from mild to severe. Although some patients can dissemble and passed out, some may lose their control. In severe cases, involuntary physical violence may be observed. Although it is usually perceived as a spoil by the society, it may cause the patient's life become unbearable. In this paper, the physical violence of a misophonia patient directed to a dinner guest who smacks his mouth during eating was reported. Unfortunately, the patient could not achieve to exclude himself from the source of disturbance before exhibiting the adverse physical reaction. Therefore, this case becomes important in demonstrating the extreme involuntarily reactive nature of misophonia. Misophonia is a profoundly disturbing disorder for a patient which might exhibit spontaneous unwanted physical reactions as in this case. There is no surgical or pharmacological treatment. It has a devastating effect on the patient's quality of life. Misophonia is not classified among the current disorders in DSM-5 and ICD-10. Therefore, it should be considered as a distinct psychiatric disorder within the forthcoming editions. Unique diagnostic criteria should also be constituted to

improve the recognition of this disorder by the health professionals as well as to encourage further scientific studies.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Comorbidity/dual pathologies**

EV0157

### **Cannabis use and psychiatric disorders in youth**

A.I. Ahmed<sup>1</sup>\*, A. Choudhury<sup>1</sup>, R. Singh<sup>2</sup>, N. Viriley<sup>2</sup>

<sup>1</sup> PsyCare, Psychiatry, Delhi, India; <sup>2</sup> PsyCare, Psychology, Delhi, India

\* Corresponding author.

**Objectives.**– To study the percentage of youth seeking inpatient treatment in a 30 bedded psychiatric nursing home for cannabis use and study associated mental health conditions.

**Significance.**– Despite the use of cannabis being associated with various psychological disorders, its consumption is on a rise, especially among the youth. According to the World Drug Report, 2017, among the people undergoing treatment for various drugs, 39% (highest global average) are those who are in treatment for cannabis use.

**Methodology.**– Out of 68 patients aged 15–29 years consecutively admitted over a 2 year period for various mental health concerns, a sample of 18 patients with cannabis use was drawn.

**Inclusion criterion.**– Youth aged 15–29 years, fulfilling the ICD 10 Criterion for cannabis dependence, seeking inpatient treatment. **Exclusion Criterion:** Other psychoactive substances (excluding nicotine), or any pre-existing neurological illness.

**Results.**– Out of the 68 patients, 17 (25%) were users of cannabis. All 17 patients had associated psychological and psychiatric morbidity. 58.8% were found to have associated schizophrenia/psychosis, 17.6% had a motivational syndrome, 11.7% manifested affective disturbances, 5.8% manifested with anxiety disorder and 5.8% with cognitive impairments.

**Conclusion.**– Significant psychiatric morbidity is associated with the use of cannabis with schizophrenia/psychosis rates the highest, followed by amotivation syndrome and affective disturbance. The high rates of association illustrate the need for creation of awareness among the youth on the harmful effects of cannabis and the urgency to seek treatment to prevent further harm. There's a role of providing aid to policy makers to regulate the supply of cannabis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Aspiration pneumonia in Catatonia. An omitted vital risk and a required prevention. A series of 3 cases**

G. Anmella<sup>1</sup>\*, M. Gomez<sup>2</sup>, A. Gimenez<sup>3</sup>, S. Marques<sup>3</sup>, J. Pinzon<sup>1</sup>, S. Gomes<sup>1</sup>, P. Guzmán<sup>1</sup>, S. Madero<sup>1</sup>, M.T. Pons<sup>1</sup>, M. Sagué<sup>1</sup>, V. Navarro<sup>1</sup>, E. Parellada<sup>1</sup>, A. Benabarre<sup>1</sup>

<sup>1</sup> Hospital Clínic de Barcelona, IDIBAPS, Departament of Psychiatry, Barcelona, Spain; <sup>2</sup> Hospital de Santiago, Psychiatry, Santiago de Compostela, Spain; <sup>3</sup> Hospital do Espírito Santo, Psychiatry, Evora, Portugal

\* Corresponding author.

**Introduction and case description.**– In a 6-month period, three patients were admitted to a psychiatric hospitalization unit presenting with catatonic symptoms of different etiology. A patient with persistent depressive disorder, a patient with schizophrenia

and a patient with type II bipolar disorder. During hospitalization all three patients showed aspiration pneumonia (AP) as a clinical complication. All three patients fulfilled catatonia criteria at admission, according to the Bush-Francis Catatonia Rating Scale.

**Objectives and methods.**– The main goals of this work are to determine whether AP may pose at risk patients with catatonic symptoms, studying the clinical consequences on the evolution of hospitalized patients and evaluating the need of establishing prophylactic measures. Therefore, we conducted a research on hospitalized patients during a half year period presenting with catatonia and secondary AP and studied the cases.

**Results.**– All the patients required oxygen therapy, two of them intensive care and a patient died after secondary complications. In two patients this intercurrent condition lead to delay on electroconvulsive therapy (ECT) onset, slowing down the psychopathological remission and prolonging hospitalization. After less than 6 ECT sessions, the catatonic symptoms remitted ad interm in the 2 surviving patients.

**Conclusions.**– AP in catatonia is a poor described entity in literature. It entails an important vital risk, can lead to delay on ECT onset and can prolong hospitalization. Prophylactic measures or prevention protocols have not been published in order to manage this entity. This case series evidences the need to attend this matter and consider the establishment of prophylactic preventive measures.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Improving care for people with multimorbidity through workforce development and blended learning approaches**

C. Attoe<sup>1\*</sup>, K. Lillywhite<sup>2</sup>, S. Cross<sup>1</sup>

<sup>1</sup> South London & Maudsley NHS Foundation Trust, Maudsley Simulation, London, United Kingdom; <sup>2</sup> King's Health Partners, Mind and Body Programme, London, United Kingdom

\* Corresponding author.

Multimorbidity, the presence of two or more long-term conditions in an individual, is a significant problem across healthcare systems. In the UK, multimorbidity presents a considerable challenge, while guidance has targeted improving care for people with multimorbidities (NHS England, 2016; NICE, 2016). Multimorbidities often involve the physical health of people with severe mental illness, and the mental health of people with long-term physical conditions. Tackling this problem requires service development and health promotion, but also up-skilling of healthcare workforces, with such work underway in South London.

To evaluate the clinical impact of a workforce development initiative targeting healthcare staff through blended learning approaches using multiple interventions.

A blended learning programme of training interventions to tackle multimorbidities was implemented across healthcare settings, including e-learning methods, face-to-face training, and mental health simulation. A sequential transformative mixed-methods design was employed. Organisational level measures of training access, uptake, and confidence ( $n = 750$ ) were undertaken via surveys. Evaluations were undertaken for each intervention, focusing on quantitative measures of knowledge, confidence, attitudes, and skills, and qualitative analyses of perceived impact of training.

Analyses identified improvements in access and uptake of training, as well as staff confidence in addressing multimorbidities. Further evaluations suggested that simulation training was the most effective way to improve skills, attitudes, and confidence, while e-learning, seminars, and face-to-face training improved knowledge.

Qualitative analyses highlighted the benefits of interprofessional collaboration, system navigation, and 'networking'.

Blended learning approaches to multimorbidities involving mental illness can support workforce development, with simulation training the most effective educational intervention.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Prevalence of post traumatic stress disorder in patients attending national drug treatment centre Ireland**

Z. Azvee

<sup>1</sup>National Drug Treatment Centre, Addiction Psychiatry, Dublin, Ireland

\* Corresponding author.

Aim of this research is to meet a few objectives which are: Firstly, to look at prevalence of post-traumatic stress disorder (PTSD) in Substance Use Disorder patients. Secondly, to compare and self-rating of PTSD and clinical judgment. Thirdly, to compare trauma exposure between individuals with substance use disorder (SUD) and dual diagnosis patients. Fourthly, to perform an analysis of the characteristics of SUD/PTSD patients was performed. Fifthly, to review treatment programme based on analysis

**Study method.**– Cross Sectional design.

**Sample.**– Current attendees at National Drug Treatment Centre of 2 clinical teams.

**Results.**– The study is currently ongoing and preliminary results will be presented at the conference in 2018.

**Conclusion.**– It is a known evidence that there is a link between addiction and history of trauma. Further evidence from this study would help inform the need for further resource and parallel treatment for marginalised cohort of patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0161

### **What if an acute psychosis is treated with anticoagulants?**

S. Ben Ali\*, S. Tira, C. Bencheikh, H. Kefi, A. Oumaya

Military Hospital of Tunis, Psychiatry Department, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– The annual incidence of cerebral venous thrombosis is estimated to 3 to 4 case per 1000 inhabitants. its mode of beginning is very variable. Headache is the most common clinical symptom, it's present in 74 to 90 per cent of cases. However, there are unusual aspects making diagnosis difficult such as acute psychiatric disorder.

**Objective.**– We proposed through a clinical case, to illustrate that an acute psychotic disorder can revealed a cerebral venous thrombosis.

**Methods.**– Study of a clinical case concerning a 21-year-old patient hospitalized for acute psychiatric disorder

**Results.**– Case report: madam RB is 21 years old with no history of somatic pathology. She has had an acute setup symptomatology maked of polymorphous delusional syndrome associated to auditory, visual, ceneasthetic and olfactory hallucination, a syndrome of mental automatism and a depersonalization syndrome. The somatic examination finds a 38 degree fever with a strictly normal neurological examination. The biological analysis only finds a hyperleucocytosis 13,400. The brain scan is normal. The diagnosis

of acute psychosis is suspected, The patient receive 6 mg per day of resperidone and 5 mg per day of lorazepam for 15 per day. The evolution is marked by the absent of improvement so a cerebral MRI was practiced and it objectified an extensive right transverse sinus thrombosis. An anticoagulant treatment was started with improvement after one week and disappearance of psychiatric symptomatology after one month

**Conclusion.**– A psychiatric symptomatology can mask a neurological pathology. The practitioner must strive to eliminate the somatic urgency before concluding to a psychiatric origin

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Sleep disturbance in individuals with alcohol use disorders**

C. Cagigal<sup>1\*</sup>, T. Carvalho<sup>1</sup>, T. Silva<sup>1</sup>, E. Albuquerque<sup>1</sup>, M. Jesus<sup>1</sup>, C. Silva<sup>1</sup>, V. Martins<sup>1</sup>, C. Franco<sup>1</sup>, M. Marques<sup>2</sup>

<sup>1</sup> Coimbra Hospital and University Centre, Coimbra- Portugal, Department of Psychiatry, Coimbra, Portugal; <sup>2</sup> Faculty of Medicine, Coimbra University, Portugal, Department of Psychological Medicine, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Subjects with sleep disorders tend to self-medicate with alcohol to promote sleep or to treat anxiety symptoms. Alcoholism can, in turn, cause sleep disturbances, which can result in relapse. The chronic use of alcohol can decrease sleep time, increase sleep latency and wake time after sleep onset, and cause a deficiency in slow-wave sleep generation, as well as affect Rapid Eye Movement (REM) sleep.

**Objectives.**– The authors assess the prevalence of sleep disturbance in alcoholic patients being treated in the outpatient clinic.

**Methods.**– This is a cross-sectional analysis conducted at the Dual Disorders Unit at Coimbra Hospital and University Centre. Subjects with active alcohol abuse/dependence and the ability to consent were recruited to complete a comprehensive sleep disorder questionnaire, including a general medical, psychiatric, and alcohol abuse/dependence history as well as validated scales (e.g., Insomnia Severity Index, Pittsburgh Sleep Quality Index and Epworth Sleepiness Scales).

**Results.**– Studies have reported that individuals with insomnia are more likely to consume alcohol to sleep, and the prevalence of sleep disturbance in alcoholic patients is higher than in general population. Preliminary results from our study confirm data in the literature.

**Conclusion.**– Alcohol abuse/dependence is a public health problem that interferes with physical and mental health. Insomnia and alcoholism are EVoccurring disorders. Therefore it is recommended a routine screening for sleep problems in subjects with alcohol use disorders, promoting an individualized and integrated treatment for each patient.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0163

### **Bipolar disorder and Sjogren's syndrome: A case report**

S. Chebli\*, Y. Zgueb, U. Ouali, S. Ghezaiel, R. Jomli, F. Nacef  
Razi Hospital, Psychiatry A ward, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Sjogren's syndrome is a common connective tissue disease. It may first occur with psychiatric symptoms (mostly

depressive symptoms and anxious ones). However, the association with bipolar disorder is not well known which leads to delaying diagnosis and treatment.

**Objective.**– Our objective is to highlight that bipolar disorder could be associated with Sjogren's syndrome.

**Methodology.**– A case report

**Results.**– Mrs X is a 57-year-old diabetic patient who was first admitted for occipital migraines, agitation, boxing movements in the upper limbs and pedaling movements in the lower ones. Neurological examination revealed both a pyramidal syndrome and a posterior cordonal one. The MRI showed a periventricular white matter lesion on T2-weighted. EEG was normal. The Cerebrospinal fluid analysis revealed a pathologic IgG index. HIV and hepatitis C virus serologies and VDRL/TPHA were all negative. The anti-DNA test, antinuclear antibodies and anti-SSA/Ro and anti-SSB/La tests were negative; rheumatoid factor and total complement were normal. Oral and ocular sicca syndrome were suspected from history-taking and confirmed by Schirmer test. The Salivary gland biopsies showed a lymphocytic infiltration, scored 4 using Chisholm's criteria. Psychiatric assessment revealed a bipolar disorder type II with an onset on post-partum. We also noticed a hysterical personality. The patient showed significant improvement with corticosteroid therapy associated with immunosuppressive treatment and mood stabilizer.

**Conclusion.**– Neuropsychiatric manifestations in Sjogren's syndrome are common and can occur not only during its course, but also at the onset of the disease. In our view, a more rigorous analysis of clinical background should be done by psychiatrists so to help early diagnosis and treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0164

### **The particular association between recurrent depression and persistent delusional disorder**

C.A. Crisan<sup>1\*</sup>, B. Suci<sup>2</sup>, D. Chiorean<sup>3</sup>, V.U. Zdrenghea<sup>1</sup>

<sup>1</sup> Iuliu Hatieganu University of Medicine and Pharmacy, Neurosciences, Cluj-Napoca, Romania; <sup>2</sup> Children's Emergency Hospital, Adult Psychiatry, Cluj-Napoca, Romania; <sup>3</sup> Children's Emergency Hospital, Adult Psychiatry, Romania

\* Corresponding author.

**Introduction.**– The association of two Axis I diagnoses in psychiatry is not a rule, but there are some exceptions and, in these cases the process till a correct and complete diagnosis is complicated.

**Objectives.**– The presentation of a clinical case that describes an unusual association of two Axis I diagnoses.

**Methods.**– A 53-year-old male, diagnosed with recurrent Major Depressive Disorder and Persistent Delusional Disorder (according to ICD-10 and DSM-5), known with alcohol abuse, had four depressive episodes, all of them severe. He was initially diagnosed only with Persistent Delusional Disorder and after one year the diagnosis of Major Depressive Disorder was established. Schizoaffective disorder was excluded.

**Results.**– Over the course of the illness, the clinical picture included systematized delusions of jealousy with congruent behaviour, associated with periods of real depressive episodes when the delusions were not present. Treatment consisted of high doses of antidepressants, atypical antipsychotics and mood stabilizers. As a particular aspect, the prescription of antidepressants did not worsen the delusional symptoms. These were constantly present between episodes more as a personality trait.

**Conclusions.**– The psychiatric disorders show variable clinical symptoms making it difficult to differentiate one from each other.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Implementing and development of dual diagnosis services in institute of psychiatry – Ain Shams University; psychosocial collates (ongoing research)**

S. ElGhonyem<sup>\*</sup>, M. Atef, L. Abobakr

Ain Shams University, Neuropsychiatry Department, Cairo, Egypt

\* Corresponding author.

*Introduction.*– Effective dual diagnosis programs combine mental health and substance abuse interventions that are tailored for the complex needs of patients with co morbid disorders. Our main objective of this ongoing research to study the impact of developing dual diagnosis service in Ain Shmas University Institute of Psychiatry and to identify the psychosocial factors associated with patients suffering from dual diagnosis and the impact of these factors on the severity of their condition.

*Methods.*– Implementing and development of Dual Diagnosis services in the Institute of Psychiatry- Ain Shams University started since August, 2015. Our service program included both outpatient clinic twice weekly and inpatient service both individual and group therapy. The ongoing study had started September 2015 till the end of December 2017. Both sexes were included irrespective to their socioeconomic status, aged 18–55 yrs old and accepted to participate in the study. They were assessed with semi structured clinical interview of Institute of psychiatry, SCID I and ASI. Preliminary results showed that Substance induced psychosis followed by substance induced mood are the most prevalent diagnoses among the studied sample, young aged males with low to middle socioeconomic status. Most incriminated substance is cannabinoids (hash and synthetic cannabis – Voodoo) exact results can't be declared till the end of the study [1,2].

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Eosinophilia induced by clozapine: A case report and review of the literature**

A.S. Ellouze<sup>1\*</sup>, O. Moula<sup>2</sup>, M. Mlika<sup>2</sup>, R. Ghachem<sup>2</sup>

<sup>1</sup> Razi Hospital, Psychiatry B, Sfax, Tunisia; <sup>2</sup> RAZI Hospital, Psychiatry B, Menouba, Tunisia

\* Corresponding author.

*Introduction.*– Clozapine is an atypical antipsychotic that has been used in the treatment of schizophrenia and other psychotic disorders especially resistant ones. It needs extensive monitoring. Besides of agranulocytosis, eosinophilia has been associated with the use of clozapine especially in the first weeks of its introduction. *Objectifs.*– To study the continuation of the treatment with clozapine in the absence of organs damages when eosinophilia occurred. *Methods.*– A study of a case of eosinophilia that occurred during the introduction of Clozapine in an adult diagnosed with resistant schizophrenia.

*Results.*– An eosinophilia occurred four weeks after the introducing of clozapine (1300/cmm), the dose of clozapine was 300 mg/day. The clozapine was continued at the dose of 300 mg. After four weeks her eosinophil count decreased and settled down to less than 300/cmm and the dose of clozapine was increased to 400 mg/day without any increase of eosinophil count.

*Conclusions.*– The current report shows further evidence that it may be unnecessary to cease treatment in all patients who develop a transient benign eosinophilia induces by clozapine. Careful haematological monitoring should be considered.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

*Objective.*– The aim of the present study was Evaluation Of the effectiveness of object relation couple therapy on amending ineffective communication patterns and sexual dissatisfaction of couples being victim of domestic violence.

*Method.*– The present study was quasi-experimental, pretest-posttest with control group. The study population included all couples referring to the private counseling Center for protecting Victims of Violence. The study sample consisted of 40 spouses (20 couples) who referred to this association and were recruited voluntarily through available sampling method in Tehran, Iran in 2016. Data were collected using Spouse abuse questionnaire and Communication Patterns Questionnaire (CPQ). Data were analysed using SPSS software through covariance analysis.

*Results.*– The findings of this study indicated a statistically significant decrease in the mean score of the experimental group in both post-test. Also, in comparison with the control group, there was a statistically significant decrease in the mean scores of the anxiety and depression ( $p < 0.01$ ).

*Conclusion.*– The results of the present study demonstrated that object relation couple therapy on amending ineffective communication patterns and sexual dissatisfaction of couples being victim of domestic violence

*Keywords:* Object relation couple therapy; Communication patterns; Sexual dissatisfaction; Couples.

### **“Broken hearts”: Cardiovascular mortality in bipolar disease – About a clinical case**

E. Fernandes<sup>1\*</sup>, L. Castanheira<sup>1</sup>, F. Alves<sup>2</sup>, J. Jeronimo<sup>1</sup>, L. Sousa<sup>1</sup>, C. Rodrigues<sup>1</sup>, C. Almeida<sup>1</sup>, L. Bastos<sup>1</sup>, J. Pereira<sup>1</sup>

<sup>1</sup> Centro Hospitalar de Lisboa Norte - Hospital de Santa Maria, Psychiatry, Lisbon, Portugal; <sup>2</sup> UNIDADE Local de Saúde do Alto Minho EPE, Psychiatry, Viana do Castelo, Portugal

\* Corresponding author.

**Introduction.**– Bipolar disorder is associated with several medical conditions contributing to substantial morbidity and mortality being the most common medical problems obesity, diabetes mellitus and subsequent cardiovascular disease (CVD).

**Objectives.**– To describe a clinical case paradigmatic of cardiovascular mortality in a bipolar patient and make a review of the literature on the subject. To call attention to the need to increase awareness and recognition about cardiovascular diseases in this patients population.

**Methods.**– Bibliographic research was conducted through the Pub Med in the Medline library and clinical information was obtained through medical records and clinical interviews with the patient.

**Results.**– A 47-year-old man with psychiatric history since his early twenties, when the first manic episode is reported. At that time, the patient started treatment with mood stabilizers and antipsychotics, which he continued for the next two decades. As medical history, the patient presented obesity and had unmedicated dislipidemia and hypertension. He also had history of stroke at age 40. At day 10 of the last admission for new manic episode (September 2015), the patient was found in cardio-respiratory arrest in the bed. Autopsy revealed, as cause of death, ischemic heart disease.

**Conclusions.**– Compared with individuals with no history of mental illness, individuals with bipolar disorder are at increased risk of premature death from CVD. Developments in the prevention, detection and treatment of metabolic risk factors and lifestyle changes in this group are essential in improving care and prognosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0169

### **The risk of thromboembolism in psychiatric patients: Review of the literature and clinical cases**

L. Ferreira<sup>1\*</sup>, C. Ferreira<sup>2</sup>, L. Castanheira<sup>2</sup>, R. Gasparinho<sup>1</sup>, N. Fernandes<sup>1</sup>, A. Rosa<sup>1</sup>

<sup>1</sup> Hospital Distrital de Santarém, Departamento de Psiquiatria e Saúde Mental, Santarém, Portugal; <sup>2</sup> Centro Hospitalar Lisboa Norte, Serviço de Psiquiatria, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Arterial and venous thromboembolism are common causes of morbidity and mortality in the western world. Hospitalized psychiatric patients have some specificities such as: obesity induced by psychotropic drugs, physical restraint, possible catatonia, potential dehydration and treatment with antipsychotics or antidepressants. Some studies have shown that psychotropic drugs themselves may modify the risk of TE.

**Objective.**– Our aim is to correlate the clinical aspects of venous thromboembolism (VTE) with the clinical cases presented.

**Methods.**– We searched Internet databases indexed at MEDLINE using the keywords: (schizophrenia OR bipolar OR depression) AND (venous thromboembolism OR pulmonary embolism).

**Results.**– We describe two cases of pulmonary embolism (PE): a 79-year-old woman with antidepressant treatment hospitalized for

EP, and a 56-year-old woman with schizophrenia and antipsychotic therapy hospitalized for severe bilateral EP. VTE is a serious disease that can be complicated by EP and is a major cause of morbidity and mortality in non-surgical hospitalized patients. Risk of VTE is increased in psychiatric patients, especially in schizophrenia and bipolar disorder. The associations between VTE and depression are less clear. Antidepressants and antipsychotics may be a risk factor. The risk of VTE with typical and atypical antipsychotics varies with type of drug and is highest just after starting the drug.

**Conclusion.**– Psychotropic drugs are widely prescribed, so understanding the association between TE and underlying pathophysiological mechanisms is of major importance. The prescription of psychotropic drugs should be cautious and especially, it should be based on clinical assessments of the associated benefits and risks.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0170

### **Depression as a comorbid factor in patients with tuberculosis attending the rural government TB Hospital in Tamil Nadu, India**

D.L. Francis

Tamil Nadu Dr MGR Medical University, Public Health, Chennai, India

\* Corresponding author.

**Background.**– Tuberculosis (TB) remains a leading infectious cause of morbidity and mortality throughout the world. Medication non-compliance has been recognised as one of the drawbacks in the successful management of this disease. TB is associated with psychiatric morbidity, particularly depressive disorder, and this has been recognised as a cause of poor compliance and a cause of increased morbidity and mortality from the disease. Despite this recognition, little attention is paid to the identification of depression among TB patients. This study was designed to determine the prevalence of depression in patients with TB attending the rural Government TB hospital in Tamil Nadu, India and to find out the factors that may be associated with this.

**Methods.**– All consenting TB patients attending the hospital completed a socio-demographic questionnaire and nine-item HADS scale designed to screen for depression and anxiety, in outpatient and inpatient settings.

**Results.**– A total of 130 patients participated in the study of whom 61% were males and 39% were females. The mean age of the respondents was range 25–70 years. 57% of the patients had depression. Socio-demographic factors and a clinical factor (persistent cough) were significantly associated with depression.

**Conclusion.**– Measures to reduce depression among patients with TB should include effective symptom control, particularly of coughing, and measures to improve the financial status of this group of patients. Financial empowerment of patients may reduce depression in them, improve the compliance rate to anti-TB medication, and could furthermore bring an improvement to their quality of life.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0171

### Schizo-obsessive disorder. A case report

M. García-Poggio Fernández-Renau, M.G. Eliche Moreno, R. Molina Cambra, S. Bravo Herrero, J.F. Cruz Fourcade, A. Muñoz Domenjó, M. Salvador Robert, Á. Martínez Fernández, E. Ramos García  
Hospital Universitario de Móstoles, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Obsessive-compulsive symptoms and obsessive-compulsive disorders are frequent in patients with schizophrenic disorders, and it is argued that this high prevalence of comorbidity between both illnesses is due to common risk factors. In this way, there is a new clinical entity called schizo-obsessive disorder that has been proposed for a group of patients who present both diagnoses.

**Objectives.**– To know the clinical characteristics and outcome of patients diagnosed with this disorder.

**Methods.**– We review recent literature about this disorder related to a case admitted to our Mental Health Centre. A 64-year-old woman with long-term schizophrenia, that presented at the moment of the consultation obsessive thoughts, especially of a sexual nature.

**Results.**– It was requested a cranial computed tomography (CT) scan and a complete analysis, in which no significant alterations were observed. After several consultations, the patient was diagnosed with schizo-obsessive disorder.

**Conclusions.**– We should take into account the schizo-obsessive disorder when patients present with both delusional and obsessive symptoms, or in patients with a previous diagnosis of schizophrenia that also present with obsessive symptoms. Although there is some controversy with this disorder, the frequency of appearance of both symptoms together makes us think that it is a new clinical entity.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Dual diagnosis in the psychiatric emergency room: 20 years ago and today

N. Garrido-Torres<sup>1</sup>, J. Piedra Cristobal<sup>2</sup>, M.P. Cordero Ramos<sup>3</sup>

<sup>1</sup> Hospital Juan Ramón Jiménez, Psychiatry, Huelva, Spain; <sup>2</sup> La Palma del Condado mental health unit, Social work, Huelva, Spain; <sup>3</sup> CTA polígono sur, Substance abuse, Seville, Spain

\* Corresponding author.

Dual diagnosis refers to an individual who suffers from both an addiction disorder and a mental illness. It is also known as EV-occurring disorders.

**Objective.**– Determine the prevalence of Dual diagnosis in our psychiatric emergency room today and 20 years ago.

**Methods.**– Data on 74 consecutive admissions visited in a psychiatric emergency room of a general teaching hospital during a period of six months in 1996 were collected and were compared with data on 74 consecutive admissions in a psychiatric emergency room in 2006.

**Results.**– A total of 122 admissions were included. 19 (22%) had dual diagnosis disorder, 9 (7%) had substance abuse disorder (SUD), and 94 (71%) had non-substance abuse disorder (NSUD). Alcohol, Cocaine, and cannabis heroin were the substances most frequently found respectively. Differences among groups of years (1996 and 2006) were found in age and type of illicit drug use. Cannabis-psychosis association were more frequently in 2006 than 1996.

**Conclusions.**– Dual diagnosed patients at the emergency psychiatric room presented as both clinical and social important problems.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0173

### Suicidal behavior and alcohol intake admissions in the psychiatric emergency room

N. Garrido-Torres<sup>1</sup>, J. Piedra Cristobal<sup>2</sup>, P. Diaz Cordero<sup>3</sup>

<sup>1</sup> Juan Ramón Jiménez Hospital, Psychiatry, Huelva, Spain; <sup>2</sup> La Palma del Condado Mental Health Unit, Psychiatry, Huelva, Spain; <sup>3</sup> Seville, Spain

\* Corresponding author.

Alcohol abuse is the commonest type of substance dependence worldwide. Suicide is major public health issue. Therefore, given the enormous socioeconomic burden of the latter, investigating their possible relationships is almost mandatory.

**Objective.**– Determine the relationship between suicidal behaviour and alcohol intake in patients admitted in the psychiatric emergency room. To outline the characteristics of the population.

**Methods.**– Data on 74 consecutive admissions visited in a psychiatric emergency room of a general teaching hospital during a period of six months were collected and analysed.

**Results.**– A total of 74 admissions were included. A positive correlation between alcohol intake and drug overdose as suicidal method was found. Drug intake by younger people (<25) is more frequently than older people. There was not significant difference between males and females.

**Conclusions.**– The admissions to the psychiatric emergency room for drug overuse and alcohol intake in young people is a common and important finding

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0174

### Psychiatric susceptibility: Case report

M. Gómez García\*, A. Álvarez Astorga, S. Gómez Sánchez, M. De Lorenzo Calzón, N. De Uribe Vitoria, A. Rodríguez Campos  
Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain

\* Corresponding author.

**Introduction.**– Steroids are drugs widely used in clinical practice, but are frequently associated with neuropsychiatric adverse effects as depression, mania, followed by psychosis, delirium and mixed states.

**Objectives.**– To present a clinical case that reflects the relationship between high doses of corticosteroids and the onset of psychopathology, especially in people with psychiatric background.

**Material and methods.**– Descriptive study of a clinical case and bibliographic review on the subject.

**Results.**– A 23-year-old woman with psychiatric background from the age of 18, due to toxic-induced Psychotic Disorder. Well-controlled since then with Paliperidone 6 mg, although at age 22, due to alcohol abuse, Antabuse was also prescribed. One year later, she was diagnosed with acute hepatitis, that after liver biopsy and autoimmune study, was diagnosed with Autoimmune Hepatitis. Antabuse and Paliperidone were withdrawn and Prednisone 60 mg daily was prescribed. After initial analytical improvement, the patient was discharged. However, two weeks later she presented manic symptoms severe enough to need admission in the Psychiatry Department. After ruling out other possible causes, she was diagnosed with Psychotic episode induced by corticosteroids.

**Conclusion.**– Treatment with corticosteroids may be associated with psychiatric disorders, especially when high doses are prescribed. Therefore, the dose of corticosteroids should be as low as possible, especially in patients with psychiatric background.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Psychiatric and neurocognitive function in patients with adrenal incidentaloma

S. Grassi<sup>1\*</sup>, A. Caldiroli<sup>1</sup>, G. Carnevali<sup>1</sup>, V. Morelli<sup>2</sup>, M. Arosio<sup>2</sup>, I. Chiodini<sup>3</sup>, M. Buoli<sup>1</sup>

<sup>1</sup> University of Milan- Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Department of Psychiatry, Milan, Italy; <sup>2</sup> University of Milan, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Department of Medical Sciences and Community Health, Milan, Italy; <sup>3</sup> Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Unit of Endocrinology and Metabolic Diseases, Milan, Italy

\* Corresponding author.

**Introduction.**– Hypothalamic-pituitary-adrenal axis is involved in the pathophysiology of psychiatric disorders. Mood and anxious symptoms are common in endocrinological diseases, such as Cushing's syndrome caused by a chronic excess of cortisol.

**Objectives.**– To evaluate psychiatric and neurocognitive function in patients with Adrenal Incidentaloma (AI).

**Methods.**– We enrolled 18 patients (M 6, F 12, mean age 64.3 years) referred to Endocrine Unit for AI. We included 12 patients with Subclinical Hypercortisolism (SH) and 6 without SH as control group. SH was diagnosed in subjects presenting at least two altered parameters out of urinary free cortisol (UFC) levels above the upper limit of normal values, cortisol after 1 mg-dexamethasone suppression >3 mg/dL, ACTH levels <10 pg/ml. We evaluated mental health by Hamilton Depression Rating Scale, Brief Psychiatry Rating Scale, Young Mania Rating Scale, Clinical Global Impression Severity, Global Assessment of Functioning, Sheehan Disability Scale (SDS). Moreover we explored neurocognitive function in 9 patients, younger than 65 years, by the Brief Assessment Cognition Schizophrenia (BACS) test.

**Results.**– We did not find any correlation between the adrenal function parameters and the psychometric evaluation. We found a negative correlation between the Verbal Memory (item of BACS test) and UFC levels ( $p=0.038$ ). In 6 patients a new psychiatric disorder was diagnosed (4 generalized anxiety disorder, 1 cyclothymia, 1 major depressive disorder). Patients with SH showed significantly higher scores of perceived stress, assessed by SDS, than individuals without SH ( $4.4 \pm 1.7$  vs  $1.8 \pm 1.7$ ,  $p=0.01$ ).

**Conclusions.**– Psychological and neurocognitive function should be evaluated in AI patients regardless of the presence of SH.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0176

### Psychiatric symptoms in systemic lupus erythematosus: A case report

A. Hakiri<sup>\*</sup>, H. Ben Ammar, R. Nefzi, Z. ElHechmi  
Razi Hospital, f, Manouba, Tunisia

\* Corresponding author.

**Introduction.**– Systemic lupus erythematosus (SLE) is a chronic, systemic autoimmune inflammatory disease. It can affect the nervous system. psychiatric and neurological abnormalities are common

features of this disease, including cognitive changes, mood and anxiety disorders, acute confusional state and psychosis.

**Objectives.**– Illustrate the association of SLE and neuropsychiatric symptoms.

**Methods.**– A case report and literature review.

**Results.**– Mrs. A.S is a 46 year-old woman married at the age of 27 with no children. She was diagnosed with lupus at the age of 36, with a cutaneous, articular and renal involvement. she was treated with high-doses of corticosteroids. Two years after the diagnosis of lupus, she was transferred to the psychiatry department for disorders that have occurred in the past year. Psychiatric symptoms were atypical and were simultaneous with the renal relapse of SLE. It included delirium, behavioural disorders, carelessness, emotional indifference and auditory hallucinations. the brain scan did not show any lesions and the cerebral MRI has not been done. The patient was treated with chlorpromazine, and for her renal relapse with high doses of corticosteroides with a clinical improvement after 2 months of hospitalisation. The patient was then lost to follow-up. the psychiatric symptoms of this patient could be attributed to neurolupus, side effects of corticosteroides or a comorbidity between SLE and psychosis.

**Conclusion.**– It is estimated that up to 75% of patients suffering from SLE will experience neuropsychiatric manifestations at some point in the course of the disease. Neuropsychiatric symptoms are amongst the main causes of morbidity and mortality in SLE.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0177

### Dual diagnosis and treatment: The experience of a multiprofessional team in mental health

J. Jaber<sup>\*</sup>, J. Verissimo Jr, A. Hollanda, R. Trapaga  
Clínica Jorge Jaber, Saúde Mental, Rio de Janeiro, Brazil

\* Corresponding author.

**Introduction.**– The work was developed with the transversal descriptive analysis of the data obtained with a population hospitalized in a psychiatric clinic in the city of Rio de Janeiro, in the period of five years. 1.832 patients were assessed, whereas 494 presented dual diagnosis, that is, an association between a psychoactive substance use disorder and another concomitant psychiatric diagnosis. **Objectives.**– The main objective of the research is to know, in the population of hospitalized patients, the distribution of the most prevalent psychiatric diagnosis associated with the psychoactive substance use disorders.

**Methods.**– The work consisted of the evaluation of all the patients who were admitted to the clinic in the period of five years, from 2012 to 2016, using the ICD 10 for the diagnosis of the dual pathologies. All the patients were evaluated by anamneses done by the multiprofessional team. Biochemical examinations were done and, when necessary, neuroimaging and neuropsychological examinations were requested were treated with the use of psychoactive drugs, cognitive behavioural psychotherapy, a 12-step program, art therapy and moderate physical activity.

**Results.**– In the evaluation carried out, the most frequent diagnoses associated with the psychoactive substance use disorders: depression (33,8%), bipolar disorder (24,5%), personality disorder (13,7%), schizophrenia (10,6%), non-schizophrenic psychosis (9,1%) and other diagnoses (8,3%).

**Conclusion.**– It was also evidenced the increase in the capacity of recognition of the dual diagnosis as this entity has been receiving more attention in national and international studies. The effectiveness of the proposed treatment will be evaluated in later work.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0178

### **Neuropsychiatric involvement in patients with systemic lupus erythematosus in Albania**

M. Jordhani<sup>\*</sup>, V. Duraj, D. Ruci, A. Kollcaku  
UHC Mother Teresa- Tirana- Albania, Rheumatology Clinic, Tirana, Albania

\* Corresponding author.

*Introduction.*– Systemic Lupus Erythematosus(SLE) is an autoimmune disease that affects a lot of organs of the body, producing a broad spectrum of clinical findings. Neuropsychiatric involvement is one of the most important and aggressive disorders related to SLE.

*Objectives.*– This is an observational study that aimed to evaluate the most frequent types of neuropsychiatric disorders related to SLE, in patients with SLE and consulted at Rheumatology clinic at UHC “Mother Teresa”, Tirana, Albania.

*Methods.*– Forty-four patients with SLE for more than 3 years were evaluated for neuropsychiatric disorders. They were hospitalized or outpatients at Rheumatology Clinic. There were 34 females and 10 males. Neurologist and psychiatrist consults were performed to achieve information about their disorders. Every patient was completed with the necessary examinations.

*Results.*– Twenty-five patients(56.81%) had neuropsychiatric involvement that was related to SLE. From 34 females with SLE, 23 were found with light, moderate or severe neuropsychiatric involvement(67.64%): 3 with seizure disorders(13.04%), 2 with cerebral vasculitis (8.69%), 7 females had headache (including migraine & benign intracranial hypertension)(30.43%), 5 patients had anxiety disorders(21.73%) and 6 patients with cognitive disorder(26.08%). There were found only 2 males with neuropsychiatric involvement: 1 with cranial neuropathy and 1 with anxiety disorder.

*Conclusion.*– In this study it's seen that neuropsychiatric involvement is one of the main complications of SLE. More than half of the patients were affected. The most frequent neuropsychiatric complications appear to be headache, anxiety and cognitive disorders. There should be a more detailed approach towards patients with SLE in order to diagnose and treat neuropsychiatric disorders related to SLE.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0179

### **Binge eating disorder and social anxiety disorder: Are they related?**

P. Jorge  
Psychiatry resident at Centro Hospitalar do Médio Tejo, Hospital de Tomar, Portugal, Psychiatry, Tomar, Portugal

\* Corresponding author.

*Introduction.*– Research has consistently shown that anxiety disorders are common among individuals with eating disorders. However, scarce research has examined anxiety disorders in people with binge eating disorder, in particular the relation between Binge Eating Disorder (BED) and Social Anxiety Disorder (SAD).

*Aim and methods.*– Revision of the existing studies concerning if SAD and BED are related. Pub Med was used as a research source, with the search terms “social anxiety disorder” and “binge eating disorder”.

*Results.*– In our research we found some studies that clinically associated social anxiety with BED. However they have not done statistics studies. For example, the presence of SAD has been shown to be correlated with binge eating frequency in Koskina et al study.

*Discussion and conclusion.*– We found a correlation between SAD and BED in some studies. The fear of negative evaluation has been linked to disordered eating and increased food intake. It has predicted body image dissatisfaction and dysfunctional eating attitudes. Individuals with SAD may overeating to manage emotions, which may lead to weight gain and resulting feelings of shame, and further overeating to manage feelings of shame. BED is considered a public health problem because of its impact on psychiatric, physical, and social functioning. Based on this link between SAD/BED, the importance of examining anxiety (in particular social anxiety) in relation to eating disorder psychopathology becomes essential. Psychological and pharmacological interventions for binge-eating disorder and sad have previously demonstrated efficacy.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0180

### **Arachnoid cyst in patient with schizophrenia: A case report**

R. Jouini<sup>\*</sup>, M. Karoui, L. Robbana, F. Ellouze, F. Mrad  
Razi Hospital, Psychiatry G, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Arachnoid cyst is a rare intracranial condition that is usually detected by accident. The most common clinical manifestations are neurological, depending on the size and the localization of the cyst. Psychiatric presentation seems to be uncommon. Yet, there had been few cases reporting the coexistence of arachnoid cyst and psychiatric disorder in the literature.

*Objective.*– This case report aims to investigate the coexistence of arachnoid cyst and psychotic symptoms and to discuss the possibility of a causal relationship between the MRI-identified lesion and a patient's psychiatric symptoms.

*Method.*– We analysed the case of 25-year-old patient who is suffering from psychotic symptoms and frequently admitted in our department for severe relapses.

*Results.*– We present the clinical report of 25-year-old patient with past family history of psychosis, characterized by the insidious development of psychotic symptoms: Delusion of persecution, auditory hallucinations and aggressive behaviour. The cerebral magnetic resonance imagery revealed the presence of a cyst in the left temporal lobe. The surgical intervention was recused by the neurosurgical department. The therapy consisted on atypical antipsychotic without obtaining full remission of psychotic symptoms. The fact that remission was obtained by performing neurosurgery in some reported cases leads to discuss the possibility that the lesion played a role in the pathogenesis of the psychiatric symptoms.

*Conclusion.*– More studies are required to determine an eventual etiological relationship between arachnoid cyst and psychiatric disorder and to optimize the therapeutic approach in cases involving their coexistence.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0181

### Prevalence of psychiatric disorders in Thai patients with epilepsy

S. Kuladee<sup>1</sup>, P. Srisopit<sup>1</sup>, A. Boongird<sup>2</sup>, P. Wisajan<sup>1</sup>, S. Jullagate<sup>1</sup><sup>1</sup> Faculty of Medicine Ramathibodi Hospital, Psychiatry, Bangkok, Thailand; <sup>2</sup> Faculty of Medicine Ramathibodi Hospital, Medicine, Bangkok, Thailand

\* Corresponding author.

**Introduction.**– Many studies have shown that there are higher psychiatric problems in patients with epilepsy (PWE) compared to those in the general population. In Thailand, however, the prevalence of psychiatric disorders among PWE has not been reported.

**Objective.**– To study the prevalence and characteristics of psychiatric disorders in Thai PWE.

**Methods.**– A cross-sectional study was conducted at Ramathibodi Hospital. A total of 170 patients (aged 18 years old or above) diagnosed as epilepsy by neurologists were recruited at the outpatient neurology clinic. Demographic and clinical characteristics were collected. Participants were evaluated for any psychiatric disorders according to the Diagnostic and Statistical Manual of Mental Disorders, 4th edition, using the Mini-International Neuropsychiatric Interview. Prevalence of psychiatric disorders was determined. Chi-square test and logistic regression were applied to analyse the associations between psychiatric disorders and associated factors.

**Results.**– Among 170 participants (mean age 43.5), 43 (25.3%) fulfilled diagnostic criteria for one or more psychiatric disorders. The prevalence of depressive disorders was shown to be highest at 10.0%, followed by psychotic disorders (8.2%), bipolar disorder (7.1%), anxiety disorders (5.3%), and obsessive-compulsive disorder (2.9%). Electroencephalogram (EEG) abnormalities in temporal lobe were found to be a significant predictor of having psychiatric disorders in PWE (adjusted odds ratio 4.01, 95% confidence interval: 1.47–10.92, P-value = 0.007).

**Conclusions.**– The prevalence of psychiatric disorders among Thai PWE was higher than in the general population. Screening for psychiatric disorders in this population is recommended, especially in those with EEG abnormalities in temporal lobe.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### I am ill, but I am not; a case study on factitious disorder and malingering

J.Y. Leong

Institute of Mental Health, National Addictions Management Services, Singapore, Singapore

\* Corresponding author.

**Introduction.**– Factitious disorder (FD) is a psychiatric condition whereby a person creates signs/symptoms or induces injury/illness in themselves or others to assume the sick role. In malingering, the person does so for secondary gain, e.g. money. FD and malingering can be difficult to identify, differentiate and manage, taxing resources at times. Other medical/psychiatric comorbidities may exist and complicate the picture.

**Objectives.**– This case study covers a challenging case, investigating the patient's symptoms, obstacles faced by clinicians/allied health-care staff, and management.

**Methods.**– Case-notes and discharge summaries from psychiatric and general hospitals were reviewed.

**Results.**– A 37-year-old Chinese gentleman follows up with us for benzodiazepine and alcohol abuse and FD/malingering. He cuts himself, claiming he was attacked or holding a knife while intoxicated or having a seizure. He also self-induces haematemesis. He

has visited psychiatric and general hospital emergency departments multiple times over the years, often refusing investigations and treatment and discharging against medical advice, at times merely hours after presenting. He asks for referral letters for investigations, only to decline them. Multiple scopes and imaging have been performed, and treatments given. At times he asks for social-service funding or to stay for “rest”. Other times there are no evident gains. A grand round was held, concluding that he had features of both malingering and FD. A multi-disciplinary team is now employed in his management.

**Conclusion.**– Further studies into FD and malingering are needed, for more data on clinical profiles and evidence-based management.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Anxiety and depression in patients with substance use disorders

R. Sellami<sup>1</sup>, R. Masmoudi<sup>1</sup>, S. Hentati<sup>1</sup>, A. Zahaf<sup>2</sup>, I. Baati<sup>1</sup>, I. Feki<sup>1</sup>, A. Feki<sup>1</sup>, J. Masmoudi<sup>1</sup><sup>1</sup> Hédi Chaker University Hospital, psychiatry “A”, Sfax, Tunisia; <sup>2</sup> Tunisian Association for the Prevention of Drug Addiction, Tunisian Association for the Prevention of Drug Addiction, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Substance use disorders are commonly comorbid with other psychiatric disorders.

**Objective.**– To investigate the relationship between addiction, anxiety and depression.

**Methods.**– This is a descriptive and analytical cross-sectional study involving 50 patients with substance use disorders. They were compared to 50 control patients matched for age. The evaluation focused on demographic data, personal and family history, and characteristics of addictive behaviours. Anxiety and depression were assessed using the Hospital Anxiety and Depression Scale (HADS).

**Results.**– The average age of patients was 30.86 years (SD=8.07 years). The patients were single in 74% of the cases; 34% of the subjects were unemployed. The average age of onset of consumption was 22.42 years (SD=6.91). The primary substance of abuse, excluding tobacco, was cannabis (60%), followed by heroin for 20% of subjects, Buprenorphine (12%), psychotropic drugs (4%) and alcohol (2%); 42% of subjects reported polyconsumption. The mean duration of substance use was 8.24 years. Anxiety and depression were found in 46% and 38% of cases respectively. The comparative study found that patients with substances use had significantly higher scores of anxiety and depression than control subjects (p respectively=0.000 and 0.000). The depression score was correlated with early onset of substance use ( $r = -0.260$ ,  $p = 0.05$ ) and polyconsumption ( $p = 0.007$ ).

**Conclusion.**– Our study showed that anxiety and depression were associated with substance use. An emotional evaluation of patients with substance use disorders is necessary in order to optimize the care of these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0184

### Lipid profile and glucose in patients with schizophrenia, unipolar depression

M. Moalla<sup>1</sup>, R. Sellami, I. Baati, A. Feki, I. Feki, J. Masmoudi  
 CHU Hédi Chaker Sfax, Tunisia, department of psychiatry "A", Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Schizophrenia, unipolar depression and bipolar disorder are severe psychiatric disorders. Patients have increased mortality, in part, related to metabolic abnormalities.

**Objectives.**– The aim of this study is to investigate differences in triglycerides (TGA), cholesterol (TC), HDL, LDL and glucose levels in patients with acute schizophrenia, unipolar depression and bipolar disorder.

**Methods.**– This was a transversal study. We did a blood tests to 125 patients admitted to our unit during a period of 3 months. Analysis were done next day after admission.

**Results.**– The mean age of our patients was  $39.96 \pm 13.26$ . Seventy-six percent of them (N=95) were men. Mean TGA level was: schizophrenia:  $1.10 \pm 0.46$  mmol/L, unipolar depression:  $1.13 \pm 0.43$  mmol/L, bipolar disorder:  $1.45 \pm 0.79$  mmol/L, inter-group differences were significant ( $p=0.016$ ). Mean TC level was: schizophrenia:  $4.09 \pm 0.95$  mmol/L, unipolar depression:  $4.09 \pm 1.25$  mmol/L, bipolar disorder:  $4.03 \pm 0.94$  mmol/L, inter-group differences were not significant ( $p=0.9$ ). Mean LDL level was: schizophrenia:  $2.46 \pm 0.69$  mmol/L, unipolar depression:  $2.72 \pm 1.19$  mmol/L, bipolar disorder:  $2.36 \pm 0.6$  mmol/L, inter-group differences were significant ( $p<0.038$ ). Mean glucose level was: schizophrenia:  $4.53 \pm 1.6$  mg/L, unipolar depression:  $4.64 \pm 1.63$  mg/L, bipolar disorder:  $4.72 \pm 1.8$  mg/L, inter-group differences were not significant ( $p=0.08$ ). The proportion of patients having metabolic abnormalities was 16% for TGA (TGA >2 mmol/L), 3.4% for TC (TC >6 mmol/L), and 25.4% for hyperglycemia (glucose > 6 mmol/L). Glucose and lipids abnormalities were correlated to age and female sex.

**Conclusions.**– Our results confirm that there is a high prevalence of lipid and glucose abnormalities in patients with schizophrenia and mood disorders. Women and aged patients are at particularly high risk.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Diagnostics brain contusion comorbid with combat stress

S. Moroz<sup>1</sup>, B. Mikhailov<sup>2</sup>, S. Ryzhenko<sup>1</sup>, I. Yavorska<sup>1</sup>, R. Khaitov<sup>1</sup>

<sup>1</sup> Comunal institution Dnipropetrovsk regional clinical hospital named after I.I. Mechnikov, Psychoneurology department, Dnipropetrovsk, Ukraine; <sup>2</sup> Kharkiv Medical Academy of Postgraduate Education, Psychotherapy department, Kharkiv, Ukraine

\* Corresponding author.

**Objectives.**– Solution of the problem for differential diagnosis brain contusion comorbid with combat stress and post-traumatic stress disorder. We identified a group of patients, delivered from anti-terrorist operation zone with mental disorders which have not previously met and did not fit clinical picture of post-traumatic stress disorder. Therapy of post-traumatic stress disorder did not have an effect.**Methods.**– Clinic-psychopathological examination, neurologist and otolaryngologist examination; registration and analysis of EEG; MRI and CT of the brain, audiogram, neuropsychological examination.

**Results.**– An increased convulsive readiness or subclinical epileptiform activity, localized mainly in temporal, frontotemporal or frontal parts of the brain was discovered due to analyzing EEG mapping results in 85,19% cases. Decrease of the amplitude of biopotentials in alpha and theta ranges of rhythms, slow rhythms dominance in prefrontal parietal-temporal divisions, obliterating of interhemispheric asymmetry were also diagnosed. MRI and CT examinations of brain did not reveal any organic brain damage, significant violations were not discovered during neurological examination. The audiograms of these patients showed an increase in bone-air thresholds conduction at all frequencies, presence of bone-air interval of 15-30 dB in acute period. Neuropsychological testing allowed to have a possibility to identify various kinds of higher mental functions disorders which were not total, had the partial disturbance character, often with violations either praxis or gnosis.

**Conclusions.**– Provided data allowed to diagnose brain contusion. The therapy of concussion made it possible to obtain a high therapeutic effect.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0186

### Somatogenic depression and comorbidity with cardiovascular diseases

B. Mykhaylov<sup>1\*</sup>, O. Kudinova<sup>2</sup>, V. Mykhaylov<sup>3</sup>

<sup>1</sup> Kharkov medical academy of postgraduate education, Psychotherapy, Kharkov, Ukraine; <sup>2</sup> Kharkiv medical academy of postgraduate education, Psychotherapy, Kharkov, Ukraine; <sup>3</sup> Kharkiv National Medical University, Kharkiv, Ukraine, Psychiatry, Kharkiv, Ukraine

\* Corresponding author.

Contemporary tendention of increase of depressive disorders, due to somatogenic origin. We to studied clinical structure of somatogenic depression in 120 patients, (60 patients with myocardial infarction (MI) and 60 patients with cerebral stroke (CS). Examination of the patients was carried out in four stages.

The first stage in MI patients-pain (86,7%), phobic (83,3%), asthenic - anxious (43,3%) syndromes.

The second stage in MI pain (50,0%), phobic (40,0%) and asthenic - anxiety (33,3%) syndromes. The third stage asthenic-depressive (33,3%), pain (30,0%), anozognostic syndromes (23,3%).

During the fourth stage in MI patients -asthenic-anxiety syndrome in 13,3% of cases, phobic syndrome in 10,0% of cases and attitude to the disease in 16,7%.

The first stage in CS patients- cognitive syndrome (83,3%), asthenic syndrome (66,7%).

The second stage in CS patients -cognitive (66,7%), pain (53,3%), asthenic syndrome (40,0%), anozognostical (10,0%), depressive (33,3%), hypochondriac (10,0%), anxious (16,7%), hysterophorm (6,7%) syndroms.

The fourth stage in CS patients asthenic-depressive 33,3% of patients, asthenic-anxiety in 23,3%, asthenic-hypochondriac 13,3%, phobic 16,7% of patients, anozognostical 5,0% cognitive 73,3% syndroms.

The multimodal based system of psychotherapeutical correction of in MI and CS patients were developed.

The proposed system demonstrated a significant improvement in 80% of MI patients and 77% of CS patients, a partial improvement in 10% of MI patients and in 13% of CS patients.

### Traumatic experiences among alcohol users

H. Nafaa\*, A. Ouanass

Mohammed V university, faculty of medicine and pharmacy of Rabat, Arrazi psychiatric hospital, sale, Morocco

\* Corresponding author.

**Introduction.**– Single or repeated traumatic events, whether they are old or new are often found in the biography of addicted patients. Furthermore, post-traumatic stress disorder leads in many cases to the development of addictive behaviour with or without substance. The state of post-traumatic stress disorder is a major public health issue with a prevalence ranging from 1 to 9% in the general population. Important and complex relationship between alcohol and psychological trauma has been demonstrated by studies conducted mostly on the victims of aggression, or exaction, collective disasters, or among veterans.

**Methods.**– This is a descriptive cross-sectional study on a sample of 100 patients who have suffered from a psychological trauma in a moment of their life, from childhood to adulthood, and the alcohol addiction began after this life event. The objective is to study the psychopathological profile of these subjects, to improve their management which should be early and appropriate for a better prognosis. We used the Post-traumatic stress disorder Checklist scale.

**Results.**– A 90% of the alcohol users had experienced an adverse life event. 20% were women, whereas men were 80% of the sample. The traumatic events were: rape and child abuse (40%), car accident causing damage (30%), loss of a family member (10%), terrorist attack (1%), other traumatic events (9%)

**Conclusion.**– The results of the present study suggest that post-traumatic stress disorder is deeply connected to adverse life events, and the toughest is the traumatic event the more severe the alcohol abuse is.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0188

### Long-term goals in psychological care for multiple sclerosis patients

E. Nikolaev<sup>1</sup>, N. Vasil'eva<sup>2</sup>, T. Karavaeva<sup>3</sup>, E. Chekhlyat<sup>3</sup>

<sup>1</sup> Chuvash State University, Department of Social and Clinical Psychology, Cheboksary, Russia; <sup>2</sup> Chuvash Republic Clinical Hospital, Neurology Unit, Cheboksary, Russia; <sup>3</sup> Bekhterev National Center for Psychiatry and Neurology, Department of Neuroses and Psychotherapy, Saint-Petersburg, Russia

\* Corresponding author.

**Introduction.**– Multiple sclerosis (MS) is a chronic neurologic autoimmune disease with frequent comorbid psychiatric disorders. Its common symptoms are usually accompanied by problems in psychological functioning which require active psychological care. **Objectives.**– The aim was to determine long-term goals in psychological care for MS patients as the disease progresses.

**Methods.**– The study was done on the sample of 104 MS patients with the case history for 1–29 years who completed psychological questionnaires that covered their relevant symptoms and personality traits.

**Results.**– It was found out that at the initial stage of MS psychological care should be focused on psychological diagnosing and informing a patient through establishing an efficient contact with him/her, informing them about the disease and necessary lifestyle, identifying the patient's psychological status and current problem areas. As MS progresses the accent is placed on

promoting the patient's motivation and coping: motivation for attainable positive changes, correction of the disease representation and non-effective communication skills, and development of stress managing skills. The next step is associated with the emphasis on the patient's intrapersonal resources: working out coping strategies; neutralization of negative emotional experience; developing self-regulation skills, positive experience of interpersonal relations, positive self-attitude, and personality integration. On the stage of severe cognitive and physical dysfunction, the accent may be placed on supportive care: sustaining the obtained results, emotional support, and social support.

**Conclusions.**– The findings of this study may be taken into consideration when providing an appropriate psychological care to MS patients with prospects of long-term disease progression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Mood disorder in HIV infection

A. Trabsa<sup>1</sup>, V. Vilella<sup>2</sup>, L. Martínez<sup>1</sup>, E. Boix<sup>2</sup>, C. Macías<sup>1</sup>, C. Masferrer<sup>1</sup>, O. Orejas<sup>1</sup>\*

<sup>1</sup> Neuropsychiatry and Addictions Institute INAD- Parc de salut Mar, Psychiatry Hospitalization, Barcelona, Spain; <sup>2</sup> Consorci Sanitari de Mataró, Psychiatric hospitalization, Mataró, Spain

\* Corresponding author.

**Introduction.**– Psychiatric disorders, particularly mood disorders, have a profound effect on the use of and adherence to highly active antiretroviral therapy (HAART) among patients with human immunodeficiency virus (HIV) infection. HIV infection and mood disorders have features in common, and each is a significant risk factor for the other.

**Objective.**– The objective is to highlight the clinicians on the importance of screening and treating affective disorders among patients with HIV infection.

**Methods.**– Two cases of HIV infected patients with comorbid mood disorder and torpid evolution by poor adherence to treatment are reported. A brief literature review on this subject is done.

**Results.**– Major depression has been shown to alter the function of killer lymphocytes in HIV-infected patients and may be associated with the progression of HIV disease. HIV-positive patients with mental disorders are less likely to receive and adherence to antiretroviral therapy. First case-report: a man 52 years-old, HIV-positive since 1985 with a comorbid bipolar disorder, with recurrent depressions and poor adherence to both treatment with a rapidly exitus laetalis. Second case-report: man 45 years-old, HIV-positive since 1992 with a comorbid depressive disorder, non-adhered to both therapy and HIV-associated dementia.

**Conclusions.**– Depressive disorders are common in HIV infection. Antiretroviral regimens for HIV-infected patients require strict adherence. Untreated depression has been associated with medication non-adherence. Understanding the contribution of depression and its subsequent treatment on antiretroviral therapy adherence might direct clinicians toward earlier identification and more aggressive treatment among this population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

<sup>2</sup> University Hospital Puerta del Mar, Psychiatry, Cádiz, Spain; <sup>3</sup>

University Hospital Puerto Real, Psychiatry, Puerto Real, Spain

\* Corresponding author.

We present the case of a 50-year-old woman who attends emergency services due to agitation in the context of multiple toxic substances abuse and abandonment of psychopharmacological treatment. She was diagnosed of schizophreniform disorder due to multiple substance use, 10 year evolution of HIV without adherence to treatment, and hepatitis c virus. Finally, admission to psychiatry is indicated. There was difficulty in exploring the psychotic symptoms due to lack of collaboration, she was not approachable and very hostile, suspicious, irritable, and defiant, referring to kinesthetic hallucinations and self-referential ideas of prejudice. In analysis she presented anemia, leukopenia and thrombocytopenia, so interconsultation was carried out with the Hematology and Infectious Services for case evaluation.

Initially the patient refused any type of clinical intervention, she was informed of the need for treatment and follow-up given the risks presented (until then she had not correctly followed any antiretroviral treatment regimen). She was treated with prolonged-release antipsychotics (Paliperidone Palmitate 75 mg IM) given his lack of adherence and accepted. Subsequently, she shown a remarkable clinical improvement, and she begins to become aware of the severity of the physical and psychiatric conditions, agreeing to follow medical monitoring and treatment. We emphasize the importance in cases of difficult management the possibility of administering injectable treatment of prolonged release, because it allows to control the psychiatric symptomatology and in this case also allows to treat the organic disease. The paliperidone palmitate does not interact with antiretroviral treatment, so it would be indicated in these cases.

### Comorbidity between body dysmorphic disorder and schizophrenia

B. Oueslati\*, F. Fekih-Romdhane, O. Zerriaa, H. Nefzi, I. Ghazeli, R. Ridha

Razi Hospital, Forensic Psychiatry, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– Patients suffering from body dysmorphic disorder have an increased concern about their physical appearance. This concern may be related to either real or imaginary physical defects. On the other hand patients with schizophrenia may present delusional ideas about their body image.

*Objectives and methods.*– Our objectives were to illustrate and discuss the association of body dysmorphic disorder and schizophrenia throughout a case report.

*Results.*– We report the case of a 45-years-old male patient who has begun to have an exaggerated concern about his physical appearance since the age of 15. He was convinced that his chest looked feminine. This conviction yielded to behaviours of camouflage (wearing wide clothes) and verification (compulsive mirror

gazing, multiple medical consultations). After an abdominal examination performed by a physician at the age of 19, the patient had a delusional conviction that his testes were displaced. Throughout the following years, other delusions came to surface (bewitchment, persecution, revendication, grandeur and erotomania). Additionally, social and professional functioning were altered (introversion, frequent employer changes, indebtedment). At the age of 45, the patient committed a homicide attempt against his work partner. The offense was motivated by bewitchment and persecution delusions. Body dysmorphic disorder's symptoms are currently present.

*Conclusions.*– Body dysmorphic disorder may precede schizophrenia then persist as a comorbid disorder. Early and close psychiatric management of adolescents with body dysmorphic disorder is mandatory. Screening for schizophrenia should be one of the main follow-up process axes in such patients.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Clinical experience on guanfacine use in patients with adhd and substance use disorder: A case series

R.F. Palma-Álvarez\*, E. Ros-Cucurull, N. Martínez-Luna, A. Esojo, A.C. Abad, M. Robles-Martínez, L. Grau-López, J.A. Ramos-Quiroga, C. Roncero

Vall Hebron University Hospital, Psychiatry, Barcelona, Spain

\* Corresponding author.

*Introduction.*– Attention deficit hyperactivity disorder (ADHD) is a common disorder in adults, and frequently comorbid with substance use disorders (SUD). The guanfacine is drug approved only for child and youth, but some studies have been explored its use in adults. Furthermore, it has been suggested that guanfacine could be useful when SUD is presented as comorbidity.

*Objectives.*– To describe clinical experience about guanfacine use in ADHD patients with SUD attended in an Addiction Unit In Barcelona.

*Methods.*– A case series description of patients with ADHD and SUD attending an Addiction Outpatient center in Barcelona who have been treated with guanfacine. The patients were evaluated with Visual Analogue Scale (VAS) for craving, before and after treatment.

*Results.*– The sample consisted predominantly on males, the main substances used were: cocaine, heroin, cannabis and alcohol. All patients had good tolerability to guanfacine, and mostly presented a decrease in craving and impulsivity.

*Conclusions.*– Guanfacine could be a new pharmacological strategy in treatment for ADHD in adults with SUD.

*Conflict of interest:*

I have received fees as speaker from Mundipharma and Exeltis

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0193

### Hypoglycemic-induced hallucinations in a patient with pancreatic insufficiency

R. Patel

Bronx-Lebanon Hospital-Mt Sinai Health System, Psychiatry, Bronx, USA

\* Corresponding author.

*Background.*– Auditory hallucinations have been described in conjunction with many life circumstances and diseases, including religious phenomena, bereavement, drug intoxication, sensory

deprivation, and near-death experiences, as well as psychiatric or neurological disorders (Nicolson et al., 2006). This case report aims to bring awareness to clinicians the identification and treatment of hypoglycemic-induced hallucinations and recounts the treatment course of a psychiatric patient with new-onset auditory hallucinations.

**Methods.**– The patient is a 35-year-old African American male with past psychiatric history of major depressive disorder, past medical history of diabetes mellitus and pancreatic insufficiency contextual to multiple gunshot wounds, who presented to our adult outpatient psychiatry clinic for evaluation and treatment of residual depressive symptoms and new-onset psychotic symptoms including auditory hallucinations and paranoia.

**Results.**– Patient's fasting blood sugar demonstrated a critically low value, thus the patient was contacted and subsequently brought to the medical emergency department for stabilization and observation. Patient's acute psychotic symptoms and paranoid features subsided after correction of hypoglycemia and his antidepressant medication was resumed. He was discharged to follow up with outpatient psychiatry for continued treatment of his residual depressive symptoms.

**Conclusions.**– New-onset auditory hallucinations in a 35-year-old man can have a broad differential diagnosis. Careful medical evaluation of psychiatric patients is crucial in determining the etiology of new-onset symptoms. Patients should therefore be informed of the possibility of new-onset symptomatology with coexisting medical comorbidities and should work with clinicians to formulate a plan to manage potential hypoglycemia-induced phenomena.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Opioid maintenance therapy in subjects receiving antipsychotic for schizophrenia**

A. Dervaux<sup>1</sup>, L. Plancke<sup>2\*</sup>, P. Trouiller<sup>2</sup>, A. Amariei<sup>2</sup>, M. Tahon<sup>3</sup>, O. Cottencin<sup>4</sup>, T. Danel<sup>2</sup>

<sup>1</sup> CHU Amiens, Service de Psychiatrie et Addictologie de liaison, Amiens, France; <sup>2</sup> Fédération régionale de recherche en psychiatrie et santé mentale des Hauts-de-France., F2rsm, Amiens, France; <sup>3</sup> Direction régionale du service du contrôle médical des Hauts-de-France, Direction régionale, Lille, France; <sup>4</sup> CHU de Lille, Service d'Addictologie, Lille, France

\* Corresponding author.

**Introduction.**– Schizophrenia is associated with high rates of abuse or dependence of nicotine, cannabis, alcohol, or cocaine. Very few studies assessed the frequency of opioid use disorders in subjects with schizophrenia. Moreover, to our knowledge, there is no study investigating the frequency of subjects receiving opioid maintenance therapy among patients receiving antipsychotic medications.

**Objectives.**– To assess the frequency of subjects receiving opioid maintenance therapy in patients receiving antipsychotic medications.

**Methods.**– A data set from National Information System of French healthcare Social Security which covers 97% of the French population was matched with the public and private hospitals inpatients and outpatients diagnosis data system, using the social security number which all French citizen affiliated to the French Health System have. All subjects from Hauts-de-France area, North France, receiving opioid maintenance therapy, i.e. methadone, buprenorphine, or buprenorphine/naloxone, and antipsychotics prescribed by any Medical Doctor (e.g., hospital physicians, general practitioners, psychiatrists...) in patients with ICD-10 diag-

noses of schizophrenia, schizotypal disorders, delusional disorders, brief psychotic disorders, substance/medication-induced psychotic disorders, schizoaffective disorders, and other schizophrenia spectrum disorders in 2015, were included in the study.

**Results.**– The analysis of the data sets showed that among the subjects with ICD-10 diagnoses of schizophrenia spectrum included in the study and receiving antipsychotic medications ( $n = 20473$ , 0.4% of the general population), 2.6% received methadone or buprenorphine ( $n = 532$ ).

**Conclusions.**– The rates of patients with schizophrenia spectrum receiving opioid maintenance therapy was not uncommon, more frequent than the rate of subjects receiving opioid maintenance therapy in the general population (0.70%).

### **A systematic review of dual disorders**

M.D.L.C. Ramirez Dominguez<sup>\*</sup>, L. Hernandez Gonzalez, M. Nuñez Caro

Psychiatrist, Psychiatrist, Aljaraque, Spain

\* Corresponding author.

**Introduction.**– Dual diagnosis is a growing problem in the Western society, despite the fact that there are no relevant studies that examine this issue, non-specific protocols to address them.

**Objectives.**– Raising the awareness of the importance of dual diagnosis both its prevalence and special features that presents need a different performance plan from them separately.

**Results.**– In addition to that, a common point between depression and alcohol disorders lies in the deterioration of cognitive functions. Some complications in the treatment of patients with dual diagnosis are adherence, interference between the two treatments and the failure of medical or psychological prescriptions.

**Conclusions.**– Dual diagnosis has very specific characteristics that we must know in order to develop therapeutic strategies adapted to the present conditions. All this suggests that the combination of treatments for both diseases would be more effective, especially for those who

claim to use alcohol as self-medication.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0196

### **Depression during an acute psychotic decompensation of schizophrenia: Diagnosis and management: A case report**

A. Rebai<sup>\*</sup>, T. Racha, M. Olfa, G. Rym

Hospital Razi, Pinel Psychiatry B, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– The prevalence of depressive symptoms in patients with schizophrenia ranges from 10% to 75% in different studies. Depressive symptoms are most often found during the first acute psychotic episode and in schizophrenics with several recurrences. Adequate management of depression aims to improve the prog-

nosis of schizophrenia, as it is an important and decisive factor in recidivism.

**Objectives.**– Diagnosis of depression concomitant with an acute psychotic episode in schizophrenics. Management, efficacy and safety of antidepressants associated with antipsychotics.

**Methods.**– Through a clinical case, we will discuss the diagnosis and the management of depression concomitant with an acute psychotic episode in schizophrenic patients.

**Results.**– The patient is a 28-years-old woman hospitalized for suicidal ideation. The patient had a delirious syndrome with predominantly auditory hallucinations and a dissociative syndrome. The diagnosis of schizophrenia was evident according to DSM criteria. The patient also had a severe depressive symptomatology of sadness with self - depreciation, guilt ideas and a negative vision of the future. She had a Calgary score of 19 indicating the severity of the depressive symptoms. The patient was treated with an atypical oral neuroleptic at first but considering a categorical refusal to take her treatment and given the non availability of long-acting injectable atypical antipsychotic, she received Haloperidol decanoate. The prescription of antidepressants was not advocated because of the supposed risk of exacerbation of delirium.

**Conclusions.**– Adequate management of depression in the same rank of psychotic relapse should be advocated to ensure complete remission and rapid reinsertion of the subject.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0197

### **Can we prevent substance use disorder in ADHD patients?**

H. Saiz Garcia<sup>1\*</sup>, M.Á. Álvarez de Mon<sup>2</sup>, V. Pereira<sup>2</sup>, A. Rosero<sup>1</sup>, L. Montes<sup>1</sup>, E. Mancha<sup>1</sup>

<sup>1</sup> Complejo Hospitalario de Navarra, Psychiatry, Pamplona, Spain; <sup>2</sup> Clínica Universidad de Navarra, Psychiatry, Pamplona, Spain

\* Corresponding author.

**Introduction.**– The prevalence of is about 5% in children and 2.5%. This disorder is sometimes infradiagnosed because of its multidimensional symptoms, which can confuse the practitioner to identify the core symptoms of ADHD. Validated assessment scales and high-yield clinical questions can help diagnose adults with ADHD. Patients with ADHD may be at high risk of developing a substance use disorder. It depends of many factors, such as impulsive behaviour, psychosocial problems, affective disorders or self-treatment of ADHD disorder with psycho-stimulant drugs.

**Methodology.**– A review was conducted aiming to clarify the triggers and possible mechanism of prevention in ADHD patients to prevent a EVoccurring substance use disorder. The literature search was conducted in Pub Med data reviewing articles dating between 2013 and 2017.

**Results.**– 1. Guidelines suggest that the most impairing symptom of ADHD should be treated first. But, for example, treating ADHD with SSRIs is related with an increase in substance-related events in short term. 2. Many studies have suggested that treating both adult and adolescents with stimulants for ADHD is related with a reduction of substance use disorder. 3. Treatment of ADHD has also been associated with a reduction of psychosocial problems that can lead to substance use disorders.

**Conclusions.**– Early detection and treatment of ADHD is an important fact to prevent the future development of a substance use disorder. Untreated ADHD can lead to behavioural, social, functional and mental health problems. Some studies may suggest a need for increased doses in population with SUD to achieve optimal ADHD symptom control.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Antiepileptic drugs and psychopathology of epilepsy**

S. Daoud<sup>1\*</sup>, N. Farhat<sup>1</sup>, N. Charfi<sup>2</sup>, H. Haj Kacem<sup>1</sup>, O. Hdiji<sup>1</sup>, S. Sakka<sup>1</sup>, M. Damak<sup>1</sup>, M. Maalej<sup>2</sup>, C. Mhiri<sup>1</sup>

<sup>1</sup> Habib Bourguiba hospital, Neurology, Sfax, Tunisia; <sup>2</sup> Hedi Chaker Hospital, Psychiatry, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Psychopathology in epilepsy has a multifactorial etiology and antiepileptic drugs (AEDs) constitute one of many determinants that are both neurobiological and psychosocial.

**Objective.**– To determine psychotropic effects of AEDs in patients with epilepsy.

**Methods.**– We conducted a cross-sectional study involving 54 patients with epilepsy who were treated in the neurology department of Habib Bourguiba Hospital in Sfax, Tunisia. We used the Mini International Neuropsychiatric Interview for the diagnosis of Axis I psychiatric disorders. We tried to evaluate the associations between AEDs and psychiatric comorbidities.

**Results.**– Thirty-six patients were treated with monotherapy and 18 were on polytherapy. Twenty eight patients had psychiatric comorbidities. Eleven patients had major depressive disorder (valproate: 5, barbiturates: 1, carbamazepine (CBZ): 1, polytherapy: 4). Panic disorder was noted in 8 cases (valproate: 3, carbamazepine: 4, polytherapy: 1). Carbamazepine intake was associated with generalized anxiety disorder (2 CBZ on monotherapy, one associated with valproate and one with barbiturates) and with dysthymia (2 on monotherapy and 4 on polytherapy). While social phobia and agoraphobia seem to be linked with valproate (6/7 patients and 6/9 patients respectively). In the group of patients on polytherapy, 55% had psychiatric comorbidities vs 50% in the group on monotherapy.

**Conclusions.**– Selection of antiepileptic drug therapy for patients with epilepsy is usually focused on an agent's ability to suppress seizures, but other attributes of the drug should be considered such as adverse effects which can include psychiatric disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **“Sexsomnia”: An uncommon parasomnia associated with potential major psychological consequences**

M. Sequeira<sup>1\*</sup>, A. Martins<sup>2</sup>, B. Trancas<sup>1</sup>, T. Maia<sup>1</sup>

<sup>1</sup> Hospital Professor Doutor Fernando Fonseca- EPE, Amadora, Portugal, Department of Psychiatry, Lisboa, Portugal; <sup>2</sup> Hospital Professor Doutor Fernando Fonseca, EPE- Amadora, Portugal, Department of Neurology, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– The term “Sexsomnia” refers to a form of parasomnia in which abnormal sexual behaviour is exhibited in sleep. Initially described in 1897, it was rarely reported in the literature until a decade ago, possibly because of patient's understandable difficulty in disclosing due to negative feelings<sup>1</sup>. A growing attention has been focused on this disorder, primarily driven by its forensic implications, aiming for a better understanding and characterization of this parasomnia<sup>1-3</sup>.

**Objectives.**– We propose to present and scrutinize a clinical case of sexsomnia in all clinical dimensions in order to draw attention to its potential mental health impact.

**Methods.**– We present a case of a 55-year-old woman with 18 month's history of sexsomnia and explore its characteristics, focusing on its differences from those previously mentioned in the literature, as well as on the psychosocial impact of this disorder.

**Results.**– Besides the potential occurrence of violent episodes, with possible forensic consequences, we realize that differences of profile and presentation of sexsomnia have little effect in the resulting psychological distress, whose approach, together with pharmacological treatment, seems to configure the most effective strategy in order to relieve its consequences.

**Conclusions.**– The description of the particular characteristics of this manifestation along with the other cases already described in the literature help to further clarify the clinical profile of this condition. We also highlight the resulting psychological distress, which had major impact in the patient's global quality of life, underscoring the need for an effective dialogue between psychiatry and neurology.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Prevalence of hypertension and associated factors in patients attending a community psychiatry service in North India

S.M. Singh\*, A. Sharma, P. Agrawal, M. Sharma, A. Avasthi  
pgimer, Psychiatry, Chandigarh, India

\* Corresponding author.

**Introduction.**– Persons suffering from mental illness are known to have higher rates of cardiovascular morbidity and mortality. However data regarding prevalence of hypertension and associated factors such as obesity, physical activity, family history of diabetes, body mass index (BMI), smoking status etc in patients with psychiatric illness are scarce.

**Objectives.**– This study reports the preliminary results of a larger project that aims to find the prevalence of hypertension and associated factors in patients attending a community outpatient psychiatry service of a tertiary hospital in North India.

**Methods.**– The study design was approved by the institute ethics committee. Written informed consent was obtained. Patients aged 18 years or above were included. Sociodemographic and clinical details were recorded. Blood pressure and anthropometric details were measured as per World health organisation norms. Family and medical history was inquired into. Activity levels were measured using global physical activity questionnaire.

Table 1

Variables	Male	Female	Total
Hypertension	17	13	30
Central obesity	14	36	50
BMI	25	15	40
	Within norms		
Overweight	8	8	16
Generalized obesity	12	32	44
Activity as per GPAQ	6	14	20
	Insufficiently active		
Active	39	41	80
Tobacco use	20	1	21
Alcohol use	18	0	18
First degree relative with diabetes	2	6	8
Known hypertension/diabetes/coronary artery disease	5	8	13

**Results.**– The results of a 100 patients (45 males and 55 females) are reported (Table 1)

**Conclusions.**– There is a significant prevalence of hypertension and contributory factors in patients with mental illness in the community. Implications are discussed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Anorexia nervosa symptoms in a young woman with treatment-resistant schizophrenia – Challenges in diagnosis and treatment

H.T. Tan<sup>1</sup>\*, C.S.N. Kwok<sup>2</sup>, H.Y. Lee<sup>2</sup>, G.M.Y. Tan<sup>1</sup>

<sup>1</sup> Institute of Mental Health, General Psychiatry, Singapore, Singapore; <sup>2</sup> Singapore General Hospital, Psychiatry, Singapore, Singapore

\* Corresponding author.

**Introduction.**– Comorbidity of eating disorders (ED) in schizophrenia is poorly understood. ED in schizophrenia is difficult to assess due to diagnostic overlap and atypical presentations, and treatment strategies can be challenging to implement.

**Objectives.**– We describe a case of comorbid anorexia nervosa (AN) in a young woman with treatment-resistant schizophrenia.

**Case.**– Miss H. is a 27-year old single woman, the older of two children from a lower-middle class family, with no family history of mental illness. She presented with school and food refusal at age 9, and was diagnosed with depression. This was revised to schizophrenia when she exhibited disorganized and paranoid behaviour at age 12. Due to treatment-resistant disorganized behaviour, she has been a long-stay patient of Institute of Mental Health (IMH) since age 19. Her body mass index ranges between 9.8-16.8, due to persistent food refusal and recurrent vomiting as she feels fat. She was diagnosed with possible anorexia nervosa at age 18. Full assessment and treatment of AN was hampered by her psychotic symptoms and cognitive deterioration. She is currently stable on fluoxetine 60 mg/day, olanzapine 20 mg/day and IM flupentixol 40 mg 4-weekly, with the mainstay of treatment to encourage oral intake. Whilst a multi-disciplinary team, reward-based system and close supervision has been partially effective, improvement has been difficult to sustain.

**Conclusions.**– We report a case of likely AN comorbid in a young woman with chronic schizophrenia. This case illustrates the diagnostic overlap between restrictive eating in ED and food refusal in psychosis, as well as the challenges in treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0202

### Dual pathology approach among chronic mental disorders; a retrospective descriptive study

A. Trabsa<sup>1</sup>\*, V. Vilella<sup>2</sup>, E. Monteagudo<sup>1</sup>, M. de Dios<sup>1</sup>, D.

Sanagustin<sup>1</sup>, S. Pérez<sup>1</sup>, C. Masferrer<sup>1</sup>, O. Orejas<sup>1</sup>

<sup>1</sup> Hospital del Mar, Psychiatry, Barcelona, Spain; <sup>2</sup> Hospital de Mataró, Consorci Sanitari del Maresme, Psychiatry, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Dual pathology in mental health is defined by the World Health Organization (WHO) as the “co-occurrence in the same individual of a psychoactive substance use disorder (SUD) and another psychiatric disorder”. The approach and the literature of

this comorbidity use to be focused on acute psychiatric patients, not taking into consideration patients who are in subchronic or chronic psychiatric units. This fact could impair the achievement of a complete and multidisciplinary management among these patients.

**Objectives.**– To describe the presence of SUD and its characteristics in a chronic mental disorder sample of patients.

**Methods.**– A total of  $n=201$  patients who were hospitalized in a medium-long term stay psychiatric Unit were registered between June 2014–September 2017. Database information was completed with electronic medical records. Descriptive analysis was performed with SPSS Statistics.

**Results.**– From 201 chronic patients sample, 89 (44.3%) were associated to SUD clinical history. From total patients with SUD clinical history, 60 (67.4%) maintained active substances consumption during hospitalization at Chronic Psychiatric Unit. From the patients who were associated to SUD, 82 (92.1%) presented polysubstance SUD: 70 were associated to nicotine, 42 to cannabis, 38 to alcohol, 16 to cocaine, 9 to amphetamines, 3 to benzodiazepines and 4 to other psychoactive substances.

**Discussion.**– According to our results, patients who are hospitalized in medium-long term psychiatric units present important comorbidity with SUD. Therefore, it should be borne in mind to include these patients in dual pathology approach. Further studies should not dismiss chronic patients in order to not underestimate this population in dual pathology research.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Dandy-walker malformation-like condition revealed by a refractory schizophrenia: A case report and literature review**

M. Tréhouit<sup>1,2,3\*</sup>, N. Zhang<sup>4</sup>, M. Blouet<sup>4</sup>, A. Borha<sup>5</sup>, S. Dollfus<sup>1,2,3</sup>

<sup>1</sup> CHU de Caen, Service de psychiatrie, Caen, France; <sup>2</sup> Normandie Université-EA7466-ISTS, GIP Cyceron, Caen, France; <sup>3</sup> Normandie Université- UNICAEN, UFR de Médecine, Caen, France; <sup>4</sup> CHU de Caen, Service de radiologie, Caen, France; <sup>5</sup> CHU de Caen, Service de neurochirurgie, Caen, France

\* Corresponding author.

**Introduction.**– Dandy-Walker Malformation is a rare congenital malformation involving cystic dilatation of the fourth ventricle, enlarged posterior fossa, complete or partial agenesis of the cerebellar vermis, elevated tentorium cerebelli, and hydrocephalus. Previous research highlighted a possible role for the cerebellum in schizophrenia as well as the contribution of underlying brain malformations to treatment resistance.

**Objectives/methods.**– Here, we present a case of a Dandy-Walker Malformation-like condition revealed by a refractory schizophrenia in a 24-year-old male patient. We also conduct a literature review of all previously published case reports or case series of EVoccurring posterior fossa abnormalities and schizophrenia or psychosis using a Pub Med search query to better understand the potential link between these two disorders.

**Results.**– A 9-month hospital stay was needed to address the treatment-resistant psychotic symptoms, and the patient continued to experience moderate symptoms despite the prescription of various antipsychotic and antidepressant medications. After an irregular initial medical follow-up, the patient is currently treated with 350 mg daily clozapine and 20 mg daily prazepam and still exhibits moderate anxiety without delirious thoughts, however allowing him to re-enroll in University. Regarding the literature, twenty-four cases published between 1996 and 2017 were identified, reviewed and compared to the present case report.

**Conclusions.**– This case report and literature review further illuminates the pathophysiology of psychotic disorders including the potential role of the cerebellum, reinforces the importance of a multidisciplinary approach for the neurological and psychiatric management of patients with schizophrenia, and highlights optimal pharmacological management strategies for treatment-resistant schizophrenia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0204

### **Health and gender differences in relation to stress response**

P.J.M. Van Wijngaarden-Cremers

*Dimence, Centre for Developmental Disorders, Zwolle, The Netherlands*

\* Corresponding author.

**Background.**– According to a proposal for a new definition of health (Huber et al., 2011), health is not as the WHO definition still stipulates absence of disease and a state of complete mental, physical and social wellbeing, but the capacity to adapt under different circumstances, including the burden of disease.

**Goal.**– Life and the burden of disease is considered in relation to gender. The question is whether women are more vulnerable to ill/health for a series of gender/bound reasons.

**Methods.**– The scientific literature was searched and questioned on various relevant issues: What is the role of gender in gene-environment interactions? Are there gender related neurobiological differences in the development of stress regulation? What is the role of childrearing and of social/economic circumstances?

**Results.**– Gender is an essential intermediate factor between genetic predisposition that influences brain and psychological development leading to behaviours and coping mechanisms that are different across sexes. Stress regulation is different in men as compared to women. The much shorter but far more intense reaction of the hypothalamus-pituitary-adrenergic system in women has impact on immune-reactions but especially on vulnerability for psychopathology. This tendency appears to have been strengthened by the different ways of childrearing.

**Conclusions.**– There are both neurobiological but also environmental (child rearing) differences in the physiology of stress response between women and men. Under the same circumstances men will react with a higher vulnerability to infections, cardio-vascular and metabolic disorders. Women are more prone to react with depression and anxiety and develop autoimmune diseases.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0205

### **Analysis of psychiatric comorbidities in type I Diabetes mellitus and step-wise diagnosis approach proposal**

O. Vasiliu

*“Dr. Carol Davila” Central Military Hospital, Psychiatry, Bucharest, Romania*

\* Corresponding author.

**Background.**– Type I diabetes mellitus (DM) is frequently associated with psychiatric -especially depressive or anxiety- disorders.

**Objective.**– To analyze, based on the data from literature, the prevalence of psychiatric EVmorbidities in patients diagnosed with type

I DM and to propose an algorithm for these patients' evaluation focused on early detection and treatment of psychiatric disorders. *Methods.*– Main electronic database were searched (MEDLINE, Pub Med, Cochrane, EMBASE, Google Scholar) for trials regarding the prevalence of psychiatric diagnoses in adult patients with type I diabetes mellitus.

*Results.*– A number of 11 observational studies published between 2000 and 2017 have been selected, which included 1320 patients aged over 18, diagnosed with type I DM. Relevant data was found for the prevalence of several psychiatric disorders- generalized anxiety disorder (21-22.7%), dysthymia (6-18.2%), panic disorder (2.5-8.2%), social phobia (5.5-7%), and major depression (4.6-16%), while for eating disorders and neurocognitive disorders studies' results were not conclusive. An algorithm for the evaluation of adults diagnosed with type I DM should be implemented in order to detect as early as possible these psychiatric disorders and to treat them adequately. The inclusion of validated psychometric scales like Hamilton Depression Rating Scale, Hamilton Anxiety Scale, Brief Psychiatric Rating Scale, Global Assessment of Functioning and a structured interview like MINI 6.0 are considered necessary for this purpose.

*Conclusions.*– There is a high prevalence of psychiatric disorders in adult patients with type I DM and an early detection of these conditions could improve the prognosis and quality of life in this population.

*Conflict of interest:*

EV0206

### **Schizophrenia with obsessive-compulsive features: two comparative case reports: Obsessive-compulsive symptoms onset-before versus following psychosis**

M. Vedeau\*, A. Serban, C. Marginean, I. Dragomir  
*Emergency Country Hospital Cluj, Psychiatry I, Cluj Napoca, Romania*  
\* Corresponding author.

*Introduction.*– The association of Obsessive-compulsive symptoms (OCS) in patients with schizophrenia has become more and more frequent as literature suggests it. Symptoms may occur before, simultaneously or after the onset of psychosis. Two case reports will be presented, each of them having different onset times of the OCS.

*Objectives/aims.*– Two case reports of patients from our psychiatric ward will be presented here. Our aim is to show the frequent and relevant co morbid burden that Obsessive-compulsive symptoms are in schizophrenia and the challenge to find an effective treatment.

*Methods.*– Based on literature search, two cases are presented. We performed a systematic search through Pub Med to find more data on schizophrenia with Obsessive-compulsive symptoms. Yale-Brown Obsessive-compulsive Scale and Positive and Negative Symptoms Scale were applied to both patients.

*Results.*– The two patients are both under treatment with Sertraline (150mgs/day versus 50 mgs/day) added to the anti-psychotic medication with a stable evolution and partially good control of the symptoms. Y-BOCS scores decreased from scores initially indicat-

ing severe OCS for both patients to mild (Y-BOCS 15) and moderate (Y-BOCS 20) following the supplementation of the treatment with sertraline.

*Conclusions.*– Although antidepressants normally augment the tableau of psychosis, when this is accompanied by Obsessive-compulsive features, antidepressant medication, sertraline in our case, ameliorated both psychosis and OCS with Y-BOCS and PANSS scores decreasing and showing improvement.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0207

### **Comorbidity in hospitalized patients with schizophrenia**

V. Videnova<sup>1</sup>\*, B. Stefanovski<sup>2</sup>, N. Manusheva<sup>3</sup>

<sup>1</sup> *Psychiatric Hospital Skopje, emergency psychiatry, Skopje, FYR Macedonia;* <sup>2</sup> *Psychiatric Clinic Skopje, biological psychiatry, Skopje, FYR Macedonia;* <sup>3</sup> *Psychiatric Clinic Skopje, psychophysiology, Skopje, FYR Macedonia*

\* Corresponding author.

*Introduction.*– There is an insufficient awareness of comorbidity in schizophrenia on the part of patients, caregivers, health care providers, and researchers. Comorbidity has often been under-recognized and underdiagnosed in psychiatric patients, especially among those with schizophrenia.

*Objective.*– The aim of this study is to analyze comorbidity in hospitalized patients with schizophrenia.

*Methods.*– Medical charts of 96 inpatients with schizophrenia (42 male and 54 female, aged 19-65) were retrospectively analysed in terms of comorbidity.

*Results.*– Comorbid substance abuse was found in 17 patients, 7 patients had personality disorders, while 34 had anxiety disorders.

*Conclusions.*– Comorbid substance abuse leads to poorer medication compliance, higher rates of rehospitalization, poorer adjustment and treatment response in schizophrenia patients. Increased likelihood of violent behaviour and greater use of emergency services are also associated with substance abuse in schizophrenia. Comorbidity has negative impact on treatment outcome in schizophrenia patients which affects the prospects of discharge in this patients and their quality of life

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0208

### **Is bariatric surgery a valid treatment for our psychiatric obese patients?**

L. Villain<sup>1</sup>\*, M. Deloze<sup>2</sup>, D. Nocca<sup>2</sup>, P. Courtet<sup>1</sup>, S. Guillaume<sup>1</sup>

<sup>1</sup> *University Hospital Lapeyronie, Post Emergency Psychiatry, Montpellier, France;* <sup>2</sup> *University Hospital Saint Eloi, Bariatric surgery, Montpellier, France*

\* Corresponding author.

*Introduction.*– Obesity is a major health issue in psychiatric patients with a prevalence up to 20% in depression and 55% in schizophrenia. Bariatric surgery is the more effective treatment for obesity but psychiatric patients have less access to it.

*Objectives.*– In this presentation, we will sum up the current literature and show results from a study focusing on the effects of a sleeve gastrectomy among psychiatric patients on psychotropes prescription and the efficacy of the surgery.

*Methods.*– A retrospective cross-study was conducted in our unit, we included patients who underwent a Sleeve gastrectomy and had a preoperative psychiatric disorder (mood disorder, schizophrenia).

The analysis focused on weight and psychiatric changes with data collection in two stages: before surgery and two years after surgery. *Results.*– Over the 74 patients included, the effectiveness of the sleeve gastrectomy at two years found a success rate of 72.9% and an average loss of 67% of excess weight; those results are comparable to what can be expected in general population. Severity of psychiatric illness was not associated with reduced efficacy of surgery; in deed, among the 11 patients suffering from bipolar disorder or schizophrenia, only one failed. Finally, effectiveness of surgery significantly led to the reduction or discontinuation of treatment while patients with failed surgery had slightly modified treatment, linked to insufficient psychiatric care.

*Conclusion.*– Our study found no specific effect of the psychiatric disorder or the psychoactive drug on the result of the surgery. Further studies appeared necessary to better understand psychiatric factor at risk for surgery.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0209

### **Psychoorganic syndrome: Between dementia, depression and delirium (case study)**

S. Čekerinac<sup>1</sup>, V. Vuković<sup>2\*</sup>

<sup>1</sup> General hospital Sremska Mitrovica, Psychiatric ward, Sremska Mitrovica, Serbia; <sup>2</sup> Special hospital for psychiatric disorders “dr Slavoljub Bakalović”, Unit for crisis states and early interventions, Belgrade, Serbia

\* Corresponding author.

*Introduction.*– Patients between 60 and 70 years often present a poorly delineated diagnostic category with multiple somatic comorbidities, and can easily slip between the cracks of narrowly defined domains of specialty care.

*Case summary.*– A 65 year old patient presented to the ER department with clouded consciousness, agitation, myoclonus and high fever. Initial assessment by an infectologist ruled out a central nervous system infection, while neurological assessment revealed no acute cerebrovascular injury (CT scan showed no pathological lesions). Further workup revealed low sodium levels, detailed patient history uncovered severely restrictive food and water intake prior to admission indicating a diagnosis of hypovolemic hyponatremia. Furthermore, the patient had been found three weeks prior with his shirt around his neck, a suspected suicide attempt. He had been undergoing private psychiatric treatment for three months because of low mood and nihilistic delusions (treatment: olanzapine, sertraline, mirtazapine) and was previously treated in 2012 (depressive episode, achieved full remission). After being stabilized symptoms of low mood and mild confusion persisted, the patient was transferred to the psychiatric ward. An MRI scan showed a large number of ischaemic lesions in the striatum and white matter. Psychological testing revealed mild cognitive deficits and lowered affective control. The drug regimen was changed (risperidone, sertraline, memantine, lorazepam) which was followed by withdrawal of affective symptoms and confusion.

*Conclusion.*– Attention to underlying somatic causes and adequate communication and cooperation with somatic medicine is essential, but special care should also be dedicated to elderly patients who exhibit symptoms in several psychopathological domains.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **A case with Asperger's disorder and comorbid schizophrenia responded to clozapine**

H. Yesilkaya<sup>1\*</sup>, O. Sahmelikoglu Onur<sup>2</sup>, O. Akay<sup>2</sup>, E. Subas<sup>2</sup>, E. Cesur<sup>2</sup>, G. Teksin<sup>2</sup>

<sup>1</sup> Bakirkoy Prof. Dr. Mazhar Osman Training and Research Hospital for Psychiatry, 7. Psychiatry Department, Istanbul, Turkey; <sup>2</sup> Bakirkoy Prof. Dr. Mazhar Osman Training and Research Hospital for Psychiatry, <sup>3</sup> Psychiatry Department, Istanbul, Turkey

\* Corresponding author.

*Introduction.*– It is suggested that frequency of schizophrenia and other psychotic disorders is high in cases with Asperger's disorder (AD) and in their families. On the other hand, information regarding management of schizophrenia in cases with AD is limited. In this presentation, a 21-year-old case with AD and comorbid schizophrenia, is reported. Her psychotic symptoms did not respond to sodium valproate, risperidone, melatonin, quetiapine, olanzapine, lamotrigine, aripiprazole, clomipramine, respectively.

*Case.*– A 21-year-old female, with history of AD and has been using haloperidole 15 mg/day, biperidene 4 mg/day, oxcarbazepine 300 mg/day, chlorpromazine 600 mg/day for 4 months, had symptoms of irritability, compulsions of checking, increased amount of speech and agitation. These symptoms had begun 2 weeks ago. She had been diagnosed with AD 11 years ago, hospitalized for 7 times since then and advised to take sodium valproate, risperidone, melatonin, quetiapine, olanzapine, lamotrigine, aripiprazole, clomipramine. Her lab work up was unremarkable, including urine toxicology. In her psychiatric examination, puerile attitude, preservation, compulsions of checking, auditory hallucinations were noted. The patient met DSM 5 criteria for schizophrenia and AD, was followed with treatment including haloperidole 20 mg/day, biperidene 10 mg/day and chlorpromazine 400 mg/day. Despite of 7 sessions of ECT, the symptoms of the patient continued. The treatment was changed to clozapine 25 mg/day and the dose was gradually increased to 125 mg/day. Within 10 days, her symptoms were totally improved and she was discharged from the hospital with the treatment of clozapine 125 mg/day.

*Conclusion.*– This case is important for demonstrating that clozapine can be effective in resistant cases of schizophrenia as seen in AD.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Consultation liaison psychiatry and psychosomatics**

EV0211

### **Patterns of referrals to consultation-liaison psychiatry in a tertiary care hospital in Oman: Cross-sectional study**

A. Altoubi<sup>1\*</sup>, H. Al Qataybi<sup>1</sup>, M. Rodger<sup>2</sup>

<sup>1</sup> Oman medical speciality board, Psychiatry, Muscat, Oman; <sup>2</sup> Sultan Qaboos University, Department of Behavioral Medicine, muscat, Oman

\* Corresponding author.

*Background.*– Growing and accumulative evidence in the field supports that Consultation-liaison (C-L) psychiatry as a cost-effective

service in shortening the length of stay in the hospital with early detection and treatment of mental illnesses.

**Objectives.**– This study is the first research implemented in the Sultanate of Oman to review all patterns of referrals to the consultation liaison team from various in-patient departments at Sultan Qaboos university hospital, Muscat, Oman.

**Methods.**– All patients referred from the medical and surgical wards from May 2015 to December 2015 were evaluated for inclusion in the study. A data collection sheet was designed to record the patients' demographics, reason of admission, presence of medical or surgical EVMorbidity and reason for referral to C-L psychiatry and whether a psychiatric diagnosis presents prior to the referral. The recorded data were analysed using descriptive statistical methods.

**Results.**– A total of 104 patients were referred to C-L psychiatry over the indicated period of the study. A majority of the referrals were from acute medicine unit (32.7%), neurology unit (15.4%) and surgery department (9.6%). The most common reasons for referral were depressed mood (28.8%) and abnormal behaviour (24%). Major depressive disorder (30.8%) was the most commonly diagnosed psychiatric disorder followed by substance use disorder (8.7%).

**Conclusion.**– C-L psychiatry is an important utility for general hospitals in order to ensure a high- standard quality of care provided to patients. Additionally, C-L psychiatrists should play a significant role on sensitizing other health professionals toward detecting early signs of mental disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Building psychiatry outpatient consultation-liaison focusing on access, targeting the quality and gain continuing education as result. The step by step to implement the service**

R. Antunes dos Santos<sup>1\*</sup>, R. Calzada<sup>2</sup>, T. Sarmiento<sup>2</sup>, J. Septimo<sup>2</sup>, S. Lustosa<sup>2</sup>, G. Graciano<sup>2</sup>

<sup>1</sup> University of Brasilia, Medicine School, Brasilia, Brazil; <sup>2</sup> Hospital Universitario de Brasilia, Psychiatry, Brasilia, Brazil

\* Corresponding author.

Psychiatry outpatient clinics very often have long lists waiting for the first consultation to finally come into the system. The role of a psychiatry outpatient clinic inside the chain of care can be debated to achieve the goal to provide quality care and access. This study describes step by step the strategies and plans to implement an outpatient clinic in a university hospital. The plan began in 2014 when the time in the waiting list to have a psychiatry consultation was about 2 years. The university hospital was moving to very specialized services (psychosis, mood disorders, etc.) and general psychiatry would be no longer practiced inside the hospital borders, but in the community settings. A task force of psychiatrists from university hospital worked analyzing all the requests and the potential patients in the waiting list. After analysis patients were referred to specialized services, general psychiatry or family physicians as needed. In 2016, when the list achieved the zero time the ordinary referral system was shut down and the psychiatry' consultation-liaison, PCL, started activities. The PCL service was developed to answer calls from any specialty inside university hospital outpatient clinics immediately. A psychiatrist from the team analyses the selected patient with the physician, the resident and the student from the specialty that called. The team, with the psychiatrist, decides together which service will be the best to

care for the treatment of each patient, depending on the level of complexity and specialization required.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0213

### **Delusional parasitosis: Interest of an hospital-centered “skin and brain network”**

A. Bensussan<sup>1\*</sup>, C. Rometti<sup>1</sup>, P. Delaunay<sup>2</sup>, M. Hamm<sup>1</sup>, M. Benoit<sup>1</sup>

<sup>1</sup> Nice University Hospital, Psychiatry, Nice, France; <sup>2</sup> Nice University Hospital, Parasitology, Nice, France

\* Corresponding author.

**Introduction.**– The impact on quality of life of patients with delusional infestation is major, but its complex management has not received any medical guideline. With the objective to cope with this clinical problem in a general hospital, we have proposed new strategies to improve the holistic care of this patients.

**Method.**– In a case study approach, we have recruited patients suffering from delusional infestation in the dermatology and parasitology departments of the Nice university hospital from April 2016 to July 2017.

**Results.**– Our clinical observations led us to consider delusional parasitosis as a trouble expressed by a hypochondriac presentation, with a sensitive personality, systematic interpretations, mixed hyperthymia and pathomimic attitude. The biographical history reveals the presence of psychological trauma in childhood, the personality traits are organized around a complex of shoring and dependence, with impulsiveness, aggressiveness, tendency to conformism and addiction. Consultations are difficult situations which highlight all the patient's defence mechanisms. Given this observation, we have repeatedly aimed patient's hospitalization. This experience seems to be an ideal support to fight against the processes of idealization and cleavage. Its objectives would be to carry out the aetiological investigation, to provide skin care and to involve psychiatric care.

**Conclusion.**– Although descriptive, our observations suggest going from multidisciplinary to transdisciplinarity, in which collaboration and close coordination between the various protagonists needs more order. The creation of a “Skin and Brain network” involving referents in parasitology, dermatology and psychiatry was born at Nice University Hospital to reach therapeutic goals and improve healthcare.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0214

### **Altered brain metabolism associated with functional motor disorder**

I. Conejero<sup>1\*</sup>, L. Collombier<sup>2</sup>, E. Olié<sup>3</sup>, P. Courtet<sup>3</sup>, M. Abbar<sup>4</sup>, J. Lopez Castroman<sup>4</sup>, E. Thouvenot<sup>5</sup>

<sup>1</sup> Nîmes University Hospital, Psychiatry, Nîmes, France; <sup>2</sup> CHU de Nîmes, Nuclear Medicine, Nîmes, France; <sup>3</sup> Department of Emergency Psychiatry and Post-Acute Care- Hôpital Lapeyronie, CHU de Montpellier, Psychiatry, Montpellier, France; <sup>4</sup> CHU de Nîmes, Psychiatry, Nîmes, France; <sup>5</sup> CHU de Nîmes, Neurology, Nîmes, France

\* Corresponding author.

**Objectives.**– The HYCORE study aims at evaluating alterations of brain metabolism during first episode in patients with functional movement disorders, and their association with persistent physical disability at 3 months and 6 months follow-up.

**Methods.**– We assessed alteration of brain metabolism at rest using 18FDG-Positron emission tomography during two scan sessions: at symptoms onset and 3 months later, and motor impairment was evaluated using Expanded Disability Status Scale (EDSS score). First scans were compared with those of 13 controls without neurological impairment or any motor disability.

**Results.**– At that time, 22 patients performed initial scan session and 14 patients were evaluated with second scan at 3 months. Preliminary results show a hypoactivation of right frontopolar and right orbitofrontal cortex at symptoms onset in patients compared with controls. Moreover, patients had greater activation of right primary motor cortex and right caudate compared with controls. Patients with complete recovery within 3 months follow-up had an increased activation of ventral anterior cingulate and right frontopolar cortex, increased left anterior cingulate cortex and increased right thalamus between initial and second PET-scan. Analysis of brain imaging at 3 months show that patients with persistent motor disability have greater posterior cingulate cortex activation compared with patients with complete recovery.

**Conclusion.**– Preliminary results of HYCORE study show baseline altered activation of primary motor area, basal ganglia and orbitofrontal cortex in patients with motor conversion disorder. Our findings suggest that brain markers are associated with complete recovery and the existence of “state markers” associated with motor disability.

### Psychiatric symptoms as debut form of multiple sclerosis

N. De Uribe-viloria<sup>1\*</sup>, R. Hernandez Anton<sup>1</sup>, S. Gomez Sanchez<sup>1</sup>, C. Noval Canga<sup>1</sup>, H. De La Red Gallego<sup>1</sup>, A. Alvarez Astorga<sup>1</sup>, A. Alonso Sanchez<sup>1</sup>, M. De Lorenzo Calzon<sup>1</sup>, M. Gomez Garcia<sup>1</sup>, C. Capella Meseguer<sup>1</sup>, E. Rodriguez Vazquez<sup>1</sup>, B. Talavera De La Esperanza<sup>2</sup>, L. Rodriguez Andres<sup>1</sup>, F. De Uribe Ladron de Cegama<sup>1</sup>  
<sup>1</sup> Hospital Clinico Universitario De Valladolid, Psychiatry, Valladolid, Spain; <sup>2</sup> Hospital Clinico Universitario De Valladolid, Neurology, Valladolid, Spain

\* Corresponding author.

**Introduction.**– Although psychiatric symptoms are well described to happen along the course of Multiple Sclerosis, their presence at the initial stages of the illness is less common and somewhat anecdotal. This implies delays in diagnosis and treatment and therefore poorer prognosis and quality of life.

**Objectives.**– We aim to reflect on the interrelation between psychiatric symptoms and somatic processes, to avoid misdiagnosis.

Table 2. Sleep duration in adolescents with different SDQ points subgroups (hours:minutes).

SDQ scales	Self rated SDQ (points subgroups)			p
	Average (unlikely to be clinically significant) n=314	Slightly raised (may reflect clinically significant problems) n=114	High (substantial risk of clinically significant problems) n=53	
Total difficulties score	9:01	7:49	8:10	0,014
Conduct problems score	8:58	8:12	8:42	0,026
Emotional symptoms score	8:48	9:20	8:08	0,437
Hyperactivity score	8:53	8:22	7:53	0,058
Peer problem score	8:58	8:28	8:13	0,461

Figure 1

**Methods.**– We present the case of 56-year old woman, with unknown psychiatric or somatic history, brought by her family after a period of important physical and social decay. Coincident with the death of her parents 8 years ago, she became more and more isolated, abandoning her job, relationships and self-care, and occasionally speaking to herself. She denies any symptoms but sadness and apathy since the death of her father. An exhaustive study comprising functional neuroimage, laboratory tests and psychological tests was carried.

**Results.**– MRI: multiple hyperintense images in juxtacortical, cortical and periventricular white matter, along with loss of parenchyma, compatible with MS (Fig. 1). Electroencephalography: within normality. BCSE, MCMI-III: low insight, high distrust, emotional lability.

**Conclusions.**– Psychiatric symptoms can be the first sign of a neurological process, often leading to misdiagnosis and treatment. A correct anamnesis and clinical suspicion is necessary in order to run adequate procedures and achieve better diagnosis and treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Temporal trends of drug requests in the Addiction Liaison Psychiatric Unit in Hospital Del Mar

J.J. Fuentes Valenzuela<sup>1,2\*</sup>, D. Sanagustín<sup>1,2</sup>, M. Roldán<sup>1,2</sup>, I. González<sup>1,2</sup>, M.P. Frings<sup>1,2</sup>, M.F. Fonseca<sup>1,2</sup>, A.M. Rodríguez<sup>1,2</sup>, C. Tamarit<sup>1,2</sup>, M. Torrens<sup>1,2,3</sup>

<sup>1</sup> Institut de Neuropsiquiatria i Addiccions INAD. IMIM, Parc de Salut Mar, RTA, Barcelona., Psychiatry, Barcelona, Spain; <sup>2</sup> Institut Hospital Del Mar d'Investigacions Mèdiques-IMIM- Parc de Salut Mar- RTA, Barcelona., Psychiatry, Barcelona, Spain; <sup>3</sup> Facultad de Medicina, Universidad Autónoma de Barcelona, Barcelona, Psychiatry, Barcelona, Spain

\* Corresponding author.

**Introduction.**– Drug Use disorders are frequently associated to other medical problems and Addiction Liaison Psychiatric Units are requested to manage them. There are drug and drug users' facts associated to the temporal evolution of the main drug requests.

**Objectives.**– To analyze temporal trends in the characteristics of all medical requests to the Addiction Liaison Psychiatry Unit from January 2010 to December 2016.

**Materials and methods.**– Study data was obtained from all patients that were referred to the Addiction Liaison Psychiatry Unit during 7 years in Hospital del Mar (Barcelona, Spain). Demographics and clinical data (substance use, dual diagnosis, medical diagnosis) were obtained and analysed by semesters.

**Results.**– The Addiction Liaison Psychiatry Unit referred 2011 medical drug related request during 7 years. There were significantly differences in main drug requests by semester but there was no a clearly drug evolution tendency along these years. In relation to the drug there were no significantly differences as to gender, civil status and foreign origin but there were differences about medical service origin request. It was observed an increased proportion of heroin related requests in 2015 and 2016 (19-21,4%).

**Conclusions.**– There are many facts involved in the reason of the drug prevalence in the Addiction Liaison Psychiatry Unit. There is not a drug evolution tendency in samples referred to the addiction unit. Is needed more data to know why there is some differences in the main drug request depending on the medical service.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Calcium metabolism and psychosis: A case report and brief literature review

S. Gomes Pereira<sup>1</sup>, D. Esteves de Sousa<sup>2</sup>, M. Albuquerque<sup>2</sup>, A. Neves<sup>1</sup>, M. Costa<sup>2</sup>

<sup>1</sup> Centro Hospitalar de Lisboa Ocidental, Psiquiatria e Saúde Mental, Lisboa, Portugal; <sup>2</sup> Hospital of Cascais, Departamento de Psiquiatria e Saúde Mental, Alcabideche, Portugal

\* Corresponding author.

To report a case of DiGeorge Syndrome, as hypoparathyroidism and alterations of the calcium metabolism with calcifications of the basal ganglia, and briefly review the current literature about these pathologies.

We reported the case of a man of 54 years, hospitalized for behavioural changes with 1 month of evolution, persecutory delusions and auditory-verbal hallucinations. Personal history of Noonan Syndrome, epilepsy and hypoparathyroidism (diagnosed with DiGeorge syndrome in the internment, because of doubts raised with the clinical picture). Analytically, with diminished iPTH, calcium and Vit.D; Ac. Anti-thyroglobulin positive. EEG with increased theta activity. TC-EC with bilateral calcification of the lenticular nuclei. It was observed improvement of the patient, under antipsychotic therapy and calcium supplementation.

DiGeorge syndrome is a genetic disorder caused by the deletion of a portion of chromosome 22, q11.20 location, and is characterized by abnormalities of the face, hypoparathyroidism, heart defects, mental retardation, epilepsy and cognitive and behavioural changes. Hypoparathyroidism is a disease caused by decreased parathyroid hormone. The most frequent cause is the surgical trauma, with others less common. Can cause calcifications of the basal ganglia, with psychotic symptoms. The diagnosis is based on the clinical history, physical examination and laboratory and imaging studies, particularly serum levels of PTH and calcium. Treatment consists in maintaining calcium levels within normal limits, by administering regular doses of calcium and vitamin D. This case demonstrates the close link between calcification of the basal ganglia and psychosis. *Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Frequency of NMS features in anti-NMDA receptor encephalitis presenting with psychiatric symptoms

R. Gurrera

VA Boston Healthcare System, Mental Health/Psychiatry, Brockton, USA

\* Corresponding author.

*Introduction.*– Initial signs of anti-NMDA receptor encephalitis (anti-NMDArE) often include hallucinations, delusions and behavioural symptoms that suggest a primary psychiatric disorder. In most cases the patient is evaluated first by a psychiatrist, and antipsychotic medications are administered. Unfortunately, other clinical features of anti-NMDArE overlap with neuroleptic malignant syndrome (NMS), further obscuring the diagnosis and complicating management. It is not known how many patients with anti-NMDArE are at risk for NMS misdiagnosis, but recognizing these disorders promptly is essential because their treatments are distinct and both can cause severe long-term disability when treatment is delayed.

*Objectives.*– To estimate the frequency of NMS-like features in anti-NMDArE patients at risk for inappropriate treatment with antipsychotic medications.

*Methods.*– Computerized searches of EMBASE and Pub Med databases were conducted in January 2017 to identify anti-NMDArE cases presenting with behavioural symptoms. Four clusters of clinical signs commonly used to diagnose NMS were scored: hyperthermia, autonomic dysfunction (urinary incontinence, diaphoresis, and elevated blood pressure, heart rate or respiratory rate), mental status changes (disorientation, confusion, or diminished arousal), and rigidity/catatonia (including mutism). *Results.*– The search yielded 37 men and 163 women with mean(S.D.) ages 38.2(16.4) and 30.7(10.8) years, respectively. Clinical features associated with NMS were common, and their relative frequencies varied by sex, as follows (M vs. F): hyperthermia (18.9% vs. 25.8%), autonomic dysfunction (21.6% vs. 32.5%), mental status changes (59.5% vs. 55.8%), and rigidity/catatonia (29.7% vs. 44.8%). *Conclusions.*– NMS-like clinical features are common in anti-NMDArE, and are more likely to be observed in women.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0219

### Primary central nervous system lymphoma in immunocompromised patient with debuting psychiatric disorder: A case report

P. Herrera-Gener\*, C. Alario Ruiz, J. Verdugo Verdugo, E. Bozieux, F.C. Ruiz Sanz

Complejo Asistencial Universitario de Palencia, Department of Mental Health, Palencia, Spain

\* Corresponding author.

*Background.*– Medical illnesses affecting the central nervous system may initially manifest with psychiatric symptoms. Although rare, intracranial occupying lesions such as primary lymphoma can mimic a debuting psychiatric disorder, especially when associated with other risk factors for secondary psychiatric symptoms, such as immunocompromised patients. Despite this knowledge, neuroimaging studies are not currently recommended as a screening tool in psychiatric patients, with the exception of those with atypical characteristics, which would indeed warrant a specific diagnostic process in order to ensure proper clinical judgement.

*Case presentation.*– A 27-year old Hispanic male with untreated AIDS and no prior psychiatric history was admitted in the Emergency Department for personality changes over the last weeks, including child-like behaviour, apathy, mutism, biological rhythm disturbances, enhanced sensorial perception and mild intermittent headache. Initial computed tomography scan revealed intracranial occupying lesion suggesting primary central nervous system lymphoma as the most likely diagnosis. Psychiatric symptoms paralleled the evolution of the primary illness during hospitalization, which worsened progressively until the patient's decease one month after admission.

*Conclusion.*– There are currently no features to differentiate primary from secondary psychiatric disorders with assurance. However, some clinical and epidemiological characteristics can effectively point toward a medical disease as the main cause for the psychiatric symptoms. Therefore, temporal causal relation, an elderly onset and other atypical presentations should be followed by a more thorough diagnosis process including detailed history, complete physical and neurological examination, laboratory evaluation and brain imaging, so as to improve patients' prognosis and chances of appropriate therapeutic approach.

### Somatogenic depression on cardiovascular diseases patients

O. Kudinova<sup>\*</sup>, B. Mykhaylov, B. Fedak*Kharkiv medical academy of postgraduate education, Psychotherapy, Kharkiv, Ukraine*

\* Corresponding author.

In research, based on the systematic approach of evaluating results of complex clinical-psychopathological, psychodiagnostical investigation myocardial infarction and cerebral stroke patients the clinical structure features, regularities in the formation, development and course of somatogenic depression and associated disorders on these patients was determined. At patients with cardiac infarction in acute period the pain syndrome is the main one, leads to severe psycho-emotional disorders. Against the background of cognitive function preservation phobic, anxiety and depressive symptoms prevail, their intensity depends on the severity of pain. Subsequently, the primary psycho-emotional constituent element disappeared and anxiety-depressive disorders developed along with hypo- and anozognostical type of personal condition perception. At cerebral stroke patients disorders of level of consciousness were primary with cognitive and asthenic disturbances with subsequent formation of psycho-emotional disorders, anxiety and depressive disorders with hypochondrical elements on the basis of persistent cognitive impairments.

### Wernicke-Korsakov or why alcohol can turve clinical judgement

L. Manarte

*Faculty of Medicine, Psychiatry, Lisbon, Portugal*

\* Corresponding author.

*Objective.*– To describe how a relatively common syndrome, which is mostly caused by alcohol, can sometimes be confused and hide other really rare causes. To make a reflection on how epidemiology can make doctors be thrown off the track.

*Methods.*– Using a description of a 53 year-old woman with imbalance, nystagmus and a familial anemia. I used the clinical examination, laboratory and history of this patient and reviewed related bibliography.

*Results.*– After reviewing the whole clinical process i found that: MR-EC showed Wernicke-Korsakoff typical signs. The patient had no solid alcohol history. Her mother describes a strange behaviour since early adolescence. This Wernicke-Korsakov its out of the track and clinical staff its not used to consider out-off the box hypotheses. *Conclusion.*– Can a syndrome like Wernicke-Korsakoff be attributed to a “functional” cause? How “rare” can be a cause on our daily practice? Finding the “real” cause of this patient made us think about the importance of Liaison Psychiatry and the vital need to search for early clinical history.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0222

### Evaluation of mindfulness-based stress reduction (MBSR) for management of palpitations in Egyptian sample

A. Meshref<sup>1\*</sup>, M. Sarhan<sup>2</sup><sup>1</sup> AL-Azhar University -Faculty OF Medicine, Psychiatry, Cairo, Egypt;<sup>2</sup> AL-Azhar university -faculty of medicine, cardiology department, cairo, Egypt

\* Corresponding author.

Aims of this study were (1) to evaluate the efficacy of MBSR for the treatment of benign palpitations, (2) follow up improvement in heart palpitations with 24 h Holter recordings.

*Methodology.*– Thirty one participations reporting heart palpitations of at least three months duration were recruited in outpatient Cardiology clinics. Compared with thirty patients used as a control.

*Exclusion criteria.*– Included prior pathological cause of palpitation. Refuse to attend MBSR program.

*Methods.*– Participants were scheduled for an ECG and physician examination. Participants were randomly selected and 24 h Holter recordings were collected at two time points: 1) baseline (before MBSR classes), 2) 8 weeks after baseline.

*Results.*– The 24 h Holter recordings were analysed in both the time domain and frequency domain There were no significant differences between the MBSR and Control groups on any of the HRV measures at baseline or 10 weeks. We found an association between HRV balance (as measured by the Ln LF/HF ratio) and improvement in palpitations in the MBSR group ( $r = .8$ ,  $p < 0.001$ ). MBSR participants reported a significant reduction in heart palpitations at the end of the MBSR training, on average a difference score of 2.4 (SD = 1.2) on an 8 point palpitation frequency scale, while the control group did not report any change with an average difference score of 0.2 (SD = .97). This difference was significant with  $F = 13.5$ ,  $p < 0.002$ .

*Conclusion.*– MBSR training may be an effective treatment for Patients with benign palpitations

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### On psychiatry and psychosomatics

E. Neu<sup>1\*</sup>, M.C. Michailov<sup>1</sup>, U. Welscher<sup>1</sup>, H. Schumitz<sup>1</sup>, A.Hofstetter<sup>2</sup>, G. Weber<sup>3</sup>, E.R. Weissenbacher<sup>4</sup><sup>1</sup> Inst. Umweltmedizin c/o ICSD e.V., PharmaEVPhysiology, Munich,Germany; <sup>2</sup> Univ. Muenchen, Klinikum Grosshadern Dir. a.D.,Munich, Germany; <sup>3</sup> Univ. Lxbg. & Vienna, Fac. Psychol. Dean, Vienna,Germany; <sup>4</sup> Univ. Muenchen Med. Fak. & Premium Med. Clinic Dir.,

Munich, Germany

\* Corresponding author.

*Objectives.*– Psychopathology needs new integrative therapy-models considering application of psycho-somatic (Th.v.UEXKÜLL) and somato-psyhic (Y.IKEMI) approaches caused by high complex interaction of psychic-physiological-pharmacological-social factors [1-3], appointed also by Emperor AKIHITO during opening-ceremony of ICPM-Congr. in Kobe: “total symptoms of mind-body, seeking ways of holistic care”.

*Methods.*– Psychic/body-training by occidental/oriental practices (patients/probands). Evaluation of psychic-“polar-attitude-list”/physiological-parameters: heart-rate, blood-pressure, etc.

*Results (recent/earlier).*– Observations demonstrate strong positive influence on psycho-somatic parameters after music[1], respiratory[2], yoga-physical[3] therapies. Items of psycho-physiological (relaxed), emotional (tranquil/happy), cognitive (few/ordered-

thoughts), voluntary (active/spontaneous), social (open/assertive), consciousness (clear/sleepy) categories are significantly positive changed 25-50%. The 3 therapies have specific psychic effects, e.g. items “relaxed/tranquil” after respiratory- (+45/50%) and music- (+20/5%), also item “open” after music-therapy (+25%) are positive, but negative after respiratory-therapy (-20%). Items are stronger changed before then after surgical-intervention. Psychic effects are correlated with positive physiological ones, e.g. heart/respiratory-frequency decreased 25-30%, voluntary-apnoea prolonged 55%. Mountain altitude (>2000-3000 m), hypothermia (<20 to 0°C) influenced positively psychic-items, heart rate/blood-pressure decrease ( $p < 0.05-0.01$ ,  $n = 125$ ).

**Conclusions.**– Integrative psycho-somatic therapy incl. occidental/oriental (yoga, tai-chi, Zen, etc.) approaches in context of integral anthropology could be applied for psychic disorders. Different methods are with preference, e.g. for depression is suitable respiratory/physical-training (activation), for mania: music-therapy (with inhibitory-effect). Systematically research about influence of single/combined psychosomatic therapies on psycho-physiological disturbances is necessary, i.e. how could be influenced, e.g. epilepsy, schizophrenia, e.g. by respiratory-therapy/hypothermia/etc. (hypo-/hypercapnia: inhibitory/excitatory effects on CNS-structures).

\* Corresponding author.

We present the case of a 55-year-old male who entered Nephrology due to acute renal failure due to psychopathological decompensation, in which the clinic was predominantly delirious of prejudice. He presented delusions with episodes of aggressiveness next to important social problems, with neglect in personal self-care and abandonment of treatment and medical monitoring. Urgent intervention is required as well as dialysis given the situation. As Analytical results presented urea 410, creatinine 8.3, potassium 7.68. The renal ultrasound scanning showed chronic nephropathy. Once the organic pathology is stabilized, it is transferred to the Psychiatry Unit.

The adequate approach of the psychiatric pathologies that accompany the renal insufficiency demands to make a differential diagnosis and to take into account the complex psychosocial and biological interactions that originate them. The approach of the patient receiving dialysis and pluripatology should include multidisciplinary teams that employ psychotherapeutic strategies and consider individual and family elements. We emphasize the importance of the medical monitoring and care of patients diagnosed of

severe mental disorder with concomitant organic pathology, since it could lead to severe situation that conditions the patient's life. In this kind of patients close monitoring should be done as well as establishing psychoeducation programs for patients and families. *Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Alexithymia and non-psychotic mental disorders in patients with hypothyroidism

O. Pityk<sup>1\*</sup>, I. Kuzhda<sup>2</sup>

<sup>1</sup> Ivano-Frankivsk National Medical University, Department of Psychiatry, Narcology and Medical Psychology, Ivano-Frankivsk, Ukraine; <sup>2</sup> Ivano-Frankivsk Regional Children Hospital, Ophthalmological Department, Ivano-Frankivsk, Ukraine

\* Corresponding author.

In the formation of non-psychotic psychiatric disorders in patients with thyroid pathologies neurohumoral mechanisms are important, and one reason is psychosomatic relationship. The modern concept of relationships includes alexithymia model, since this psychological property is considered as caused by the imbalance between the functions of the limbic system and the cerebral cortex, and as a result of violations of the interaction between the child and mother. In addition, the situation of chronic physical illness is regarded as one that provokes a crisis of development (and in fact, identity crisis) and therefore is a traumatic situation, that is a risk factor for the development of mental disorder. Toronto Alexithymia scale proposed by Taylor G. was used. 50 patients with hypofunction of the thyroid gland were investigated. 84% of patients had a rate alexithymia more than 74 points, 12% were classified as areas of uncertainty and only 4% of patients according to the method proved non-alexithymic. It was found also that patients with an uncertain alexithymia level had difficulties in describing their inner feelings, did not give much attention to the absence of well-being in the emotional sphere, believed that painful symptoms of mental health problems are caused by only thyroid pathologies, even during sighting surveys ignored the presence of emotional stress and conflict experiences that showed a reduced capacity for understanding and expressing their own feelings, low emotional resonance. Thus, alexithymia radical in the personal structure of such patients should be taken into consideration during psychotherapeutic and psycho-corrective interventions.

EV0226

### Cerebellar cognitive affective syndrome

O.E. Rodriguez

Burnie Hospital, Community Mental Health, Broadbeach, Australia

\* Corresponding author.

*Background/objectives.*– Cerebellar cognitive affective syndrome (CCAS) is a condition that arises from cerebellar lesions. CCAS can easily be overlooked by medical teams; therefore a bibliographic review will facilitate the understanding of symptoms in order to effectively diagnose and provide a holistic early treatment approach.

*Methods.*– A case report of a 72 year old woman with bilateral cerebellar lesions with high pre-morbid function presented with classic symptoms of CCAS. Multidisciplinary workup included medical, psychiatric, neuropsychological assessment (R-BANS (Form

1), Digit Span, Verbal fluency tests, the Hayling Test, the Delis-Kaplan Executive Function System) as well as other investigations (neuroimaging and blood tests) were conducted on the patient to confirm CCAS and exclude other differential diagnoses.

**Results.**– The results from the medical assessments conducted showed symptoms of cerebellar dysfunction. A psychiatry and neuropsychological review revealed aggression, irritability, disinhibition, deterioration in cognitive function and personality changes. A multidisciplinary team was formed to rehabilitate the patient however patient was non-compliant with therapy. The patient was prescribed Seroquel 50 XR and she responded well to the medication.

**Conclusion.**– This case review illustrates the challenges associated with engaging a CCAS patient in rehabilitation activities due to cognitive and mood disorders. The use of psychotropic medications can be an effective method in improving cognition and mood disorders in CCAS patients. Early psychiatry and psychological intervention can significantly improve the overall outcome of a patient diagnosed with CCAS.

### **Neurocognitive profile, mental problems and mental disorders in patients with early stages of HIV infection**

P. García, P. Jazir, C. Filizzola, H. Santamaría García\*  
Pontificia Universidad Javeriana, Psiquiatría, Bogotá, Colombia

\* Corresponding author.

HIV-associated neurocognitive disorders (HAND) may include neurological disorders of various severities such as AIDS dementia complex (ADC) also known as HIV dementia and HIV-associated dementia (HAD), HIV encephalopathy, and Mild Neurocognitive Disorder (MND). As it seems HIV-associated neurocognitive disorders are associated with a metabolic encephalopathy induced by HIV infection and fueled by immune activation of macrophages and microglia. Despite of different cognitive alterations have been described in HIV patients at different stages of HIV infection, so far little is known about the neurocognitive state of patients at very early stages of HIV infection. In addition, little is known about which mental health factors are related to the presence of cognitive alterations in patients with HIV infection. Here, we explored the neurocognitive profile of a group of cases of HIV patients at very early stages of HIV infection assessing the cognitive profile and the presence of mental symptoms in different stages of the course of HIV infection. As control groups, we studied a healthy control group and a group of patients with mild cognitive impairment due to neurodegenerative causes. Our results suggested that cognitive processes are sensitive to very early neuropathological changes in HIV infection and those alterations are usually related to mental symptoms. Noteworthy, our results also showed that neurocognitive profile of HIV patients differs from those cognitive alterations in patients with mild cognitive disorders associated to primary neurodegeneration. Our results highlighted the importance of neurocognitive exploration at very early stages of HIV infection to improve diagnoses and interventions.

### **Depression, anxiety, alexythymia and psychiatric comorbidity in chronic headache patients**

D. Sarikaya Varlik<sup>1</sup>, T. Uyar<sup>2</sup>, C. Varlik<sup>3</sup>, S. Polat<sup>4</sup>

<sup>1</sup> Istanbul Bagcilar Research and Education Hospital, Department of Psychiatry, Istanbul, Turkey; <sup>2</sup> Kackar State Hospital, Department of Neurology, Rize, Turkey; <sup>3</sup> Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Research and Education Hospital, Istanbul, Turkey; <sup>4</sup> Rize Recep Tayyip Erdogan University Research and Education Hospital Department of Psychiatry, Rize, Turkey

\* Corresponding author.

**Aim.**– The aim of this study is to evaluate the depression, anxiety and alexythymia levels of chronic headache patients and to determine the psychiatric comorbidity.

**Method.**– In this study, 42 tension type headache patients (TTH) and 43 chronic migraine headache (CMH) patients according to the diagnostic criteria established by the Headache Classification Committee of the International Headache Society, were recruited from patients seeking treatment at Kackar State Hospital neurology out-patient unit. Inclusion criteria were, presence of TTH or Migraine headache at least 3 months, being 18-65 years of age, and at least having primary school education. Sociodemographic data form, Beck Depression Inventory (BDI), Beck Anxiety Inventory (BAI), Toronto Alexythymia Inventory (TAI) and face to face psychiatric interview were done by a clinician to make psychiatric diagnosis due to Diagnostic and Statistical Manual of Mental Disorders-5 (DSM-5)

**Results.**– Overall, 77.6% ( $n=66$ ) were female, 69.4% ( $n=59$ ) were married, 40% ( $n=34$ ) had psychiatric treatment history. Complaining about pain in the other parts of body was significantly high in TTH group ( $p=0,032$ ). Stress factor onset of headache is more common in TTH group but not significant. Depression is the most common psychiatric comorbidity 55,8% ( $n=29$ ). There is no significant difference between BAI, BDI and TAI scores

**Conclusion.**– Psychiatric comorbidity is common in the chronic headache patients. To definitive speak, studies are needed on a large scale by comparison with healthy controls.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Mood disturbances in women with polycystic ovary syndrome**

N. Halouani\*, M. Turki, S. Ellouze, J. Aloulou, O. Amami  
Hedi Chaker university hospital, psychiatry "B" department, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Polycystic Ovary Syndrome (PCOS) is one of the most common endocrine disorders in women during their reproductive age. It is characterized by a wide spectrum of symptoms related to the disturbances of reproductive, endocrine, and metabolic functions. These physical disorders can impair sexual functioning and cause emotional distress, including symptoms of anxiety and depression.

**Objective.**– To assess the relationship between PCOS and anxiety and depression.

**Methods.**– We conducted a cross-sectional, descriptive and analytic study in the outpatient of Endocrinology department of Hedi Chaker University Hospital, SFAX, TUNISIA, among 30 women with PCOS, and 30 controls. We used the Hospital Anxiety and Depression Scale (HADS) to detect depressive and anxious symptoms.

**Results.**– The mean age of patients was 32.3 years. The mean global score of HADS and subscales HAD-A (Anxiety) and HAD-D (Depression) were respectively 18.2, 10.4 and 7.8. More than half of patients (53.3%) and 26.7% of controls had a certain anxiety state, with a significant difference ( $p=0.035$ ). Thirty percent of patients had a certain depression state, compared with 6.7% in the control group, the difference was also significant ( $p=0.042$ ). A significant correlation was found between depression sub-scale and spaniomenorrhoea ( $p=0.017$ ).

**Conclusion.**– Our study showed that psychological function is impaired in women with PCOS. Thus, apart from the medical treatment, clinicians should pay attention to the psychosocial dimension of this affection within a multi-disciplinary approach, in order to improve life satisfaction and coping of affected women.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Quality of life in women with polycystic ovary syndrome

N. Halouani\*, M. Turki, S. Ellouze, J. Aloulou, O. Amami  
Hedi Chaker university hospital, psychiatry "B" department, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Polycystic Ovary Syndrome (PCOS) is a multifactorial pathology characterized by several physical disorders which can lead to a significant deterioration in female quality of life (QoL).

**Objective.**– To assess QoL in women with PCOS, as well as associated factors.

**Methods.**– It was a cross-sectional, descriptive and analytic study, conducted in the outpatient of Endocrinology department of Hedi Chaker University Hospital, SFAX, TUNISIA, among 30 women with PCOS, and 30 controls. QoL was assessed through the Short Form-36 Health Survey (SF-36). It is a standard diagnostic tool containing 36 questions grouped into 8 domains (D1: Physical Functioning; D2: Role limitations due to physical problems; D3: Bodily Pain; D4: General Health; D5: Vitality; D6: Social Functioning; D7: Role limitations due to emotional problems and D8: Mental Health).

**Results.**– Several clinical parameters (Hirsutism, spaniomenorrhoea, and obesity) were significantly more frequent in women with PCOS ( $p<0.001$ ;  $p<0.001$  and  $p=0.005$  respectively). According to SF-36, QoL of women with PCOS was significantly impaired compared with controls (46.66% vs 0%;  $p<0.001$ ). Most QoL domains for PCOS women were lower than those for controls. There were statistically significant differences in four domains: D3, D4, D5 and D8 ( $p<0.001$  for each of these domains).

**Conclusion.**– PCOS is a heterogeneous disorder that not only affects women's body image, but also undermines their QoL, as it has been highlighted in our study. This could contribute to an exacerbation of illness effects, and then, darken the prognosis. Thus, this issue needs to be taken seriously in the clinical practice, in the doctor-patient relationship.

### Attitudes of Tunisian psychiatric nurses towards suicide

S. Ben Fadhel<sup>1</sup>, M. Daoud<sup>2</sup>, T. Abir<sup>2</sup>, K. Mehdi<sup>2</sup>

<sup>1</sup> Hospital Razi, mannouba, Mannouba, Tunisia; <sup>2</sup> Razi hospital, Mannouba, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– According to the Tunisian social observatory, suicide rates have risen since 2011 and have reached record levels in the year 2016. Psychiatric nurses are an integral part of the health-care team but little is known about their attitudes to suicide. The aim was to assess nurses' attitudes towards suicide whilst evaluating the influence of sociodemographic characteristics and religious beliefs on their views.

**Methods.**– A sample of fifty nurses working in the psychiatric hospital RAZI, Tunisia, was recruited. Participants completed the Arabic religiosity scale and the Suicide Behavior Attitudes Questionnaire (SBAQ).

**Results.**– The mean age of the sample was  $29,9 \pm 7,7$  years. Sex ratio was 1. Mean duration of service in a psychiatric ward was  $8,5 \pm 6,7$  years. Many professionals (56%) regarded themselves as "prepared to handling with patients under the risk of suicide", and 52% of the psychiatric nurses felt "capable of perceiving when a patient is under the risk of suicide". Few professionals (9%) agreed with the right a person has to commit suicide. It is defended the notion that 'life is God's gift, therefore only He can take it back' (76%). 12% of the total sample expressed the belief that suicide is not associated with a psychiatric disease. Religiosity impacted negatively on the feelings and professional capacity towards suicide.

**Conclusion.**– Nurses could benefit from continuing professional education to build their knowledge about suicide and reinforce positive attitudes, thus minimizing the stigma surrounding the matter.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### "Nuptial psychosis" in two siblings: A case report

F. Ellouze\*, W. Homri, N. Mariem Wassila, A. Cyrine, B. Nesrine, B.R. Imen, L. Raja

CHU Razi, Psychiatry C, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Marriage, and especially the nuptial period, has been recognized as a stressor that can decompensate certain psychotic disorders. However, "Nuptial psychosis" is an almost unknown entity whose literature is poor. Thus, studies treating its clinical characteristics and its evolution remain scarce.

**Objectives.**– The aim of our study was to compare the clinical differences and the possible evolution of a nuptial psychosis in two brothers.

**Methods.**– This is a study conducted from the case of two brothers diagnosed with a "Nuptial psychosis" and hospitalized in the department of psychiatry C of the Razi hospital in Tunis, Tunisia.

**Results.**– Mr. F.A, 43 years old, hospitalized in the psychiatric department of the Razi hospital, in April 2005, one month after an unconsumed marriage and Mr. A.A, his 34-year-old brother, hospitalized in the same department in July 2009, a week after his marriage. The two brothers shared a symptomatology made up of quirks of behaviours, delusions and hallucinations. Mr. A.A, however, had depressive elements which did not occur in his brother

at the time of the onset of the disorder. The evolution was marked by a *restitutio ad integrum* for Mr. F.A, whereas the symptoms of Mr. A.A evolved towards the installation of a schizophrenia.

**Conclusion.**– Despite the existence of several shared stressors, the evolution of an acute psychotic episode was different between two brothers, which allows us to question the role of certain social and genetic factors in the installation of schizophrenia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **What a fright! (Koro syndrome. A case report)**

C. Aguilar Romero<sup>1</sup>, I. Garcia Hoyos<sup>1\*</sup>, I. Zabaleta andreu<sup>1</sup>, C. Sanahuja Muñoz<sup>2</sup>, J. Klotz<sup>3</sup>

<sup>1</sup> Hospital Universitario de Fuenlabrada, Psiquiatría, madrid, Spain; <sup>2</sup> Hospital de Fuenlabrada, Psiquiatría, Madrid, Spain; <sup>3</sup> university, Psychiatry, New York, USA

\* Corresponding author.

**Introduction.**– Koro syndrome is characterized by intense anxiety that the penis (vulva or nipples in females) is shrinking or retracting and will recede into the body. This condition is extremely rare in western countries, but has been epidemic in Southeastern Asia. The condition is more common in males and is classified within Obsessive-compulsive and Related Disorders by DSM V. In this report, we describe a patient presenting with concerns about genital retraction diagnosed as acute and transient psychosis necessitating hospitalization and the usage of anti-psychotics.

**Objectives.**– Describe a case report and try to understand which diagnosis would be more accurate and why.

**Methods.**– A description of a patient presenting the symptoms described in a literature review found through Medline and manuals of mental disorders.

**Results.**– A 26-year-old Spanish man arrived at the Emergency Room with a panic attack and the worry that his penis was smaller than usual, in the context of an acute dermatological reaction. Following his clinical evolution, we will explain the difficulties with making an accurate diagnosis, and the decision to classify his symptoms as Koro Syndrome.

**Conclusions.**– Awareness of this diagnosis is needed to provide optimal care to patients that may need an intense follow up and antipsychotic drugs in order to prevent chronicity of the condition.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The Investigation of Problems of Migrant Students and Their Relationship to Psychopathology**

E. Kotsotsiou<sup>1\*</sup>, E. Tsoumani<sup>1</sup>, M. Gouva<sup>2</sup>

<sup>1</sup> University of Applied Sciences of Thessaly TEI, Research Laboratory of Care, T.E.I. of Thessaly, Larisa, Greece, Larisa, Greece; <sup>2</sup> TEI of Epirus, Research Laboratory Psychology of Patients Families and Health Professionals, T.E.I. of Epirus, Greece, Ioannina, Greece

\* Corresponding author.

**Introduction.**– Due to the phenomenon of immigration in Greece, many issues arise both regarding intercultural education and higher education of migrants. One of these, which is not highlighted, is the problems of higher education students who finished a Greek school and gained access to Greek universities.

**Objectives.**– The purpose of this research was to investigate the problems of the first-generation migrant students and to correlate these problems with the psychopathology.

**Methods.**– The sample consisted of students and immigrants from 18 to > 25 years old, students from Greek academic institutions. The research tools used were: a) the Psychopathology Scale (Symptom Checklist 90-R - SCL-90); and b) the State-Trait Anxiety Inventory (STAI) Spielberger c) (LOT-R); (d) The Other Shame Scale (OAS); (e) Experience of Shame Scale (ESS); and a socio- demographic and social representation questionnaire.

**Results.**– Single-factorial and multifactorial analysis was used from which it emerged that: a) female immigrant women have higher levels on the scales: inferior (OAS), empty (OAS)), Total Internal Shyness (ESS), Characteristic Shame (ESS), Behavioral Shame (ESS), Bodily Shame (bodily shame) (ESS, Trait Anxiety (STAI), Somatization (SCL-90), Interpersonal Sensitivity (SCL-90) and Depression (SCL-90).

**Discussion.**– The results of our study reveal high levels of psychopathology among migrant and migrant students, and this is explained by the way their migrant parents live and the different culture they are obliged to cope with and adapt to, but also marginalized by society, a situation that leads to their exposure to a variety of risks to their mental health.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0235

### **Psychometric Properties of the Multicultural Personality Questionnaire–short Form (MPQ-SF) in Persian speaking university students**

A. Homayouni

Department of psychology-Bandargaz Branch-Islamic Azad University-Bandargaz-Iran, Department of psychology, Iran

\* Corresponding author.

**Introduction.**– Personality and culture are very important and effective concepts in behavioural sciences. Each culture can form the personality and behaviour of people in its society. So, the paper aimed to study psychometric properties of the Multicultural Personality Questionnaire–Short Form (MPQ-SF) in Persian speaking university students.

**Method.**– In this study, Multicultural Personality Questionnaire–Short Form (MPQ- SF) was used that developed by Van Der Zee and et al (2013) at the University of Groningen in the Netherlands. The Multicultural Personality Questionnaire is a personality assessment questionnaire to explain behaviours when people are interacting with people from different cultures. 381 university students were chosen and responded to MPQ-SF. The MPQ-SF assesses Cultural empathy, Flexibility, Social Initiative, Emotional stability and Open-mindedness. For analyzing the data Cronbach Alpha, Spearman-Brown Coefficient and Pearson correlation coefficient were used. Also Buss & Perry aggression Questionnaire was used to diverger validity.

**Results.**– The findings showed that Kaiser–Meyer–Olkin measure of sampling adequacy was .84, and Bartlett’s Test of Sphericity was 5.42 that were significant at .000. Also, reliability analysis showed that MPQ-SF had good internal consistency. Cronbach’s Alpha for all items was .81, and Spearman-Brown Coefficient was .58. Also correlation of MPQ-SF with aggression Questionnaire was -.388 that was significant at .000.

**Conclusions.**– The findings showed that the MPQ-SF is a reliable and valid assessment tool for measuring Multicultural Personality in Iranian samples.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Intercultural aspects of depression: Feelings and thoughts of low self-esteem, guilt, persecution and prejudice**

L. Jouini<sup>1\*</sup>, U. Ouali<sup>1</sup>, M. Ghazzai<sup>2</sup>, Y. Zgueb<sup>1</sup>, R. Jomli<sup>1</sup>, F. Nacef<sup>1</sup>  
<sup>1</sup> Razi Hospital, "A" Adult Psychiatry Department, Tunis, Tunisia; <sup>2</sup> Razi Hospital, Child and Teenager Psychiatry Department, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Guilt and low self-esteem are frequently described in depression in Western societies, and are part of the criteria for major depressive episode within the Diagnostic and Statistical Manual of Mental Disorders (DSM). However, in Tunisian depressed patients, ideas of prejudice and persecution are frequently observed. Might these - very diverse - feelings and thoughts be influenced by culture?

*Objectives.*– To determine the frequency of feelings and thoughts of guilt, low self-esteem, persecution and prejudice among an Arab Muslim sample of depressed patients.

*Methods.*– Guilt, low self-esteem, prejudice, and persecution were evaluated in 95 patients with depression. Unipolar Depression (UD) or Bipolar Disorder (BD) were diagnosed using the DSM IV–criteria. Socio-demographic and clinical data were recorded.

*Results.*– Fifty patients were diagnosed with UD (52,6%) and 45 with BD (47,4%). Patients experienced feelings of guilt (4,2%, n = 4), low self-esteem (23,2%, n = 22), ideas of persecution and prejudice (8,4%, n = 8). These feelings and thoughts were not associated with age, diagnosis, sex, instruction level, marital status, a history of hospitalization or suicide attempts.

*Conclusions.*– Our results may reflect the cultural and religious impact on the clinical expression of depressive episodes. Whereas beliefs of divine punishment and individualism may explain the prevalence of guilt in Western cultures, more important interdependence within family and society, history of colonization, and thus a more external locus of control may explain the feelings of persecution and prejudice in Arab-Muslim societies.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0237

### **Mental illness in theological perspective**

I.I. Moldovan<sup>1\*</sup>, A. Olteanu<sup>2</sup>, C. Bredecean<sup>3</sup>  
<sup>1</sup> SCJUT. TIMISOARA County Emergency Clinical Hospita, psychiatry, Timisoara, Romania; <sup>2</sup> Scju Timișoara County Emergency Clinical Hospital, Psychiatry, Timisoara, Romania; <sup>3</sup> Timișoara County Emergency Clinical Hospita, Psychiatry, Timisoara, Romania

\* Corresponding author.

*Introduction.*– Religion and psychiatry, despite the sinuous relationship they have had since antiquity, centered on "human well-being" as the main purpose of their work. The concept of "mental illness - madness", varies by age, culture, awareness and acceptance. The objective of this paper is to highlight how mental disorder is perceived by representatives of theology.

*Methods and materials.*– The sample included 31 male participants, with education and occupations in Christian Orthodox Theology, aged between 19 and 76 years. An online questionnaire was applied, consisting of 17 questions that assess the concept of men-

tal disorder. Responses were collected in a Microsoft Excel sheet along with socio-demographic variables.

*Results.*– Overall, 54.84% of subjects define mental disorder as a disease, while 45.16% perceive it as an absence of faith or a human weakness in the face of suffering. Regarding the therapeutical approach to psychiatric illness, 29% of the subjects considered for medical treatment, the rest opting for other forms of therapy. 65% of the subjects believe that religious practices and religion can favorably resolve a psychiatric disorder in the absence of medical intervention.

*Discussions and conclusions.*– The diversity in understanding and approach to "mental illness" by representatives of Christian Orthodox theological environment originates- most likely- from reporting to normality; for without this "normality" one can not determine and define the illness. If in psychiatry, mental illness is a deviation from normality in the theological vision mental illness is not related to an environmental model, but the ideal model and responsive to standard fulfillment.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Psychometric questionnaire of cultural factors comorbidity of obsessions and major depressive disorders in Iranian samples**

G.A. Nikpour<sup>1\*</sup>, A. Homayouni<sup>2</sup>

<sup>1</sup> Department of Psychology- Allameh Tabatabaai University- Tehran, Iran, Iran; <sup>2</sup> Department of Psychology, Bandargaz Branch, Islamic Azad University, Bandargaz, Iran, Iran

\* Corresponding author.

*Background and purpose.*– Cultural signs may be found among people that speak a local dialect or live in a specific region or historical period. These cultural signs could influence psychopathology. The aim of this study was to design and validate a questionnaire that could evaluate the cultural factors causing concurrent obsessions and major depressive disorders in Iran.

*Methods.*– To design the questionnaire, 10 psychologists and psychiatrists who were members of academic boards were questioned by an open questionnaire. Then, the answers to the questions were classified and based on exploratory factor analysis the questionnaire containing 11 factors and 79 questions were confirmed. Internal homogeneity was analysed by Cronbach's alpha.

*Results.*– The findings of Cronbach's alpha for all factors showed that the highest reliability was 0.90 and the lowest was 0.42. In exploratory factor analysis using Varimax rotation 11 factors were extracted that predict 47.3% of the scale variance. 25 factors were extracted of which 14 had less than three items, therefore they were omitted because of not being able to acquire reliability as sub factors. Accordingly, a questionnaire containing 11 factors and 79 questions was constructed.

*Conclusion.*– The findings showed that the instrument could identify the cultural factors that cause concurrent obsession and major depressive disorders in Iran.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0239

### **Multidisciplinary and cultural intervention with complex trauma survivors**

W. Noureldin<sup>1\*</sup>, S. Sylvie Fagard Sultan<sup>2</sup><sup>1</sup> Minia University, Psychology, Al-Minia, Egypt; <sup>2</sup> René Descartes University, Psychology, Paris, France

\* Corresponding author.

We aimed to:

- supporting improved personalized care planning particularly for persons with Complex trauma short term or long term needs from refugees and migrants;

- the implementation of the “Common Core Principles to Support Self-Care”;

- improved career and professional opportunities within an innovative and dynamic working environment through weekly multidisciplinary training;

- empowering patients to take the lead in managing their long term conditions outside acute services and in their own homes where appropriate;

- improving health and well-being outcomes for patients by offering person centre EVordinated care.

*Methodology.*– Qualitative research is characterized by its aims, which relate to understanding some aspect of social life, and its methods which (in general) generate words, rather than numbers, as data for analysis.

*Results.*– We prevent development of PTSD after this awareness in our following patients who's subjected to S.v close collaboration between Health and mental health professionals and Social Care Services in most of cases. Increased Community partnership to refer the cases who's in need to social support or caring outside the clinic. We noticed also what's called: Trans disciplinary working - This is a natural development from our multidisciplinary work. Barriers between different disciplines break down and roles within the team are redesigned to make the optimum use of team skills and knowledge.

*Assessments.*– We're noticed also fostering a positive, supportive team culture creates an environment where staff can deliver high-quality holistic care to their patients.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Armed conflict and post-conflict; challenge for transcultural psychiatry in Colombia**

J.D. Páramo Díaz [juandavidparamo@gmail.com](mailto:juandavidparamo@gmail.com)

Pontificia Universidad Javeriana, avenue 7B #134B-66, Bogotá, Colombia

Corresponding author.

Early Career Psychiatrists at Hospital Universitario San Ignacio, Pontificia Universidad Javeriana

The armed conflict in Colombia emerged due to a combination of economic, political and social factors in the country 60 years ago. According to a study by Colombia's National Centre for Historical Memory, identified different characteristics that marked armed conflict: was complex, discontinued, with huge regional differences, dreadful and deep political roots. Through the Final Agreement to End the Armed Conflict and Build a Stable and Lasting Peace, signed at November of 2016, between FARC-EP guerrilla and government, tries to transform by a political and legal forms, the structural causes of the armed conflict. The methodology used in this investigation is a narrative research of cultural issues of psy-

chiatry and the framework of Transcultural Psychiatry in armed conflict settings. According to a historical and sociopolitical context, recognizing the impact of the armed conflict on population mental health, the role of Transcultural Psychiatry lay on a repertoire of methodologies, backgrounds and perspectives. This field will be useful to understand the impact, but also the significance, of traumatic experiences and protection process linked to war, and find new approaches to community and individual interventions, based on a comprehensive view of social and cultural boundaries. *Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Executive function characterization and theory of mind in leaders of the religious manifestations of catholics, pentecostals and christians in Santa Marta, Colombia**

K. Perez-Correa<sup>1</sup>, F. Roman<sup>2</sup><sup>1</sup> Universidad Cooperativa de Colombia, Facultad de Psicología, Santa Marta, Colombia; <sup>2</sup> Universidad Maimónides, Doctorado de Psicología con Orientación en Neurociencia Cognitiva, Buenos Aires, Argentina

\* Corresponding author.

The objective of the research is to identify the existing characteristics in processes of social cognition related to Theory of Mind and Executive Functions in the religious leaders that integrate the Catholic, Pentecostal and Christian GNG doctrines in the city of Santa Marta, Colombia, to be compared with a group of non-participants.

The study was transversal type and comparative of quantitative cut. In this one the instruments of the Reading the Mind in the Eyes, the Faux Pas Recognition Test, the Empathy Quotient to evaluate social cognition and Theory of Mind as well as NEUROPSI and the Stroop Test were used to evaluate the executive functioning.

An analysis of the ANOVA variance was employed to compare the yields of the groups. The main results show that the associated processes in social cognition such as levels of attention and concentration in Catholics vary between  $3,83 \pm 0,87$ , in Pentecostals  $3.77 \pm 0.72$  and in Christians GNG  $4,00 \pm 0.91$  ( $P < 0.05$ ) while visual detection in Catholics  $12.47 \pm 1.52$ , Pentecostals  $11.93 \pm 1.59$  and  $12.17 \pm 1.36$  ( $P < 0.05$ ). It was evidenced that there are differences in cognitive processes and executive functions in doctrinal groups. In addition, there is a need to continue to deepen, in the area of research in understanding the phenomenon

### **Variations in memory failure across 10 cultures**

A. Soliman<sup>1\*</sup>, R. Alfar<sup>2</sup>, S. Alsebaie<sup>3</sup><sup>1</sup> Qatar University, Social Sciences, Doha, Qatar; <sup>2</sup> Kafr Elsheikh University, Psychology, Kafr Elsheikh, Egypt; <sup>3</sup> Umm Alqura University, Psychology, Makkah, Saudi Arabia

\* Corresponding author.

People with and without psychological problems commonly report memory problems. The present study reported results from 10 Arab countries (Algeria, Egypt, Jordan, Kuwait, Lebanon, Palestine, Qatar, Saudi Arabia, Syria and Yemen). In total, 2174 participants aged 21 to 62 years completed an internet based everyday memory questionnaire. A multi-group confirmatory factor analysis was conducted to examine the organizational structure of everyday

memory across the 10 Arab cultures and to examine whether everyday memory failure is underpinned by the same latent factor (s) across all Arab cultures. The results revealed five pure latent factors common to everyday memory failure across all the Arabian cultures studied. The Syrian participants were the best and the Egyptians were the worst at everyday memory functions, particularly in the age range between 40–50 years. The results are discussed in light of literature on everyday memory and Arab cultural variations.

### **Cultural background and barriers to mental health care for Crimean Tatar adults with depressive and anxiety disorders**

V. Sroevsky

*Medical Academy named after S.I. Georgievsky, Psychiatry, narcology, psychotherapy with courses of general and medical psychology, Simferopol, Russia*

\* Corresponding author.

Crimean tatars take near 12,1% of Crimean Republic population. Over one-third of Crimean Tatar adults may not receive treatment for serious mental illnesses. The main idea of this research is to discover the assessment of medication adherence in two ethnic groups in Crimea Republic in Comparing: Russian and Crimean Tatar.

*Aim.*– A reliable and valid measure is essential for the assessment of medication adherence. Until now, no patient-reported medication adherence measure has been validated in Crimea Republic. The aim of this study was to validate a modified 4-item Morisky–Green–Levine Medication Adherence Scale in Crimean Tatar patients with Depressive and Generous Anxiety Disorders in Simferopol.

*Methods.*– A cross-sectional survey was conducted in a comparative sample of Ethnic Russian and Crimean Tatar outpatients Generalized Anxiety Disorders in Simferopol. Respondents completed Russian version of the modified 4-item Morisky–Green–Levine Medication Adherence Scale. The scale scores ranged from 0 to 4, with higher scores indicating better medication adherence. Reliability was assessed using Cronbach's alpha. Content validity was assessed by expert review. Construct validity was examined using factor analysis and hypothesis testing.

*Results.*– A total of 74 (36 Crimean Tatar and 39 Ethnic Russian) respondents have completed the modified Morisky–Green–Levine Medication Adherence Scale. 30.5% had a score of 0–1, 2, 3 and 4, respectively. The internal consistency of the scale was moderate (Cronbach's alpha = 0.59). Principal component analysis showed that the four items loaded onto one factor (eigenvalue = 1.75). Respondents with higher scores were Russian ( $P < 0.001$ ) and had better adherence to prescriptions ( $P < 0.001$ ).

EV0245

### **Cultural aspects of vaginismus therapy: A case series of Tunisian patients**

Y. Zgueb<sup>1</sup>, U. Ouali<sup>2</sup>, M. Said<sup>2</sup>, S. Chebli<sup>2</sup>, R. Jomli<sup>2</sup>, F. Nacef<sup>2</sup>

<sup>1</sup> Doctor, Psychiatry A ward, Tunis, Tunisia; <sup>2</sup> Razi Hospital,

Psychiatry A ward, Tunis, Tunisia

Corresponding author.

*Introduction.*– Vaginismus can be a cause of non-consumption of marriage and of infertility. It impacts on the quality of the marital relationship. Cognitive behaviour therapy (CBT) is recommended.

*Objectives and methodology.*– The aim of our study is to draw attention to aspects of traditional Arab-Muslim culture which should be taken into consideration during the treatment process. We present a series of three patients in whom cultural issues played an important role during CBT.

*Results.*– Patient (1) consulted with a desire to have a child. Her whole family is aware of her difficulties and the fact that she is in psychotherapy, and sometimes her mother in law even accompanies the couple to therapy. This puts additional pressure on the couple, who is already worried about its status and reputation within the larger family-structure. Patient (2) consulted after 7 years of marriage. She had been very reluctant to consult in psychiatry, and had a defloration in gynecology. She felt guilty because, as a Muslim woman, she has to satisfy her husband. Patient (3) had a "TASFIIH": this is a traditional ritual supposed to make the girl indeflorable. It is removed before marriage. As a child, the patient had a strict religious education; the main goal was to protect her virginity.

*Conclusion.*– Cultural aspects and religious thoughts must be taken into consideration in the management of vaginismus; CBT should be adapted to the context of the person and the history of the couple.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0246

### **Cultural aspects of mindfulness based cognitive therapy: A case series of Tunisian patients**

Y. Zgueb<sup>1</sup>, U. Ouali<sup>2</sup>, L. Jouini<sup>2</sup>, S. Chebli<sup>2</sup>, R. Jomli<sup>2</sup>, F. Nacef<sup>2</sup>

<sup>1</sup> Doctor, Psychiatry A ward, Tunis, Tunisia; <sup>2</sup> Razi Hospital,

Psychiatry A ward, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Mindfulness Based Cognitive Therapy (MBCT) is widely recommended for several mental disorders. Despite the Eastern origin of meditation there are many explanatory models and techniques which are based on Western cultural concepts.

**Objectives and methodology.**– The aim of our study was to draw attention to traditional aspects of Arab-Muslim culture and how these can be used to adapt the treatment and influence the outcome of MBCT. We present a series of four patients who received MBCT in our department and in whom cultural and religious issues played an important role during treatment.

**Results.**– The four patients suffered from Major Depressive Disorder (MDD). Patient (1) declined the proposal since he made a confusion between Buddhism and meditation arguing that it opposes Islam. Patient (2) was more committed to therapy after several sessions using the religion as a value, whereas normally the spiritual side is not discussed very often during the sessions. Patient (3) did not tolerate much physical pain during the sessions, with a preference for short meditations and visits to a traditional healer. Patient (4) wanted to discuss the content of thoughts which is not usually done in MBCT principle. He reported that his family does not understand his space of silence.

**Conclusion.**– Tunisian society is very oriented towards interdependence. The expectation of a magical effect from an active and directive therapist is highly anticipated since the beginning of the therapy, despite the establishment of an initial contract noting that MBCT is an experimentation based on the present moment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0247

### **A cultural analysis of medical risk and its inspiration for solution to medical dispute**

Y. Zhu

Tongji University, Medical school, Shanghai, China

Research showed that whether in the east or west there are numerous medical disputes, but the severity was significantly different. Western Medicine, as one of the earliest scientific technology that login China, brought the violent collision of east and west cultures, which may give the reason on why the medical dispute was widely swept over the east land for years. In this study, the medical dispute as the starting point to discuss the remarkable different cultural values between the east and west. Originated from the source of risk recognition, this discussion compared Chinese and Western divergence in the concept of medical risk and analysed the two sides of the medical treatment in order to reveal the deep understanding of the medical essence, offering a view of medical dispute from a global perspective. We need to establish a web-community specially for doctors and patients to talk problems, debate contradiction and explain why. The following new patients and doctors will learn experiences on how to get along, thus they may know each other before meeting. This idea was inspired from IBCT, which is the integration of behavioural couples therapy, if we can give up wishes to change the others, the ideal behaviour seems to occur naturally, so as to establish a more intimate and satisfactory relationship. Similar to exposure therapy: both sides were allowed to desensitize to subsequent conflicts, so once it happens, it's a negotiable issue with more acquired strategies and less third party intervention.

### **Psychological problem in cancer patients in rural India (West Bengal) – Experience of an NGO**

M. Aditya

Chief Caregiver, Palliative Care, Purba Medinipur, India

\* Corresponding author.

**Introduction.**– As in any developing countries state of West Bengal in India has a huge psychological burden of cancer patients in any stage coming from rural area where awareness regarding the usefulness of cancer care in rather poor. Objective of this study is to identify the main psychology difficulties in achieving the above goal in a rural village setting in India.

**Method.**– Newly diagnosed or survivors cancer patients in need of psychology support in various villages in of rural India were selected for this study. Their symptoms and managements in that rural surroundings were evaluated by an NGO (guidance of oncologist or psychologist) working in that area. An attempt was made to identify the main obstacles in getting proper psychological support as well as cancer care in a rural setting.

**Results.**– Apart from pain, fatigue psycho-social problem also main symptoms affecting these patients. In most patients pain and other symptoms were managed by different therapy but fear or mental trauma were grossly inadequate due to lack of properly trained counsellor or psychiatric manpower in the rural India. However regular homecare visits by a group of social workers were of immense help in these cancer patients. NGO team was well guided by oncologist and psychiatric specialist.

**Conclusion.**– There is a wide gap of trained manpower in this filled in rural areas of India. Dedicated groups from rural area itself need encouragement and proper training, so that difficult symptoms can be managed locally along with necessary social and psychological support to these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The level of diabetes related distress among a sample of diabetics in Riyadh, Saudi Arabia**

H. Alrashid<sup>\*</sup>, R. Alzuhairi, A. Aljuhani, M. albogami, N. Alghamdi, A. Fayed

Princess Nora bint Abdulrahman university, Medicine, Alkhobar, Saudi Arabia

\* Corresponding author.

**Introduction.**– Diabetes Related Distress (DRD) is a negative emotional reaction to stresses associated with diabetes. Many studies investigated depression in Saudi diabetics, but little is known about DRD.

**Objectives.**– To estimate the level of DRD among Saudi patients and its determinants.

**Methods.**– A cross sectional study of consented 157 diabetics was conducted. Diabetes Distress Scale (DDS) evaluates distress over the past month was used. It measures distress at four subscales namely; Emotional Burden (EB), Physician-related Distress (PD), Regimen-related Distress (RD) and Interpersonal Distress (ID). It classifies patients into No DRD and clinically significant DRD. Reliability of DDS was excellent as indicated by Cronbach's alpha ( $\alpha=0.91$ ). Adherence to treatment (AT) was estimated as reported

by patients and glycemic control was assessed using the latest HbA1c results.

**Results.**– The average participants age was  $44.5 \pm 16.0$  years and 65% were female. Clinically significant DRD was detected in 37% of participants, EB and RD in 40.8%, PD in 46.5%, and ID in 32.5%. Total DRD and all its subscales were insignificantly associated with gender, economic level, marital status, education, type or duration of diabetes ( $P > 0.05$ ). DRD, EB and PD level deteriorated significantly with numbers of diabetes complications and improved by advancement of age. DRD was negatively and significantly correlated to AT ( $r = -0.38$ ,  $p < 0.01$ ). Furthermore, increasing DRD was associated with increased HbA1c, therefore demonstrating poor glycemic control ( $r = 0.23$ ,  $p < 0.01$ ).

**Conclusions.**– DRD is commonly reported among Saudi diabetics and is directly affecting AT, therefore, it is negatively affecting their glycemic control as measured in HbA1c.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Effect of laughter therapy by Kataria method on depression of elderly residing at nursing home**

S. Asiri<sup>1</sup>\*, F. Mohammadnejad<sup>2</sup>, N. Mokhtari<sup>1</sup>, E. Kazemnejad<sup>3</sup>

<sup>1</sup> Guilan University of Medical Sciences, Department of Community Health, Rasht, Iran; <sup>2</sup> Mazandaran University of Medical Sciences, Kiasar Medical and Health Center, Kiasar, Iran; <sup>3</sup> Guilan University of Medical Sciences, Department of Biostatistics, Rasht, Iran

\* Corresponding author.

**Introduction.**– World population is getting old and depression is the most common mental disorder in the elderly. It is necessary to seek useful, harmless and low-cost methods to promote mental health of older adults. Laughter therapy is an alternative therapy for depression.

**Objective.**– This study aimed to determine the effect of Kataria method laughter therapy on depression of elderly residing at Nursing Home in Rasht city (Iran).

**Methods.**– In a randomized controlled trial, elderly 60 years and older with mild and moderate depression were selected by random sampling method from elderly residing at nursing home. The participants were assigned into experimental ( $N = 47$ ) and control ( $N = 47$ ) groups by random allocation. Data were collected using Geriatric Depression Scale and demographic questionnaire. The participants of experimental group attended a laughter therapy program consisting of two 30-minute sessions per week lasting for 5 weeks. Then the data were analysed using the Mann-Whitney, Wilcoxon and logistic regression tests and SPSS ver.16 software.

**Results.**– Mean score of depression in control and experiment groups showed no significant difference but Mann-Whitney test indicated significant difference in mean and score changes of depression in both groups after intervention ( $P < 0.0001$ ). Based on logistic regression model, two variables of age ( $P < 0.02$ ) and number of children ( $P < 0.037$ ) were predictors of depression; as with every five years increase in age after 60; the level of depression decreased and it increased with increase in number of children.

**Conclusion.**– Laughter therapy is an affordable and easily accessible way that has positive effects on depression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The silent minority: Men who need acute inpatient care for depression in the 21st century inner-city**

D. Codling\*, R. Kaylan, L. Dratcu

King's College London, IoPPN, London, United Kingdom

\* Corresponding author.

**Introduction.**– As most mental healthcare in the UK is now provided in the community, it is increasingly uncommon for admissions for depression. Inpatient care is usually indicated for severe or treatment-resistant depression. We assessed male patients on an inpatient unit regarding factors underlying their admission.

**Methods.**– We reviewed 200 most recent admissions to our acute inner-city unit, admitting working-age men. We identified those discharged with a primary ICD-10 diagnosis of depression and collected data on demographics, comorbidities, illness duration, previous treatments and reason for admission.

**Results.**– Twelve patients (6%) aged  $43.8 \pm 12.2$  years had a diagnosis of depression on discharge. Most ( $n = 11$ ) lived independently, were single ( $n = 9$ ) and unemployed ( $n = 7$ ). 50% had no family support. Ten had been prescribed antidepressants before but were unknown to local services ( $n = 8$ ) and had not received any intervention prior to admission. Mean illness duration of 4.7 years but they had few previous admissions (0-5, median 1). Most had a comorbid medical ( $n = 8$ ) and/or substance misuse disorder ( $n = 8$ ). 10 were admitted voluntarily, and were feeling suicidal on admission. Five had attempted suicide prior to admission. Most were treated with first-line antidepressants (11/12), 6 were switched and 4 maintained, with 3 receiving additional psychotropics.

**Discussion.**– This small group of patients admitted due to risk of harm to self, were admitted for risks rather than to treatment-resistance, and despite long duration of illness, had rarely been known to services. Our data suggests that this population only receive specialist help at crisis point requiring admission. Further work is required to understand why this is.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Depression in patients with breast cancer**

J. Cvetkovic

Faculty of Medicine- Priština, Kosovska Mitrovica, Katedra za neurologiju i psihijatriju, Kosovska Mitrovica, Serbia

**Introduction.**– Breast cancer is the most common female cancer and one of the leading causes of death in women. A large number of studies are suggesting an association between depression and cancer. The nature of this connection, despite numerous studies, has not been sufficiently known yet.

**Objective.**– Comparison of the clinical course of depressive disorder in the breast cancer patient group with depression of patients with cancer-free depression.

**Method.**– The study included 153 patients. The experimental group was composed of 103 patients with breast cancer and a control group including 50 healthy persons. During the research we used the following standardized and structured questionnaires. The obtained data were analysed using standard statistical method.

**Results.**– Initial inquiries showed that patients were in shock of the diagnosis, but after a while the reactions subside. Testing of depression with Hamilton's and Montgomery-Asberg scale, in patients who are on cancer treatment compared to control group showed a statistically significant difference at the baseline and after six months, and by age. A multivariate model of evaluation of the

importance of risk factors for the occurrence of depression, in women who have had children, who were under stress and who had family psychiatric disorder were at greater risk for developing depression at baseline, independent predictors of occurrence of depression during treatment.

**Conclusion.**– Depression is significantly more frequently recorded in patients with breast cancer.

**Keywords:** Breast cancer; Depression; Risk factors; Assessment tools,

### Transient febrile reaction after electroconvulsive therapy in an adult female patient with major depressive disorder

W. Dai<sup>\*</sup>, J.W. Liew, S.W. Ong, H.S. Ong, M.Y. Tan  
Institute of Mental Health, General Psychiatry, Singapore, Singapore

\* Corresponding author.

**Introduction.**– Electroconvulsive therapy (ECT) is a safe and effective treatment for major depressive disorder (MDD). Common side effects of ECT include headache, muscle pain, nausea, and mild short term memory impairment. ECT-associated febrile reaction has been rarely described.

**Objectives.**– We describe a case of transient febrile reaction after ECT in an adult female patient with MDD and resistant suicidal thoughts.

**Case.**– Ms. Y. is a 34-year-old Filipino lady with newly-diagnosed MDD and resistant suicidal thoughts treated with ECT. She has no significant history of medical or psychiatric disorders, substance abuse or dependence. However, she has strong family history of depression. She was hospitalized for her first depressive episode with low mood, delusions of reference and guilt, resistant suicidal thoughts and multiple suicidal attempts. After a poor response to medication trials, ECT was initiated. Her mood improved with ECT but her first and second ECT treatment sessions were complicated by transient fever and tachycardia, which resolved without treatment. Thorough physical examination and investigations were unremarkable except for raised C reactive protein (CRP) and erythrocyte sedimentation rate (ESR) but no infective cause was found. Subsequent ECT sessions were uneventful.

**Conclusions.**– We report an unusual case of transient febrile reaction after ECT in an adult female patient with newly-diagnosed MDD and resistant suicidal thoughts, which may have been caused by ECT.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0254

### The place of electroconvulsive therapy for melancholic patients with dementia

M. Daoud<sup>1</sup>, Z. Azzouz<sup>1</sup>, S. Ben Fadhel<sup>1</sup>, A. Taamallah<sup>1</sup>, A.A.

Tounsi<sup>1</sup>, R. Bouzid<sup>2</sup>

<sup>1</sup> Razi Hospital, psychiatry, Mannouba, Tunisia; <sup>2</sup> Mohamed Taher Maamouri Hospital, psychiatry, Nabeul, Tunisia

\* Corresponding author.

**Introduction.**– Electroconvulsive therapy (ECT) is a biological treatment procedure utilized worldwide as one of the most effective biological treatment modalities for various severe,

treatment-refractory or treatment-resistant psychiatric disorders, in particular, major depressive disorder.

**Objective and method.**– The work aims to study the therapeutic efficiency of electroconvulsive therapy (ECT) through three cases of patients suffering from melancholic depression associated to dementia treated by this therapy.

**Results.**– OUR respectively 72, 66 and 63-year-old patients were followed for bipolar disorder or for a recurring major depressive disorder associated to dementia. They presented a severe relapse of their mood disorder resistant to the medical treatment, which indicates electroconvulsive therapy. The number of session varied from 9 to 16 sessions for every patient. Remission of the depressive symptoms was obtained also stabilization or amelioration of the MMSE score.

**Conclusion.**– The frequency of the drug resistant forms of mood disorder especially the depressive one gives a dominating place for the electroconvulsive therapy which represents no contraindication for the ages subjects or having cognitive disorders which she can stabilize even to improve.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Use of ketamine in treatment-resistant depression

N. De Uribe-viloria<sup>\*</sup>, M. De Lorenzo Calzon, M. Gomez Garcia, A. Alonso Sanchez, H. De La Red Gallego, A. Alvarez astorga, S. Gomez Sanchez, R. Hernandez Anton, C. Noval Canga, C. Capella Meseguer, E. Rodriguez Vazquez, S. Cepedello Perez, A. Rodriguez Campos, L. Rodriguez Andres, G. Medina Ojeda, F. De Uribe Ladron De Cegama  
Hospital Clinico Universitario De Valladolid, Psychiatry, Valladolid, Spain

\* Corresponding author.

**Introduction.**– Several lines of research are trying to unveil new ways of dealing with treatment-resistant depression. Ketamine is a dissociative anaesthetic also known for its indications in chronic-pain treatment and it may have potential use in depression management.

**Objectives.**– We aim to better understand the indications and possible effects of intravenous ketamine in the management of depression.

**Methods.**– We present a 63-year old patient, admitted for treatment with a series of 6 intravenous administrations of ketamine. Although some improvement was observed in the first days, it disappeared less than a week after finishing the treatment. Headache after injections was mentioned as a side effect.

**Results.**– We found that the mechanism by which ketamine alleviates depressive symptoms is still not fully understood, although it may involve several pathways (fig.1). Side effects ranged from mild to severe (fig.2). Other issues are yet to be established.

Table 1 :

Variables	Male	Female	Total	
Hypertension	17	13	30	
Central obesity	14	36	50	
BMI	Within norms	25	15	40
Overweight	8	8	16	
Generalized obesity	12	32	44	
Activity as per GPAQ	Insufficiently active	6	14	20
Active	39	41	80	
Tobacco use	20	1	21	
Alcohol use	18	0	18	
First degree relative with diabetes	2	6	8	
Known hypertension/diabetes/coronary artery disease	5	8	13	

Fig 1.

**Conclusions.**– Ketamine's potential long-term effects are hard to predict. Other questions such as dosage, rate, frequency of administration and treatment duration are yet to be defined. This means that, while ketamine sheds a new light in depression management, its use should still be reserved to few, well-chosen patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0256

### **Catatonia. A case report**

M.G. Eliche\*, M. Garcia-Poggio

Psychiatry, Hospital de Mostoles, Mostoles, Madrid, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– Electroconvulsive therapy (ECT) is recommended to achieve short-term improvement of severe depression after an adequate trial of standard treatment options have been proven ineffective and/or when the condition is considered to be potentially life-threatening.

**Objectives.**– To evaluate the efficacy of ECT in a patient, diagnosed with previous depressive episodes, with catatonic symptoms.

**Methods.**– We review recent literature related to a clinical case admitted to our Psychiatric Ward and evaluate the efficacy of ECT in catatonia. A 64-year-old woman presented with hypomaniac symptoms in our Emergency Service after she was discharged due to a depressive episode and treated with ECT.

**Results.**– After being evaluated by the Psychiatric Emergency Service and diagnosed with hypomaniac symptoms; the physician prescribed two antipsychotics. Swiftly, the patient blocked and stopped moving in a catatonic state.

**Conclusion.**– We should take into account ECT as an effective treatment of catatonic symptoms. This diagnosis is not frequent and in previous literature is related with schizophrenia more than with affective disorders. However it is more prevalent in the second one.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Study on personality traits that are correlated with anxiety in women who gave birth in Timis county**

V.R. Enatescu<sup>1</sup>, M. Craina<sup>2</sup>, A. Gluhovschi<sup>2</sup>, I. Papava<sup>1</sup>, R. Romosan<sup>1</sup>, A. Gridjac<sup>1</sup>, V. Enatescu<sup>3</sup>, E. Bernad<sup>2</sup>, I. Enatescu<sup>4</sup>

<sup>1</sup> Victor Babes University of Medicine and Pharmacy, Psychiatry, Timisoara, Timis County, Romania; <sup>2</sup> Victor Babes University of Medicine and Pharmacy, Obstetrics and Gynecology, Timisoara, Timis County, Romania; <sup>3</sup> West Medica Clinic, Psychiatry, Satu Mare, Romania; <sup>4</sup> Victor Babes University of Medicine and Pharmacy, Child Care and Neonatology, Timisoara, Timis County, Romania

\* Corresponding author.

**Introduction.**– Perinatal anxiety has begun to gain recognition particularly in the last decades. Furthermore, it appears that anxiety is more expressed in the antenatal period compared to the postnatal period. Personality might have a mediating role in the expression of perinatal clinical anxiety.

**Objectives.**– The principal objective was to psychometrically quantify anxiety throughout the perinatal period and to identify the personality traits that are significantly associated with the presence of anxiety.

**Method.**– In the initial sample of 202 pregnant women that were evaluated in the antenatal period, 142 of them also agreed to participate in the postnatal evaluation. State and trait anxiety were evaluated with STAI-Y where a total score larger than 40 on the first 20 items (form Y1) was required to classify the anxiety as clinically significant. Personality traits were assessed with the NEO-FFI inventory. Perinatal depression was assessed by the Edinburgh Postnatal Depression Scale using a cut-off > 13.

**Results.**– A total of 68 of the pregnant women (33.7%) presented with clinically significant anxiety while in the postnatal period anxiety was clinically significant for only 22 of the mothers (15.5%). Antenatal state anxiety showed direct correlation with neuroticism and inverse correlation with extraversion while postnatal state anxiety showed direct correlation with neuroticism.

**Conclusions.**– Neuroticism showed as being a stable and representative aspect of personality during the perinatal period in women who developed anxiety; that might also play a mediating role in the occurrence of anxiety and depression during the entire perinatal period of vulnerable women.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0258

### **Family status and depressive disorder**

C. Homorogan\*, I.R. Adam, B. Ruxandra, R. Ioana, P. Anca-Livia, B. Cristina

University of Medicine, Department of Neuroscience, Timisoara, Romania

\* Corresponding author.

**Introduction.**– Family is the social structure in which all elements are interconnected, interdependent and bidirectionally influenced. Family functioning is related to the physical and psychological well-being of family members and its dysfunctionality affects the family as a whole. Depressive disorder is influenced by an unhealthy family environment. The intra-familial status could be an important predictor of the clinical course of depressive disorder.

**Objectives.**– We wanted to see how the evolution of the depressive illness and the number of relapses are influenced by family functioning.

**Methods.**– A sample of 34 adults diagnosed with major depressive disorder, who were hospitalized in the Psychiatry Clinic of Timisoara, were analysed by socio-demographic parameters (age, gender, family status, education level, professional status) and by the number of relapses and the evolution of the disease. The data were statistically analyzed.

**Results.**– There is a positive correlation between a good family functioning and a lower number of relapses, also between a good family functioning with a shorter evolution of the disease. In both genders, being married is associated with a later onset of the depression, but regarding the evolution of the disease and the number of relapses, getting married was more protective for men than to women.

**Conclusion.**– This results may confirm the importance of family functioning, regarding the onset and in the evolution of depressive disorder, for each gender.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0259

### **Post-stroke depression: About a case**

Á. Izquierdo de la Puente\*, P. Del Sol Calderón, M.I. Hidalgo Rodrigo, S. Boi

Hospital Puerta de Hierro de Majadahonda, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction and goals.**– The aim of this case is to perform a review of post-stroke depression.

**Clinical case.**– A 63-year-old patient suffering from depressive symptomatology consisting of irritability, tendency to cry, anhedonia, apathy, and significant cognitive failures after experiencing an Ictus stroke in April 2016. Due to these symptoms, a treatment with vortioxetina 10 mg is initiated. After one month of treatment, the patient presents an overall improvement of the mood and secondary cognitive deterioration.

**Discussion.**– Post-stroke depression is a direct physiological consequence of a cerebral vascular disease, being the most prevalent affective disorder. It has not been shown that the localization of the stroke is a more frequent predictor, however, it is directly related to the size of the affected area. It generates loss of autonomy, greater cognitive deterioration, and mortality (3–4 times higher). Regarding treatment, SSRIs are the first-line antidepressants because they are the safest. They present the least side effects, with a rapid onset of action and anxiolytic effect. However, at present, vortioxetine is considered another treatment option due to its few adverse effects. This drug does not alter blood pressure or have effects on QT and it improves cognitive deterioration.

**Conclusion.**– Although there is no clear scientific evidence on the etiopathogenesis of PSD based on the location of the ICTUS, IPD is a real pathological entity that plays a key role in patient healing. Therefore, it is important to address it without delay, to improve the patient's quality of life.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0260

### **Clinical expression of unipolar and bipolar depression in a Tunisian patient sample**

L. Jouini<sup>1\*</sup>, U. Ouali<sup>1</sup>, M. Ghazzai<sup>2</sup>, Y. Zgueb<sup>1</sup>, R. Jomli<sup>1</sup>, F. Nacef<sup>1</sup>  
<sup>1</sup> Razi Hospital, "A" Adult Psychiatry Department, Tunis, Tunisia; <sup>2</sup> Razi Hospital, Child and Teenager Psychiatry Department, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– The clinical features of depression differ in unipolar and bipolar depression. Linking depressive symptoms to each disease is important for treatment planning.

**Objectives.**– The aim of our study was to identify differences in the clinical expression of unipolar and bipolar depression

**Methods.**– Ninety-five patients with a diagnosis of clinical depression were interviewed using the Structured Clinical Interview for DSM IV for mood disorders. Patients then received a diagnosis of Major Depressive Disorder (MDD) or Bipolar Disorder (BD).

**Results.**– MDD patients experienced more loss of appetite (81,3%), weight loss (83,3%), insomnia (92,7%), agitation (10,0%), fatigue (54,3%), decreased ability to think (70%), memory problems (5,6%) whereas BD patients had an increased appetite (35,0%), weight gain (25,9%), hypersomnia (10%), psychomotor retardation (54,3%), loss of energy (71,4%), more feelings of guilt (20%) and low self-esteem (90,9%), indecision (45,5%), recurrent suicidal thoughts, plans and attempts (75,6%). Regression analysis showed that BD was characterized by more significant feelings of excessive guilt and low self-esteem (57,8% vs 32%,  $p=0,022$ ), more suicidal thoughts (32,5% vs 13,3%,  $p=0,031$ ) and more suicidal attempts (20% vs 0%,  $p=0,002$ ).

**Conclusions.**– OUR study supports the findings of previous publications aiming at identifying psychopathological characteristics that might serve as indicators of bipolarity in patients with a history of depression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0261

### **Additional exercise treatment in major depression improves body composition and reduces cardiovascular risk factors – A randomized and controlled pilot study**

K. Kahl

Hannover Medical School, Psychiatry, Social Psychiatry and Psychotherapy, Hannover, Germany

\* Corresponding author.

**Objective.**– Major depressive disorder is associated with an increased risk of developing cardiometabolic disorders and frailty. Early changes associated with these disorders are alterations in body composition, i.e. the amount of intra-abdominal (IAT) and pericardial adipose tissue (PAT), and decreased muscle mass. Several studies found increased intra-abdominal and pericardial adipose tissue in MDD, and decreased muscle mass. We therefore studied the influence of additional exercise treatment on body composition measures in MDD.

**Methods.**– Forty-two patients with MDD were included in this study, and body-composition data were complete in 30 patients. Of these, 20 patients received structured, supervised and tailored sport therapy (EXERCISE) additional to guideline based treatment, and 10 received treatment-as-usual (TAU). Pre-post measurements were performed 6 weeks after starting the intervention or TAU, and IAT, PAT and muscle mass were determined using magnetic-resonance tomography.

**Results.**– Repeated measurements ANOVA revealed that volumes of PAT decreased significantly in the EXERCISE group compared to TAU ( $P<0.05$ ), and muscle mass increased significantly in the EXERCISE group ( $P<0.05$ ). IAT also decreased slightly in the EXERCISE group, although this did not reach statistical significance.

**Conclusion.**– This study demonstrates that additional exercise treatment improves body composition measures in MDD, thereby reducing the risk for the development of cardiometabolic disorders and muscular frailty. Exercise treatment may be recommended as integral part of guideline based MDD treatment, particularly as prevention strategy to improve physical health and reduce the risk for cardiometabolic disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0262

### **Effect of Papaver Rhoas hydro-alcoholic extract on depression in mice**

A. Kazemi<sup>1\*</sup>, N. Reza<sup>2</sup>, K. Majid<sup>3</sup>, M. Reyhaneh<sup>1</sup>, B. Raha<sup>2</sup>

<sup>1</sup> Shiraz university of medical sciences, Student Research Committee, Shiraz, Iran; <sup>2</sup> Islamic Azad University Marvdasht-branch, Department of Psychology, Marvdasht, Iran; <sup>3</sup> School of Pharmacy, Shiraz University of Medical Sciences, Department of Pharmacology and Toxicology, Shiraz, Iran

\* Corresponding author.

**Introduction.**– Depression (a kind of mood disorder) is a threatening disease. Side effects of synthetic antidepressant drugs, leads to attempt for discovery of natural drugs.

**Objective.**– In this study, the authors evaluated the effects of Papaver rhoas hydro-alcoholic extract against reserpine induced depression in mice.

**Methods.**– A total of 42 male BALB/c mice were divided into 6 groups of 7 mice, separately. Positive and negative control groups received fluoxetine (20 mg/kg, i.p.) and reserpine (5 mg/kg, i.p.) and vehicle mice received normal saline (1 mg/kg, i.p.), respectively and treatment groups received Papaver rhoeas hydro-alcoholic extract at concentrations of 50, 100, 200 mg/kg, 18 h after administration of reserpine. Mice were then studied with behavioural tests (forced swimming and rotarod). Finally, mice's blood antioxidant capacity was measured.

**Results.**– Significant difference ( $P < 0.001$ ) in the duration of immobility time between reserpine treated and vehicle groups was obtained. Papaver rhoeas hydro-alcoholic extract at define concentrations, reduced the duration of immobility time and significantly improved blood antioxidant capacity.

**Conclusion.**– According to the results, Papaver rhoeas can be a good candidate for use as a natural drug with antidepressant effects.

**Keywords:** Papaver rhoeas hydro-alcoholic extract; Depression; Forced swimming test

EV0263

### **Cerebral folate deficiency in treatment resistant depression: A literature review**

S. Kousgaard Khan\*, J. Nørgaard Kjær  
Psychiatric Research academy section Q, Psychiatric hospital Risskov, Aarhus, Denmark

\* Corresponding author.

**Introduction.**– Approximately 15% of patients with depressive disorders do not respond to any of the current treatments available and are categorized as treatment-resistant. A recent study by Pan et. al. examined patients with treatment resistant depression for metabolic disorders. A greater proportion of the participants had metabolic disorders, cerebral folate deficiency being the most frequent. Treatment of folate deficiency resulted in a decrease of depressive symptoms. The study was limited by a small number of participants.

**Objectives.**– The aim of this study was to make a review of clinical studies in cerebral folate deficiency and depression.

**Methods.**– We searched in MEDLINE using the MeSH vocabulary (folic acid, folic acid deficiency, depressive disorder, treatment-resistant) and the phrase: cerebral folate deficiency. Non-clinical studies were excluded.

**Results.**– We found 771 articles of which 753 were excluded. Earlier studies going back to the 1960's did identify an association between folate deficiency and depression. These studies only concerned peripheral folate deficiency. One recent case-control study included spinal fluid in the tests of folate compounds in patients treatment-resistant depression. They found an association between treatment-resistant depression and cerebral folate deficiency. Treatment with folic acid while continuing the prior antidepressive treatment resulted in a decrease of depressive symptoms.

**Conclusion.**– Previous studies indicated folic acid as a potential adjuvant therapy to improve inadequate response to antidepressants. However only two articles studied cerebral folate deficiency in treatment-resistant depression and thus the requirement for spinal fluid analysis in diagnosing treatment-resistant depression is still to be determined.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Comprehensive analysis of suicidal behavior in depressive disorders in cancer patients**

H. Kozhyna\*, K. Zelenska, V. Mykhaylov, S. Isayenko, V. Koshchii  
Kharkiv National Medical University, Psychiatry, narcology and medical psychology, Kharkiv, Ukraine

\* Corresponding author.

Recently, the relevance of the problem of depression in cancer practice has increased significantly, where their prevalence ranges from 40 to 60% according to various authors.

**The aim of the study.**– The study of the phenomenology of suicidal behaviour in depressive disorders in cancer patients.

**Material and methods.**– for the purpose of studying our goal, we carried out a comprehensive examination of 154 patients of both sexes with an oncological pathology I and II stage in which depression was diagnosed. The main group consisted of 103 patients with signs of suicidal behaviour, control - 51 patients (men) without signs of suicidal behaviour. Malignant neoplasm is a psycho-traumatic factor for the patient, and leads to the development of depressive disorders, and suicidal behaviour. In the clinical picture of depressive disorders in patients with oncological pathology dominated mood depression, the affect of yearning and anxiety, the coverage of the experiences of acute grief in connection with the diagnosis of cancer, with the narrowing of cognitive functions and the domination of the content of mental trauma in consciousness. In the formation of suicidal behaviour of cancer patients with depressive disorders, high rates, according to clinical scales of anxiety and depression, high level of suicidal risk in combination with low level of death consciousness, and suicidologic anamnesis are a leading role.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0265

### **Depressive disorders in internally displaced persons**

H. Kozhyna\*, V. Korostiy, K. Zelenska, V. Mykhaylov, V. Gaponov  
Kharkiv National Medical University, Psychiatry, narcology and medical psychology, Kharkiv, Ukraine

\* Corresponding author.

**Introduction.**– According to the Guiding Principles on Internal Displacement, internally displaced persons are persons who have been forced or obliged to leave their homes, in particular as a result of extreme situations, and who have not crossed an state border.

**Aim.**– to study clinical features of disorders in Internally Displaced Persons.

**Methods.**– We have a complex psychopathological and psychodiagnostic research 115 IDPs in volunteer center, located at the central train station in Kharkiv.

**Results.**– There were clinical and psychopathological signs of depressive disorders in Internally Displaced Persons analysed. Anxiety, asthenia, asthenic-apathetic and melancholy variants of depressive disorders in there were clinical and psychopathological signs of depressive disorders in in Internally Displaced Persons analysed. In this study there were the markers of suicide risk for Internally Displaced Persons determined: high suicide risk, low death self-consciousness, high anhedonia level, clinical manifestations of anxiety and depression by The Hospital Anxiety and Depression scale, severe anxiety and depression by The Hamilton Anxiety Rating Scale, major depressive episode by the Montgomery-Asberg Depression Rating Scale. There were approaches to differentiated prevention of suicidal behaviour in

depressive disorders in Internally Displaced Persons validated, that include pharmacotherapy, psychotherapy and psychoeducation.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0266

### **Depression in the Elderly: socio demographic and clinical profile**

N. Halouani, I. Lajmi\*, S. Ellouze, R. Naoui, J. Aloulou, O. Amami  
Hedi Chaker Hospital, Psychiatry, Sfax, Tunisia

\* Corresponding author.

*Introduction.*– Depression is a major problem of public health because of its high prevalence, its consequences in particular suicide and its impact on the quality of life and autonomy. It is a frequent disease that can affect elderly and need an adapted therapeutic coverage.

*Objectif.*– Raise the socio demographic and clinical profile of the elderly with major depressive episode.

*Methods.*– This is a descriptive study, including all the patients with a major depressive episode according to the DSMIV, and hospitalized in the psychiatric department in the Hedi Chaker hospital, Sfax, Tunisia during a period of 16 years (from 2000 to 2015).

*Results.*– Total number of patients was 30. The mean age was 69 years and 8 months. Sex ratio (M/F) was 0.66. they were married in 80% of cases and illiterate in 46.6% of cases. Somatic comorbidity was present in 53.3% of patients. The motifs of hospitalisation were: sadness (43.3%), psychomotor instability (30%), suicidal ideas (3.3%), somatic pains(13.4%), insomnia (6.7%) and delusional ideas(3.3%). Personality disorder was associated in 16,7% of cases.

*Conclusions.*– Depression is a major public health problem in the elderly and is more common among married women of average socioeconomic status with a history of chronic somatic diseases. But it still misdiagnosed. There are many reasons for this, whether it is the lack of early identification, the under estimation of depressive affects by family and the patient himself. Depression should be systematically discussed especially if there is a disturbance of food or sleep.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Psychiatric manifestations of primary Sjögren's syndrome. A case report**

I. Lajmi\*, I. Baati, A. Feki, R. Sellami, I. Feki, J. Masmoudi  
Hedi chaker University Hospital, Department of Psychiatry A, Sfax, Tunisia

\* Corresponding author.

*Introduction.*– Sjögren's syndrome is an autoimmune disease, characterized by typical dryness of the mouth and eyes associated to involvement of other exocrine glands as well as a wide variety of organs and systems. Central nervous system involvement in primary disease is a rare but significant complication. It can manifest with focal or diffuse neurological deficits including psychiatric disorders. Our observation is an illustration of the psychiatric manifestations.

*Case presentation.*– We report the case of Mrs R, 56 years old, with a medical history of primary Sjögren's syndrome, who presented in 2017 to a psychiatry department for irritability and insomnia. She described having sad mood, fatigue, shortened attention span, poor concentration, and memory deficits. She reported difficulty making decisions and performing daily activities. She did not have suicidal

ideas, but she had a lowered self-reported quality of life. Control MRI of the brain and spinal cord showed the presence of T2 hyperintense foci in the cerebral white matter (high signal intensity on T2-Flair in the subcortical and periventricular areas) and subcortical cerebral atrophy. She did not respond to a 40 mg daily dose of fluoxetine during 4 months. Therefore, she had received escitalopram (10 mg/day) for 3 months, but only insomnia was resolved.

*Conclusion.*– This case highlights the difficulty of managing psychiatric disorders due to primary Sjögren's syndrome.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Correlations between suicidal ideation and suicide attempts in patients with recurrent depressive disorder**

M. Maria-Mihaela<sup>1</sup>, L. Dehelean<sup>2</sup>, A.M. Romosan<sup>3</sup>, R.S. Romosan<sup>4</sup>

<sup>1</sup> 1st year resident in adult psychiatry-, "Pius Brnzeu" Emergency County Hospital, 2nd Psychiatric Clinic, Timisoara, Romania, Timisoara, Romania; <sup>2</sup> Associate Professor, Discipline of Psychiatry, Department of Neurosciences, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, Timisoara, Romania; <sup>3</sup> PhD Candidate, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, Timisoara, Romania; <sup>4</sup> Assistant Professor Discipline of Psychiatry, Department of Neurosciences, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania, Timisoara, Romania

\* Corresponding author.

*Introduction.*– Depression is a major debilitating mental disorder that affects millions of people around the globe across all sexes, ethnicities, and age barriers. One of the most important risks of a patient with recurrent depressive disorder are suicidal thoughts.

*Objectives.*– To estimate the presence of suicidal ideation and suicide attempts in patients with recurrent depressive disorder, and to find the relationship between the two.

*Methods.*– Fifty-three outpatients diagnosed with recurrent depressive disorder, currently with a severe depressive episode without psychotic symptoms -according to ICD-10 criteria-, were included in this study, which was carried out in Timisoara, Romania, between 2015–2017. To assess the severity of the depressive episode and suicidal ideation, we used the MINI Interview and the Hamilton Rating Scale for Depression (HAM-D).

*Results.*– We found that the incidence of suicide attempt was 32.64% in patients with suicidal ideation. Attempters scored higher in suicidal ideation, impulsivity and agitation whilst with non-attempters, general somatic and hypochondriasis symptoms were more often present. Young male patients with severe depression, who are unmarried and also show psychomotor agitation are more likely to attempt suicide.

*Conclusions.*– Early detection of suicidal ideation is essential in possibly preventing suicide attempts.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Depression in Patients with multiple sclerosis**

R. Masmoudi<sup>1</sup>, N. Halouani<sup>1</sup>, M. Aissi<sup>2</sup>, S. Fathallah<sup>3</sup>, I. Mahmoud<sup>2</sup>, J. Aloulou<sup>1</sup>, M. Frih<sup>2</sup>, O. Amami<sup>1</sup>

<sup>1</sup> Hédi Chaker University Hospital, psychiatry "B", Sfax, Tunisia; <sup>2</sup> Fattouma Bourguiba University Hospital, Neurology, Monastir, Tunisia; <sup>3</sup> Fattouma Bourguiba University Hospital, Psychiatry, Monastir, Tunisia

\* Corresponding author.

**Introduction.**– Multiple sclerosis (MS) is a chronic demyelinating disease of the central nervous system that can affect physical, cognitive, social and psychological functioning of patients.

**Objective.**– We aimed to estimate the prevalence and examine associated factors of depression in persons with MS.

**Methods.**– We conducted a cross-sectional study involving 32 patients diagnosed with MS and confirmed with the criteria of Mac Donalds 2010 and followed at the Neurology Department of University Hospital of Monastir. We used the Expanded Disability Status Scale (EDSS) to assess the clinical severity and the functional deficits in multiple sclerosis. Depression was assessed by the Beck Depression Inventory Short Form, which consists of 13 items, a score > 5 indicates depression.

**Results.**– The average age of patients was  $36 \pm 7$  years; 81.3% were female. The mean age of onset of disease was 30 years. The average Disease duration was 6 years. EDSS score ranged between 0 and 6. Depression was found in 43.7% of cases; 3.1% of subjects were classified as severe on depression scale. Depression was correlated with EDSS score ( $p=0.03$ ) and progression index ( $p=0.04$ ).

**Conclusion.**– In our study, depression was frequent and was strongly correlated with the degree of disability of MS. Screening, clinical diagnosis and treatment of depressive symptoms should be integrated into the management of patients with MS.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Use of vortioxetine in a sample of patients

B. Mata Saenz\*, I. Morales Saenz, F. García Lázaro, V. Muñoz Martínez

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– Vortioxetine is a 5-HT<sub>3</sub>, 5-HT<sub>1D</sub>, and 5-HT<sub>7</sub> antagonist, a 5-HT<sub>1A</sub> agonist, and a 5-HT<sub>1B</sub> partial agonist. It is used in major depressive disorder. Overall, 69.5% of patients referred to our Unit by Primary Care have depression, anxiety or both of them. It makes antidepressants essentials every day.

**Objectives.**– To analyse the effect of the vortioxetine in patients attended in Mental Health Unit.

**Methods.**– In relation to a case series of 12 patients we collected the following variables: (1) demographic variables, (2) diagnosis impression, (3) improvement with the drug, (4) monotherapy or not, (5) side effects, and (6) maintenance treatment.

**Results.**– Of the total of patients, 58.3% were females. Average age was 58.92 (standard deviation 17.784). All of them were followed for depressive disorder. All but one were treated with vortioxetine as monotherapy. 5 patients had side effects: 1 of them had urticaria and the rest digestive symptoms. Of these patients, one could continue with treatment by lowering the dose, but the other four ones had to stop the treatment. 10 patients' cognitive performance were significantly improved, as well as, apathy, anxiety and anhedonia. The other 2 patients didn't improve with treatment. Lower doses of benzodiazepines were possible thank to the improvement of anxiety.

**Conclusions.**– Vortioxetine had shown to be a good antidepressant in control of anxiety, depression and cognitive symptoms due to depressive disorder. The main side effects patients report are digestive symptoms. Sometimes we can use lower doses to improve these side effects.

### DEEP I – Depression Early Prediction Inventory – Measurement of prodromal states of affective disorders

A.K. Schwientek, V. Stegmüller, F. Hellen, C. Theisen, F.

Schultze-Lutter, E. Meisenzahl\*

University of Düsseldorf, Psychiatry, Düsseldorf, Germany

\* Corresponding author.

**Objective.**– Depressive Disorders are a challenge to public health systems. Its highly costs and mortality demand effort to reduce prevalence and incidence rates. Building up early recognition tools, an estimation of the disease risk and immediate interventions are in need for this purpose. The aim of the project is to develop evidence-based valid CHR-D criteria and a reliable instrument for their assessment.

**Methods.**– Based on a semi-structured-clinical interview, quantitative and qualitative data was analysed with respect to clinical data and demographic data as well as information about the duration and symptoms of the prodromal phase of a depressive episode. 85 subjects with a depressive episode were interviewed. Six patients were excluded. In sum N = 79 interviews were viable for data analysis.

**Results.**– Altogether 93.7% of the participants reported changes in wellbeing in terms of a prodromal phase. Participants described significantly varying duration of the prodromal phase with an average of 10 months (SD = 17.08, range = 0.5 - 75, Mdn = 3.00). No statistically significant gender differences or differences regarding the phase of the illness were found. Using qualitative methods to analyze early prodromal changes in wellbeing, sleep disturbances (41.8%), somatic complaints (41.8%) and worries/anxieties (26.6%) were frequent. Thereby gender- and age-specific differences were found.

**Conclusion.**– These results indicate the need for accompanying awareness campaigns to support early help-seeking. Physicians will need an early prediction screener to efficiently use this window of opportunity to identify and refer people at possible CHR-D and plan adequate preventive measures together with a mental health professional.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

Institute of Pedagogical Sciences, Faculty of Social Science, Piotrków

Trybunalski Branch, Jan Kochanowski University in Kielce,

Department of Psychology, Kielce, Poland

\* Corresponding author.

**Introduction.**– Bipolarity, i.e. features of subthreshold bipolar disorder, is considered a marker of treatment resistance in the course of depression. Social jetlag is defined as a misalignment between biological and social time, i.e. the actual sleep-wake pattern. It has been previously associated with greater degree of obesity, tobacco smoking and poor mood.

**Objective.**– To assess the link between social jetlag (SJL) and bipolar features in the context of chronotype, depressive symptoms and sleep quality among patients with mood disorder.

**Methods.**– The group comprised 60 ambulatory patients with depressive episode, either first or in the course of recurrent depressive disorder or bipolar disorder. The patients completed questionnaires: Hypomania Checklist (HCL-32, bipolar features), Chronotype Questionnaire, Pittsburgh Sleep Quality Inventory (PSQI), Beck Depression Inventory (BDI) and sociodemographic questionnaire, including items concerning sleep-wake pattern. A multiple linear regression model was constructed for prediction of the HCL-32 score.

**Results.**– The determination coefficient for the model was  $R^2 = 0.26$ . HCL-32 score was predicted by SJL ( $\beta = -1.10$ ,  $p < 0.01$ ) and age ( $\beta = -0.22$ ,  $p < 0.01$ ), but not by sex, body mass index, pack years of smoking, morningness-eveningness, BDI score and PSQI score ( $p > 0.05$ ). An interaction between age and SJL was diagnosed ( $\beta = 0.20$ ,  $p < 0.01$ ; Figure).

**Conclusions.**– The relationship between SJL and bipolar features may depend on patient's age. Thus, high SJL might be a marker of treatment-resistant depression in patients over 50, but not younger ones.

### **Investigate the relationship between optimism, depression and life satisfaction in students**

M.M. Naderi

Islamic Azad University, Azadshahr Branch, Iran, Psychology, Azadshahr, Iran

\* Corresponding author.

**Introduction and purpose.**– The main purpose of this study was to explore the relationship between the optimism and depression with life satisfaction in students.

**Methods.**– The main method in this study was descriptive-analytic. The subject was 180 students in Islamic Azad University, Azad Shahr branch, who were chosen randomly. They answered to the researcher-made questionnaire, Beck Depression Inventory (BDI), Optimism Questionnaire and Life Satisfaction Scale. Data were analysed through SPSS software with descriptive-deductive base, ANOVA and Pearson's correlation.

**Results.**– Data analysis indicated the high negative correlation between the optimism and depression of university students. With the increase of the student's optimism, their depression decreased ( $P < 0.01$ ). Depression was significantly associated with the life satisfaction. With the increase of the student's life satisfaction, their depression decreased ( $P < 0.01$ ).

**Conclusion.**– The study indicates the close relationship between the optimism, life satisfaction and depression of university students. Reinforcement and assimilation of optimism in students can lead them toward increased mental health.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The role of Circadian preferences and biological rhythm disturbances in depressive patients: A descriptive study**

Ç.D. Şahbaz<sup>1</sup>, A.M. Özçelik<sup>2\*</sup>, İ. Kırpınar<sup>1</sup>, E.A. Duman<sup>3</sup><sup>1</sup> Bezmialem University, Department of Psychiatry, Istanbul, Turkey;<sup>2</sup> Bezmialem University, Medical Faculty, Istanbul, Turkey; <sup>3</sup> Istanbul, Turkey

\* Corresponding author.

It is known that chronotypes and sleep quality affect symptom severity of depression but no study has addressed specifically the relationship between circadian preferences and somatic symptoms, and current medical comorbidities in depressive patients.

This study aims to examine the potential association between chronotypes and somatic symptomatology. The hypotheses of this study are: (1) Eveningness patients have more severe somatic symptoms and medical comorbidities in depression. (2) Eveningness indicates a predisposing trait in depression besides biological rhythm disturbances. (3) Biological rhythm and chronotypes can influence symptom clusters of depression.

A total of 101 drug naive patients from the ages of 17–65 ( $M = 40.18$ ,  $SD = 11.54$ ; 75% female) were recruited from Bezmialem University, Istanbul. The Morningness-Eveningness Questionnaire (MEQ) was applied and patients were categorized into three subtypes: morning, intermediate, and evening types. Biological rhythm disturbances and sleep features were measured by the Biological Rhythms Interview of Assessment in Neuropsychiatry (BRIAN) and Pittsburgh Sleep Quality Index (PSQI). Depression levels were evaluated through the use of the Hamilton Rating Scale for Depression (HRSD).

An ANCOVA yielded a significant effect of chronotype on depression such that evening types had higher depression scores than morning and intermediate types controlling for age and BRIAN-Sleep Cluster ( $p < .001$ ). The effect remained significant when depression scores were calculated for only somatic symptoms or with ( $p < .001$ ) or without sleep-related items. Finally, this effect explained more of the variance in depression in patients with a comorbid disorder ( $n = 47$ ; 19% variance;  $p < .05$ ).

The results indicate that apart from biological rhythms, chronotypes may serve as a vulnerability factor for depression. This vulnerability maybe further associated with somatic symptomatology and comorbid disorders.

EV0275

### **The role of anhedonia in suicide risk**

M. Pompili

Sapienza University of Rome, Dept. of Neurosciences, Mental Health and Sensory Organs, Suicide Prevention Center, Rome, Italy

\* Corresponding author.

Anhedonia that is the inability to experience pleasure, with blunted affects and emotions. Anhedonia coexist both the inability to desire contact with rewarding stimuli and to enjoy pleasure in stimulating or usually rewarding activities. It may affect one, or more, or all aspects of life: food, sex, somato-sensory experiences, etc. The risk of suicide is strongly related to anhedonia. In the case of suicidal behaviour, clinicians may ask “why now?” as a time to explore the vicissitudes that have led to the suicidal gestures or behaviours. It is important to discuss the suicidal ideation with the patient without fearing that this may increase the risk, on the contrary help to explore hopelessness, anhedonia, insomnia,

severe anxiety, decreased concentration and psychomotor agitation. Anhedonia is particularly dangerous for suicide risk when it associated with unbearable psychological pain and the components of the perturbation of the mind. Such components are the heightened inimicality (acting against the individual's best interest); the exacerbation of perturbation (refers to how disturbed the individual is); the increased constriction of intellectual focus; tunneling or narrowing of the mind's content (dichotomous thinking); and the idea of cessation: the insight that it is possible to stop consciousness and put an end to suffering. This presentation will go over main issue of the phenomenology of the suicidal mind, paying attention to the role of anhedonia in the precipitation of suicide as well as a conditions affecting survivors, that is those who lost a dear one by suicide.

### **Mental disease and self-esteem**

M.D.L.C. Ramirez Dominguez\*, A.M. Carrasco Sanchez, L. Hernandez Gonzalez

*Psychiatrist, Psychiatrist, Aljaraque, Spain*

\* Corresponding author.

*Introduction.*– Self-esteem is a dynamic and multidimensional process that is built and rebuilt throughout the life cycle, can be affected when people face vital challenges, such as illness

*Objective.*– With this premise we intend to study the quality of this factor in our population

*Results.*– The most striking fact obtained is the persistence of a mostly low self-esteem in the mental health center group; compared to a predominantly high self-esteem in the control group.

*Conclusions.*– These data are consistent with other studies that point to the fact that a high level of self-esteem would relate to a population with better mental health, while low levels would be associated with a population with mental disorders.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0277

### **Group approach to depression: A study in the Province of Huelva**

M.D.L.C. Ramirez Dominguez\*, A.M. Carrasco Sanchez, L. Hernandez Gonzalez

*Psychiatrist, Psychiatrist, Aljaraque, Spain*

\* Corresponding author.

*Introduction.*– Given the increase in depressive symptoms, such as mental disorder and in comorbidity in organic diseases, we propose a group therapeutic approach, whose effectiveness is supported by multiple studies and as a way of reducing the pressure of care in mental health units.

*Objectives.*– Promote an active attitude of patients, as responsible agents in their pathology and treatment process.

– Identification and adaptive expression of emotions.

– Strengthening self-esteem.

– Provide adaptive coping strategies in the face of psychological distress.

*Results.*– In our experience we confirm what has been affirmed in different studies about a therapeutic efficacy at least equal to individual psychotherapy, with the consequent optimization of the increasingly limited resources of public health.

*Conclusions.*– We can verify as a distinctive feature of group psychotherapy versus the individual, as the changes experienced by the patients, they are socializing, enhancing this change in the rest

of the participants, in a mutual support that potentiates more active roles that away from the initial passivity.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0278

### **From anxious to catatonic: A brief case description**

A. Román\*, V. Pereira, F. Nuria

*Clinica Universidad de Navarra, Psychiatry, Pamplona, Spain*

\* Corresponding author.

*Introduction.*– Individuals with mood disorders are at increased risk for one or more comorbid disorders. Catatonia is characterized by psychiatric and motor symptoms, as described in the Bush-Francis rating scale, and is associated to psychiatric, neurological, medical and drug-induced disorders.

*Objectives.*– To describe the management of a patient with severe catatonia in an inpatient unit.

*Methods.*– Review of medical history from clinical records and qualitative study of scientific literature.

*Results.*– A 33-year old male with recurrent depressive disorder is admitted to the inpatient unit after some time with poor therapeutic adherence, presenting with paranoid delusions, hallucinations and severe catatonia. Psychopharmacological treatment included sertraline 200 mg/day, quetiapine 300 mg/day, clonazepam 2 mg/day. Six effective sessions of electroconvulsive therapy were required, with full remission of symptoms. Paliperidone was finally prescribed to better adherence and control of psychotic symptoms. Schizoaffective disorder was finally diagnosed.

*Conclusion.*– Schizoaffective disorder has characteristics of schizophrenia and affective disorders. Patients with schizoaffective disorder might present as schizophrenia with prominent affective symptoms, others as a mood disorder with accused schizophrenic symptoms, and others a mixed clinical syndrome. The FDA has approved Paliperidone as the specific medication to treat schizoaffective disorder. Additionally, the availability of long acting injectable formulations could be helpful for patients who don't have good treatment adherence to oral medications.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0279

### **“Male depression?”– First results of the study to gender-specific expressions of depressive symptoms and factors of influence**

V. Rößner-Ruff\*, J. Krieger, D. Hoins, I.T. Graef-Calliess

*Klinikum Wahrendorff GmbH, Forschung & Entwicklung, Ilten, Germany*

\* Corresponding author.

*Introduction.*– Although depression is one of the most prevalent disorders, our understanding of potentially gender-specific expressions of depressive symptoms is still limited. The concept of male depression (MD) constitutes that women express more so called typical depressive symptoms while men also offer so called atypical depressive symptoms like aggressiveness, irritability, alcohol misuse. Current findings of studies on this topic are heterogeneous. Moreover the effect of factors like psychiatric comorbidities, gender-related norms and characteristics or personality-related aspects to the expression of depressive symptoms is still unclear.

*Objective.*– Investigation of the following issues:

– Do any gender-specific differences exist in the atypical expression of symptoms between male and female patients with a unipolar depressive disorder? Focus: Is the concept MD evident?

– Do the described factors effect the expression of atypical depressive symptoms?

**Methods.**– Male and female patients with a diagnosis of depressive episode or recurrent depressive disorder (ICD-10), who are treated in in-patient or day clinical settings of different psychiatric institutions in Germany will be studied. There are no limitations to further diagnosis, age or other factors. To analyze the objective different self-rating questionnaires will be used.

**Results.**– The results of the study might possibly clarify whether there exist any gender-specific differences in the expression of depressive symptoms and by which factors they might be caused. First results of the study will be presented.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0280

### The Features of emotional processing in patients with affective disorders

M. Balashova<sup>1</sup>, G. Rupchev<sup>2\*</sup>, I. Pluzhnikov<sup>2</sup>

<sup>1</sup> Lomonosov Moscow State University, Faculty of Psychology, Moscow, Russia; <sup>2</sup> Federal State Budgetary Scientific Institution "Mental Health Research Center", Laboratory of Psychopharmacology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Today a model of cold and hot cognition which opens up new opportunities for investigating the mechanisms of violations in depressive disorders actively develops. The description of these two systems promotes an understanding of interaction between the cognitive and affective spheres. However, at the present time there is no neuropsychological battery, which helps to conduct a comprehensive study of the cognitive-affective sphere in patients with affective disorders.

**Objective.**– Elaboration and adaptation of a complex of neuropsychological tests comprised of emotionally loaded material.

**Aim.**– Description of neurocognitive symptoms and their division into cold and hot violations with the designation of their brain and psychological mechanisms.

**Methods.**– A total of 33 patients diagnosed with depression according to ICD-10 (F31.3, F31.4, F31.5, F32.1, F33.1, F33.2, F34.0, F34.1), 14 males and 19 females, aged 33 ± 16, disease duration 13 ± 12 years, and 33 healthy controls, 17 males and 16 females, aged 36,5 ± 15,5. Standardized neuropsychological tests and tests base on emotiogenic stimuli were administered.

**Results.**– There is a neurocognitive deficit in patients with affective disorders manifested in changes of a psychomotor speed and the work of number cognitive functions. These patients demonstrate a decreased attention to negative stimuli combined with a decreased attention to positive stimuli.

**Conclusion.**– Patients with depressive disorders are more prone to distortion of cognitive activity in emotiogenic conditions. The abnormal processes of hot cognition in these patients conceptualize such a core symptom of depression as anhedonia, which is a probable endophenotype of depression.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0281

### Early clinical predictors of long-term morbidity in major depressive disorder

G. Serra<sup>1\*</sup>, A. Koukopoulos<sup>2</sup>, L. De Chiara<sup>3</sup>, L. Tondo<sup>4</sup>, G. Sani<sup>3</sup>, R.J. Baldessarini<sup>5</sup>

<sup>1</sup> Pediatric Hospital Bambino Gesù, Department of Neuroscience, Roma, Italy; <sup>2</sup> Centro Lucio Bini, Centro Lucio Bini, Roma, Italy; <sup>3</sup> Sapienza University, NESMOS Department, Roma, Italy; <sup>4</sup> McLean Hospital-Harvard Medical School, Department of Psychiatry, Belmont MA, USA; <sup>5</sup> McLean Hospital, Harvard Medical School, Department of Psychiatry, Belmont MA, USA

\* Corresponding author.

**Aim.**– To identify early clinical factors predictive of later morbidity in major depressive disorder (MDD).

**Introduction.**– MDD generally is more severe following juvenile vs. adult onset, and early anxiety disorders may increase risk for later mood disorders. Less clear is whether these or other features may predict long-term morbidity in MDD in adult years.

**Methods.**– We carried out systematic analyses of detailed clinical information on 116 adults with DSM-IV MDD at risk for 17 years (from the first major depressive episode to the last assessment at the study center), to identify early clinical factors associated with long-term morbidity through follow-up and clinical treatment at Lucio Bini Mood Disorder Center, Rome. Bivariate comparisons were followed by multivariable linear regression modeling of associations of selected factors with %-time-ill.

**Results.**– Estimated time in major depressive illness averaged 25.3 ± 24.1% of months ill during 17.0 ± 14.6 years at risk. First psychiatric antecedent occurred at age 25.8 ± 19.3 years, or at an average of 11 years before a first-lifetime MDE, which occurred at age 36.8 ± 15.1 years. With multivariable regression modeling, three factors were independently and significantly associated with long-term depressive morbidity, ranking statistically as: [a] initial major depressive episode with agitated-mixed, or psychotic features, [b] anxiety syndromes prior to a first major depressive episode, and [c] anxiety symptoms in childhood.

**Conclusion.**– Early anxiety symptoms and syndromes and agitated-mixed or psychotic initial depressive episodes predicted more long-term depressive morbidity.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Management of treatment resistance in major depressive disorder

B. Suci<sup>1\*</sup>, C. Crisan, I. Miclutia

Iuliu Hațieganu University of Medicine and Pharmacy Cluj-Napoca, Department of Neurosciences, Cluj-Napoca, Romania

\* Corresponding author.

**Introduction.**– Major Depressive Disorder is a highly prevalent psychiatric illness, with a frequently chronic course, which represents an important source of morbidity, mortality and diminished quality of life.

**Objectives.**– The description of a clinical case, part of a large number of depressed patients that fail to respond to one or more evidence based antidepressant treatment, given in adequate duration and dose.

**Methods.**– A 45-year-old male, diagnosed with recurrent major Depressive Disorder and impulsive personality disorder (according to ICD-10 and DSM-V), known to abuse alcohol, had 8 depressive episodes, all of them severe, with suicidal thoughts. At least 2 episodes associated psychotic features, the onset of the first episode

was at the age of 35 after a negative life event, and none of the episodes had a response to the first antidepressant received.

**Results.**– Considering the clinical picture, a number of risk factors for treatment resistance were identified. The last depressive episode was treated with a combination of 2 antidepressants, an atypical antipsychotic and 2 anticonvulsants, in high doses. There was no evidence of a comorbid medical condition. The clinical picture improved, with complete remission after two months, time in which he was hospitalized.

**Conclusions.**– In the future, clinical research should improve the understanding of treatment resistance in affective disorders and their management.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0283

### **Reduced Ability to Experience Positive Emotional States in the Patients Diagnosed With Recurrent Depressive Disorders—Initial Findings**

A. Skiba, P. Żuchowicz, K. Bliźniewska, P. Gałęcki\*, M. Talarowska  
Medical University of Lodz, Department of Adult Psychiatry, Lodz, Poland

\* Corresponding author.

**Introduction.**– Affective space may be described using its valence, by distinguishing positive and negative emotions. Recurrent depressive disorders (RDD) represent an affective disorder having an impact on a human being's ability to regulate emotions. During recurrent depressive disorders, we observe difficulties in adequate identification of both own emotional states and the emotional states of other people.

**Objectives.**– The objective of this study is to determine whether the number of depression episodes in recurrent depressive disorders is linked with the level of intensity of negative and positive emotions, understood as current emotional states and permanent affective features.

**Methods.**– The study group comprised 107 individuals, including 67 patients diagnosed with recurrent depressive disorders and 40 healthy people qualified to the control group. The Polish adaptation of the PANAS scale (Positive and Negative Affect Schedule) by D. Watson and L.A. Clark was used to assess emotions as a state and feature. The number of depression episodes was determined based on the Hamilton Depression Rating Scale (HDRS) by M. Hamilton.

**Results.**– Statistical analyses revealed significant inversely proportional relationships between the number of depression episodes and the intensification of positive emotions as current mental states ( $p=0.0141$ ). Absence of statistically significant data regarding the link between the number of depression episodes and the intensity of negative emotions as current emotional states, and between the number of depression episodes and the intensity of negative emotions as permanent affective features.

**Conclusions.**– A greater number of depression episodes are associated with a reduced ability to experience positive emotional states.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**Introduction.**– A focus on alternative models of delivering mental health services was observed during the last years. As technology becomes more accessible and user friendly for both mental health specialists and their patients, the adoption of online tools that could provide evaluations and treatment increases.

**Objective.**– For patients with mental health problems, access to specialists that could provide evaluation and psychotherapy is usually difficult, stigmatising and time and cost inefficient. Our objective was to evaluate the results after one year experience with an online platform providing psychotherapy sessions in Romania.

**Methods.**– Platform analytics tools could provide accurate data about traffic, patients demographics, the number of sessions, their type, the problem addressed, sessions' outcome, patient satisfaction.

**Results.**– The platform was used by more than 100 psychotherapists and more than 6000 patients have created an account. More than 600 sessions were recorded during the first year of existence. The adoption rate of the platform is growing as the number of accounts and sessions is higher by each month.

**Conclusion.**– Online platforms could be a good alternative to provide mental health services to underserved populations or to increase access to psychotherapy at a lower cost and in a less stigmatising environment. Precautions should be considered regarding data protection and legal aspects of the services provided.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Post-partum depression and acute effects of ocitocin: Study protocol**

M. Donadon<sup>1\*</sup>, F.D.L. Osorio<sup>2</sup>

<sup>1</sup> Medical School at Ribeirao Preto, Neuroscience and Behavior, Ribeirao Preto, Brazil; <sup>2</sup> University of São Paulo, Neurociências e Ciências do comportamento, Ribeirão Preto, Brazil

\* Corresponding author.

**Introduction.**– The puerperium is a period of a woman's life that needs special attention because it involves innumerable physical, psychic, hormonal changes and social interaction with the baby. It is also known that postpartum depression (PPD), whose etiology is multifactorial, which involves, among other aspects, the recognition of facial expressions of emotion (REFE). Some studies have pointed to an improvement in the performance of tasks involving the REFE when subjects received acute oxytocin administration (OCT), since the latter has an important role in social relations, favoring trust and modulating cognition and social perception.

**Objectives.**– (a) To evaluate and compare the REE of infants and adults in healthy mothers with PPD and according to the response rate and response bias; (b) Evaluate the acute effects of OCT in the

MRE process in mothers in the puerperal phase with PPD compared to controls.

*Materials and methods.*—Fifteen mothers with a diagnosis of PPD and 15 control mothers were evaluated through a cross-over, double-blind clinical trial using OCT (24 IU) and placebo. Other secondary variables such as personality, postnatal negative thinking and anxiety are also measured by self-report questionnaires. Data analysis was/will be performed using the statistical program Statistical Package for the Social Sciences (SPSS),  $p < 0.05$  was adopted as a level of significance.

*Results/discussion.*—The study is in the execution phase, it is expected to find a better performance in cognitive tasks after administration of oxytocin

*Disclosure of interest.*—The authors have not supplied their declaration of competing interest.

### **Dilemmas: Couch in crisis versus cyberspace is the post human frontier**

R.S. Ilhan<sup>1\*</sup>, V. Vukovic<sup>2</sup>, S. Nikolic Lalic<sup>3</sup>, J. Mitic<sup>4</sup>

<sup>1</sup> Dr. Nafiz Korez Sincan State Hospital, Psychiatry, Ankara, Turkey; <sup>2</sup> Special psychiatric hospital, acute psychosis, Vrsac, Serbia; <sup>3</sup> Special psychiatric hospital, affective disorders, Vrsac, Serbia; <sup>4</sup> Special psychiatric hospital, psychogeriatrics, Vrsac, Serbia

\* Corresponding author.

*Abstract.*—The improvement of information technology (IT) has been reshaping how people seek information about their health. Could the 'digital revolution' present an opportunity for improving the availability, efficacy, quality and cost-effectiveness of care? What is the role for end users, policy makers and practitioners.

*Methods.*—A literature search of relevant studies published between 2012 and 2017 was conducted, using MEDLINE and Google Scholar databases, canvassing English-language publications. Patients often turn to the internet for data on their symptoms or their prescribed drugs, with a significant tendency toward self-diagnosis. However, the validity of the data is disputable and can lead to medical risks. Modern devices constantly produce a stream of data liable to severe exploitation, with the availability and security of this data remaining an unsolved hazard - from individuals performing identity theft, to stigmatization by potential employers or abuse by multinational corporations. New pathways to treatment are offered, from self management to mobile health apps to online therapeutic modalities, more robust evidence for the actual effectiveness of these technologies is sorely lacking. Recent development in the area of neural networks and artificial intelligence opens up several intriguing questions. Several research teams are working the answer in the form of virtual counselors (SimSensei's Ellie; Oshi-el; Avatar Therapy), and we may well be facing the extinction of human experts.

*Conclusions.*—From Freud's couch to cyberspace, the setting has irrevocably changed. New solutions are needed to ensure privacy and safety, especially through the creation of professional and ethical guidelines and review of legal policies.

*Disclosure of interest.*—The authors have not supplied their declaration of competing interest.

### **E-mental health: What uses for what needs?**

M. Morgiève<sup>1,2\*</sup>, D. Sebbane<sup>1,3</sup>, B. De Rosario<sup>1</sup>, S. Kabbaj<sup>1</sup>, V. Demassiet<sup>1</sup>, J.L. Roelandt<sup>1</sup>

<sup>1</sup> World Health Organization Collaborating Centre for Research and Training in Ment, EPSM Lille-Metropole, Lille-Hellemmes, France; <sup>2</sup> Fondation FondaMental, Albert Chenevier Hospital–Psychiatry Department, Paris, France; <sup>3</sup> University of Lille, Forensic psychiatry, Lille, France

\* Corresponding author.

*Introduction.*—E-mental health leads to major socio-anthropological changes.

*Objectives & methods.*—In order to access the representations, expectations and actual uses of its public, we carried out a qualitative study based on ten focus groups with general practitioners, psychiatrists, psychologists, social workers, occupational therapists, nurses, caregivers, users, user representatives and general public ( $n = 70$ ).

*Results.*—The interviewees express different lines of tension that new technologies engender in the field of mental health. What was previously strictly under the jurisdiction of physicians tends to be fragmented and distributed over different actors and locations. New technologies reposition care in the field of domestic rather than therapeutic activities. The conception of care as an autonomous activity in the subject's life is thus questioned: "Is jogging tracking a mental health tool?". The ideal of social autonomy through technology is part of the new logic of health democracy and empowerment, linked to a strong contemporary aspiration to performance. Participants emphasize the risk of a social injunction to autonomy for the digitally engaged patient, while empowerment may become a set of obligations.

*Conclusions.*—Given the ways in which digital data is generated, stored and used, e-health practices started as personal and private become inextricably intertwined into shared networks and economies. The participants interviewed highlight how e-mental health can actively participate to constitute identity, social life, social relations and social institutions.

*Disclosure of interest.*—The authors have not supplied their declaration of competing interest.

### **Anonymous online counselling with psychiatrist**

S. Onrust

Telepsychiatric service, Doktor SOS online, Doboj, Bosnia, Hercegovina

\* Corresponding author.

*Introduction.*—There are more people suffering from mental health (MH) problems than those asking for professional help. Some of the common reasons why they don't ask for professional help are embarrassment, shame, fear of privacy problems and service costs. In order to provide the possibility to ask about MH related problems anonymously cost-free, an online contact-form is placed on the website administered by a psychiatrist. E-mental-health services provide a chance for first contact and earlier entry to the treatment for those who have never been treated before.

*Objectives.*—To examine who is interested in anonymous online counselling and who can benefit; would it be used for the first contact or second opinion; what is the daytime distribution of questions in order to set the adequate services.

**Methods.**– All questions asked via contact-form were reviewed including gender, age, kind of MH problems, time when the first question was asked, previous MH treatment.

**Results.**– Women were asked 79% questions mostly related to depression, anxiety, relationship problems, helping others with MH problem. Men asked about depressive and anxiety problems, addictions, psychotic and OCD related problems. Women younger than 30 asked 46% questions men 39%. This was the first contact with MH professional for 54% women and 40% men. Questions were asked 24 hours, peaks occurred several times.

**Conclusions.**– Younger people, especially female who never had contact with the MH provider and in the early phase of disorder have interest in anonymous online counselling and may benefit from it.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0289

### **Active implementation of a computerized cpg for major depression in primary care: 18-month follow-up**

M. Cavero<sup>1</sup>, J.A. Monreal<sup>2</sup>, N. Cardoner<sup>2</sup>, M.D. Moreno<sup>3</sup>, E. Bellerino<sup>3</sup>, V. Pérez-Solà<sup>4</sup>, D. Palao<sup>2</sup>

<sup>1</sup> Hospital Clinic, Psychiatry Service, Barcelona, Spain; <sup>2</sup> Parc Taulí-University Hospital, Mental Health Service. CIBERSAM, Sabadell, Spain; <sup>3</sup> Institut Català de la Salut, SAP Vallès Occidental, Sabadell, Spain; <sup>4</sup> Hospital del Mar, Institut de Neuropsiquiatria i Addiccions. CIBERSAM, Barcelona, Spain

\* Corresponding author.

A computerized version of a Clinical Practice Guideline for Major Depression (e-CPG-MD) was integrated into the Electronic Clinical Records of Primary Care (PC) in Catalonia (Spain). This new IT tool offers the opportunity to improve clinical outcomes in the management of MD. e-CPG-MD allows access to accurate help during the visit, improving MD diagnosis, treatment and follow-up and taking into account suicide risk.

**Objectives.**– To evaluate the effectiveness of an active implementation process of an e-CPG-MD in PC at 6 months and 18 month of follow-up.

**Methods.**– A cluster randomized clinical trial was conducted in 10 Primary Care Centers (PCC) in Barcelona. In five of ten PCC a multifaceted implementation process of the e-CPG-MD was applied from month 1 to month 6. The active process included: interactive training program, regular feedback audit, educational outreach visits and periodic reminders.

**Results.**– At 6 months, we observe a significant increase in use of the e-CPG-MD (4.1% + 3.1% vs. 52.7% + 7.3%,  $p < 0.001$ ) in the active PCCs. In addition, the diagnosis of MD increased significantly (rate quotient = 1.56,  $p < 0.001$ ) as well as the recognition of moderate and severe MD (13.6% vs 41.1%,  $p = 0.002$ ). At 18 months, the use of e-CPG-MD remained significantly higher in the active PCCs (23,7+ 8,9 vs 6,5+ 8,6;  $p = 0,025$ ). In addition, the adequacy of treatment improved significantly: 74% of patients with moderate to severe MD received adequate treatment in active PCCs, while only 52% of them received adequate treatment in the control PPCs ( $p = 0,003$ ).

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0290

### **Comparative effectiveness of multicomponent behavioral ehealth interventions for weight-loss in overweight and obese adults: A critical review and meta-analysis**

I. Podina<sup>1</sup>, F. Liviu<sup>2</sup>

<sup>1</sup> University of Bucharest, Psychology, Bucharest, Romania; <sup>2</sup> Babes Bolyai University, Evidence-Based Psychological Assessment and Interventions Doctoral School, Cluj-Napoca, Romania

\* Corresponding author.

**Introduction.**– Currently, multicomponent behavioural interventions for weight-loss are the recommended golden standard of intervention in obesity. However, less is known for the efficacy of technologically (eHealth) mediated counterparts.

**Objectives.**– Therefore, the aim of the meta-analysis was to compare the relative efficacy of multicomponent behavioural eHealth interventions for weight-loss against standard in person active treatment and control (i.e. no treatment, wait-list, placebo, usual care) at post-treatment and follow-up.

**Methods.**– Forty two randomized controlled trials that (a) compared an eHealth intervention for weight-loss to a control or an active treatment and (b) that focused on overweight and/or obese adults were selected.

**Results.**– Findings indicated that eHealth interventions were more effective than control groups ( $g = 0.37$ , 95% CI: 0.27 to 0.47), but not more effective than active treatment in reducing weight ( $g = -0.31$ ; 95% CI: -0.43 to -0.19). Potential moderator variables were examined.

**Conclusions.**– Currently, eHealth interventions for weight loss might not be at an optimal level of user interaction to match in person treatment in efficacy. Overall, the quality of reporting and the design of eHealth interventions studies must be improved. Other limitations and possible implications will be discussed.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0291

### **Acceptance of eMental service in Bangladesh – Findings from a qualitative research**

T. Rashid Soron

Telepsychiatry Research and Innovation Network, Telepsychiatry Innovation Lab, Khulna, Bangladesh

\* Corresponding author.

**Background.**– Mobile network coverage has reached to almost every community all over the world and it opened a new window to ensure mental health service using the mobile phones and other online service such Facebook or email. However, the level of acceptance of emental health service is yet to be explored in many low and middle income countries such as Bangladesh.

**Objectives.**– This study aimed to explore the acceptance of mental health service through mobile phone and other electronic sources among the people of different strata.

**Methodology.**– Individual semi structured qualitative interviews were conducted with 32 person of different back grounds that were selected from stratified random sampling from multiple sites of Dhaka Division and Jessore District. The study was conducted from June 2017 to August 2017 and each Face to Face interview took average 40 minutes.

**Results.**– Most of them (approximately 93%) said a mental health service over phone or online would be the greatest help for them. A professors of psychiatry remarked emental health service could

be the best option for the low resource settings like Bangladesh. A house wife shared that his husband was always reluctant to take her to psychiatrist due to social stigma. However, she thought if there was any help through mobile or online she could have the access of the treatment.

**Conclusion.**– The study revealed a high demand for emental health service in the society and it has the potential to make a remarkable contribution in reducing mental health treatment gap.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0292

### **Heath Information-seeking behavior on digital information exchange platforms: A meta-analysis**

D. Sendler\*, M. Duplaga

Jagiellonian University Medical College, Department of Health Promotion, Cracow, Poland

\* Corresponding author.

**Introduction.**– This meta-analysis looks at 20 years worth of studies where discussion boards were proved useful in mental health promotion.

**Methods.**– We conducted literature search using combination of keywords [help-seeking AND/OR forum(s) AND/OR discussion AND/OR help]. The search was conducted in September of 2017, using five databases– Pub Med, Google Scholar, Web of Science, Scopus, and CrossRef. Our search criteria included any studies published since 1980. Initial search yielded 206 hits. After removing duplicates, we were left with 202 results. Relevant abstracts were screened, helping us to identify 71 relevant studies.

**Results.**– We clustered resulting studies into several themes with an average of 5 studies representing each category. The greatest number of studies ( $n = 14$ ) were in the “disease specific support” category, while “sexual health” category had the smallest number of studies ( $n = 2$ ). “Self-destructive” behaviours described use of forums in helping people manage suicidal thoughts. “Medication use and drug abuse” concerns safety profile of various drugs. “Health decision making” shows how people choose their health proxy. “Parenting and family life” forums target new parents. “Eating disorders” sites cater toward teenagers with bulimia and anorexia. “Disease-specific” support are forums where people discuss symptoms of specific ailments. “Healthcare workers talking” is about nurses and physicians cross-exchanging information about how to best promote healthy behaviours. “Emotional support” describes sites where people seek psychological help. “Sexual health” concern teenagers seeking advise on safe sex practices.

**Conclusions.**– These data show that discussion forums have wide-ranging application in health promotion.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **From the lab into people’s lives: Setting a roadmap for mental healthcare assistive technologies derived from psychophysiology**

S. Silva<sup>1,2</sup>, S. Soares<sup>3,4,5</sup>, S. Brás<sup>1,2</sup>, J.M. Fernandes<sup>1,2</sup>, M. Coroa<sup>6,7\*</sup>, N. Madeira<sup>6,7</sup>, T. Santos<sup>8</sup>, P.J. Ferreira<sup>1,2</sup>

<sup>1</sup> University of Aveiro, Institute of Electronics and Informatics Engineering of Aveiro, Aveiro, Portugal; <sup>2</sup> University of Aveiro, Dep. Electronics, Telecommunications and Informatics, Aveiro, Portugal; <sup>3</sup> University of Aveiro, Department of Education and Psychology, Aveiro, Portugal; <sup>4</sup> Instituto Superior de Psicologia Aplicada ISPA,

William James Research Center WJCR, Lisbon, Portugal; <sup>5</sup> Karolinska Institutet, Department of Clinical Neuroscience- Division for Psychology, Stockholm, Sweden; <sup>6</sup> Coimbra Hospital and University Centre, Psychiatry Department, Coimbra, Portugal; <sup>7</sup> University of Coimbra, Department of Psychological Medicine- Faculty of Medicine, Coimbra, Portugal; <sup>8</sup> Baixo Vouga Hospital Centre, Psychiatry and Mental Health Department, Aveiro, Portugal

\* Corresponding author.

**Introduction.**– Psychophysiological studies have been providing valuable data with potential impact on how mental care is organized and delivered. However, research would widely benefit from an effectively translational approach that could harness gathered knowledge and deliver tools for monitoring and managing mental health, expected to evolve into personalized and preventive systems assisting patient’s daily life. For instance, the definition of the psychophysiological correlates of patients’ anxiety could evolve into custom anxiety management technologies with strong impact on their functioning.

**Objectives.**– To gather critical perspective over the requirements and routes for translational research that can rapidly move from psychophysiology towards mental healthcare assistive technologies.

**Methods.**– A literature review was performed covering sensing technology, psychophysiology, data mining, computer science and human-machine interaction. Relevant studies were critically analysed to identify opportunities and gaps for translational research in psychophysiology.

**Results.**– Scarce studies of mildly translational research in mental healthcare were reported, particularly lacking solutions that reach patients outside consultation rooms. Most works originate from teams that are not multidisciplinary. In the present work, we identified the importance of different fields of expertise to attain the overall goal of patients’ well-being.

**Conclusions.**– To guarantee a truly translational research in mental health assistive technologies, based in psychophysiology, multidisciplinary teams need to be involved from early on, designing experiments and tentative scenarios. Suggestions are provided for future research in order to successfully address identified gaps in methodological and technological settings.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0294

### **Treatment approach “Robin” for adolescents at high risk for developing a psychotic disorder: Therapy modules enhanced by a smartphone application**

N. Traber-Walker\*, M. Gerstenberg, S. Metzler, S. Walitza, M. Francini

University Zurich, Department of Child and Adolescent Psychiatry and Psychotherapy, Zurich, Switzerland

\* Corresponding author.

**Background.**– The aim of preventing psychotic disorders has led researchers to focus on early identification of individuals at high risk for psychosis and to treat the attenuated psychotic symptoms (APS) in the pre-psychotic period. Although APS are common in adolescence and associated with a marked reduction in functioning, the evidence base required to guide effective interventions for adolescents with APS is limited. The clinicians from the specialized outpatient care for early intervention in psychosis in Zurich have developed the treatment approach “Robin” (standardized manual and smartphone App) for adolescents with APS. The manual is

targeting APS, improvement of quality of life and daily functioning. The therapy modules are based on evidence based treatment strategies in adolescents with first episodes of psychosis. It follows the guidelines on early intervention in clinical psychosis high risk states of the European Association for Psychiatry. The intervention also includes a smartphone application for supporting the patients between sessions. This application targets real-time symptom assessment, medication adherence, and provides coping strategies for dealing with symptoms of psychosis and daily life hurdles.

*Methods/results.*– The treatment approach “Robin” is being evaluated with a systematic clinical intervention trial. Since August 2017, first participants have been included and their treatment has started.

*Conclusion.*– Even though young patients with APS may profit from specialized treatment approaches, little is known about age-appropriate treatment strategies in this vulnerable age group. This is one of the first controlled trials to test the efficacy of a specific treatment program for adolescent patients with APS.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0295

### Quality of life of municipal public servants in a Southeastern Brazilian city measured with the web-form WHOQOL-BREF

C. Varanda\*, A.R. Poppe, M.D.G. Aulicino, A. Macedo Filho  
Universidade Paulista, Institute of Human Sciences, Santos, Brazil

\* Corresponding author.

The measurement of health-related quality of life (HR-QOL) has become useful for guiding policy makers in the implementation of preventive and interventive public health policies. WHOQOL-BREF is one of the most used measurements of HR-QOL because it consists of items concerned with the individuals' perception of their position in life in various contexts. The web-form WHOQOL-BREF has shown validity and reliability in a previous study and it allows access to a large population of individuals, as well saves time and money. This option was used among municipal public servants in a southeastern Brazilian city. 565 subjects participated, 29% were male and 71% female, 56.8% are between 41 and 60 years old. The environmental domain has the lowest scores (Mean=55.49; SD=14.58, especially lack of financial resources (Mean= 2.72, SD=0.85), against physical (Mean= 64.85; SD= 17.12); psychological (Mean=65.04; SD= 15.60) and social domain (Mean= 65.15; SD= 17.66). Freedom, physical safety and security, home environment, financial resources, opportunities for acquiring new information and skills, participation and opportunities for leisure activity, physical environment, transport and health and social care are assumed to be an issue of concern among the participants. Environment-related issues are crucial indicators of progress and sustainability of a country especially economic resources in a developing country such as Brazil. The Web-form WHOQOL-BREF showed to be an economic and fast way of collecting data that are meant to be considered for designing and implementing policies addressing this scenario.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

\* Corresponding author.

The majority of people uses Internet every day to acquire needed information. A wide range of information regarding mental health can be found on the Internet and there are various ways of communication, one of them are Internet forums. Internet forums have become the source of information for any health or psychosocial problem. Participation and communication in the forums are anonymous, which greatly contributes to honest and immediate communication, especially on sensitive topics such as mental illness.

The aim of this study was to examine the motives for using depression Internet forums in Croatia.

The study sample consists of 297 user-generated posts on the largest Croatian depression Internet sub-forum over a period of one year, analysed using qualitative methodology-grounded theory.

The results showed that the majority of depression Internet forums user in Croatia use Internet forums to receive emotional support from others with the same illness. Other important reasons were to exchange information about medications, symptoms and prognosis of the illness.

Users of depression Internet forums in Croatia, mostly use those forums to receive emotional support from others with the same illness. For some of the users, Internet forums are the first place where they seek help to cope with symptoms of depression. Because of this reason, Internet forums could be used to detect untreated individuals who could then be provided earlier with psychiatric treatment.

### Mental capacity to consent treatment in anorexia nervosa patients

A. Alvarez Astorga<sup>1</sup>\*, L. Gallardo Borge<sup>1</sup>, M. Gomez García<sup>1</sup>, S. Gomez Sanchez<sup>1</sup>, C. García Montero<sup>2</sup>, H. De la Red Gallego<sup>1</sup>, A. Alonso Sanchez<sup>1</sup>

<sup>1</sup> HCU Valladolid, psychiatry, Valladolid, Spain; <sup>2</sup> Hospital Provincial de Avila, Psiquiatría, Avila, Spain

\* Corresponding author.

*Introduction.*– Controversies about involuntary treatment in anorexic patients have always existed. Changes in neural networks that these patients have and their neuropsychological difficulties make much more difficult the volitive capacity evaluation. Some studies justify these cognitive difficulties as a consequence of low weight while others affirm that decision-making ability does not improve with weight gain.

**Objectives.**– Studying Spanish judicial process of involuntary admission and evaluation of volition in anorexia nervosa disease through a case.

**Methods.**– Woman 19 years old who was diagnosed of anorexia nervosa since 15 years old. From the age of majority has lost 10 kilograms of weight, refuses to receive treatment and presents high levels of mental rigidity. Her life was in danger. Psychiatrist and Endocrinologist evaluated that she and her family did not understand the risk and we asked for a judicial authorization.

**Results.**– She received forced feeding and treatment at the hospital and currently she is in a good weight, she collaborates on her own treatment and her cognition capacity has improved.

**Conclusions.**– Spain does not have validated protocols to evaluate decision capacity in anorexic patients. Other countries use some scales but they aren't specific to this disease.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Developing a cultural sensitive CBT (c-CBT) program for eating disorders in Egypt; the pathway to standardized treatment protocol**

R. Aly

*Egyptian Association of Cognitive Behavior Therapy, President, Cairo, Egypt*

\* Corresponding author.

Recent research suggests an emergence of eating disorders [ED] in non-western settings for unknown reasons. This presentation investigates the presence of ED in Egypt & the Arab world. Our aim is to explore relevant factors amongst women at risk of ED and stakeholders involved with mental health care and policy-making. Studies of cognitive behaviour therapy (CBT) for treatment of eating disorders demonstrate that CBT is effective in the management of eating disorders. Yet most studies was conducted & concluded in the western world. Cultural differences between populations mandate adaptation of cognitive & behavioural techniques in the management of these specific disorders to avoid high dropout rates and ensure higher outcomes from treatment.

### **Association between vegetarianism and pathological motivations**

G. Arina\*, A. Bykov

*Lomonosov Moscow State University, Department of neuro, and pathopsychology, Moscow, Russia*

\* Corresponding author.

**Introduction.**– Similar to other forms of transformational bodily practices (Tkhostov, 2002, Rasskazova 2012), vegetarianism could be considered as a cultural form of a consciously chosen model of food behaviour (Ruby, 2012), as well as a possible disorder of psychosomatic regulation and symptomatic behaviour (Michalak, 2012). The phenomenon of vegetarianism still remains underexplored from the perspective of clinical psychology.

**Objectives.**– The study aims to address aspects of eating disorders within the domain of vegetarianism and its different types.

**Methods.**– A total of 51 ovo-lacto vegetarians and vegans in Russia participated in an interview and completed EAT-26 (Garner, 1982).

**Results.**– The results of interview and EAT-26 screening test (average result of 6) indicate a low likelihood of eating disorders for

vegetarians. EAT indicators appear to be significantly ( $p < 0.05$ ) higher among vegans and health-motivated vegetarians but still below the suggested threshold of 20. The study presents two case studies ( $EAT > 34$ ) where vegetarianism takes the form of a “substitute” behaviour, based on the psychological mechanisms inherent in anorexia nervosa, including ambivalent attitude towards oneself, negative body image, difficulties in social adaptation. However, emotional states and value orientations of these respondents differ fundamentally from the normative picture typical for the rest of the sample.

**Conclusions.**– The study does not provide evidence of association of vegetarianism and eating disorders. However, vegetarian food preferences (the strictest in particular) can serve as a form of behavioural manifestation of pathological motivations, which are not apparent, as they tend to receive a positive connotation in vegetarian subculture and do not look maladaptive.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The alteration of the sensory consciousness of the self as a trigger mechanism determining binge in eating disorders: A comparison between two single case studies**

E. Atzori

*Member of World Association of Dual Disorders WADD, “Tuberose Residence”, Protected Community for Adolescents and Young Adults., Rome, Italy*

\* Corresponding author.

A difficulty to perceive and interpret accurately cognitive stimuli that originate from the body, with a difficulty to perceive and describe emotions correctly has been identified for a long time in patients with Eating Disorders.

The objective of this paper is to enhance the research into possible psychic factors at the base of a deficit in the sensory consciousness of the Self, for which the inner image of the body and the person does not have a strong mental representation, with the consequence that the relationship between the psychological and the somatic part of it appears exposed to a break-down.

In this paper binge eating is conceptualized as an attempt to overcome a proprioceptive difficulty through sensation seeking. The craving and the repetition of the pathological behaviour is interpreted as a failing attempt to reconstruct the body scheme in a fragmented Self, or at risk of fragmentation through a memory of the sensations experienced using an inanimate object, in relationship with which an increase of symbolic capability, achievable only through a human relationship, is impossible. To corroborate this hypothesis I propose two single- case studies of binge eating disorder, that describe the application of an integrated method in which the use of standardized instruments as MMPI, SCL-90-r, EDI 2-3, TAS-20, test-retested in a frame time of ten and seven years, is flanked with the interpretation of dreams, based on the theoretical platform of Massimo Fagioli's “Human Birth Theory”, in order to render greater diagnostic certainty and more incisive therapeutic treatment.

### Features active correction of patients with nervous anorexia and nervous bulimia

I. Belokrylov\*, A. Bryukhin, E. Okonishnikova, T. Lineva  
Peoples' Friendship University of Russia RUDN University,  
Department of Psychiatry and Medical Psychology, Moscow, Russia  
\* Corresponding author.

**Introduction.**– We studied the relation to physical activity and other active methods of weight loss patients with eating disorders (ED). Assessed the degree of weight loss, depending on the use of exercise, food restriction, use of diuretics and laxatives.

**Objective.**– To identify features of physical activity of patients with ED at the initial, an anorectic and cachectic stages of the disease.

**Methods.**– We examined 55 patients with ED who underwent inpatient treatment in a psychiatric hospital. The study methods were: clinical assessment, anthropometry, questionnaires, psychometrics, statistics.

**Results.**– Patient's age was 15-35 years. 29 people (52%) suffered from anorexia nervosa, 26 patients (48% f) nervous bulimia. In the premorbid is engaged in sports 88% of the patients, 32 per cent of them in sections, 56% trained on their own. Never played sports 12% of patients. At the initial stage of restricted portions, refused to eat and used physical activity 84% of the surveyed; used laxatives and diuretics 23%. In a state of cachexia with a body mass index less than 15 has received 28%; less 20 - 44%; normal range - 28% of cases.

**Conclusions.**– Inadequate physical activity is the leading method of figure correction and body weight in the initial period and at the stage of active correction in the majority of patients with ED, along with the pathological feeding behaviour.

The publication was prepared with the support of the Peoples' Friendship University Program 5-100.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Binge eating disorder, High Body Mass Index and depression: Study of a non-clinical population in Sfax (Tunisia)

W. Bouattour<sup>1\*</sup>, L. Aribi<sup>2</sup>, N. Mseddi<sup>2</sup>, F. Charfeddine<sup>2</sup>, O. Amami<sup>2</sup>  
<sup>1</sup> University hospital center Hedi Chaker, Department of Psychiatry, Sfax, Tunisia; <sup>2</sup> University hospital center Hedi Chaker, Department of Psychiatry B, Sfax, Tunisia  
\* Corresponding author.

**Introduction.**– Binge Eating Disorder (BED), an actual eating disorder diagnosis in the DSM-5, is characterized by recurrent episodes of binge eating without regular compensatory behaviours such in Bulimia Nervosa. The BED would be 2 to 3 times more common than bulimia nervosa and it would affect 10% of obese people. Several studies have highlighted the seriousness of this food-borne disorder considered a public health problem. In addition, associated psychological disorders, including depression, have a high probability of occurrence.

**Objectives.**– To evaluate the prevalence of BED in a non-clinical population and to appreciate the relationship of this disorder with increased body mass index (BMI) and depression.

**Methods.**– A cross-sectional study including 280 randomly recruited subjects. BED was diagnosed using the Binge Eating Scale (BES). Depression was assessed by the Beck Depression Inventory.

**Results.**– The prevalence of BED was 12.1%. It was qualified as moderate in all cases. Obese subjects had a higher prevalence of BED

than subjects without obesity (23% versus 8.7%;  $p=0.033$ ); The average score of BES was also higher ( $p=0.005$ ). BED was correlated with depression ( $p=0.000$ ). Depressed subjects had a higher average score of BES ( $10.83 \pm 7$  versus  $7 \pm 1.46$ ;  $p=0.000$ ).

**Conclusion.**– Our study shows that BED is quite common in our population. It has also just supported the association of BED with obesity and depression. This emphasizes the need for screening and treatment of BED to prevent the occurrence of somatic and psychological comorbidities.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The role of working memory for cognitive control in anorexia nervosa versus substance use disorder

S. Brooks<sup>1\*</sup>, H.B. Schioth<sup>2</sup>, S.Y. Young<sup>3</sup>, S.G. Funk<sup>1</sup>  
<sup>1</sup> University of Cape Town, Psychiatry, Cape Town, South Africa; <sup>2</sup> Uppsala University, Neuroscience, Uppsala, Sweden; <sup>3</sup> Stellenbosch University, Psychiatry, Cape Town, South Africa  
\* Corresponding author.

**Introduction.**– Prefrontal cortex executive functions, such as working memory (WM) interact with limbic processes to foster impulse control. The rising trend of research into cognitive control of impulsivity, using various related terms reflects the importance of research into impulse control, as failure to employ cognitions optimally may eventually result in mental disorder.

**Objectives.**– Against this background, a novel approach is taken, using an impulse control spectrum model—where anorexia nervosa (AN) and substance use disorder (SUD) are at opposite extremes—to examine the role of WM for cognitive control.

**Methods.**– A summary of WM processes in the healthy brain and then a systematic review of the neuropsychological, neural and genetic findings of AN and SUD.

**Results.**–  $n=15$  studies of AN with a total of  $n=582$  AN and  $n=365$  HC participants; and  $n=93$  studies of SUD with  $n=9106$  SUD and  $n=3028$  HC participants. WM load/capacity are considered to support the neural process of excessive epistemic foraging (cognitive sampling of the environment to test predictions about the world) in AN that reduces distraction from salient stimuli. There is a link between deficit WM and reduced cognitive control in people with SUD who are prone to 'jumping to conclusions' and reduced epistemic foraging.

**Conclusions.**– WM training is considered as a novel research tool and an adjunct to enhance treatment that improves cognitive control of impulsivity.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Two cases of pica leading to cerebral thrombosis

I. Chaari\*, O. Hdiji, S. Sakka, F. Kharrat, H. Hajkacem, N. Farhat, M. Dammak, C. Mhiri  
Habib Bourguiba Hospital, Department of Neurology, Sfax, Tunisia  
\* Corresponding author.

**Introduction.**– Pica is defined by the Diagnostic and Statistical Manual of Mental Disorders (DSM5) as a persistent eating of non-nutritive and non-food substances. It is considered inappropriate to the individual's developmental level and cultural practices.

**Aim.**– We report two cases of Pica causing severe anemia and cerebral thrombosis in 2 non-pregnant women.

Case 1: A 42-year-old woman was admitted for acute headache and an amputation of the right visual field. Neurological examination found a right homonymous hemianopsia. Cerebral MRI showed a superior longitudinal sinus thrombosis. Blood analysis revealed an iron-deficiency anemia (5 g/dl). Medical history taking revealed coal consumption during the past 3 years, which started 2 years after her last pregnancy. The patient received iron supplementation and anticoagulant treatment. The behaviour was controlled within one month of discharge.

Case 2: A 34-year-old woman with no medical history admitted for intracranial hypertension syndrome associated with left hemiparesis complicated with status epilepticus. Angio-MRI showed superior sagittal sinus thrombosis. The etiological investigations revealed a severe iron-deficiency anemia, her hemoglobin level was 6,3 g/dl. The patient admitted that she has been eating soil for 10 years. She received treatment with Valproate, iron supplementation and vitamin K antagonist. The treatment was discontinued 3 months later. Her anemia was corrected and the behaviour ceased completely within 4 months of discharge.

**Conclusion.**– Pica is an unusual and intriguing condition that may lead to serious consequences via severe anemia. Through these cases, we emphasize the importance of its early detection to prevent potentially deadly complications.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### REVAM: Virtual reality and anorexia nervosa

D. Clus<sup>1</sup>, N. Le Bigot<sup>2</sup>, C. Buche<sup>3</sup>, S. Montavon<sup>1</sup>, S. Berrouguet<sup>1</sup>

<sup>1</sup> CHRU Brest, Finistère, Brest, France; <sup>2</sup> Université de Bretagne Occidentale, Finistère, Brest, France; <sup>3</sup> CERV, Finistère, Brest, France

\* Corresponding author.

**Introduction.**– Anorexia Nervosa is a severe psychiatric illness with a high risk of relapse and a high mortality rate. High body dissatisfaction is a risk factor for relapse. Prevention and therapeutic interventions could be improved by focusing on body dissatisfaction. Virtual reality offers many advantages for the management of this multifactorial pathology. REVAM study uses a new virtual reality approach to work on body dissatisfaction.

**Objectives.**– The main objective will be to evaluate the acceptability and tolerance of the use of virtual reality on body image disorders in patients with anorexia nervosa.

**Methods.**– REVAM is a study carried out at the C.H.R.U Brest, with the European Virtual Reality Center, on 20 patients with anorexia nervosa. The protocol will combine several tools of virtual reality (Head mounted display, Kinect, Rubber Hand Illusion) and a third person point of view (back view) to encourage immersion in the virtual environment and identification with the avatar.

**Results.**– The main hypothesis is the acceptance and tolerance of this entire technological device for patients with anorexia nervosa.

**Conclusions.**– The acceptability and tolerance of this research will allow to consider a new study evaluating the effectiveness of this technique on the body dissatisfaction with a preventive aim on relapses. We hope, eventually, to allow a better reappropriation of the new limits of the body when the patient has reached a very low BMI and to accustom the patient to the image of her body in phase of weight gain.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0306

### Eating behaviors in a portuguese community sample: Differences regarding age and educational level

I. Rodrigues<sup>1</sup>, C. Marques<sup>2</sup>, T. Santos<sup>3</sup>, A.T. Pereira<sup>2</sup>, M. Coroa<sup>2,4\*</sup>, A. Macedo<sup>2,4</sup>

<sup>1</sup> University of Coimbra, Faculty of Medicine, Coimbra, Portugal; <sup>2</sup> University of Coimbra, Psychological Medicine- Faculty of Medicine, Coimbra, Portugal; <sup>3</sup> Baixo Vouga Hospital Centre, Department of Psychiatry and Mental Health, Aveiro, Portugal; <sup>4</sup> Coimbra Hospital and University Centre, Psychiatry, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– Eating disorders (ED) are potentially serious psychiatric disorders whose incidence has increased. They constitute a significant public health problem because of the disability they cause, as well as the considerable associated mortality rates. Female adolescents and young adults are the most affected individuals.

**Objectives.**– To analyze the differences in eating behaviours between age groups and between different educational levels in a Portuguese community sample of young individuals.

**Methods.**– A total of 307 students attending middle school, high school or university (mean age 16.42 ± 2.42; 60.9% females) voluntarily participated in the study by filling a validated self-report questionnaire, the Eating Disorder Examination Questionnaire.

**Results.**– There were statistically significant differences in shape concern subscale between participants aged 15 years or less and participants aged over 15 years ( $p = .034$ ), in which those older than 15 years scored higher than the youngest. Comparing middle school, high school and university students, there were significant differences in the total score ( $p < .001$ ) and in every subscale (restriction,  $p = .017$ ; food concern,  $p < .001$ ; shape concern,  $p < .001$ ; weight concern,  $p < .001$ ). University students scored higher than middle and high school students in all dimensions, except in the restriction subscale in which there were no differences between high school and university students.

**Conclusions.**– Maladaptive eating attitudes and behaviours seem to increase in late adolescence. These results showing that university years constitute a vulnerable stage for the development of ED symptoms, are in line with previous studies.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0307

### Binge eating disorder in adolescent – An indian perspective

R. Dikshit<sup>1\*</sup>, S. Karia<sup>2</sup>, N. Shah<sup>3</sup>, S. Sonavane<sup>4</sup>, A. Desousa<sup>5</sup>

<sup>1</sup> Speciality Medical Officer, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>2</sup> Assistant Professor, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>3</sup> Professor, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>4</sup> Additional Professor, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>5</sup> Research Associate, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India

\* Corresponding author.

**Introduction.**– Eating disorders are common psychiatric disorders, which typically has onset in adolescence, and are associated with high morbidity/mortality; Binge Eating Disorder (BED) being one of them. Despite of its consequences, limited data exists about BED amongst adolescent population in India.

**Objectives.**– To study prevalence of binge eating in urban Indian adolescent population. To compare adolescents with binge eating

disorder and non binge eating disorder on socio-demographic variables and eating patterns.

**Methods.**– A cross-sectional study included 2000 participants from 8th–12th grade English medium school in Mumbai, India. The data was collected through self report questionnaire which included demographic details, Binge Eating Scale, Eating Pattern Questionnaire. Statistical analysis was performed and  $p < 0.05$  was considered statistically significant.

**Results.**– The prevalence of binge eating was 86.9%. The mean age was 15.05 years. There was statistical significant difference found in following correlates female ( $P=0.0001$ ), 11 years of education ( $P=0.0001$ ), nuclear family ( $P=0.0001$ ), upper middle class ( $P=0.0001$ ), overweight ( $P=0.0001$ ), irregular menses ( $P=0.0001$ ). The eating pattern showed binge eating patterns amongst adolescents; eating out ( $P=0.008$ ), daily ( $P=0.0001$ ), brunch ( $P=0.001$ ) and the participants wanted to change their existing food habits ( $P=0.0001$ ).

**Conclusion.**– The study revealed a high prevalence rate of binge eating disorder amongst adolescents in India. This is an indication for taking necessary actions to create cognizance among the general population about the detrimental effects of Binge eating disorder. The study also shows that binge eating is associated with overweight (BMI 26–30) which can in future lead to serious physical and psychological consequences.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0308

### **Interpersonal reactivity in eating disorders: A systematic review and meta-analysis of literature studies**

G. Fico<sup>1\*</sup>, V. Cardi<sup>2</sup>, V. Ruzzi<sup>1</sup>, C. Ken<sup>2</sup>, J. Treasure<sup>2</sup>, A.M. Monteleone<sup>1</sup>

<sup>1</sup> Università degli Studi della Campania “Luigi Vanvitelli”, Department of Psychiatry, Napoli, Italy; <sup>2</sup> Institute of Psychiatry, Psychology & Neuroscience, Department of Psychological Medicine, King’s College London KCL, London, United Kingdom

\* Corresponding author.

**Introduction.**– Impaired social functioning has been implicated in the onset and maintenance of Eating Disorders (EDs). Abnormal psychosocial processes may promote abnormal stress responses leading to cumulative changes in regulatory stress systems.

**Objectives.**– The aim of this systematic review was to summarize the studies that investigated reactivity to interpersonal stress through experimental tasks in patients with EDs.

**Methods.**– Main electronic databases were searched for articles published up to December 2016, using specific keywords. The PRISMA guidelines were followed. Included studies investigated emotional, behavioural, physiological and/or neural responses to acute social task exposure employing experimental paradigms in ED individuals. 36 studies, of the 1920 screened, were included in the review and 14 of them in the meta-analysis.

**Results.**– The included studies provided evidence of self-reported emotion dysregulation and heightened attentional bias towards negative social stimuli in ED patients. Although some evidences of a lower heart rate increase after stress exposure seems to emerge in subjects with anorexia nervosa (AN), biological data are scarce. fMRI studies further support differences in brain processing of social stimuli in EDs. No studies investigated the effect of social stress on eating behaviour in AN and bulimia nervosa.

**Conclusions.**– ED patients differ from healthy controls in the response to social stress more than to other form of stress. They show dysregulation of emotional and behavioural responses and, possibly, of the autonomic system response. Our findings support

the hypothesis that ED people engage in a mood regulation effort when experience negative social interactions.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Families of patients with anorexia nervosa: What should be their place in inpatient treatment? – The Geneva model**

C. Alberque<sup>1</sup>, G. Gkinis<sup>1\*</sup>, C. Xourgias<sup>2</sup>

<sup>1</sup> Geneva University Hospital, Service de Psychiatrie de la Liaison et d’Intervention de Crise, Geneva, Switzerland; <sup>2</sup> Département de l’Instruction Publique de la culture et du sport, Office MédiEVPédagogique de Genève, Geneva, Switzerland

\* Corresponding author.

**Introduction.**– Family implication in anorexia nervosa treatment remains indispensable, with family therapy proving to be more effective compared to individual psychotherapy. Nonetheless, the modalities of family intervention are far from uniform, especially within the hospital setting. UPHA is a combined psychiatric and medical unit whose mission is the multidisciplinary care of patients suffering from anorexia nervosa with a BMI < 12. Faced on a daily basis with the need to successfully incorporate the families of anorexic adolescents into the treatment process, we were bound to reflect on how to maximize this intervention’s efficacy.

**Objectives.**– After a brief literature review, we attempt by means of 2 clinical vignettes to describe our model’s framework and particular traits and b) to compare it with other models of family intervention.

**Methods.**– Unlike common practice (family therapy by a therapist not directly involved in daily inpatient care), we propose weekly meetings between the family and the our unit’s direct caregivers (nurse and medical resident), in presence of the head of the department (trained in systemic psychotherapy) and the attending psychiatrist (trained in psychoanalytical psychotherapy), the latter two being in charge of the therapeutic frame.

**Results.**– Our model diminishes family resistance, attenuates splitting defensive processes and gives families a central role in the inpatient treatment.

**Conclusions.**– The Geneva model is a viable alternative to be considered for further testing, especially for inpatient anorexia with a low BMI.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0310

### **Facilitating communication and reducing shame in eating disorders by using animation**

M.M. Guala<sup>1\*</sup>, L. Lescanne<sup>2</sup>

<sup>1</sup> University Hospital Odense, Psychiatry, Odense, Denmark; <sup>2</sup> Sønc, Production, Viborg, Denmark

\* Corresponding author.

**Introduction.**– Eating Disorders are often associated to shame and stigma. Shame is usually a barrier for people to communicate about themselves. We want to explore whether short films made by animators with patients and their psychiatrist can help people with Eating Disorders to overcome their difficulties by revealing in creative ways the symptoms they are ashamed about.

**Objectives.**– To collaboratively produce films about Eating Disorders symptoms with experts in animation, patients and their psychiatrist, in order to use them in clinical practice as a facilitator for

patients to share their symptoms. To ease shame about symptoms by showing the films in group therapy, and therefore facilitating and encouraging patients to share their feelings regarding their concerns associated with their condition.

**Methods and results.**– Through collaborative reflection of a team made of patients, their psychiatrist and experts in animation and storytelling, two symptoms were chosen and explored, resulting in 2 films focusing on over-eating and over-exercising. All the production process was done in close collaboration and within an interdisciplinary framework. The films will be shown in group therapy.

**Conclusion.**– The project will be evaluated with qualitative methods and the results will be ready to be presented in EPA 2018.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0311

### **Severe and enduring anorexia nervosa (SE-AN): Case report and literature review**

J.E. Ibáñez Vizoso\*, F.J. Gómez Beteta, J. Pemán Rodríguez, M. Tenorio Guadalupe, M. Villanueva Gallego, G. Montero Hernández, Í. Alberdi Páramo

Hospital Clínico San Carlos, Psychiatry, Madrid, Spain

\* Corresponding author.

Anorexia nervosa carries one of the highest mortality rates for any psychiatric disorder with 10-15% of fatal outcomes. It is certain that several treatments have been developed and shown to be effective; however, it is precisely in those who develop a more chronic and severe form of the illness (what we will call from now Severe and Enduring Anorexia Nervosa, SE-AN) where little progress has been achieved.

In this poster we aim to present the case of Almudena, a 32 years old woman who has been fighting her SE-AN for nearly 20 years. In this period, she has had over 50 hospital admissions, multiple complications and severe social dysfunction. This time she is admitted in our hospital for the first time, after changing her hospitalization area. Her weight is 31 and her IMC near 11. We will review the literature of SE-AN and discuss the available strategies to fight this disorder.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0312

### **Relationship between body composition and EDI-2 subscales in a cohort of women with eating disorders**

S. Iceta<sup>1,2\*</sup>, B. Segrestin<sup>2,3</sup>, C. Betry<sup>4</sup>

<sup>1</sup> Inserm U1028, CNRS UMR5292, CRNL, *Psychiatric Disorders: from Resistance to Response*, Lyon, France; <sup>2</sup> CHU de Lyon, *Centre Référent pour les TCA, Hôpital Femme Mere Enfant*, Bron, France; <sup>3</sup> *Centre de Recherche en Nutrition Humaine Rhône-Alpes CRNH-RA, Laboratoire Carmen, Pierre Bénite*, France; <sup>4</sup> *University of Nottingham, Department of Life Sciences, Nottingham, United Kingdom*

\* Corresponding author.

**Introduction.**– Patients with restrictive anorexia nervosa display a lower percent of fat-mass (FM) and a higher percent of fat-free mass (FFM) than patients with bingeing-purging subtype. Furthermore, a growing body of evidence suggests an important role of FFM on eating behaviour in the general population.

**Objectives.**– The aim of this study was to assess the links between FFM and FM ratio (FFM/FM), on the one side, and Eating Disorder Inventory, version 2 (EDI-2) subscales, on the other side.

**Methods.**– Data were retrospectively collected from patient records. All the female patients addressed to our tertiary reference centre for eating disorders and who completed body composition assessment with DEXA and EDI-2 questionnaire were included ( $n = 73$ ).

**Results.**– The mean BMI of the cohort was  $17.4 \pm 3.2 \text{ kg/m}^2$ . FFM/FM was significantly related to EDI2 bulimia ( $\tau = 176, P = 0.048$ ) and EDI2 body dissatisfaction ( $\tau = 169, P = 0.044$ ) using Kendall rank correlation. Using ROC curve, we demonstrated that FFM/FM can be used to diagnose bulimia symptoms (defined by a score on EDI-2 bulimia  $\geq 2$ ) (AUC = 0.65,  $P = 0.029$ ) with a cut-off of 4.00. Patients with FFM/FM  $> 4.00$  had lower BMI and lower FM, but no significant difference in terms of FFM.

**Conclusions.**– There is a strong relationship between body composition and bulimia symptoms. Our data suggest that patients with eating disorders but without bulimia symptoms are able to lose fat mass while maintaining fat-free mass. Furthermore, this phenotype is associated with a greater body satisfaction.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0313

### **Predictors of treatment outcome in adolescent outpatients with anorexia nervosa**

C. Jaite<sup>1\*</sup>, E. Pfeiffer<sup>1</sup>, C. Thurn<sup>1</sup>, U. Lehmkuhl<sup>1</sup>, H. Salbach<sup>2</sup>

<sup>1</sup> *Charité-Universitätsmedizin, Child and Adolescent Psychiatry, Berlin, Germany*; <sup>2</sup> *Freie Universität Berlin, Clinical Psychology and Psychotherapy, Berlin, Germany*

\* Corresponding author.

**Introduction.**– The knowledge on baseline predictors that influence treatment outcome in adolescents with eating disorders is quite limited. This study aimed to determine predictors of treatment outcome in adolescent outpatients with anorexia nervosa (AN).

**Methods.**– The sample included 81 adolescent patients ( $M_{\text{age}} = 16.9$ ,  $SD_{\text{age}} = 1.8$ ) with AN according to DSM-IV. Patients were randomly assigned to either 25 weeks of CBT or 25 weeks of DBT. Before (T0) and after treatment (T1) the Structured Inventory for Anorexic and Bulimic Syndromes (SIAB-EX), the Eating Disorder Inventory-2 (EDI-2) and the Symptom-Checklist-90-R of Derogatis (SCL-90-R) were applied. For each participant body height (m) and body weight (kg) were measured to calculate the body mass index (BMI) and the BMI percentile. The following baseline variables were examined as possible predictors: age, BMI, duration of illness, subtype of AN, various axis I diagnoses, eating disorder-specific and general psychopathology as well as treatment group (CBT/DBT). Linear regression analyses were conducted to identify the predictors of the BMI and the EDI global score at the end of treatment.

**Results.**– A higher BMI ( $p = .048$ ), a lower age ( $p = .018$ ), and a lower eating disorder-specific psychopathology ( $p = .004$ ) were associated with a better outcome at the end of outpatient treatment. The other studied predictors showed no prognostic impact on the treatment outcome.

**Conclusions.**– Further research is necessary to investigate whether patients with severe AN might benefit from specific treatment approaches.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0314

### When physical activity in anorexia nervosa is no more a part of the problem but a part of the solution

D. Jansa<sup>1\*</sup>, K. Golja<sup>2</sup>, P. Jenkole<sup>3</sup>

<sup>1</sup> Health Center Kranj, Mental Health Department, Radovljica, Slovenia; <sup>2</sup> Faculty of Sport, Kinesiology, Ljubljana, Slovenia; <sup>3</sup> Sport Center Biofit, Sport Center Biofit, Bled, Slovenia

\* Corresponding author.

Our main goal (objectiv) is to present a practical, working approach to solving the problem of eating disorders by combining psychiatric and psychotherapeutic treatment with kineziology (exercise) at the same time and the same place.

We want to reduce obsessive hyperactivity, stabilize hormonal status, minimize the role of stress hormones, strengthen nervous system, improve clinical picture and make the body functional again.

At the same time the socialization process is taking place because they train in a nice surrounding together with other people and going through individual and group psychotherapeutical process as well.

The workout must stimulate muscle growth (increase body mass.), so we stop the cardio and replace it with weight training.

The most important thing is to eliminate quantity and go for quality. A short, suitable exercise program does the trick.

We call this Psycho-Kinesio therapy.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0315

### Anorexia nervosa in child and adolescents

J. Jerónimo<sup>1\*</sup>, A. Serrano<sup>2</sup>

<sup>1</sup> Hospital de Santa Maria, Psychiatry and Mental Health Department, Lisboa, Portugal; <sup>2</sup> Hospital Garcia de Orta, Child and Adolescents Unit, Almada, Portugal

\* Corresponding author.

Anorexia nervosa (AN) is characterized by self-induced starvation coupled with fear of gaining weight or of becoming fat and disturbance in the way in which one's body weight or shape is perceived. The findings associated with AN in children and adolescents are similar to those in adults. However, children and adolescents frequently do not endorse fear of gaining weight or body image dissatisfaction. Its treatment is complex and challenging, and sometimes hospitalization is needed.

Our Unit is a multidisciplinary team, formed in 1989, that provides both outpatient and inpatient treatment.

Our aim is to present and discuss AN treatment program in children and adolescents, Revision and statistical analysis of all hospitalized AN' patients' clinical files under 18, from 1 January 2007 to 31 December 2016 were made. Treatment outcome was assessed by BMI variation.

It is important to recognize AN in children and adolescents and being alert for its potential complications. The interruption of puberty, growth retardation, interference with peak bone mass acquisition and brain development can be potentially irreversible. Early detection and intervention are mandatory.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0316

### Anorexia nervosa and bone metabolism

J. Jerónimo<sup>\*</sup>, J. Santos

Hospital de Santa Maria, Psychiatry and Mental Health Department, Lisboa, Portugal

\* Corresponding author.

*Introduction.* – Anorexia Nervosa (AN) is a mental health disorder primarily affecting female adolescents and young women. It is mainly characterized by restriction of energy intake, intense fear of gaining weight and a distorted body image. The food restriction and compensatory behaviours can cause electrolytic, endocrine and metabolic disturbances, like decreased bone mineral density (BMD) which is one of the most common.

*Objective.* – The objective of this poster is to perform a literature review of complications of AN its treatment and present a clinical case.

*Methods.* – Studies were searched from Pub Med database with the following keywords: Eating disorders, Anorexia nervosa, Osteoporosis, Bone mineral density. A comprehensive manual search, including search from the reference list of included articles, was also performed.

*Results.* – Increased bone resorption, changes in bone microarchitecture, and decreased peak bone mass condition the decrease in bone mineral density (BMD), which is common in AN. About 50% of patients have BMD loss, with a 7 times higher risk of fracture than normal controls. The hypothesis that low calorie intake, with low ingestion of calcium and vitamin D is the major cause for BMD was not valid.

*Conclusion.* – As several facts contribute to loss of BMD in AN, the earlier identification of decreased is crucial. Studies of treatment focused on nutritional rehabilitation and weight gain, in order to stop losing BMD, show great results.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0317

### Anorexia nervosa and bone metabolism: An extreme case

J. Jerónimo<sup>\*</sup>, E. Reis, J. Santos

Hospital de Santa Maria, Psychiatry and Mental Health Department, Lisboa, Portugal

\* Corresponding author.

Anorexia Nervosa (AN) is a mainly characterized by restriction of energy intake, intense fear of gaining weight and a distorted body image. The food restriction and compensatory behaviours can cause electrolytic, endocrine and metabolic disturbance.

*Objective.* – The aim of this communication is to present a clinical case.

*Methods.* – Studies were searched from Pub Med database with the following keywords: Anorexia nervosa; Osteoporosis; Bone mineral density.

*Results.* – P., female, 35 years old, with a restrictive AN since the age of 14. After being admitted as an inpatient in our unit, she was followed only for an year, till she was 15 years old. From 15 to 28 years old, she referred a progressive decrease in her weight. At 35 years of age, she was submitted to an orthopedic surgery because of osteoporotic fractures, with a 10 cm decrease in height. When recovering from surgery at the hospital, she lost 10 kg (BMI 9.91 kg/m<sup>2</sup>). Because of this complication she was readmitted in our unit.

*Conclusion.* – The evaluation of BMD is necessary in order to start an earlier treatment, with better prognosis. Patients with onset of AN

during childhood and adolescence have worst prognosis because they achieved lower BDM peak.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0318

### Patients with eating disorders: Outcome inpatient care

J. Jerónimo<sup>\*</sup>, R. Santos, E. Reis, J. Santos  
Hospital de Santa Maria, Psychiatry and Mental Health Department, Lisboa, Portugal

\* Corresponding author.

Eating disorders (ED) are characterized by a persistent disturbance of eating behaviour that results in altered consumption of food and significantly impairs physical health or psychosocial functioning. ED classified in DSM-5 are anorexia nervosa (AN), bulimia nervosa (BN), binge eating disorder, pica, rumination disorder, avoidant/restrictive food intake disorder (ARFID), other specified feeding or eating disorder (OSFED) and unspecified feeding or eating disorder (UFED).

ED' treatment is complex and challenging and sometimes hospitalization is needed. Criteria for hospitalization in ED are defined and NICE clinical guidelines are among the most frequently used.

To present and discuss our units results of the inpatient treatment program.

Review of clinical files of all patients hospitalized at our unit from 1 January 2014 to 31 December 2016 followed by statistical analysis of data. Treatment outcome was assessed by body mass index (BMI) variation. BMI was determined at baseline, discharged, 6 months and 12 months after discharged.

Anorexia nervosa was the most frequent diagnosis. A remarkable high medical and/or psychiatric comorbidity was presented. When looking for compensatory behaviours presented by inpatients we notice the major predominance of vomiting, either isolated, or in association with misuse of laxatives.

Inpatient treatment for patients with eating disorders in our unit is considered only for those whose disorder has not improved with appropriate outpatient treatment, associated with high or moderate physical risk, or for whom there is a significant risk of suicide or severe self-harm. So, most inpatients at have disorders of high severity.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Is outpatient enhanced cognitive behavior therapy (CBT-E) for eating disorders a suitable treatment method for adults with severe anorexia nervosa?

S. Frostad<sup>1</sup>, Y.S. Danielsen<sup>1,2</sup>, G.Å. Rekkedal<sup>1</sup>, C. Jevne<sup>1</sup>, R. Dalle Grave<sup>3</sup>, U. Kessler<sup>4,5\*</sup>

<sup>1</sup> Haukeland University Hospital, Department of Eating Disorders, Bergen, Norway; <sup>2</sup> University of Bergen, Department of Clinical Psychology, Bergen, Norway; <sup>3</sup> Villa Garda Hospital, Department of Eating and Weight Disorders, Garda- VR, Italy; <sup>4</sup> Haukeland University Hospital, Psychiatric Department, Bergen, Norway; <sup>5</sup> University of Bergen, Department of Clinical Psychiatry, Bergen, Norway

\* Corresponding author.

*Introduction.*– Enhanced cognitive behaviour therapy (CBT-E) is a viable and promising outpatient treatment method for adults

with Anorexia Nervosa (AN), but its suitability for the treatment of patients with severe AN (defined as BMI < 16), commonly treated in intensive settings of care, has not been assessed.

*Methods.*– During 2013/2014, 49 patients with severe AN consecutively admitted to the Department for Eating Disorders at the Haukeland University Hospital in Bergen, Norway, were evaluated for outpatient CBT-E. BMI was recorded at baseline and 12 months. *Results.*– Out of the 17 patients with severe AN who started the treatment, 7 fulfilled at least 40 sessions of outpatient CBT-E over a 12 months period. Among the ten patients not completing the treatment, the main reason for leaving therapy was lack of motivation (n = 5). In the seven patients completing outpatient CBT-E there was a significant and large weight gain after 12 months. The mean BMI in this group was 14.0 (1.1) at baseline and 18.9 (2.1) one year after start of CBT-E. Five of seven patients reached a BMI ≥ 18.5.

*Conclusions.*– This data show that outpatient CBT-E might be a suitable treatment approach for a subpopulation of patients with severe AN. Although more than half of the patients did not complete the treatment, the remaining patients achieved a significant increase in BMI one year after start of therapy.

### Investigation of peripheral vitamin D in subjects with eating disorders

F. Marciello<sup>1\*</sup>, V.M. Buonomenna<sup>1</sup>, G. Cascino<sup>1</sup>, G. Fico<sup>1</sup>, E. Castaldo<sup>2</sup>, G. Perruolo<sup>3</sup>, P. Formisano<sup>3</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> University of Campania "Luigi Vanvitelli", Department of Psychiatry, Naples, Italy; <sup>2</sup> University of Salerno, Department of Medicine and Surgery, Section of Neurosciences, Salerno, Italy; <sup>3</sup> University of Naples "Federico II", Department of Translational Medical Sciences, Naples, Italy

\* Corresponding author.

*Introduction.*– Epidemiological studies have shown a significant association between low vitamin D levels and increased risk of various neuropsychiatric disorders including schizophrenia, depression and bipolar disorder. The role of vitamin D in Eating Disorders (ED) needs to be more deeply investigated.

*Objective.*– Our study aimed to assess peripheral levels of vitamin D in subjects with Anorexia Nervosa (AN) and Bulimia Nervosa (BN) and to investigate its role in ED psychopathology.

*Methods.*– Fifty-six ED women (37 with AN, 19 with BN) and 26 healthy women (HC) volunteered for this study. Serum concentrations of 25(OH)-vitamin D [25(OH)D] were measured. Participants filled in eating-related psychopathological rating scales.

*Results.*– Eighteen percent of the participants (27% AN, 5% BN, 15% HC) had vitamin D deficiency (<20 ng/mL), while vitamin D insufficiency [25(OH)D between 20 and 30 ng/mL] was detected in 43% of subjects (49% AN, 37% BN, 38% HC). AN women had significantly lower 25(OH)D concentrations compared to both BN subjects (p < 0.01) and HC (p < 0.01); there was no significant difference in 25(OH)D concentrations between BN and HC groups. We found no significant association between 25(OH)D concentrations and psychopathological scales scores in the 3 groups.

*Conclusions.*– These results show that underweight AN women have serum vitamin D levels lower than HC, likely because of malnutrition. No significant reduction of 25(OH)D is present in BN subjects. Moreover, 25(OH)D concentrations seems to have no influence on ED psychopathology. However, further studies are needed to better explore the meaning of vitamin D deficiency in AN.

### **Contributions of body image internalized and externalized shame to eating psychopathology**

S. Oliveira<sup>1</sup>, J. Marta-Simões<sup>2\*</sup>, C. Ferreira<sup>2</sup>

<sup>1</sup> University of Coimbra, Faculty of Psychology and Educational Sciences, Coimbra, Portugal; <sup>2</sup> CINEICC, Cognitive and Behavioural Centre for Research and Intervention University of Coimbra, Clinical Psychology, Coimbra, Portugal

\* Corresponding author.

Although shame has been regarded as a key mechanism in the development and maintenance of body image and eating-related difficulties, research on the specific effect of body image-focused shame on eating psychopathology remains less explored. This study tested the hypothesis that the impact of shame on eating psychopathology symptoms is carried by the effect of self-focused negative evaluations regarding body image (internal body shame) and the perception that others negatively evaluate and criticize one's body image (external body shame).

This study's sample included 285 young women aged between 18 and 35 years old. Participants filled demographic data and self-report questionnaires accessing external shame, body image shame, and eating psychopathology. A path model was conducted to test a model which hypothesized that internalized and externalized dimensions of body shame may act as mediators on the association between global shame and eating psychopathology, controlling BMI's effect.

Internal and external experiences of body image-focused shame are positively and highly associated with eating psychopathology. Path analysis corroborated the plausibility of the tested model and demonstrated that the effect of general feelings of shame on eating-related difficulties is fully mediated by internalized and externalized body shame.

These findings confirmed the well-established association between shame and eating difficulties and suggest that it is not the experience of general feelings of shame that directly leads to eating psychopathology severity, but rather it is the specific and painful emotions of internalized and externalized body image-focused shame that have strong direct effects on disordered eating.

### **The Body Compassion Scale: A confirmatory factor analysis with a sample of Portuguese adults**

C. Ferreira<sup>1</sup>, J. Marta-Simões<sup>1\*</sup>, S. Oliveira<sup>2</sup>

<sup>1</sup> CINEICC, Cognitive and Behavioural Center for Research and Intervention University of Coimbra, Clinical Psychology, Coimbra, Portugal; <sup>2</sup> University of Coimbra, Coimbra, Portugal

\* Corresponding author.

The relationship between self-compassion and positive mental health outcomes is well established. Considering the emerging importance of body image, a growing body of research has specifically focused on the importance of self-compassion to prevent and treat body image and eating-related disorders, and chronic diseases. In this context, the Body Compassion Scale (BCS; Altman et al., 2017) has proved its worth in further informing the understanding of how individuals relate to their bodies.

The present study aimed at exploring BCS's factor structure through Confirmatory Factor Analysis (CFA), and examining its psychometric properties in a sample of Portuguese adults.

A mixed-gender sample (N = 595) of participants aged between 18 and 50 was used. Participants completed self-report measures of body compassion, body image shame, body appreciation and eating psychopathology.

CFA's results revealed good local and global adjustments, and indicated the Portuguese BCS to replicate the three-dimensional structure originally identified. BCS presented high internal reliability ( $\alpha_{\text{Defusion}}=.90$ ;  $\alpha_{\text{CommonHumanity}}=.93$ ,  $\alpha_{\text{Acceptance}}=.88$ ,  $\alpha_{\text{BCSGlobalScore}}=.88$ ), and good convergent (with body appreciation) and divergent validities (with body image shame and eating psychopathology).

Findings corroborated the adequacy of BCS's factor structure and supported its validity to access a self-to-body relationship based in competences of defusion, acceptance and common humanity. As expected, body compassion was positively linked to an attitude of acceptance, care and kindness toward the body, and negatively with body image-focused shame and eating psychopathology symptoms. This measure is of potential utility for guiding and measuring interventions to promote health-related behaviour (e.g., positive body image).

EV0323

### **The crucial role of shame experiences in the explanation of eating disorder symptomatology**

A.L. Mendes<sup>\*</sup>, C. Ferreira, I.A. Trindade

CINEICC, Cognitive and Behavioural Centre for Research and Intervention University of Coimbra, Clinical Psychology, Coimbra, Portugal

\* Corresponding author.

The lack of feelings of safeness, acceptance and connectedness in social relationships and fear of receiving compassion from others are both adverse factors associated with higher experience of shame and with several psychopathological symptoms.

The present study intended to test a theoretical model which hypothesised that the effects of social safeness and pleasure and fear of receiving compassion from others on disordered eating attitudes and behaviours are mediated by general feelings of shame and body-image related shame.

The sample of this study comprises 517 women from the Portuguese general population, aged between 18 and 35, who completed an online survey.

The path model accounted for 59% of the variance of disordered eating and showed excellent model fit indices. Results demonstrated the direct effect of social safeness and pleasure and of fear of receiving compassion from others on external shame and body-image related shame, however, their effect on disordered eating was totally carried (i.e., mediated) by the mechanisms of body-image related shame. In fact, women who reported lower feelings of social safeness and connectedness in social relationships and higher tendency to fear receiving compassion from others appear to experience negative emotions, such as external shame and body-image related shame, which appear to explain disordered eating attitudes and behaviours.

These findings highlight the importance of developing intervention programs which target maladaptive defensive processes (e.g., shame and body-image related shame) through self-compassion and acceptance attitudes, especially to deal with body image and eating difficulties.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0324

### **Physical appearance-focused social comparison as a source of disordered eating: The mediator role of shame and self-judgment**

A.L. Mendes\*, C. Ferreira, I.A. Trindade

*CINEICC, Cognitive and Behavioural Centre for Research and Intervention University of Coimbra, Clinical Psychology, Coimbra, Portugal*

\* Corresponding author.

Social comparisons based on physical appearance have been highlighted as a risk factor for eating psychopathology. Previous studies revealed that women who compare negatively their body image with others tend to feel that they are inadequate and inferior and, therefore, tend to engage in eating-related disordered attitudes and behaviours. However, the mechanisms underlying this link remain unclear.

The current study aimed to examine whether the association of social comparison through physical appearance and eating-related disordered attitudes and behaviours would be explained by the mechanisms of external shame and self-judgment, while controlling for the effects of body mass index. The sample comprised 400 Portuguese women, aged between 18 and 55 years old, who completed validated self-report measures.

Path analyses explained 35% of the variance of disordered eating and demonstrated excellent model fit indices. Results revealed that social comparison through physical appearance presented a significant direct effect on disordered eating attitudes and behaviours, and an indirect effect through the mechanisms of self-judgment and external shame. Specifically, unfavourable social comparison through physical appearance appears to explain higher levels of eating disorder symptomatology, via increased self-judgmental attitudes towards one's failures or inadequacies and feelings that one's personal characteristics are seen by others as unattractive.

These results seem to emphasize the relevance of developing self-compassionate skills in the promotion of a more positive relationship with one's own body image and self, rather than adopting a self-judgmental attitude and maladaptive processes and strategies that block this adaptive and caring attitude.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0325

### **The effect that secure attachment holds on women's physical appearance-related social comparison**

A.L. Mendes, C. Ferreira

*CINEICC, Cognitive and Behavioural Centre for Research and Intervention University of Coimbra, Clinical Psychology, Coimbra, Portugal*

\* Corresponding author.

In Western societies, physical appearance is a self and other's central evaluative dimension, especially in women. Previous theoretical accounts have suggested that the lack of a secure attachment is highly associated to unfavourable social comparisons, especially through physical appearance and body-eating maladaptive attitudes. However, the link between secure attachment and social comparison based on physical appearance is still scarcely studied.

The present study aimed to explore whether the association between secure attachment and social comparison through physical appearance would be explained by the mechanisms of social safeness and self-criticism. Participants were 130 Portuguese women, aged between 18 and 53 years old.

The tested path model explained 36% of the variance of social comparison through physical appearance and presented excellent model fit indices. Results showed that secure attachment holds an indirect effect on social comparison based on physical appearance through the mechanisms of social safeness and self-criticism. These findings seem to suggest that a lack of early secure attachment is linked to decreased feelings of social safeness and pleasure and to the adoption of self-critical attitudes, which appear to explain unfavourable social comparison through physical appearance.

These findings suggested that it is not the lack of a secure attachment that directly leads to an unfavourable social comparison through physical appearance but rather is its indirectly effect via a poorer experience of social safeness, acceptance and connectedness and the engagement in self-critical attitudes.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Male Body Attitudes Scale: Confirmatory factor analysis and its relationship with body image shame and body compassion**

C. Ferreira, S. Oliveira, J. Marta-Simões, A.L. Mendes\*

*CINEICC, Cognitive and Behavioural Centre for Research and Intervention University of Coimbra, Clinical Psychology, Coimbra, Portugal*

\* Corresponding author.

In the last decades, mental health research has significantly invested in the study of body image. This effort has mostly consisted in the study of women's desire to become thinner, and its relationship with psychopathological concerns and poor mental health indicators. Nonetheless, recent data has pointed the importance of analyzing men's body image concerns, namely aspirations to improve muscularity and to lower body fat. The creation of the Male Body Attitudes Scale (MBAS; Tylka et al., 2005) has allowed the examination of male concerns about muscularity, body fat and height, contributing to a greater interest in studying men's body image.

The present study aimed at exploring MBAS's structure (via Confirmatory Factor Analysis, CFA) and psychometric properties, in a sample of Portuguese adult men.

A sample of 241 men, aged between 18 and 60, participated in the study by completing demographic data and self-report questionnaires (body-focused shame, male body attitudes, body compassion).

The suitability of the originally found three-factor solution was confirmed, representing male attitudes toward their own body muscularity, fat and height. Adequate internal consistency values were found for MBAS's global score and subscales (Cronbach's alpha values ranging from .78 to .92). MBAS revealed good psychometric properties, and showed to be positively associated with body-focused shame, and negatively with body compassion.

This self-report measure seems to represent an important indicator of men's attitudes toward their own body image characteristics, and thus contribute for future research on male body image and eating-related difficulties.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Is it possible to become addicted to food? A theoretical model of food addiction spectrum

A. Piccinni, F. Mucci<sup>1</sup>, A. Veltri, D. Marazziti

Università di Pisa, Dipartimento di Medicina Clinica e Sperimentale, Pisa, Italy

\* Corresponding author.

**Introduction.**– The hypothesis that food can be addictive has long been rejected and is still much debated because it is essential for survival; in this prospective we should be all dependent from food. The concept of food addiction enhances our confusion to understand excessive overweight and obesity. It is also hard to explain why some people eat well beyond their biological requirements.

**Objectives.**– The aim of the study was to identify and to better understand the behavioural and neurobiological similarities between overeating and drug addiction, as well as to deepen the knowledge of the central metabolic, neurochemical and environmental factors that drive the food over-intake.

**Methods.**– A systematic review of the available literature was conducted by searching the electronic databases MEDLINE, Embase, PsycINFO and Cochrane, combining the search strategy of free text terms and exploded MESH headings.

**Results.**– PET and fMRI studies showed changes in dopaminergic D2 receptors expression and in metabolic cortical areas activity overlapping between obese subjects and drug abusers. The opioid system may orientate the appetite towards specific macronutrient classes, or mediate various aspects of appetitive behaviour. Chronic over-activation of HPA axis acts on neuromodulators such as leptin and ghrelin, while causing modification of the rewarding properties of feeding and increasing the so-called hedonic or emotional eating.

**Conclusions.**– We propose the existence of an “overeating spectrum”, including different degrees of attachment to food, generally considered as a tolerable habit or personal attitude, but almost always resulting in body weight gain and risk for metabolic diseases.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Family based therapy in a Singapore eating disorders program

K.W. Ng<sup>1\*</sup>, H.Y. Lee<sup>1</sup>, C. Kwok<sup>1</sup>, K. Ann<sup>1</sup>, E. Chan<sup>2</sup>, H.C. Low<sup>2</sup><sup>1</sup> SGH, Psychiatry, Singapore, Singapore; <sup>2</sup> SGH, Medical Social Work, Singapore, Singapore

\* Corresponding author.

This descriptive study aims to look at family based therapy (FBT) for Anorexia Nervosa (AN) in a Singapore eating disorders program. Review of medical records of patients diagnosed with AN in our treatment program between 2012 and 2015 was carried out. Demographic and clinical characteristics of patients who took up FBT were compared with those who took up treatment as usual (TAU). Clinical outcomes were also measured.

Total of 77 patients with AN were referred for FBT. Majority was female (96.1%) and of Chinese ethnicity (75.3%). 69 of the patients did not report conflict between the parents. Almost a third of them required hospitalization on presentation. The mean age at presentation was 14.26 years and mean body mass index (BMI) was 15.3 kg/m<sup>2</sup> at presentation. Mean percentage estimated body weight (%EBW) was 77.12% at presentation. Mean duration of illness was 1.3 years. Almost half of the patients who were referred took up FBT. There were only 2 male patients in this group and

almost three quarters were of Chinese ethnicity. Majority did not report conflict between the parents. The mean age at presentation of this group was 14.33 years and mean body mass index (BMI) was 14.8 kg/m<sup>2</sup> at presentation. Mean %EBW of this group of patients was 75.36% at presentation. Mean duration of illness was 1.36 years. Outcome measures such as weight restoration and return of menstruation were collected. Rating scales measuring eating disorder psychopathology, anxiety and depression and clinical impairment were also collected.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Hormonal contraception may enhance cognitive functions in eating disorders

B. Nobile<sup>1\*</sup>, L. Maimoun<sup>2</sup>, I. Jaussent<sup>1</sup>, S. Beziat<sup>1</sup>, M. Seneque<sup>3</sup>, S. Thiebaut<sup>3</sup>, P. Lefebvre<sup>4</sup>, E. Renard<sup>4</sup>, P. Courtet<sup>3</sup>, S. Guillaume<sup>3</sup><sup>1</sup> Inserm U1061, Clinical and epidemiological research in neuropsychiatry, Montpellier, France; <sup>2</sup> Inserm U1046, Physiology and Experimental Medicine of the Heart and Muscles- University of Montpellier, Montpellier, France; <sup>3</sup> CHU, Department of Emergency Psychiatry and Post-Acute Care, Montpellier, France; <sup>4</sup> CHU, Department of Endocrinology, Diabetes, and Nutrition, Montpellier, France

\* Corresponding author.

**Introduction.**– Growing evidences suggest a role of sexual hormones, in maintaining cognitive function. Eating disorders (EDs) are known to be associated with cognitive impairment. Given the low levels of sexual hormone found within those patients it might be possible that hormonal contraception would enhance their cognitive functions. The aim of this study was to assess the performance in four cognitive functions known to be impaired in EDs (anorexia and bulimia nervosa) according to hormonal contraception intake.

**Methods.**– This is a retrospective study on a cohort of 230 women with EDs according to the DSM-V criteria. Cognition was assessed using: D2 (attention), IGT (decision making), Brixton (set-shifting) and Rey figure test (central coherence). Data were analysed in univariate model, variables associated with the outcome ( $p < 0.10$ ) were included in the logistic regression models to estimate the adjusted odds ratios (OR) and 95% confidence intervals (CI) for hormonal contraception effect on neuropsychological test.

**Results.**– Patients were aged between 15 and 45 and 39.1% were taking hormonal contraception (oral, transdermal or intrauterine). After multiple adjustments, hormonal contraception intake was significantly associated with greater scores to D2 and IGT compared with no hormonal contraception intake. Conversely, Brixton and Rey Figure test scores were not significantly associated with hormonal contraception intake.

**Conclusions.**– This study shows that hormonal contraception has benefic effects on cognitive function in women with EDs. This positive effect might be taken into account in the risk-benefit balance when introducing hormonal contraception.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0330

### Psychometric evaluation of the dysmorphofobia patients with anorexia nervosa and bulimia nervosa

E. Okonishnikova<sup>1</sup>, I. Belokrylov, A. Bryukhin, T. Lineva, V. Karnozov, G. Kirsanova  
Peoples' Friendship University of Russia RUDN University,  
Department of Psychiatry and Medical Psychology, Moscow, Russia  
\* Corresponding author.

**Introduction.**– Anorexia nervosa (AN) and bulimia nervosa (BN) occur predominantly females, take one of the first places in the risk of fatal outcome among mental disorders, have a tendency to chronicity, disability with social disadaptation and high suicidal risk. The psychopathological basis of these diseases is dysmorphophobia, characterized by intrusive, overvalued or delusional ideas of physical disability. The significant role of dysmorphophobia determines the urgency of the detailed study using psychometric techniques.

**Objective.**– To assess the degree of satisfaction/dissatisfaction with one's body and its separate parts in patients with AN and BN.

**Methods.**– A total of 50 female patients with AN and BN at the age of 16-30 years (the average age is 21). The disease duration from 6 months to 12 years. The psychometric method using the validated Questionnaire image of one's own body (QIOB) and the Scale of satisfaction with one's body (SSOB), Scogarevsky's technique.

**Results.**– According to QIOB 43.4% in the category expressed dissatisfaction with their appearance, 23.3% in moderate category and 33.3% in light category, which is also not normative. According to SSOB, 43% of the patients is not satisfied with characteristics that belong to head, 53.3% is not satisfied with characteristics that belong to torso, 56.6% is not satisfied with characteristics that belong to the lower part of body. The number of dissatisfied with all of these body parts equals 40% ( $n = 12$ ), which indicates the presence of polydysmorphofobia.

**Conclusions.**– High rates of dissatisfaction with one's appearance, which are consistent with the severe somatic state of patients, require further detailed study.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0331

### Adult attachment styles and motivational systems: An exploration of their association with eating disorder psychopathology

V. Ruzzi<sup>1</sup>, A.M. Monteleone<sup>1</sup>, F. Pellegrino<sup>1</sup>, G. Fico<sup>1</sup>, V. Caivano<sup>1</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> Second University of Naples, Psychiatry, Naples, Italy; <sup>2</sup> University of Salerno, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Neuroscience, Salerno, Italy

\* Corresponding author.

**Introduction.**– An imbalance between reward and punishment systems has been involved in Eating Disorder (ED) psychopathology. According to attachment theory, early family interactions affect emotion regulation abilities in adult interpersonal relationships. Insecure attachment has been shown to predict attentional bias to social rejection in ED people and an association between anxious attachment style and sensitivity to punishment has been found in individuals with AN.

**Objectives.**– The aim of our study was to investigate the possible role of motivated behaviours as mediator of the relationship between insecure attachment and ED symptomatology.

**Methods.**– Seventy-eight participants affected by EDs and 45 healthy controls were enrolled into the study. They were asked to fill in the Attachment Style Questionnaire to investigate adult attachment style, the Eating Disorders Inventory-2 (EDI-2) to evaluate eating symptomatology and the Behavioral Inhibition System-Behavioral Activation System Scale (BIS-BAS) to assess sensitivity to punishment and to reward.

**Results.**– ED patients scored higher than HC in EDI-2 subscores, in insecure attachment style and in sensitivity to punishment (BIS score). Anxious attachment style was positively associated with sensitivity to punishment and EDI-2 subscores in ED people. The sensitivity to punishment was found to totally mediate the relationship between anxious attachment style and ED symptoms.

**Conclusions.**– These findings provide support for the relationship between attachment styles and behavioural motivation patterns in EDs and suggest, for the first time, increased behavioural inhibition as a pathway that may explain the relationship between anxious attachment and ED psychopathology. Therefore, attachment experiences and interpersonal difficulties may represent important psychotherapeutic focus.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0332

### Anorexia nervosa and personality disorder: Literature review

S. Tira<sup>\*</sup>, S. Ben Ali, C. Ben Cheikh, H. Elkefi, A. Oumaya  
Hôpital militaire principal d'instruction de Tunis, psychiatry, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Anorexia nervosa is an eating disorder of multifactorial etiology and potentially severe prognosis. The study of the personality of the anorexic is an interesting aspect for the understanding of the etiology of this disease.

**Objectives.**– The aim of this work is to describe the links between anorexia nervosa and personality disorders through a review of the literature.

**Methods.**– We reviewed the articles published in the French and English language in the MEDLINE database between 1980 and 2017 by introducing the following Keywords "anorexia nervosa", "personality".

**Results.**– The prevalence of personality disorders is higher in anorexics versus controls. The personalities belonging to cluster C of the DSM4 are the most frequent in restrictive anorexics, especially Obsessive-compulsive personality and avoidant personality disorder. In the binge-eating/purging type, the results are more heterogeneous with personality disorders belonging equally to the B and C clusters of DS 4. Personality disorders belonging to cluster B (mainly borderline type) are more frequent in the binge-eating/purging type. The presence of a p personality is highly predictive of comorbidity of anorexia nervosa with another disorder of axis1 of DSM4 and more frequently associated with suicide attempts and drug abuse. On the other hand, the association of personality disorder-anorexia nervosa is related to a poor prognosis of anorexia nervosa.

**Conclusion.**– The determination of personality disorders related to anorexia nervosa is interesting on several scales: prognosis, therapeutic, as a risk factor for psychiatric comorbidity and for understanding the multifactorial etiology of anorexia nervosa.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0333

### Pathways to clinical care in eating disorders: An Italian multi-center study

R. Vanacore<sup>1\*</sup>, U. Volpe<sup>1</sup>, A.M. Monteleone<sup>1</sup>, F. Monaco<sup>1</sup>, F. Staltari<sup>1</sup>, P. Monteleone<sup>2</sup>

<sup>1</sup> Second University of Naples, Psychiatry, Naples, Italy; <sup>2</sup> Università di Salerno, 2Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Section of Neuroscience, Salerno, Italy

\* Corresponding author.

**Introduction.**– The paths that leads patient with Eating Disorders (EDs) to specialists may frequently vary in Italian clinical care.

**Objectives.**– The present study aims to highlight the ways involved in the access of EDs patients to specialized care. Furthermore, it investigates differences regarding these pathways between the northern and the southern part of Italy.

**Methods.**– A total of 246 consecutive patients with a DSM-5 diagnosis of EDs were recruited in 8 specialized public centers. Participants into the study were asked to fill in the WHO "Encounter Form", a standardized schedule that allows to collect data regarding basic socio-demographic, clinical and pathways data.

**Results.**– The median time from the symptomatology onset to specialized care was 114 weeks. The most recurring paths of access were general practitioners (25%), psychiatrists (18%) and clinical nutritionists (17%). All patients followed a specific psychotherapy program, while psychotropic drugs were administered to only 11% of them. As shown by the 'pathways diagram', a complex care network distinguishes ED subjects. Moreover, in comparison to previous data on psychiatric patients in Italy, lower rates of direct access to specialized care resulted for patients with EDs. Our findings suggest that general practitioners follow different pathways to refer ED patients. Lastly, significant differences have been shown among centers in northern and southern Italy.

**Conclusions.**– ED people follow a various range of pathways to reach clinical care in Italy: this may suggest new considerations about the progress and the outcomes of EDs. General practitioners and clinical nutritionists should receive suitable educational programs on EDs.  
**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Puerperal irritability as a sign of something more – A cerebral venous thrombosis case

J. Borges Ferreira<sup>1\*</sup>, L. Monteiro<sup>2</sup>, R. Leite<sup>3</sup>, M. Almeida<sup>1</sup>, P. Macedo<sup>1</sup>, N. Carrilho<sup>1</sup>

<sup>1</sup> Centro Hospitalar Baixo Vouga, Department of Psychiatric and Mental Health of Centro Hospitalar do Baixo Vouga, Aveiro, Portugal;

<sup>2</sup> Magalhães Lemos Hospital, Psychiatric Hospital, Porto, Portugal; <sup>3</sup> Centro Hospitalar do Baixo Vouga, Department of Psychiatric and Mental Health, Aveiro, Portugal

\* Corresponding author.

**Introduction.**– Cerebral venous thrombosis (CVT) is an unusual condition that can present itself with a wide range of symptoms. We describe a case of a young woman who has been sent to psychiatric emergency room (ER) for suspected puerperal depression.

**Objectives.**– Highlight the importance of accessing other organic diseases that may mimic psychiatric symptoms through the analysis of a clinical case and a literature review.

**Methods.**– Case report and literature review in scientific databases– Pub Med, Cochrane Library.

**Results.**– We report a case of a suspected puerperal depression in a young woman with a background of depression. The main complaint for the psychiatry ER referral was irritability, lack of energy, sadness and loss of appetite after the delivery, two weeks before. Later she admitted episodic holocraneal headaches with good response to paracetamol. It was possible to ascertain that she had no problem bounding with her baby despite her family was worried about that. In her obstetric report was the information of an accidental perforation of the dura-mater. A CT exam revealed CVT, a relatively rare condition with multiple etiologic factors. The survival rate is 80% and there are several treatment options. The risk of recurrence is low.

**Conclusions.**– CVT in the puerperium is a life threatening complication that needs an early diagnosis and treatment. It has been suggested that lumbar puncture is itself a risk factor. Since CVT can be mistaken for a psychiatric illness it is very important to be aware of this condition.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Comparison of the opioid and non-opioid single substance exposures reporting naloxone therapy using the national poison data system

C. Holstege<sup>1\*</sup>, S. Rege<sup>1</sup>, A.D. Ngo<sup>2</sup>, J. Rizer<sup>1</sup>, S. Sharma<sup>3</sup>, N. Ait-Daoud Tiouririne<sup>3</sup>

<sup>1</sup> University of Virginia, Emergency Medicine, Charlottesville, USA; <sup>2</sup> University of Virginia, Student Health- Division of Student Affairs, Charlottesville, USA; <sup>3</sup> University of Virginia, Psychiatry and Neurobehavioural Sciences, Charlottesville, USA

\* Corresponding author.

**Background.**– Naloxone use has increased as overdose deaths have grown. This study compares the patterns of opioid (OE) and non-opioid exposures (NOE) where naloxone was reported as therapy to the U.S. poison centers (PCs).

**Methods.**– The National Poison Data System (NPDS) was queried for all single substance exposures (SSE) reporting naloxone therapy from 2000 - 2016. We descriptively assessed the demographic and clinical characteristics. Trends in naloxone reports were analysed using Poisson regression.

**Results.**– There were 131,555 SSE naloxone reports, with the calls increasing from 4,038 in 2000 to 12,852 in 2016 despite a drop in PC calls. Both NOE and OE calls demonstrated a rise of 142% and 404%, respectively. The proportion of "Not Recommended but Performed" naloxone reports increased significantly for NOE (57.1% to 78.1%) and OE (55.3% to 80.7%) calls. OE calls had a higher percentage of intentional abuse (11.1% vs 39.2%,  $p < 0.001$ ) and major clinical outcomes (16.1% vs 21.3%,  $p < 0.001$ ). NOE were more common in females (52.9% vs 41.3%,  $p < 0.001$ ) and the proportion of teenagers was greater in this group (12.6% vs 7.6%,  $p < 0.001$ ). The most frequent substances associated with NOE and OE were clonidine and heroin, respectively. The rate (per 100,000 Exposures) of NOE (136.9 to 320.5,  $p < 0.001$ ) and OE (56.3 to 274.8,  $p < 0.001$ ) exposures reporting naloxone therapy increased significantly. West Virginia demonstrated the highest prevalence of naloxone reports for both groups.

**Conclusions.**– There was an increasing trend of naloxone therapy reports without recommendations. OE demonstrated more severe effects, intentional reasons for exposures and older age groups.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Malignant catatonia due to antipsychotics

K.W. Lim

Changi General Hospital, Psychiatry, Singapore, Singapore

\* Corresponding author.

**Background.**– Catatonia is a behavioural syndrome marked by an inability to move normally, which can occur in the context of many underlying psychiatric and general medical disorders. The term catatonia is used to specify a subtype of the underlying disorder, similar to the term “psychotic features”. In the case below, it highlights the importance of identifying symptoms of catatonia for diagnosis and management to avoid further complications.

**Case presentation.**– This is a case of malignant catatonia in a 57-year-old patient who presented with altered mental status over one week. He had a background history of Substance Use disorder and had last taken drugs 2 years ago. During the admission, he was agitated on the 1<sup>st</sup> day. Olanzapine 2.5 mg was served and he calmed down. The following day, he developed fever, GCS dropped to 8 and his vital signs became unstable with fluctuating systolic blood pressure of 180 and above. He displayed mutism, negativism, immobility, rigidity and autonomic abnormalities. IV Lorazepam (1 mg QDS) was introduced and after 2 days he became afebrile and started to respond to verbal commands. His catatonic symptoms gradually improved and resolved on the 4th day.

**Conclusion.**– Early detection of symptoms, diagnosis and intervention with Lorazepam reduced the probability of fatal complications. This case report showed that early physical examination, diagnosis and intervention reduced the occurrence of serious and irreversible outcomes.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Alice in Wonderland Syndrome: A case report

S. Petrykiv<sup>1</sup>, M. Arts<sup>2</sup>, J. Fennema<sup>3</sup>, L. de Jonge<sup>4</sup>

<sup>1</sup> University of Groningen, University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, The Netherlands; <sup>2</sup> Mental Health Care, West Northern Brabant GGZ-WNB, Department of Geriatric Psychiatry and Neuropsychiatry, Bergen op Zoom, The Netherlands; <sup>3</sup> Mental Health Care Friesland GGZ-Friesland, Department of Geriatric Psychiatry, Leeuwarden, The Netherlands; <sup>4</sup> Leonardo Scientific Research Institute, Department of Geriatric Psychiatry and Neuropsychiatry, Groningen, The Netherlands

\* Corresponding author.

**Introduction.**– Alice in Wonderland Syndrome (AIWS) is a rare condition which comprises metamorphopsia, bizarre distortions of their body image, and bizarre perceptual distortions of form, size, movement or color. Currently, a specific cause of AIWS is unknown. The differential diagnosis encompasses infection, cerebral hypoxia, drug toxicity, and psychiatric disease.

**Objectives & aims.**– Case report of a patient experiencing distorted size perception of objects, derealisation and distorted sense of time.

**Methods.**– An English-language literature search was conducted using Pub Med, EMBASE searching for studies reporting symptoms in patients with AIWS.

**Results.**– Mr. H, a 45 years taxi driver, known with a minor depressive disorder and diabetes mellitus type 2. Two weeks after the initiation of therapy with SGLT-2i dapagliflozin 10 mg., 1dd1, while driving a car, he experienced illusory changes in the size, distance, or position of stationary objects in the visual field, which recurred

several times that day. On neuropsychological assessment no other abnormalities were found. Neurologic examination excluded CVA or TIA as possible causes of the visual hallucinations. Remarkably, the records from an insulin pump revealed transient hypoglycemia presenting at time of onset of the hallucinations. After immediate adjustment of glucose levels, the symptoms resolved and after a short clinical admission, the patient was discharged from the hospital.

**Conclusion.**– Our data imply that hypoglycemia is a rare, but important cause of AIWS. All patients with alterations in mental status require immediate bedside capillary glucose testing and rapid correction of blood sugar to prevent persistent neurologic sequelae.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Self-reported levels of agitation

L. Zun<sup>1</sup>, L. Downey<sup>2</sup><sup>1</sup> Mount Sinai Hospital, Emergency Medicine, Chicago, USA; <sup>2</sup>

Roosevelt University, Public Health, Chicago, USA

\* Corresponding author.

**Background.**– The primary objective of this study was to examine and identify methods of assessing levels of agitation in psychiatric patients presenting to the ED, which are not commonly involved with ED triage of psychiatric patients.

**Objective.**– The purpose of this study was to assess psychic pain on a similar rating system as somatic pain, assess levels of agitation (self-reported and observed), and compare measured psychic pain to levels of agitation.

**Methods.**– The sample population included patients, 18 years or older, presenting with a psychiatric illness to a level one inner-city Emergency Department. Patients were surveyed immediately upon arrival to ED and every 30 minutes, for a total of 2 hours using both observational or self-reported surveys. Patients were enrolled and surveys were administered by a research fellow. This study was IRB approved.

**Results.**– A total of 151 participants were enrolled and 93 completed at least 1 hour. Upon arriving to the ED, among patients who self-reported moderate/marked levels of agitation 87.3% were given agitation scores of none/mild with PANSS-EC agitation survey, and 84.4% were given none/mild by ACES calmness evaluation. Self-reported psychic pain showed significant differences from self-reported levels of agitation.

**Conclusions.**– The results show significant differences between the observational surveys and self-reported surveys and amongst the self-reported surveys. The results suggest the use of both observational and varying self-reported surveys to obtain a complete picture of patient levels of agitation and psychic pain on arrival to the ED.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Smoking, drinking and drug consumption attitudes at a Romanian music festival

Z. Abram

University of Medicine and Pharmacy from Targu Mures, Public Health, Targu Mures, Romania

\* Corresponding author.

**Introduction.**– The increasing consumption of different euphoric substances among youth opens new preventive strategies.

**Objectives**– The study of drug consumption and health attitude among the youth makes it possible to know the risk factors that show correlation with health, especially mental health.

**Methods**.– During a Romanian music festival we examined smoking, alcohol consumption and drug usage habits of young participants using a questionnaire method. The collected data were compared with data obtained during other surveys.

**Results**.– The changes of both legal and illegal drug use habits led us to conclude that the same happens in our country as in the western Union countries. The frequency of drug trials grows among the youth, the habits of drug use change, cannabis derivatives and ethnobotanical drugs dominate while the proportion of opiate users is decreasing. The statistics are alarming among music festival participants: 83% of them are smokers, 64% have been drunk more than 10 times and the majority has tried any drug, about 10% of them being frequent users.

**Conclusions**.– Our study emphasises the importance of drug-prevention strategies and concludes the importance of making more effort in order to involve the younger generation in health education programmes.

**Disclosure of interest**.– The authors have not supplied their declaration of competing interest.

EV0340

## Hypochondriasis in adulthood

M. Al-Malmi

Medical Village, Dermatology and Aesthetic Medicine, Dubai, United Arab Emirates

\* Corresponding author.

Hypochondriasis, which is now known as illness anxiety disorder, and the other somatic symptom disorders (e.g., factitious disorder, conversion disorder) are among the most difficult and most complex psychiatric disorders to treat in the general medical setting. On the basis of many new developments in this field, the DMS 5 has revised diagnostic criteria to facilitate clinical care and research. While illness anxiety disorder is included in the category of “somatic symptom and related disorders” it continues to have much overlap with obsessive-compulsive disorder and related illness.

**Objective**.– To identify the phobia and anxiety from the disease. Patients and methods many adulthood patients with different diseases were evaluated

**Results**.– The clinical data and investigations were dealing with suffering from hypochondriasis

**Conclusions**.– Hypochondriasis is very common psychological disorder in adulthood.

**Disclosure of interest**.– The authors have not supplied their declaration of competing interest.

## Doctors' attitudes toward becoming mentally ill in Saudi Arabia: Disclosure and treatment preferences

N. Alhomayed<sup>1</sup>, A. Alhadi<sup>2</sup>, A. Alsuhaibani<sup>1</sup>, A. Alwehaib<sup>1</sup>, H. Alaskar<sup>1</sup>, A. Alaman<sup>1</sup>, T. Hassan<sup>3</sup>

<sup>1</sup> King Saud University, college of Medicine, Riyadh, Saudi Arabia; <sup>2</sup> King Saud University, Psychiatry, College of Medicine, Riyadh, Saudi Arabia; <sup>3</sup> Queen's University, Psychiatry, Kingston, Canada

\* Corresponding author.

**Background**.– Psychiatric illness turns out to be a global concern among doctors. Comparing to a general population doctors are at high risk of developing mental illness. The purpose of our study is to evaluate doctors' attitudes to disclosure and treatment preferences

if they were to develop mental illness, and identify the impact of some factors that might influence the construction of their attitude

**Method**.– A quantitative observational cross-sectional study was carried out at College of Medicine –King Saud University. This study included All physicians of various Specialties who work in Saudi Arabia. A self-administered online questionnaire sent via SMS to 90,000 physicians and 823 responds till now. As the survey is still ongoing.

**Results**.– Nearly 572 (71.5%) of respondents agreed that the incidence of psychiatric illness among doctors is higher than the general population. The majority of those who reported that they have experienced a mental illness were residents (64.3%). Respondents would initially disclose their mental illness to a psychiatrist (45.5%). The most influencing factors on disclosure preference are career implications. In respect to the treatment preferences nearly half of respondents (52.8%) would choose an informal professional advice in case of an out-patient treatment. Those who chose an informal advice they haven't experienced a mental illness. In case of developing mental illness requiring in-patient treatment, the majority would select an out of area mental health facility 457(57.1%), their choice is affected by the issues of confidentiality.

**Conclusions**.– Physicians' showed positive attitudes besides the awareness of the high incidence of mental illness among themselves (Figures 1, 2, 3).

### Duration of untreated illness and its impact on social and personal functioning amongst schizophrenia spectrum patients in a rural region of Latvia

L. Berze<sup>1\*</sup>, K. Slikova<sup>1</sup>, K. Pavlovs<sup>1</sup>, S. Kikuste<sup>2</sup>, I. Sapele<sup>2</sup>, V. Bodins<sup>2</sup>, J. Zile<sup>2</sup>, I. Samule<sup>2</sup>, E. Rancans<sup>1</sup>

<sup>1</sup> Rigas Stradins University, Department of psychiatry and addiction medicine, Riga, Latvia; <sup>2</sup> Daugavpils Psychoneurological hospital, Psychiatry, Daugavpils, Latvia

\* Corresponding author.

*Introduction.* – It is a worldwide tendency to shorten the duration of untreated illness for better clinical and social outcomes.

*Objectives.* – Evaluate the duration of untreated illness and its impact on social and personal functions.

*Methods.* – Sociodemographic and clinical data, including Duration of untreated illness (DUI), were collected from all consecutive first time hospitalized schizophrenia spectrum patients in a psychiatric hospital from 01.01.2016.- 01.09.2017. The study was approved by the Riga Stradins University Ethics committee. Statistical analysis was performed using SPSS 20.0 for IMB.

*Results.* – From 86 first episode patients, 66 (36 men and 30 women) met the inclusion criteria. Patient age was Me 34.0 y. (IQR 28.0-46.0), the DUI was Me 24 month (IQR 4.0-36.0). Time spent in hospital was Me 21.0 days (IQR 13.0-28.0). 68.7% were unemployed 49.3% lived with their family members, 40.3% lived with their partner/spouse. 55.2% had not seen any specialist in relation with this problem before. Help seeking behaviour in psychiatric ER: 10.4% of patients came by themselves, 32.8% were accompanied by family members, 32.8% brought by ambulance, 22.4% brought by ambulance and police. A longer DUI was observed in connection with unemployment status ( $p=0.049$ ), for living with their relatives or by themselves ( $p=0.035$ ) and not having relationships ( $p=0.018$ ). The patients who had established their own families spent less time in hospital than those who lived with relatives ( $p=0.039$ ).

*Conclusions.* – There is strong evidence that patients in this rural region already have impaired social and personal functions before starting treatment of their schizophrenia spectrum disorders.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Stigma-discrimination related to mental disorders among Colombian students

A. Campo-Arias<sup>1\*</sup>, G.A. Ceballos-Ospino<sup>2</sup>, H. Edwin<sup>3</sup>

<sup>1</sup> University of Magdalena, School of Medicine, Santa Marta, Colombia; <sup>2</sup> University of Magdalena, School of Psychology, Santa Marta, Colombia; <sup>3</sup> Human Behavioral Research Institute, Department of Researches and Publications, Bogota, Colombia

\* Corresponding author.

*Background.* – Stigma-discrimination related to mental disorders (SDRMD) is highly frequent around the world, regardless of age and academic school level. However, there is very little information about SDRMD in Colombian students.

*Objective.* – To estimate the prevalence of SDRMD among middle- and high-school students in Santa Marta, Colombia.

*Method.* – A cross-sectional study was conducted. A sample of middle- and high-school students from one State school. The SDRMD was measured with the Reported and Intended Behaviour Scale (RIBS). The RIBS has two components, each one compounds of four items. The first component quantifies frequencies of experiences and the second one, explores attitudes towards mental disorders SDRMD. Scores for SDRMD range to four to twenty. The cut-point was twelve, thirteen or more suggested high SDRMD. Logistic regression was computed to establish association and control confounding variables.

*Results.* – A total of 350 students with ages between 10 and 17 years ( $M=13.3$ ,  $SD=1.8$ ), 188 (53.7%) students were girls and 162 (46.3%) were boys; and 236 (67.4%) were middle-school students. Scores for SDRMD were between four and twenty, mean=10.8 ( $SD=4.0$ ), a group of 99 students (28.3%) referred high SDRMD. The RIBS showed high internal consistency (Cronbach alpha 0.88). High SDRMD was associated with older age ( $OR=1.66$ , 95%CI 1.08-2.54) and male sex ( $OR=1.65$ , 95%CI 1.02-2.65), after adjusting for grade (Hosmer-Lemeshow chi squared=8.5,  $df=7$ ,  $p=0.28$ ).

*Conclusions.* – Nearly three of ten students present high SDRMD, this more prevalent among males and older students. It is needed to investigate SDRMD in other Latino-American populations.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Ethnic density associations for mental health: Systematic Review and meta-analysis of international studies

J. Das-Munshi<sup>1\*</sup>, M. Dewey<sup>2</sup>, L. Becares<sup>3</sup>

<sup>1</sup> King's College London Institute of Psychiatry, Psychology & Neuroscience, Health Services & Population Research, London, United Kingdom; <sup>2</sup> KCL, Department of Health Services Research & Population Sciences, London, United Kingdom; <sup>3</sup> University of Manchester, Cathie Marsh Institute of Social Research, Manchester, United Kingdom

\* Corresponding author.

*Background.* – Despite increased ethnic diversity in more economically developed countries it is unclear whether residential concentration of ethnic minority people (ethnic density) is detrimental or protective for mental health. This is the first systematic review and meta-analysis covering the international literature, assessing ethnic density associations with mental health outcomes.

**Methods.**– We systematically searched Medline, PsychInfo, Sociological Abstracts, Web of Science from inception to March 31<sup>st</sup>, 2016. We obtained additional data from study authors. We conducted random effects meta-analysis taking into account clustering of estimates within datasets. Meta-regression assessed heterogeneity in studies due to ethnicity, country, generation and area-level deprivation. Our main exposure was ethnic density, defined as the residential concentration of own racial/ethnic minority group. Outcomes included depression, anxiety and the common mental disorders (CMD), suicide, suicidality, psychotic experiences and psychosis.

**Results.**– We included 41 studies in the review, with meta-analysis of 12 studies. In the meta-analyses, we found a large reduction in relative odds of psychotic experiences (OR:0.82(95% CI:0.76-0.89) and suicidal ideation (OR:0.88(95% CI:0.79-0.98) for each 10 percentage-point increase in own ethnic density. For CMD, depression and anxiety, associations were indicative of protective effects of own ethnic density however results were not statistically significant. Findings from narrative review were consistent with those of the meta-analysis.

**Conclusions.**– The findings support consistent protective ethnic density associations across countries and racial/ethnic minority populations as well as mental health outcomes. This may suggest the importance of the social environment in patterning detrimental mental health outcomes in marginalized and excluded population groups.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Social issues cause admissions at psychiatric emergency service**

N. Garrido-Torres<sup>1\*</sup>, J. Piedra Cristobal<sup>2</sup>, M.P. Cordero Ramos<sup>3</sup>

<sup>1</sup> Hospital Juan Ramón Jiménez, Psychiatry, Seville, Spain; <sup>2</sup> La Palma del Condado Mental health unit, Social work, Huelva, Spain; <sup>3</sup> Center for treating addictions. Polígono Sur, Addictions, Seville, Spain

\* Corresponding author.

Social workers in mental health should work closely with individuals suffering from complex and hard to manage conditions, who are in deep emotional distress and/or who may be a danger to themselves or others.

**Objective.**– Determine the prevalence of admissions due to social problems at psychiatric emergency room.

**Method.**– Data on 176 consecutive admissions visited in a psychiatric emergency room of a general teaching hospital during a period of one year were analysed to determine the type of diagnosis and to examine the relationship between mental health problem and social problem at emergency service.

**Results.**– The different type of diagnosis were separated in 6 groups: psychosis, depression and anxiety, suicidal behaviour, dual diagnosis, personality disorders, social diagnosis. Even when social issues were present in 95% (167) of the cases, the admissions due to social issues exclusively were 13% (22). There is a positive and very strong association between social issues and dual diagnosis and social issues (homeless) and psychosis

**Conclusions.**– A social worker at emergency room should be considered as a liaison between psychiatrist, mental health nurses and patients.

The mental health Social worker should be trained in mental health issues specially illegal drug abuse and psychosis

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0346

### **Epidemiological profile of newly admitted psychotic patients in psychiatry**

R. Jouini<sup>\*</sup>, M. Karoui, L. Robbana, K. Ben Salah, F. Ellouze, F. Mrad Razi Hospital, Psychiatry G, Tunis, Tunisia

\* Corresponding author.

**Introduction.**– Psychiatric hospitalization, when indicated, provides a safe environment for patients with acute mental disturbance.

**Objective.**– This study aims to describe the epidemiological profile of patients with schizophrenia and other psychotic disorders (DSM 5) and to set up a comparison between their characteristics and the rest of the patients.

**Methods.**– A retrospective descriptive and comparative study including all newly admitted patients ( $n=240$ ). We examined demographic and clinical characteristics and we established a comparison based on the psychiatric diagnosis.

**Results.**– The average age of patients with psychotic disorder was 34 years. The majority of patients with psychotic disorder were male (61, 6%), single (72, 1%) and unemployed (59,1%). The mean duration of untreated illness was more important in patients with psychotic disorder. The mean duration between the onset of the illness and the hospitalization was more important in patients with psychotic disorder. Hospitalization modality was in 93, 6% of the cases an involuntary confinement in patients with psychotic disorder. Physical restraint was used in 21, 1% of patients with psychotic disorder and only in 8, 1% of the rest of the patients. Antipsychotics were more prescribed in the group of patients with psychotic disorder. The duration of parenteral treatment was longer in patients with psychotic disorder and the mean duration of hospitalization was more important in the same group. Almost 85% of the psychotic patients attended the first follow up visit.

**Conclusion.**– Analyzing clinical and socio-demographic characteristics of newly admitted patients enables the improvement of medical care and thus prognosis optimization.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Kendo form of martial arts as an adjunct to mindfulness, stress reduction training**

E. Koprowski

Georgetown University, Georgetown Neuro-Psychoanalysis Society/NSPA Regional Group, Chicago, USA

\* Corresponding author.

**Introduction.**– A number of recent studies have shown the general effectiveness of martial arts on stress response and reduction and mindfulness training [1,2,3]. None of these reports have investigated kendo, a prominent form of martial arts in Japan, and increasingly Europe and the U.S., whose primary emphasis is on concentration and mindfulness. Kendo practitioners concentrate on Zen-breathing, aesthetic footwork, and making precision strikes with a safe bamboo, leather, and styrofoam practice sword on three prescribed points on the target, symbolizing the head, wrist, and ribs, rather than making wild kicks, punches, or throws, as in karate, tae kwon do, etc.

**Conclusion.**– This suggests psychiatric epidemiology and social psychiatry research on that unique form of martial arts may offer new psychological insights for group-or-individual based mindfulness training, or as an adjunct to mindfulness training, and related therapeutic modalities, like Chinese tai chi [4].

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### A Review of dromomania or travel fugue: A revisit of the celebrated case of Jean-Albert Dadas

S. Kumar

Mersey Care NHS Foundation Trust, Department of Adult Psychiatry, Liverpool, United Kingdom

\* Corresponding author.

The primary aim of the poster is to study in detail the case of Monsieur Jean-Albert Dadas from Bordeaux. Monsieur Dadas for the first time to have a diagnosis of Dromomania or Travel Fugue. This explorative poster shall look into the background, context, formulation and presentation of Monsieur Dadas in the late 20th century, when he famously travelled on foot through various countries in Europe before being admitted to a hospital in France without any recollection of his travels, and was eventually diagnosed of Dromomania for the first time.

The Poster further explores a literature search to seek out any similar diagnoses or presentation known or published in the scientific world. The paper will conclude with a commentary on the relevance and validity of the diagnosis in the present day world.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Impact of fathers' prenatal mental health on children's aggressive behavior

A.L. Kvalevaag<sup>1\*</sup>, J. Aßmus<sup>2</sup>, E. Biringer<sup>1</sup>

<sup>1</sup> *Haugesund Sykehus, Department of Research and Innovation Helse Fonna HF, Haugesund, Norway;* <sup>2</sup> *Center for Clinical Research, Haukeland University Hospital, Bergen, Norway*

\* Corresponding author.

**Introduction.**– Previous studies have found an association between paternal prenatal psychological distress and children's social, emotional and behavioural development.

**Objectives.**– This study explored the association between fathers' prenatal mental health and children's aggressive behaviour (hitting others) with regard to:

– age dependence of the association;

– moderating effect of children's temperament on the association.

**Methods.**– This study is based on data from the Norwegian Mother and Child Cohort Study, Norwegian Institute of Public Health. Fathers' mental health in pregnancy was assessed by SCL-5. Children's temperament was measured by four summary scales (Emotionality, Activity, Shyness and Sociability) representing 12

of the original 20 items of the EAS Temperament Survey. The association between fathers' SCL-5 in pregnancy and children's hitting at age 18 months, 3 and 5 years was investigated in linear mixed effects models. To assess the moderating effect of children's temperament on the association between fathers' SCL-5 and children's hitting, the model was adjusted for children's temperament.

**Results.**– Hitting decreased from 18 months to 5 years independently of fathers' SCL-5 while it increased from 18 months to 3 years depending on fathers' SCL-5 (interaction time x SCL-5, B=0.046, 95% CI=(0.01,0.08)). Adjustment for children's temperament did not affect the association between fathers' SCL-5 and change in hitting (adj. interaction time x SCL-5, range B=0.042-0.048 for the four temperament sub-scales).

**Conclusion.**– Fathers' prenatal mental health is associated with change in children's hitting from 18 months to 3 years of age independently of children's temperament.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Diagnosis and gender prevalence in an adult psychiatric ward in UK: A meta-analysis

C. Lazzari<sup>\*</sup>, A. Shoka, K. Gower, B. Papanna, G. Mousailidis

Essex Partnership University NHS Foundation Trust, United Kingdom, Kingswood Centre, Colchester, United Kingdom

\* Corresponding author.

**Introduction.**– The current trend in United Kingdom is an increased prevalence of female patients admitted into non-forensic adult psychiatric wards with a diagnosis of Borderline Personality Disorder. **Objectives.**– To assess diagnoses and gender prevalence at admission in a general adult psychiatric ward in Essex, United Kingdom.

**Methods.**– The electronic records of a total of 244 discharges were examined for prevalence of diagnosis and gender in the period of 2016–2017. Meta-analysis measured the heterogeneity in proportions of the groups analysed. Gender proportions were investigated by the N-1 Chi-square test.

**Results.**– A total of 67.21% of female and 32.78% of male admissions were recorded with statistically significant heterogeneity at meta-analysis ( $I^2 = 98.33\%$ ;  $p < 0.001$ ) (N-1 Chi-sq difference = 34.43%;  $p < 0.001$ ). Additionally, the most prevalent diagnoses (Figure 1) were: personality disorder (38.24%), paranoid schizophrenia (12.44%), schizoaffective disorder (6.9%), bipolar affective disorder (3.6%), and other diagnoses (38.61%). Moreover, in this case, a statistically significant heterogeneity ( $I^2 = 97.69\%$ ;  $p < 0.001$ ) was found within diagnoses.

**Conclusions.**– Our study shows a prevalence of admissions of female patients with personality disorder, mostly borderline personality.

### Ethnic minority position and migrants status as risk factors for psychotic experiences in the general population: A meta-analysis

E. Leane<sup>1\*</sup>, J. Brunelin<sup>2</sup>, E. Poulet<sup>2</sup>, M.J. Dealberto<sup>3</sup>, S. Grot<sup>4</sup>, D. Luck<sup>4</sup>

<sup>1</sup> Centre Hospitalier le Vinatier, Service Hospitalo-Universitaire, BRON CEDEX, France; <sup>2</sup> Centre Hospitalier le Vinatier, PsyR2 Team, Bron, France; <sup>3</sup> Centre Hospitalier Saint Jean de Dieu, Service Louise Labé, Lyon, France; <sup>4</sup> Institut Universitaire en Santé Mentale de Montréal, Groupe d'Etude en Emotion et Cognition, Montreal, Canada  
\* Corresponding author.

Psychotic experiences (PEs) are common among the general population and may exist on a continuum with psychotic disorders. Unfavorable socio-environmental conditions may increase the risk to develop PEs. Despite a consequent emerging literature, the respective role of ethnic minority position (EMP) and migrant status (MS) in the development of PEs remain unclear. In the current study, we aimed to investigate the role of EMP and MS in the development of PEs.

We conducted an electronic systematic review and a meta-analysis assessing the role of EMP and MS for PEs in the general population. Sub-group analyses were performed investigating the influence of ethnic groups, host countries, age, types of PEs and scales assessing PEs on the occurrence of reporting PEs.

A total of twenty-two studies met our inclusion criteria for meta-analysis. EMP was a relevant risk factor for reporting PEs (OR= 1.44,  $p < 0.0001$ ) in high incomes country, whereas migrant status was not associated with increased risk (OR= 1.08,  $p = 0.603$ ). Results differed across ethnic groups and within countries. The greatest risk was observed in people from Maghreb and Middle East in Europe (OR= 3.30;  $p < 0.0001$ ), Hispanic (OR= 1.98;  $p < 0.0001$ ) and Black population in the US (OR= 1.85;  $p < 0.0001$ ).

EMP is a relevant factor associated with increased risk of reporting PEs, the risk being higher in more deprived and discriminated ethnic groups. However, MS is not associated with an increased risk for PEs, raising question about the precise role of socio-environmental factors along the psychosis continuum.

### Coordination programme with primary care

B. Mata Saenz<sup>\*</sup>, I. Diaz Quero, L. Asensio Aguerri, L. Nuevo Fernandez

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

\* Corresponding author.

*Introduction.*– Primary care's the first point of attention of population. That's why coordination is an important aim both improving the referrals and adapting to their needs. We have developed a coordination programme based on a direct telephone number to consult anything, visits to the primary care centres and a system of preferent referrals.

*Objectives.*– To analyse the phone calls from primary care and the preferent referrals attended.

*Methods.*– This is an epidemiological, analytic, prospective study of patients referred to our department included in the coordination programme. The following variables were collected: (1) reason, (2) demographic data, (3) attendance to appointment, (4) diagnosis impression and (5) destination of referral. The SPSS 19.0 was used to analyze the data.

*Results.*– We have used the data obtained during four months in which we have visited 15 of the 19 primary care centres of our area. We have received twenty phone calls and 11 preferent referrals. The phone calls were from 12 different centres (7 from the same city where our unit is. 45% were due to unbalanced patients). In 45% of the calls, the solution was given in the same call. In the preferent referrals, the waiting list on average was 4.27 days (standard deviation 3.228). 36.4% of patients had a depressive disorder with suicide ideation. 90.9% of patients were followed-up after this. *Conclusions.*– To continue to develop the programme is necessary. Until now, it's being considered very well among primary care professionals and it's avoiding referrals to the emergency room and hospitalizations.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Description of a sample of patients referred to a mental health unit from primary care

B. Mata Saenz<sup>1\*</sup>, E. Lopez Lavela<sup>2</sup>, L. Asensio Aguerri<sup>1</sup>, V. Muñoz Martínez<sup>1</sup>, L. Beato Fernandez<sup>1</sup>

<sup>1</sup> Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain; <sup>2</sup> Hospital La Mancha Centro. USM Tomelloso, Psychiatry, Tomelloso, Spain

\* Corresponding author.

*Introduction.*– We consider important to know the characteristics of the referrals we have. In this way, we can plan our attention according to our environment. The main origin of these referrals is primary care.

*Objective.*– To analyse the demand from primary care to know how this population is.

*Methods.*– This is an epidemiological, analytic, prospective study of patients referred to our department. The following variables were collected: 1) referral protocol, 2) reason, 3) demographic data, 4) attendance to appointment, 5) diagnosis impression and 6) destination of referral. The SPSS 19.0 was used to analyze the data.

*Results.*– The total of patients were 1503, attended between 1st July 2015 and 31st July 2017. We summarize in the next table the main characteristics (Table 1):

Table 1.

Average age	48.53 (standard deviation 18.09)	Gender	Females 60.1%
Nationality	Spanish 95.4%	Origin	Rural 60.7%
Psychiatry history	46.8%	Didn't finish their follow-up	82.1%
Show-up for their visit	75.4%	Adequacy of the demand	55.7%

The most often main diagnoses were adaptative disorder (29.2%), depressive disorder (18.4%) and anxiety disorder (12%). The variables related to patients who didn't come to the visit were: being referred from a little centre (chi square 9.556,  $p < 0.05$ ) and the type of referral (chi square 18.664,  $p < 0.001$ ). The nationality tends to be related but it isn't.

*Conclusions.*– To know the characteristics of patients referred is important to us for adapting our Unit to this reality and improve the attention and the assistance.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0354

### Analysis of patients referred to our unit after having been discharged

B. Mata Saenz<sup>1\*</sup>, L. Asensio Aguerri<sup>1</sup>, E. Lopez Lavela<sup>2</sup>, T. Rodríguez Cano<sup>3</sup>

<sup>1</sup> Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain; <sup>2</sup> Hospital La Mancha Centro. USM Tomelloso, Psychiatry, Tomelloso, Spain; <sup>3</sup> Servicio de Salud Castilla La Mancha, Mental Health, Toledo, Spain

\* Corresponding author.

**Introduction.**– Nowadays, the enormous number of patients referred to our Unit is a great problema. We can't give them a good service if we don't apply a criteria to decide who can be followed-up by Primary Care and who needs a specialised attention.

**Objectives.**– To analyse the characteristics related to patients referred to our Unit from Primary Care after having been discharged.

**Methods.**– This is an epidemiological, analytic, prospective study of patients referred to our department. The following variables were collected: (1) referral protocol, (2) reason, (3) demographic data, (4) attendance to appointment, (5) diagnosis impression and (6) destination of referral. The SPSS 19.0 was used to analyze the data.

**Results.**– The total of analyzed patients were 1503, referred between 1st July 2015 and 31st July 2017. Of these ones, 75.4% attended to our Unit. 38.3% were discharged on their first appointment. 12.1% were discharged on their second or third appointment. This means 571 patients. 7.4% of the first group (the ones who had been discharged on their first visit) were referred again from Primary Care versus 4.4% of the second group. 38.2% of these patients were referred again for worsening of the same disease. 54.5% of the total ones referred continued to be followed-up in our Unit.

**Conclusions.**– The amount of patients who were discharged on their first visit and the next 2-3 ones, and after being referred again make necessary coordination with Primary Care. It's important homogenizing the criteria for referral and discharge to avoid longer waiting lists.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Analysis of the sample of patients with severe mental disease of our unit: Demographic and clinical characteristics

B. Mata Saenz<sup>\*</sup>, A. Ramírez García, I. Díaz Quero, F. García Lázaro, I. Morales Saenz

Hospital General Ciudad Real, Psychiatry, Ciudad Real, Spain

\* Corresponding author.

**Introduction.**– Patients with mental health disease continue to be the aim of specialist attention in Psychiatry. To be able to help them properly is going to depend on knowing the characteristics of this population in our area.

**Objectives.**– To analyse the clinical and demographic variables of the sample composed by the patients with severe mental health disease in our area.

**Methods.**– This is an epidemiological, analytic, retrospective study of patients followed in our department who are included in severe mental disease programme. The following variables were collected: (1) demographic data, (2) use of substances (in the past and nowadays), (3) attendance to appointment and compliance, (4) diagnosis impression, (5) regular psychiatrist and other professionals related to the patient, (6) residential devices, (7) pharmacological treat-

ments, (8) number of admissions. The SPSS 19.0 was used to analyze the data.

**Results.**– We summarize the main variables in this table 1:

**Conclusions.**– It is necessary to design a programme for patients with severe mental health to improve their treatment (multi-professional attention included) and compliance. It's very significant the high percentage of patients without data about SUD collected.

Table 1

n	437	Gender	61.6% males
Age	50.41 (standard deviation 14.732)	Origin	41.2% urban
Diagnosis	schizophrenia 44.2%; bipolar disorder 24.7%; schizoaffec-tive 12.6%; delusional disorder 8.5%; not otherwise specified psychotic disorder 5.9%; schizotypal 4.1%	History of substances use disorder (SUD)	unknown 39.6%; yes 37.8%
Actual SUD	unknown 41.6%; no 24%	Attendance	82.6%
Compliance	92%	Number of admissions	1.71 (standard deviation 2.723)

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Pathways to psychiatry care, disability profile of patients, perceived stigma of psychiatric outpatients and caregivers: A tertiary care hospital based study

D.K. Mohinder Singh<sup>1\*</sup>, R. Wadke<sup>2</sup>, R. Ghildiyal<sup>3</sup>

<sup>1</sup> Mahatma Gandhi Missions Medical College, Navi Mumbai, Maharashtra, India, Department of Psychiatry, Mumbai, India; <sup>2</sup>

Mahatma Gandhi Missions Medical College, Navi Mumbai, Maharashtra, India, Department of Community Medicine, Navi Mumbai, India; <sup>3</sup> Mahatma Gandhi Missions Medical College, Navi Mumbai, India, Department of Psychiatry, Navi Mumbai, India

\* Corresponding author.

**Introduction.**– There is sparse literature on pathways to care, disability profile and perceived stigma among psychiatric outpatients and caregivers from developing countries.

**Objectives.**– To assess specific pathways to care, disability profile of patients and stigma experienced by patients and caregivers and explore demographic and correlation factors.

**Methodology.**– This was an observational cross-sectional survey conducted at Psychiatry Outpatient Department at a tertiary care hospital in India. Clinically stable adult patients on regular medications for at least 6 months and willing to participate were included in the study and were assessed using the data collection form and valid and reliable scales such as Sheehan Disability Scale and

Perceived Social Stigma scale. Institutional Ethics clearance was obtained. Data of 50 patients and 50 caregivers was analysed using appropriate tests with SPSS.

**Results.**– Patients were predominantly females (57.4%) from rural areas (80.3%) with mean age of 35.85 years and caregiver profiles were predominantly females (61.7%) with wives (23.3%) being the most common caregiver. Psychiatric profiles of patients were psychoses (36.67%), anxiety disorders (36.67%), mood disorders (23.33%), and substance use disorders (2.33%). Majority were referred by medical professionals (24.6%). 18.2% of patients had contacted faith healers in the past 1 year. Alarming levels of disability (scores >5) were seen in 60.7% of patients. Mean number of days lost at work were 2.75 in the preceding week before consultation. There were statistically significant associations ( $p < 0.05$ ) between total scores of Disability and Perceived stigma in patients and caregivers. **Conclusion.**– Our study has relevant clinical and social implications. **Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Disclose or conceal a diagnosis of severe mental illness? Results from Tunisian studies

U. Ouali<sup>\*</sup>, L. Jouini, Y. Zgueb, R. Jomli, F. Nacef Razi Hospital, Psychiatry A, La Manouba, Tunisia

\* Corresponding author.

**Introduction.**– In Tunisia, as in other countries around the globe, the stigma attached to mental illness (MI) prevents many people from disclosing their diagnosis.

**Objective.**– To explore the frequency of concealment and the opinions about concealment of diagnosis in two Tunisian patient samples

**Methods.**– We present the results of two cross-sectional studies: one conducted in 104 patients with severe MI (Schizophrenia and bipolar disorder) with the help of a self-established questionnaire exploring opinions about mental illness stigma, the other one conducted in 82 bipolar patients who were evaluated by the Discrimination and Stigma Scale (DISC-12). Socio-demographic and clinical data was recorded.

**Results.**– In the sample of patients with severe MI, 60% thought MI should be hidden from any future employer, and MI needs to be concealed to protect the family reputation. On the other hand, 70% would try to explain their MI to their future spouse before getting engaged. Patients stated that a large majority of siblings and parents was aware of the MI, but only about 80% of spouses, 80% of close friends, 66% of colleagues at work and 45% of employers. In the bipolar patient sample, 58,5% of patients reported concealing their diagnosis of MI.

**Conclusion.**– A majority of Tunisian patients with severe MI apprehend disclosing their diagnosis of MI. Public interventions targeting the stigma of MI as well as psychoeducational measures for patients and their families are necessary to alleviate the fear of disclosure.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0359

### Stigma in Indian patients with depressive disorder: A pilot study

B.N. Patra<sup>\*</sup>, Y.P.S. Balhara, V. Patil, S. Khandelwal All India Institute of Medical Sciences AIIMS- New Delhi, Department of Psychiatry, New Delhi, India

\* Corresponding author.

**Introduction.**– Depression has been expected to be second leading cause of disability by 2020. However, one of the barriers to effective care is stigma associated with having a mental disorder. Stigma is defined as a characteristic which individuals possess (or are believed to possess) that conveys an identity, which is devalued in a particular social context. There has been under-representation of depressive disorders.

**Objectives.**– To study the stigma experienced by the patients with depressive disorders

**Methods.**– Thirty patients diagnosed to have depressive disorder as per ICD-10, attending the psychiatry OPD of a tertiary care hospital were recruited by convenient sampling. To measure the stigma, the Discrimination and Stigma Scale -12 (DISC-12) was applied. It contains 4-sub scales i.e. unfair treatment, stopping self, overcoming stigma and positive treatment. The severity of depression was determined by applying Hamilton Depression Rating Scale (HAMD). **Results.**– The total number of sample collected was 30. The mean age of the patients was 33.87 years, mean duration of illness was 14.8 months. The mean HAMD score was found to be 13.87. Mild depression was present in 10%, Moderate depression in 63.3% and severe depression was present in 26.7% of the patients. The mean total score for unfair treatment is found to be 2.7, stopping self is 2.6, overcoming stigma is 2.7 and positive treatment is found to be 2.1.

**Conclusion.**– Stigma in patients with Depressive Disorders was found to be lower in Indian setting.

**Funding.**– This study has been funded by intramural research grant, AIIMS, New Delhi, India.

**Conflict of interest:**

This study has been funded by intramural research grant, AIIMS, New Delhi, India

### **Perception about the law of victims and guarantees in Colombian displaced persons**

K. Perez-Correa<sup>1\*</sup>, W. Salas-Picon<sup>2</sup>, R. Ferrel-Ortega<sup>1</sup>

<sup>1</sup> Universidad Cooperativa de Colombia, Facultad de Psicología, Santa Marta, Colombia; <sup>2</sup> Universidad Cooperativa de Colombia, Facultad de Psicología, Barrancabermeja, Colombia

\* Corresponding author.

**Introduction.**– For Shultz et al. (2014) the process of displacement of Colombia differs from others in the world, where the return to the origin community is almost non-existent in the population. The displaced are vulnerable facing literacy, extreme poverty and stigmatization.

**Objective.**– To characterize a sample of systematized displaced persons in the Registro Único de Víctimas (RUV).

**Method.**– Were participated  $n = 1139$  displaced persons distributed in 5 Colombian cities; the design was cross-sectional and a socio-demographic instrument was completed which included questions on compensation, assistance and restitution, guarantee of non-repetition and rehabilitation. The data were analysed through descriptive statistics.

**Results.**– The participants stated to a greater extent that they had received compensation (a third of them so indicated). By far the satisfaction measure (one-fifth part) is followed, and to a lesser degree, they recognize assistance and restitution. Attention, guarantee of non-repetition and rehabilitation appear in very few cases.

**Discussion.**– It should be noted that despite of the fact that efforts have been made in Colombia to address the victims and the Victims and Land Restitution Act (2011) has been launched, which seeks to restore the physical and psychosocial conditions of the victims. Populations affected by violence, however, these do not affect the decrease, much less the disappearance of the trauma.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Noticed aggression in the media in the field of healthcare and especially psychiatry in Slovenia**

A. Plemenitas

University Medical Centre Maribor, Department of psychiatry, Maribor, Slovenia

\* Corresponding author.

Aggression is hostile, injurious, or destructive behaviour or outlook often caused by frustration. According to hospital reports aggression of patients and their relatives in healthcare and psychiatric settings is growing in time. Aggression in the medical environment can take on different forms and threatens the well-being and safety of staff members as well as patients. Nowadays, many people can express their experience, thoughts and feelings in media that strongly influence public opinion. Therefore, media can be misused which can lead to additional stigmatisation in psychiatry. We are going to present a content review of noticed aggression in healthcare and psychiatry in written media in Slovenia. We will follow most widely read newspapers and magazines published in Slovenia during a one-year period and we will label the content as neutral, positive or hostile. We will focus on potential misuse or negative impact of the media on healthcare professionals and on the public image of healthcare and psychiatry in Slovenia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Emotional neglect in childhood predicts perceived negative attitude of others in adulthood**

R.K.R. Salokangas\*, T. From, S. Luutonen, J. Hietala

University of Turku, Department of Psychiatry, Turku, Finland

\* Corresponding author.

**Purpose.**– The attachment theory suggest that childhood adverse and trauma (CAT) experiences can have an effect on the way how individuals perceive other people and their attitude towards them. We hypothesised that CAT experiences associate with perceived negative attitude of others (AoO) in general population.

**Material and methods.**– Altogether, 692 participants drawn from the general population completed a mailed questionnaire, including the Trauma and Distress Scale (TADS), a visual analog scale with questions: "What kind of attitude other people take towards you?" and self-repot scales on close relationships (confidants), health, functioning, use of alcohol, drug abuse, depressive, psychotic and manic symptoms.

**Results.**– Males, single and divorced, unemployed and the individuals with low education, few confidants, drug abuse, poor health and functioning reported negative AoO more often than others. Negative AoO associated significantly also with psychiatric symptoms, sum of CAT experiences and separately with emotional and physical abuse and emotional and physical neglect. In multivariate analysis, female gender, age and number of confidants predicted with positive, while poor health, depressive and psychotic symptoms and sum of CAT experiences negative AoO. From the CAT domains, only emotional neglect predicted specifically negative AoO.

**Conclusions.**– Childhood adverse and trauma experiences as a whole seem to have a negative effect on the way how adult individuals perceive other people's attitude towards themselves. From the individual CAT domains, emotional neglect predicts specifically perceived negative AoO.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### School-based anti-stigma intervention: Results from an Italian pilot study

G. Sampogna<sup>1</sup>, B. Pocaï, M. Luciano, V. Del Vecchio, C. De Rosa, V. Giallonardo, M. Savorani, G. Borriello, A. Fiorillo  
 University of Naples SUN, Department of Psychiatry, Naples, Italy

\* Corresponding author.

**Introduction.**– Adolescence is a critical time for attitude change. Early implementation of anti-stigma programmes for increasing knowledge of mental disorders may encourage young people's timely help-seeking, promote social inclusion and positively impact on adult behaviours in relation to stigma. Only a few anti-stigma programmes have been implemented in youth population in Italy, the country with the longest experience of social inclusion of patients with severe mental illnesses.

**Objectives.**– (1) To implement an education and contact-based anti-stigma intervention in secondary high schools in Naples; (2) to evaluate the effectiveness of the intervention in terms of improvement of mental health knowledge; reduction of stigmatizing behaviours and attribution styles.

**Methods.**– The education and contact-based anti-stigma intervention consists of two 60-minute sessions. The study has been carried out in 3 high schools in the catchment area of Naples. All participants have been requested to complete: the Mental Health Knowledge questionnaire; the Reported and Intended Behavior Scale; the Attribution Questionnaire-9 items version. All questionnaires have been compiled at baseline (T0) and at the end of the intervention (T1).

**Results.**– A total of 107 students were recruited, mainly male, aged 16.8 ( $\pm 1.9$ ) years. At T1 a significant improvement in the level of knowledge regarding mental disorders was found ( $p < .002$ ). In particular, 65% of students reported that patients with mental disorders can recover (vs. 40% at T0,  $p < .05$ ). Moreover, avoidance attribution style was significantly reduced ( $p < .001$ ). No significant changes in reported behaviours were detected.

**Conclusion.**– Anti-stigma programmes targeted to young people can be effective for challenging stigma.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0364

### Features pathology newly diagnosed by a psychiatrist at the reception of the regional advisory diagnostic center of subarctic territory

L. Shapovalova<sup>1</sup>, K. Shapovalov<sup>2</sup>

<sup>1</sup> State Autonomous Health Agency of the Republic of Komi "Consultative and Diagnostic Center of the Republic of Komi", Diagnostic department, Syktyvkar, Russia; <sup>2</sup> State Education Agency of Additional Professional Education of Republic of Komi "Komi Republican Institute for Development of Education", Chair of Additional Education, Syktyvkar, Russia

\* Corresponding author.

**Introduction.**– According to the WHO, by 2020, mental disorders will enter the first five diseases leading to disability.

**Objectives.**– The analysis of 2041 patients with the pathology of the psychic sphere was carried out for the first time by the consultant of the regional diagnostic center of the subarctic territory, diagnosed by the psychiatrist.

**Methods analytical, statistical.**– Results among the patients with newly diagnosed diseases of the psychic sphere, the main groups were identified: F00-F09  $37.0 \pm 1.1\%$ ; F10-F19  $2.4 \pm 0.3\%$ ;

F20-F29  $0.8 \pm 0.2\%$ ; F30-F39  $2.0 \pm 0.3\%$ ; F40-F49  $52.8 \pm 1.1\%$ ; F50-F59  $1.8 \pm 0.3\%$ ; F60-F69  $0.9 \pm 0.2\%$ ; F70-F79  $0.6 \pm 0.2\%$ ; F90-F99  $1.7 \pm 0.3\%$ . The level of primary incidence of mental disorders per 100 000 population in some cities and regions of the region is much higher than the average, due to all mental disorders, and above all, psychotic and nonpsychotic, as well as psychosis and mental retardation.

**Conclusions.**– The main reason for the low level of primary mental pathology in a number of municipalities is the incompleteness of psychiatric doctors. Therefore, mental disorders are not detected and the necessary assistance to patients is not timely.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0365

### Psychiatric Evmorbidity in individuals with Parkinson's disease: Nationwide cohort study

C.C. Vasarhelyi<sup>1</sup>, M. Dr. Binzer<sup>2</sup>, E. Stenager<sup>3</sup>, M. Pankiewicz-Dulacz<sup>1</sup>

<sup>1</sup> University of Southern Denmark, Institut for Regional sundhedsforskning, Odense, Denmark; <sup>2</sup> Syddansk Universitet, Neurologisk Klinik, Sygehus Sønderjylland, Esbjerg, Denmark; <sup>3</sup> University of Southern Denmark, Psykiatrisk afdeling Odense, Institut for Regional sundhedsforskning, Odense, Denmark

\* Corresponding author.

**Introduction.**– Parkinsonian diseases are still today incurable degenerative diseases of the brain, and a reality for millions. With no curing treatment, extra effort should be made to treat symptoms and comorbidities. These individuals are estimated to be at an increased risk for psychiatric disease, but little mapping of psychiatric comorbidity exists.

**Objective.**– To determine prevalence and time of psychiatric comorbidity in patients suffering from Parkinson or Atypical Parkinson syndrome, before and after time of diagnosis.

**Methods.**– This is a cohort study using the Danish National Patient Registry and the Danish Psychiatric Central Register. This patient group is compared to a control group of people matched on age and sex, in the number of 10 controls to 1 case. The study begins early 2018. Inclusion criteria: Parkinson, Atypical Parkinson Syndrome and MSA patients younger than 65 years are all included, but evaluated separately. The cut-off age is to minimize Evmorbidities associated with increased age. Patients must have their diagnosis for 5 years, to minimize the risk of misdiagnosis. The psychiatric diseases included fall in the ICD-categories F1, F2, F3, F4 and F6; relating to substance abuse, schizophrenia, mood affective disorders, anxiety related disorders and disorders of personality and behaviour, respectively.

**Results.**– The results are under conduction.

**Conclusions (perspective).**– We expect to find higher rates of psychiatric diseases in Parkinsonian patients compared to the general population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Epidemiological profile of psychiatry in the hospital III emergencias Grau-Essalud 2012–2016

C.J. Vera Scamarone\*, J. Manrique Garcia  
EsSalud, Psychiatry, Lima, Peru

\* Corresponding author.

**Introduction.**– Epidemiological studies in Lima-Peru have given higher priority to psychotic disorders over the last twenty years. With the need to update the information, the care was digitally analysed in the adult psychiatry unit of Hospital III Emergencias Grau EsSalud, between the years 2012 to 2016. It is a retrospective study with a total population of outpatients treated in psychiatry of 52700 cases during the last 5 years (2012 to 2016).

**Objective.**– Which is the epidemiological profile of the psychiatric pathologies treated at Hospital III Emergencias Grau - Esalud?

**Method.**– We examined the statistic data generated for the Putty system of attention. Then we collect these information to being process in Excel 2006 and SSPS.

**Results.**– According to the results we have that the greatest amount of attentions have been made in patients of female sex (52%), and ranging from 16 years to 43 years (59%). According to the average percentage of the attention of the total of 52,700 cases we observed a notable variation that contrasts with the results of the studies carried out at the national level. (Figure 1)

**Conclusions.**– The paradigm of chronic psychiatric diseases in Lima has changed and we notice more acute psychiatric diseases such as acute depression and panic.

### Trends in treated prevalence of psychotic disorders in Portuguese mental health inpatient units

P. Mateus<sup>1</sup>, M. Xavier<sup>1,2\*</sup>

<sup>1</sup> NOVA Medical School, Mental Health, Lisbon, Portugal; <sup>2</sup> Health Directorate General, Mental Health, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– Despite the growing availability of community and rehabilitation mental health services in Portugal, inpatient units still have a key role in the treatment of patients with psychosis. This services also represent the largest proportion of the mental health anual budget, posing big management challenges for health services during economic crisis.

**Objectives.**– To characterise the treatment of people with psychosis in Portuguese public mental health inpatient units.

**Methods.**– Inpatient units indicators were assessed through data available in the Health System Central Administration (ACSS)

information system, using the Diagnosis-Related Groups (DRG) codification.

**Results.**– There is an increase in the number of patients with psychosis admitted in inpatient units, between 2010 an 2013 (from 10161 to 10789), and a decrease between 2013 and 2014 (from 10789 to 10640). This trend is also similar for total admission days, increasing between 2010 an 2013 (from 210982 to 220088) and decreasing between 2013 and 2014 (from 220088 to 212899). The average length of stay remained around 20 days, for the same time interval.

**Conclusion.**– The number of patients with psychosis rose between 2010 and 2013, but there was a shift in this pattern after. The same pattern can be seen in the number of admission days but not for the average length of stay, suggesting a decrease in the accessibility after 2014. Given that 2014 was the year with the biggest impact of the economic crisis in the population, the relation between health budgeting and services availability, during economic crisis, should be further investigated.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## Ethics and psychiatry

### Factors influencing ethical care for the elderly

B. Calvet<sup>1,2\*</sup>, J.P. Clément<sup>1,2</sup>

<sup>1</sup> Esquirol Hospital Center, Geriatric Psychiatry, Limoges, France; <sup>2</sup> INSERM, umr1094, Limoges, France

\* Corresponding author.

Care decision and consent search in the elderly patients are framed in terms legal and debated according to philosophical and ethical principles. However, many factors of the emotional, psychological, environmental or societal registry could be present and lead to unethical elderly care. Some cognitive or psychiatric disorders can promote an alteration of the judgment which makes be problematic to find consent to care. See only the disorder of elderly, losing sight of their humanity, their identity, their emotional life, theirs behaviours, it considers that dignity may depreciate according to the person situation. Deciding a treatment in elderly according to the ethical principles of beneficence, non-maleficence, respect and justice is essential as well as the search of consent to the care that is a moral duty. It may be difficult to make an ethical and fair decision, sometimes because of the age criterion. Social representations of old age would need to be rethought in our country. This would allow each citizen to reflect on the place and the care that we want for the elderly in Western societies.

**Functional resonance analysis method: Analyzing suicide to prevent further suicide. Life-saving efforts in the care of suicidal patients at psychiatric clinic Affektiva in Gothenburg**

M. Dellepiane<sup>1</sup>, M. Rex<sup>1</sup>, E. Von Hauswollf<sup>1</sup>, C. Boldt-Christmas<sup>1</sup>, T. Larson<sup>1</sup>, G. Jungstrand<sup>1</sup>, T. Brezicka<sup>2</sup>

<sup>1</sup> Sahlgrenska University Hospital, Psychiatry, Gothenburg, Sweden; <sup>2</sup> Västra Götaland Region, Patient safety Department, Gothenburg, Sweden

\* Corresponding author.

*Introduction.*– Suicide is the most serious event in the specialist psychiatric care, and efforts are being made to prevent it: rigorous screening, collaboration between in- and outpatient units and routines for follow-up of patients with suicidal thoughts. Suicide or suicide effort needs a work to retrospectively gather information about what in the care chain didn't work well enough, often with a root cause analysis. Our department started a project using the Functional Resonance Analysis Method (FRAM) to understand the functions of the care system, their connections and mutual interactions to analyze events such as suicide and to observe the system's ability to provide high quality care in patient safety (Figure 1).

*Objectives.*– We conducted a case-control study with a selection based on population from 2016 who committed suicide,  $n=8$  ( $N=20$ ), of which half alive controls. The analysis team reviewed all available patient documentation starting from 500 days before suicide, performing comparisons with root cause analysis.

*Results.*– This project shows that FRAM is applicable for analysis of suicide. FRAM is an important complement to traditional root cause analysis, as it raises more detailed findings. After exploration of the system's functions, 6 of them were identified as critical. Increased focus on these is likely to increase the safety of the psychiatric patients.

*Conclusion.*– FRAM is suitable for the evaluation of complex care processes, such as implementation of value-based or person-centered care. It illustrates more findings than traditional analysis and provides a valuable tool in patient safety.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

**Evidencing satanic ritual abuse (SRA) in the UK: Past, present and future**

R.H. Kurz\*, W. Wong

Outstanding Achievements, Research, Long Ditton, United Kingdom

\* Corresponding author.

*Introduction.*– The 'Memory Wars' erupted when several cases of Satanic Ritual Abuse (SRA) made headline news. This paper outlines past sources of evidence, recent cases and possible steps forward to educate victims, professionals and society.

*Objectives.*– The presentation provides a historical perspective on evidencing SRA, a lens on current efforts and proposals for raising public and institutional awareness.

*Aims.*– The presentation outlines sparse yet rich accounts of Satanic Ritual Abuse, recent exposures and avenues for tackling the issues.

*Methods.*– Books and news items were reviewed by two advocates who between them have 30 years of experience in evidencing SRA.

*Results.*– Three early UK publications (1991) were 'Blasphemous Rumours' (Andrew Boyd), 'Children for the Devil, Ritual abuse and satanic crime' (Tim Tate) and 'Chasing Satan' (Dianne Core). In 1994 Valerie Sinason and Jean La Fontaine brought out publica-

tions - on opposing sides of the Memory Wars. Recently Epstein, Schwartz & Schwartz (2011) published 'Ritual Abuse & Mind Control'. 'Annabelle Forest' (2014) published 'The Devil at the door step: My escape from a Satanist Sex Cult' which referred to the abuse regime imposed by convicted Satanist High Priest Colin Batley. Long prison sentences for disgraced Lost Prophet singer Ian Watkins for attempted baby rape and of Albert and Carol Hickmann (again) for SRA including Blood Sucking received some media exposure.

*Conclusion.*– Public exposure of SRA is crucial for fighting this cancer of society that secretly grows in our midst. Law, police and health professionals need to become more compassionate and astute in dealing with SRA and associated dissociative disorders.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0371

**Towards the involvement of caregivers in suicide prevention strategies: Ethics issues and perspectives**

V. Le Moal<sup>1</sup>, C. Mesmeur<sup>1</sup>, M. Gravey<sup>2</sup>, M. Walter<sup>1</sup>, M. Berrouiguet<sup>1</sup>

<sup>1</sup> Adult Psychiatry, Brest Medical University Hospital, Bohars, France;

<sup>2</sup> P.G3 IMT Atlantique, cs 83818, 29238 Brest cedex 03, France

\* Corresponding author.

*Introduction.*– Suicidal behaviour and deliberate self-harm are common among adults. Research indicates that maintaining contact either via letter or postcard with at-risk adults following discharge from care services can reduce reattempt risk. But, when the link between patient and care providers or healthcare services stops, the potential protective effect is lost.

*Objectives and methods.*– This paper is a reflection about the opportunities and risk of involving caregivers in suicide prevention strategies. This is based on data obtained for the C-SIAM current study (Caregivers Suicide Intervention Assisted by Messages).

*Results.*– The caregiver can be defined as a person who gives help and protection to someone. In the suicide prevention setting, he occupies a central place in the patients' social network. Meeting them, make possible to assess its involvement, its availability, its reliability, its aptitude brought in the situation. The aim is to find a balance between the hospitalization, sometimes excessive and stigmatizing and the ambulatory care. Caregivers are potential allies in suicidal prevention of their loved ones without replacing healthcare professionals. The alliance with the latter finally allows him to play a role of support and alert in case of necessity. This appropriate answer can become an intensive "tailor-made" partnership between professionals, patients and the environment.

*Conclusion.*– To conclude, it is essential to recognize the knowledge of the caregiver: the knowledge of the layman which makes them "Experts of experience" that can be integrated into research protocols as observers but also as committed actors.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Communication with the patient and their family. Ethical dilemmas

F. Myslimaj\*, M. Gokaj

*Mother Teresa Hospital, Psychiatry Adult, Tirana, Albania*

\* Corresponding author.

Fatbardha Myslimaj, Psychiatrist QSUT

Mirela Gjoka, Psychiatry Resident QSUT

*Subject.*– Communication with the patient and their family. Ethical dilemmas

*Objective.*– Promoting values such as dignity, commitment, improvement of qualification, integrity and cooperation. Every day in the practice of psychiatric, ethical problems are frequent. The basic duty of every doctor in the service of individual and public health is the protection of life, physical and mental health of human suffering and its relief. Communication with the patient is the focal point where information taken for the concerns of the moment, psychiatric history and previous treatments. Creating a empathic healthy relationships is a difficult process that requires care, good communicating skills, humanitarian and professional qualities, so that the patient feels comfortable. It often happens that communication is very difficult for many reasons. Factors that negatively affect the understanding of information are: age, language, nature of the disease, socio-economic level of affinity with the patient, the prognosis of the disease, the time available during the conversation, etc. During the communication different difficulties arise that I want to discuss in this paper.

*Methodology.*– Research and comparison with contemporary literature.

*Conclusion.*– The most important issue of which we have to cope with are, confidentiality, stigma that accompanies these patients and their family members, mental health problems that may be present to family members, the problems of serious social difficulties we face outpatient treatment of these patients. Identified social and cultural specificity are the reason that lead to problematic consequences ethical dilemma that posed for solution.

*Keywords:* Communication; Empathy; Promoting values

EV0373

### Ethical Principles in Relation to Older People

L. Pishchikova

*Charitable Fund "Gerontological protection", Ministry of Health, Russia, Moscow, Russia*

\* Corresponding author.

International studies of aging processes are recognized by the UN and the WHO as global agenda issues, which is associated with demographic, political, socio-economic, cultural, medical and criminological problems, caused by the increasing number of late age persons all over the world.

These are issues of age discrimination trend (ageism), socio-economic stratification, cruel and dismissive attitude towards elderly people, their legal and social protection insufficiency, "epidemy of dementia".

The phenomenon of ageism, considering "age" as a synonym of "dementia", can lead to the violation of right of older people, appear in general and forensic psychiatric practice, influence the reliability of diagnosis and expert assessment.

Clinical and expert analysis of 235 late age patients (revealed: "non-dement" mental disorders - 45.5%, psychosis - 7.7%, dementia -

46.8%) who underwent forensic psychiatric examination in Serb-sky Federal Medical Research Center for Psychiatry and Narcology in criminal and civil cases, helped us to formulate ethical principles in relation to older people:

Understanding aging as a favorable regulatory process during which the evolutionary development of man continues.

Observance of presumptions of mental health, sanity, capacity to contract and legal capacity to act.

Inadmissibility of ageism and discrimination in all spheres and areas.

Inadmissibility of cruel treatment, violence and neglect.

Recognition of dementia as a disease and not as a normative manifestation of aging.

Preserving dignity and respect of a person until the last stage of dementia and his right to reside in his home.

### A case study of maternal filicide–fatal maltreatment

T. Amirejibi

*Ilia State Univeristy, Mental Health, Tbilisi, Georgia*

\* Corresponding author.

Several classification systems have been proposed and established for maternal filicide, and its underlying motives: altruistic filicide, spousal revenge, unwanted child, acutely psychotic filicide and fatal maltreatment.

Current research presents a case of maternal filicide in Georgia: Subject was a 24-year-old woman, with elementary school education; In the family of origin subject reported parental discord, maltreatment, and substance abuse. This was her second marriage, she was living with a spouse, reported financial hardships, conflicts and abusive relationship with the spouse, limited social support, and housing problems (temporary housing). The subject was a primary caregiver to her three children; the firstborn was from a previous marriage. She had no prior criminal offenses, has never visited a mental health specialist or received any help; was diagnosed with a personality disorder after conviction.

While alone with her firstborn child, subject reported loss of temper, sudden explosion of anger toward the child's non-compliant behaviour; her primary intention was to discipline the child; as a form of punishment the child was physically abused, which was a recurrent event, and was struck with an object, he received a blunt force trauma to the head which resulted in death. Afterwards, she tried to revive the child and called her spouse for help.

Classification systems provide valuable information for identification of risk factors, but as maternal filicide is a multifaceted phenomenon comprising of various aspects from different domains it calls for an integrated approach from mental health, healthcare and social systems for developing and implementing preventive strategies.

### Evaluation of mobbing effects on person and personality traits. Study case

G.E. Buicu<sup>1\*</sup>, M. Gabos Grecu<sup>1</sup>, A.P. Nirestean<sup>1</sup>, C.G. Marinescu<sup>2</sup>, I. Gabos Grecu<sup>3</sup>, A. Salcudean<sup>3</sup>, T. Nirestean<sup>3</sup>, S. Turliuc<sup>4</sup>

<sup>1</sup> University Of Medicine And Pharmacy Targu Mures Romania, Psychiatry, Targu Mures, Romania; <sup>2</sup> County Hospital, Psychiatry, Pitesti, Romania; <sup>3</sup> University Of Medicine And Pharmacy, Psychiatry, Targu Mures, Romania; <sup>4</sup> University Of Medicine & pharmacy, Psychiatry, Iasi, Romania

\* Corresponding author.

**Introduction.**– Einarsen (1999) defines mobbing as the systematic persecution of a colleague, subordinate or superior, which if continued, may cause serious social, psychological and psychosomatic difficulties to the victim. The term “mobbing” has today erroneously come to be a huge general receptacle for all the conflicts and interpersonal problems breaking out in the work environment.

**Objectives.**– This study case investigate the relationships between the experience of mobbing as a persecution and harrassment phenomena at the workplace as assessed by means of the DECAS personality inventory.

**Methods.**– There are approached problems like: events at work, frequency of exposure to mobbing behaviours, victim scored of the DECAS personality inventory underlining the semnification of the mobbing on the individual destiny.

**Results.**– There is a correlation between personality traits and severity of symptoms, which get worse in our patient with an higher on emotional instability component and poor adaptability to stressful situations, indicating that personality traits should not be neglected as being a factor in understanding the mobbing phenomenon.

**Conclusions.**– To obtain remission of symptoms should include removal from the workplace, psychiatric pharmacological intervention and psychological support.

**Keywords:** Mobbing; Harrassment; Personality traits

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0376

### Personality disorders and their relationship to violent crimes

A.C. Chaves

Cruzeiro do Sul University, Criminal Law, Criminal Procedure and Forensic Medicine, São Paulo, Brazil

\* Corresponding author.

The study aimed to analyze the relationships between personality disorders (PD), substance use disorder (SUD) and criminal behaviour. 116 convicted offenders underwent two interviews to be evaluated for Axis I and Axis II disorders using the MINI INTERNATIONAL NEUROPSYCHIATRIC INTERVIEW - MINI 5.0 (1994, 1998, 2000, Sheehan DV & Lecrubier Y. - Brazilian Version 5.0.0) and the STRUCTURED CLINICAL INTERVIEW FOR DSM-IV AXIS II DISORDERS - SCID-II (First, Gibbon, Spitzer, Williams, & Benjamin, 1999–Brazilian version). A random selection was made among all offenders who were serving sentences in closed conditons in 3 prisons with the largest population located in the State of Minas Gerais, Brazil. PD occur in 56.9%, and Antisocial PD was the most frequent subtype, occurring in nearly 47.41% of the sample, followed by Borderline PD (14.66%) and Paranoid PD (12.93%). The schizotypal PD (0.86%) and histrionic PD (0.86%) were uncommon findings. Substance use disorder (SUD) occur in over 50% of the population tested, especially SUD related to the use of marijuana,

cocaine, crack and alcohol. SUD was significantly associated with PD. It was especially significant for those with Antisocial PD, what leads to the conclusion that Antisocial PD increases the risk for SUD. Performed statistical correlation tests found that the Antisocial Personality Disorder individuals make on average 1.95 more violent crimes against those who do not have this disorder. People with PD and with a history of SUD, although generally considered criminally responsible for their actions, need urgent medical and psychological care in Brazilian prisons.

### Extended symptoms. Malingering in psychiatry

H. De la Red Gallego<sup>1\*</sup>, L. Rodríguez Andrés<sup>1</sup>, A. Álvarez Astorga<sup>1</sup>, A. Alonso Sánchez<sup>1</sup>, G. Isidro García<sup>1</sup>, Y. González Silva<sup>2</sup>, C. Noval Canga<sup>1</sup>, R. Hernández Antón<sup>1</sup>, A. Pérez Escudero<sup>1</sup>, F. De Uribe Ladrón de Cegama<sup>1</sup>

<sup>1</sup> Hospital Clínico Universitario de Valladolid, Psychiatry, Valladolid, Spain; <sup>2</sup> Gerencia de Atención Primaria de Salamanca, Primary Care, Salamanca, Spain

\* Corresponding author.

**Introduction.**– Malingering is the intentional production of disproportionate or false physical or psychological symptoms motivated by conscious and external incentives. The estimated prevalence of malingering in General Medicine and Psychiatry is 8%. It is not considered a mental disorder.

**Objective.**– To present a case of malingering and discuss its ethical and legal controversies.

**Methods.**– A 35-years-old male who provides psychiatric reports from another Spanish region, diagnosed with Paranoid Schizophrenia and mild mental retardation. After months of follow-up, during when Clozapine is maintained, we observed no psychotic symptoms and noticed an unusual insight. He is admitted relating auditory hallucinations. After two days of admission he confesses malingering in order to obtain a greater degree of disability. It reports history of two drug induced psychotic episodes, remaining asymptomatic. His family confirms this information, and tell it is already described in previous psychiatric reports.

**Results.**– Clozapine is interrupted, remaining asymptomatic. The Structured Inventory of Malingered Symptomatology (SIMS) suggests the absence of a minimization of psychotic symptoms (dissimulation). The Kaufman Brief Intelligence Test (KBIT-2) reveals IQ 70. He is diagnosed with mild mental retardation and malingering. Factitious disorder and Schizophrenia are dismissed.

**Discussion.**– Malingering a psychiatric disease is an especially complex task that requires an exhaustive anamnesis. Clinical reports, development and information provided by relatives are essential. Nevertheless, it implies medical, ethical and legal controversies that should be elucidated.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0378

### Forensic psychiatric expertise of patients with severe mental illnesses

F. Guermazi<sup>\*</sup>, L. Zouari, S. Omri, N. Charfi, M. Maalej, A. Feki, N. Zouari, J. Ben Thabet, M. Maalej

Hedi chaker university hospital, psychiatry C, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Epidemiological studies confirm the indisputable link between criminological dangerousness and severe mental

disorders, which increase clearly the prevalence of violent and criminal behaviour.

**Aim.**– To dress socio-demographic, clinical and mediEVlegal profile of offenders, with severe mental illnesses (SMI), in forensic psychiatric examination.

**Methods.**– A retrospective study involving 119 patients examined during the period, from 2002 to 2017, on the occasion of a penal expertise of 643 subjects. The subjects selected ( $n = 119$ , 18.5%) met the definition of S. Hodgins for SMIs: schizophrenia (51 cases), bipolar disorder type I (36 cases), delusional disorder (10 cases), schizoaffective disorder (14 cases) and depressive disorder (7 cases).

**Results.**– The mean age of patients at the offense moment, was 35.13 years, with a sex ratio of 11. Among them, 58% were single, 31% had a primary school level, 23.5% had no profession, 17% lived in a high crime area and 27% had already committed forensic acts. Clinically, 93.3% had at least one psychiatric evaluation prior to the commitment of the crime. The treatment adherence was considerably low in 84% of cases. The crimes committed were homicide or homicide's attempt in 24.4%, violence in 21% and theft in 30.2%. The offense was related to a delirious psychopathology in 53.8%. The victim was father or mother in 15%.

**Conclusion.**– Crime caused by patients with mental disorders is not only dependent on the severity of the illness but on several interrelated factors. Interventions for reducing forensic behaviour should focus on those social and clinical characteristics.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Neuroscience, neuroderecho and neurocrimen: “A time to kill and another to heal”

G.N. Jemar<sup>1\*</sup>, I. Ramiro<sup>2</sup>, S. Mariana<sup>3</sup>, M. Ezequiel<sup>4</sup>, M.Y.N. Martín<sup>5</sup>  
<sup>1</sup> Hospital Jose Tiburcio Borda, Guardia Medica, Ciudad Autonoma De Buenos Aire, Argentina; <sup>2</sup> Sociedad Argentina de Trastornos de la Personalidad y Psicopatías, psiquiatria Forense, Buenos Aires, Argentina; <sup>3</sup> Sociedad Argentina de Trastornos de la Personalidad y Psicopatías, Psicología, Buenos Aires, Argentina; <sup>4</sup> Sociedad Argentina de Trastornos de la Personalidad y Psicopatías, Psiquiatria Forense, Buenos Aires, Argentina; <sup>5</sup> Sociedad Argentina de Trastornos de la Personalidad y Psicopatías, Neuropsiquiatria, Buenos Aires, Argentina  
 \* Corresponding author.

We propose to elucidate under this context if this type of behaviour presents a neurobiological basis, or if we find neuropathological arguments that lead us to interpret some of these processes in terms of signs and symptoms, and therefore, be possible to approach from mental health.

For this analysis, we implement knowledge from the cognitive neuroscience, specifically neuropsychology and forensic neuropsychiatry, Neurocrimen and Neuroderecho.

It was necessary for this analysis to correctly define the terminology implemented from a semiologic and nosographic point of view, understanding the neurobiological and clinical differences of impulsivity, violence, criminality and corruption.

There is clearly a neurobiological substrate that predisposes to the appearance of this type of behaviour, and each of them responds to structural, constitutive phenomena and to the influence of the environment.

Violent, criminal and corrupt behaviours present a neurobiological support in statistical terms that allow us to infer distortive processes that result in alterations in the adaptation to social coexistence. Many of these neurobiological aspects can be characterized in neuropathological terms, and therefore, turn some of

these behaviours into symptoms and signs. These findings imply the need to review legal static conclusions, although they are still insufficient to transform medical legal paradigms, but they force us to the constant analysis and ratification and case by case of them.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The cycle of violence – The risk of girls who are victims of maltreatment to become a perpetrator in adulthood

M. Kachaeva<sup>1\*</sup>, S. Shport<sup>2</sup>, S. Trushchelev<sup>3</sup>, E. Nuckova<sup>4</sup>

<sup>1</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, forensic psychiatric department, Moscow, Russia; <sup>2</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, scientific secretary of the Institution, Moscow, Russia; <sup>3</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, Senior scientific researcher, Moscow, Russia; <sup>4</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, Department of child and adolescent psychology, Moscow, Russia  
 \* Corresponding author.

**Introduction.**– Researches on female offenders have indicated a high degree of psychiatric morbidity amongst women. Since the rates of female criminality are rising it would appear important to conduct the study of the relationship between criminal behaviour and psychiatric diagnoses in female offenders.

**Objectives.**– The main purpose of this investigation is to find out origins of crimes in women and to reveal the influence of child and adolescent maltreatment on personality disorders in adult women.

**Methods.**– Clinical psychopathological, psychological, statistical.  
**Results.**– A cohort of 12 females with diagnosis of personality disorders was examined. All of them had committed crimes of violence. In the majority of the sample women had a previous history of psychiatric admissions (child psychiatric hospitals, adolescent units). The retrospective review revealed that the majority of women in their childhood were exposed to emotional, physical and sexual abuse in their families. Our results point that maltreatment may distort personality formation and social adjustment and contribute to behaviour problems, negative relation to socialization and criminal behaviour in adulthood.

**Conclusion.**– The study revealed that psychiatric disorders in childhood and adolescence are predictive of adult criminality in females. This findings may be used as prognostic indicators of development of aggression in female forensic patients. The study is supported by the Russian Fund of Fundamental Investigations 6-06-00314

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Mental health of women who are victims of domestic violence

M. Kachaeva<sup>1\*</sup>, S. Shport<sup>2</sup>, S. Trushchelev<sup>3</sup>

<sup>1</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, forensic psychiatric department, Moscow, Russia; <sup>2</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, scientific secretary of the Institution, Moscow, Russia; <sup>3</sup> Serbsky National Research Centre for Social and Forensic Psychiatry, educational department, Moscow, Russia  
 \* Corresponding author.

**Introduction.**– Domestic violence against women has increasingly been recognized nationally and internationally as a serious problem. Violence against women is a troubling phenomenon in

Russia. Meanwhile domestic abuse against women often results in longterm mental health problems.

**Objectives.**– The main aim of the study was to find out the psychological and psychiatric consequences of violence against women and to determine the origins of crimes committed by abused females.

**Materials and methods.**– A cohort of 10 females was examined by forensic psychiatrists. All women had committed crimes of violence (murders, attempted murders). Details of background, psychiatric and offending history were extracted. Each item was assessed with the help of descriptive statistics.

**Results.**– A research has been carried out on the basis of psychiatric and forensic psychiatric assessment of two groups of women who had a long history of violence by their husbands or partners. Clinical assessment has revealed depression, anxiety, low self-esteem, post-traumatic stress disorder, drug abuse. All women underwent forensic psychiatric assessment as they had committed serious crimes of violence. The research has revealed two types of homicides. Women of the first subgroup displayed pathological altruistic motivation of their children. Women of the second subgroup had committed homicides of their husbands and partners whose violence towards women escalated in severity.

**Conclusion.**– The research shows the necessity of domestic violence prevention by legal provisions and multidisciplinary research with participation of psychiatrists, psychologists, sociologists, human rights advocates and feminist societies.

The study is supported by the Russian Fund of Fundamental Investigations 16-06-00314.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### How to diagnose and tackle the radicalized mind: The role of psychiatrists in preventing modern day terrorism

C. Lazzari<sup>\*</sup>, A. Shoka, B. Papanna, G. Mousailidis  
Essex Partnership University NHS Foundation Trust, United Kingdom,  
General Adult Psychiatry, Colchester, United Kingdom

\* Corresponding author.

**Introduction.**– The Occidental world has become at risk of terrorist attacks.

**Objectives.**– To create a task force of psychiatrists to develop diagnostic instruments in order to predict the risk of radicalization and terrorist acts in general and among psychiatric population.

**Methods.**– A Delphi group of forensic psychiatrists, expert in diagnosing radicalization, indexed the radicalization risks into emotions and biased thought. Both were included into the log-rank test for hazard staged with Prochaska and DiClemente's pre-contemplation, contemplation, preparation, action, maintenance, and relapse in terrorist attack. In the simulation lab, possible terrorist attack scenarios (SIMILABTER<sup>®</sup>) are discussed while the Delphi experts, each time, stage one hundred patients according to ongoing questions, in the current research: "How many people out of 100 would be in the x Prochaska-and-DiClemente stage if the emotions were y1 and the biased thoughts were y2?". Emotions in radicalized minds are covert or expressed anger, need for recognition, forensic history for violence, isolation, and feeling betrayed. Biased Thoughts: jargon speech and absolutisms ('people', 'society', etc.) or stereotyped pseudo-philosophical jargon.

**Results.**– In the current simulation, emotions and biased thought were analysed by log-rank test for hazard staged with Prochaska and DiClemente and resulted in  $z = 0.29, P = n.s.$  (Figure 1).

**Conclusions.**– The risk of terrorist attacks in people vulnerable to radicalization either reporting specific emotions or prejudiced thoughts does not change.

Figure 1. Meta-Analysis of diagnoses at discharge in a general adult psychiatric ward.

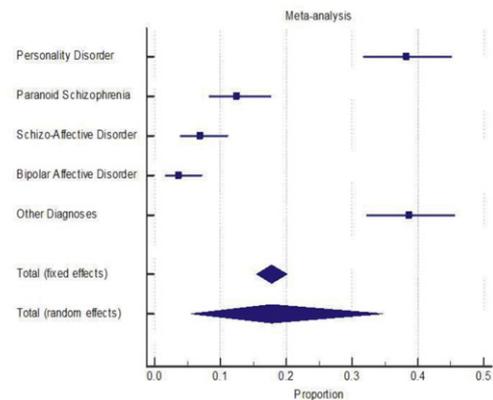

Fig 1. Hazard rate scale for terrorist attack as predicted by radicalised emotions and biased thoughts.

### Post-traumatic stress disorder in a homicide offender with schizophrenia

B. Oueslati<sup>1\*</sup>, F. Fekih-Romdhane<sup>1</sup>, O. Zerriaa<sup>1</sup>, I. Jelalia<sup>2</sup>, I. Ghazeli<sup>1</sup>, L. Menif<sup>3</sup>, R. Ridha<sup>1</sup>

<sup>1</sup> Razi Hospital, Forensic Psychiatry, Mannouba, Tunisia; <sup>2</sup> Razi Hospital, Psychiatry F, Mannouba, Tunisia; <sup>3</sup> Razi Hospital, Psychiatry D, Mannouba, Tunisia

\* Corresponding author.

**Introduction.**– Yet rarely reported in literature, the occurrence of a post-traumatic stress disorder (PTSD) is frequent among patients with schizophrenia after committing a homicide.

**Objectives.**– To highlight the fact that patients with schizophrenia may present a PTSD after committing a homicide.

**Methods.**– A case report and a review of the literature.

**Results.**– We report the case of a 29-years-old male patient suffering from schizophrenia who developed a PTSD after a patricide. The use of the Clinician-Administered PTSD Scale for DSM-5 (CAPS-5) lead to a moderate severity score. PTSD's outcome was satisfactory after two months of 20 milligrams paroxetine daily intake. Patients suffering from schizophrenia with higher risk for developing a PTSD after a homicide are those who have not been exposed to significant traumas during their childhood, those who killed a family member and those with higher rates of guilt. All of these three risk factors have been identified in our patient.

**Conclusions.**– Misdiagnosing a PTSD in homicide offenders with schizophrenia exposes them to a persistent psychological stress. This stress worsens the outcome of schizophrenia. Violent behaviour such a suicide or violent offenses may thus occur.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Specific features of alcoholics' criminal offences**

A. Prošev<sup>1\*</sup>, S. Uzun<sup>2</sup>, O. Kozumplik<sup>2</sup>, N. Žaja<sup>3</sup>, N. Mimica<sup>4</sup>

<sup>1</sup> County Hospital Čakovec, Department of Psychiatry, Čakovec, Croatia; <sup>2</sup> University Psychiatric Hospital Vrapče, University Josipa Jurja Strossmayera, School of Medicine Osijek, Department of Biological Psychiatry and Psychogeriatrics, Zagreb, Croatia; <sup>3</sup> University Psychiatric Hospital Vrapče, Department of Biological Psychiatry and Psychogeriatrics, Zagreb, Croatia; <sup>4</sup> University Psychiatric Hospital Vrapče- University of Zagreb, School of Medicine, Department of Biological Psychiatry and Psychogeriatrics, Zagreb, Croatia

\* Corresponding author.

Research on the frequency of alcoholism among the criminal offenders' population indicated high level of relation between alcoholism and criminal behaviour. The role of alcoholism in genesis of criminal offences is especially obvious in the most violent criminal offences; it is present in up to 70% of murders, and over 90% of sexual offences. The research indicated a higher frequency of occurrence of alcoholism among murderers than in other forms of violent crime. Furthermore, alcoholism affects road traffic accidents, which has been demonstrated by numerous studies conducted in this area. Alcoholism is also frequent among criminal offenders against property, as well as in robberies. The purpose of our research was to investigate the role of alcoholism related to the criminal offences. Objectives of this research were (1) to determine specific features of alcoholics' criminal offences in comparison with criminal offenders from other diagnostic categories on the basis of their demographic, psycho-social, medical and forensic characteristics, and (2) to analyze the relation between alcoholism and violent criminal offences. In conclusion, the results of the research made possible a significantly more differentiating insight into certain aspects of alcoholics, perpetrators of criminal acts and the perpetrators with other diagnostic categories. The contribution is evident in the analysis of the influence of alcoholism, i.e. alcohol-addiction on the manner of perpetrating a criminal act and the contribution of alcoholism on the predictability of violence. Aggressive behaviour in criminal acts was connected significantly with alcohol intoxication of alcoholics at the time of the committed criminal act.

### **Trauma experiences among sexual offenders: The role of emotion dysregulation**

P. Velotti<sup>1</sup>, G. Rogier<sup>2\*</sup>, M. D'Aguanno<sup>2</sup>

<sup>1</sup> University of Genoa, Educational Sciences Psychology Unit, Genoa, Italy; <sup>2</sup> La Sapienza, Dynamic and Clinical Psychology, Rome, Italy

\* Corresponding author.

*Introduction.* – Although, mentalization has been individuated as an important predictor of violent behaviours (Velotti, Garofalo, Dimaggio, Fonagy, 2017), research on sexual offenders population remains limited.

*Objectives.* – We sought to explore the associations among a childhood trauma history, emotion dysregulation and reflective functioning, comparing a sexual offenders sample with community participants

*Aims.* – To highlight the role of the trauma history in the individuals' reflective competences, considering the role of emotion dysregulation.

*Methods.* – A sample of sexual offenders and a community sample, were administered the CTQ (Childhood Trauma Questionnaire, Bernstein & Fink, 1998), the DERS (Difficulties in Emotion Regulation Scale, Gratz & Roemer, 2004), and the RFQ (the Reflective Functioning Questionnaire, Fonagy et al., 2016).

*Results.* – As expected, both levels of childhood trauma and emotion dysregulation were significantly higher in the clinical sample while levels of reflective functioning were significantly higher in the community sample.

*Conclusions.* – Coherently with others results, our study confirmed that sexual offenders showed high levels of trauma and emotion dysregulation. The peculiar patterns of associations between trauma, emotion dysregulation and reflective functioning could be informative to tailor treatment programs for these populations.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Incarceration and bullying**

A. Rokach

Center for Academic Studies, Psychology, Petach-Tikva, Israel

Bullying is garnering increased attention from the public and the academic community lately. In jail it is a particularly disturbing problem since inmates, by definition, are locked and cannot avoid whatever prison life offers, and when they are subjected to bullying its ramifications are far reaching, damaging, and may even be traumatic.

Examining the incidence of bullying in prisons, 60% reported bullying others, and 80% reported having been bullied. Most prisoners reported being afraid of bullying, which was found to have more significant negative health effects than the bullying itself. A considerable amount of research has been conducted regarding the characteristics of bullies. In general, bullies tend to display increased levels of impulsivity which results in them acting on the spur of the moment while not correctly assessing the consequences of their actions.

Interestingly, many bullies are diagnosed with conduct disorders in their childhood, such as oppositional defiant disorder (ODD) and attention deficit hyperactivity disorder (ADHD), and appear to suffer from depression. Often, bullies will have antisocial tendencies. Narcissism and self-centeredness are common characteristics of those that engage in bullying behaviours.

Addressing bullying in jail: Inmates stated that confronting the bully was the most highly recommended strategy, also victims should be given help/advice, and the incident should be reported to the officers and they should try to calm the situation down. Staff education in jail is certainly of great importance to counter bullying.

### **Management of gender dysphoria in forensic psychiatry settings in USA**

A. Tinwalla<sup>1\*</sup>, D. Sandler<sup>2</sup>

<sup>1</sup> Wexford Health sources, Mental Health, Burr Ridge, USA; <sup>2</sup> Laboratory of Forensic Sexology, Legal Medicine, and Digital Ethnography Felnett Health Research Foundation, Psychiatry, New York, USA

\* Corresponding author.

Transgender is an umbrella term used to describe people with gender identities and/or expressions not traditionally associated with the sex that they were assigned at birth. Based on extensive experience in working with transgender patients placed in cor-

rectional facilities, we offer a retrospective analysis of challenges facing execution of psychiatric practice in jail and prison systems. Transgender individuals are at risk for mental health issues, such as gender dysphoria, depression, and anxiety, if gender expression is suppressed. These issues can be exacerbated when transgender individuals are in correctional environments. Jails, prisons, and juvenile confinement facilities have a responsibility to ensure the physical and mental health and well-being of inmates in their custody, correctional health staff should manage transgender inmates in a manner that respects their biomedical and psychological needs. We will discuss the special issues that arise in the management and treatment of Gender Dysphoria in the Transgendered inmate population in correctional settings.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Are cognitive scores on the SIMS of a UK population different to the US sample?**

S. Zarate Escudero, J. Wise

CNWL NHS Foundation Trust, Brent South CMHT, London, United Kingdom

\* Corresponding author.

*Introduction.*– The SIMS is a screening instrument that assesses malingered psychopathology and neuropsychological symptoms. It has demonstrable sensitivity, specificity with very good utility in identifying malingering across multiple studies.

*Objectives.*– Our hypothesis was that as previous trials did not show symptom variance, within diagnoses, between test centres, that the domains of psychosis, low intelligence, neurological impairment, and affective disorder would be unaffected. Some of the amnesic disorder questions use US rather than UK language. There is criticism that it is not normed for a UK population and that some cognitive domain questions might be culture specific, affecting the final SIMS scores.

*Method.*– Data from 21 patients in secondary care, was collected. Data for scores on the amnesic impairment subscale, and total SIMS score was collected.

*Results.*– Overall, 21% were inpatients (57% female); average age 43. 15 tested SIMS-positive (9 female). Participants were subcategorized into their ICD 10 diagnosis: Psychosis (N=6), Affective disorders (N=9) and Personality Disorder/Substance Misuse (N=6). The Psychosis cohort were all SIMS-positive. The affective cohort had the highest scores for NI and AF categories. Personality Disorder/Substance misuse had the fewest SIMS positives, but the highest NI score (7.5) of the group. Cognitive scores were not affected.

*Conclusions.*– The SIMS accurately elicited psychopathology and malingering. Our findings suggest that UK participants scores were not affected by the cultural basis of cognitive questions, however there may be some merit in framing questions for a non-US audience, explaining that it relates to a US population; or consider replacing it with an alternative more relevant cultural question.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0389

### **The assessment and treatment of persons with mental disorder in criminal justice system – Review of legislation and practice in Georgia**

N. Zavrashvili<sup>1</sup>, M. Eliashvili<sup>2</sup>, E. Zhorzholadze<sup>3</sup>, N. Makhashvili<sup>1</sup>

<sup>1</sup> Iliia State University, Social psychiatry, Tbilisi, Georgia; <sup>2</sup> National Mental Health Centre, Psychiatry, Kutaisi, Georgia; <sup>3</sup> Parliament of Georgia, Committee of Health and Social Issues, Kutaisi, Georgia

\* Corresponding author.

*Introduction.*– Statistics shows that in most countries prevalence of mental health problems are much higher among prisoners than the general population. Country approach to regulating mental health needs of persons with mental disorder who come into contact with justice system depends on variety of cultural or legal traditions, as well as on different concepts and structures of mental health care delivery.

*Objective.*– The aim of the survey was to study and assess the established practice of implementation of the legal procedure relating to individuals who commit crime and have mental health problems in Georgia.

*Methods.*– Qualitative analysis including desk review, in-depth interview and focus group discussion was conducted. Proceeding from the research objectives the current legislation with regard of people with the mental disorder has been analysed; the interviews on the shortcomings and problems of the implementation of the law in practice have been conducted with key informants.

*Results.*– The study acknowledges that recent changes in Georgian legislation imports much of the civil law standards and processes relating to admission, detention and compulsory treatment of criminal detainees with mental health problems. However, due to the ambiguous, ambivalent and incomplete nature of the aforementioned changes, the penal and administrative courts, as well as the clinicians are facing serious difficulties and confusions in their work.

*Conclusions.*– It is discussed that there is a strong need for closer cooperation between mental health and justice systems to treat mentally disordered persons both in the system and after they are released into the community.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0390

### **Schizoaffective disorder ushering Fahr's syndrome**

O. Zerriaa<sup>1</sup>, F. Fekih-Romdhane, B. Oueslati, H. Nefzi, I. Ghazali, R. Ridha

Razi Hospital, Forensic psychiatry ward, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– Fahr's syndrome is a rare neurological condition, characterized by the deposit of intracerebral, bilateral and symmetrical non-arteriosclerotic calcifications, located in the central grey nuclei. Its clinical presentation is heterogeneous with a wide range of neurological and psychiatric symptoms. This condition can be either secondary or idiopathic.

*Objectives & methods.*– We report through this observation, a rare case of Fahr's syndrome revealed by schizoaffective disorder.

*Case report.*– Mr. M.B. was a 40-year-old man. He was hospitalized in our Forensic Psychiatric department following a dismissal for criminal responsibility for an act of sexual assault against his female neighbor. The patient had a history of three psychiatric hospitalizations since the age of 26. He was diagnosed as suffer-

ing from schizophrenia, and was put on long-acting injectable antipsychotic therapy. There was no history of chronic physical illness or drug dependence. The first psychiatric examination found an unsettled and irritable patient with familiar contact. He was neglecting his personal hygiene. He presented logorrhea, elevated mood and disorganized behaviour and speech. He reported delusions of persecution, prejudice, greatness and sexual delusions. He was diagnosed with schizoaffective disorder according to the DSM-5. We started him on haloperidol and valproate. He remained delusional and agitated, so we increased the doses of haloperidol then added olanzapine, but there was no amelioration. The CT scan prior to the initiation of clozapine showed calcifications in the lenticular nuclei suggesting Fahr's syndrome.

**Conclusion.**– This case emphasizes the importance of the role of neuro-imaging and the search for disrupted phosphocalcic metabolism in patients with treatment-resistant psychosis.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Filicide in depressive psychosis: Case report of an emotionally unstable woman slaughtering her two children**

U. Zubair<sup>1\*</sup>, R. Taj<sup>1</sup>, A. Ali<sup>2</sup>

<sup>1</sup> PIMS, SZAMBU, Psychiatry, Islamabad, Pakistan; <sup>2</sup> Poonch Medical College Rawalkot AJK, psychiatry, Rawalakot, Pakistan

\* Corresponding author.

**Introduction.**– Filicide is the murder of a child by the parent. It is associated with various psychiatric and non psychiatric conditions. **Objective.**– To present a case report of filicide and highlight the importance of accurately and timely diagnosing and managing a psychiatric disorder in order to avoid the harm towards self and the others.

**Methods.**– A thirty year old woman previously treated for the depressive psychosis was brought by the police for psychiatric assessment. She had slaughtered her two sons of 4 and 7 years of age three days ago without any guilt or remorse. She had low mood, irritability, crying spells, hopelessness and loss of sleep, appetite and sexual desires for the past six months along with the delusions of poverty and infidelity for the past two months. She was a chain smoker. Multiple deliberate self harm and suicidal attempts were reported in the past 2 months. Psychometrics revealed BDI score of 32, BPRS score of 39 and PCL-R score of 28.

**Results.**– She was diagnosed as a case of depressive psychosis with emotionally unstable personality traits leading to impaired judgment and poor comprehension of the consequences of her actions. She was put on Escitalopram 20 mg and resperidone 2 mg. Her symptoms improved in two weeks. Her husband forgave her for this act understanding the nature of her illness.

**Conclusion.**– This case report highlights the importance of accurately and timely diagnosing and managing a mental health disorder in order to avoid the harm towards self and the others.

**Keywords:** Filicide; Depressive psychosis; Forensic psychiatry

### **Methylation status of the reelin gene (RELN) promoter in the blood and cognitive performance of schizophrenic patients**

N. Kondratiev, M. Alfimova<sup>\*</sup>, A. Golov, V. Golimbet

Mental Health Research Center, Clinical Genetics, Moscow, Russia

\* Corresponding author.

Reelin plays an important role in regulation of neuronal migration during brain development and in maintenance of synaptic function in adulthood. A decreased RELN expression, which is observed in postmortem brains of schizophrenic patients, thought to be caused by RELN promoter hypermethylation and may lead to cognitive deficits seen in this disorder. The study aim was to investigate whether there is a relationship between RELN promoter methylation in the blood of schizophrenic patients and their cognitive performance. Schizophrenic patients ( $n=34$ , mean age 27.3 (SD 7.2) years, 56% women) and healthy controls ( $n=34$ , 27.8 (7.2) years, 47% women) donated blood for DNA extraction and completed a battery of neuropsychological tests assessing processing speed, verbal memory and executive functions. Methylation of 170 CpG sites within and in the vicinity of a CpG island flanking the RELN transcriptional start site was investigated using long-read single-molecule real-time bisulfite sequencing (SMRT-BS). To reduce the dimensionality of methylation data, a principal component analysis was used. The RELN promoter was predominantly unmethylated in both patients and controls. There were no significant differences in methylation between the two groups. In a multivariate linear regression analysis adjusted for age, sex, smoking and education, a cognitive composite score of patients was not associated with RELN methylation levels. Our results agree with previous studies that have not found any changes in RELN methylation in postmortem brains of elderly schizophrenic patients, regardless of the degree of their cognitive deficit. This study was supported by the Russian Science Foundation grant No. 16-15-00056.

### **Beneficial effect of lipoic acid on brain tissue when exposed to cadmium through the activity of DNase**

J. Jovanović Mirković, C. Alexopoulos

College of Nursing, Medicine, Čuprija, Serbia

\* Corresponding author.

**Introduction.**– Cadmium as a pollutant in the working environment poses a serious health and environmental problem because it is toxic, has a very long half-life in the soil and accumulates in living systems through active food chain. The main role of DNase is reflected in the regulation of the synthesis and degradation of endogenous and exogenous DNA as well as in modified DNA repair. **Objectives.**– To examine the protective role of the supplement,  $\alpha$ -lipoic acid, S-donor ligand, in the acute toxicity of a sublethal dose of cadmium.

**Methods.**– The preparation was done for testing biomaterial for making a homogenate of brain tissue albino Wistar rats, and the activity of acidic and alkaline DNase was measured spectrophotometrically.

**Results.**– The given results show that cadmium is a probable cause of the occurrence of cadmium oxidative DNA damage. It is manifested by an increased activity of acidic and alkaline DNase in homogenates of the brain tissue ( $0,57 \pm 0,12$  to  $1,28 \pm 0,39$ ). Antioxidant  $\alpha$ -lipoic acid as a potent chelator binds cadmium building a complex with it. In this way the detoxification of reactive oxygen species in rats is performed which are exposed to cadmium poisoning.

**Conclusions.**– Blocking the metal ions (Cd), due to the possibility of the complexation of metals with the added supplement ( $\alpha$ -LA), decreases its effective concentration in the investigated physiological system which is manifested by the reduced generation of free radicals.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

Vasilyev<sup>1</sup>, E. Tolmacheva<sup>1</sup>, M. Lopatkina<sup>1</sup>, R. Savchenko<sup>1</sup>, L. Nazarenko<sup>2</sup>, I. Lebedev<sup>1</sup>

<sup>1</sup> Research Institute of Medical Genetics, Tomsk National Research Medical Center, Russian Academy of Sciences, Laboratory of Cytogenetics, Tomsk, Russia; <sup>2</sup> Research Institute of Medical Genetics, Tomsk National Research Medical Center, Russian Academy of Sciences, Laboratory of Hereditary Pathology, Tomsk, Russia; <sup>3</sup> Diagnostic Center of the Altai Region, Diagnostic Center of the Altai Region, Barnaul, Russia; <sup>4</sup> Regional State Budgetary Institution of Healthcare, Altai Regional Clinical Perinatal Center “Dar”, Laboratory of Cytogenetic Investigations, Barnaul, Russia

\* Corresponding author.

**Introduction.**– The genetic diagnosis of multiple congenital anomalies/mental retardation syndrome (MCA/MR) is usually performed on lymphocytes. However, patients were described having a normal karyotype in lymphocytes but a tissue-limited mosaicism in fibroblasts.

**Objectives.**– MCA/MR diagnostics improvement.

**Aims.**– To specify the genetics of MCA/MR in patients with r(13) and r(22), whose phenotypes could not be fully explained by the ring chromosomes.

**Methods.**– aCGH with 60 K Agilent microarrays, qPCR, FISH.

**Results.**– The first patient is a 17-year-old male with neuropsychic and speech development delay, anxiety disorder, macrocephaly, microorchidism, and multiple internal anomalies. The cytogenetic analysis revealed 46,XY,r(13)(p13q34). aCGH found del13q34 and dup3q12. Del13q34 includes genes expressed in brain and testicles. Dup3q12 is associated with cancer. FISH found 50% of fibroblasts with monosomy 13. The second patient is a 4-year-old girl with severe psychomotor and speech development delay, autistic signs, aggression, sleep alteration, seizures, attention deficit-hyperactivity disorder, microcephaly, Dandy-Walker variant, and dysmorphic features. The r(22) was first detected by cytogenetic analysis in her lymphocytes. aCGH determined del22q13.32q13.33 and del3q13.31, associated with Phelan-McDermid and 3q13.31 deletion syndromes, respectively. The del3q13.31 was inherited from healthy mother. FISH-analysis found 8% of lymphocytes and 24% of fibroblasts with monosomy 22.

**Conclusions.**– Obtained results emphasize the necessity of investigation of another tissue in a patient with MCA/MR, in whom abnormalities in lymphocytes cannot fully explain the phenotype. Besides, the ring chromosomes instability was observed; therefore,

in ring chromosome carriers it is necessary to perform FISH-analysis to determine cryptic mosaicism. This study was supported by Russian Science Foundation, grant no. 16-15-10231.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0395

### Neuropsychological approach to the diagnostics of white matter brain pathology on a clinical model of patients with CADASIL disease

M. Kovyazina<sup>1,2\*</sup>, K. Fomina<sup>1</sup>, A. Moroz<sup>3</sup>, N. Kurochkina<sup>4</sup>

<sup>1</sup> Lomonosov Moscow State University, Psychology, Moscow, Russia;

<sup>2</sup> Research center of neurology, Neurorehabilitation and physiotherapy, Moscow, Russia; <sup>3</sup> Research center of neurology, Neurogenetic, Moscow, Russia; <sup>4</sup> Research center of neurology, Radiology, Moscow, Russia

\* Corresponding author.

**Introduction.**– Cerebral autosomal dominant arteriopathy with subcortical infarctions and leukoencephalopathy (CADASIL) is an inherited central nervous system disease, which is caused by NOTCH3 gene mutations. Also diffuse white matter changes and leukoaraiosis can be observed. Major neuroimaging characteristics of CADASIL with white matter hyperintensities are presented at pic.1. The mean age of the disease onset is approximately 30–40 years. Frontal lobe dysfunction, slowness of the processing speed, attention and motor control disturbances, impairment in the executive and visuospatial functions, memory loss have been described in CADASIL. Also gustatory or auditory hallucinations and “clouding of consciousness” may be presented.

**Objectives.**– White matter is an anatomical base of inter-analyzer interaction (IAI); it provides the connection between different cortex zones of analyzers systems. Clinical psychology does not have any developed methodology of experiments and tools for IAI research. It is important to investigate this interaction and disorders in neurological and psychiatric diseases involving disorders of the integrative brain activity, in particular IAI.

**Methods.**– Uznadze’s method of fixed set can be applied to identify and analysis of IAI disorder in patients with the white matter pathology, as irradiation of set from one modality to another is impossible without inter-analyzer connections.

**Results/conclusions.**– Experimental research design included eight patients with CADASIL disease and ten healthy subjects. In both groups statistically valuable differences are obtained ( $U = .0001$ ;  $P \leq 0003$ ). Such methodology can be used as an objective tool to assess the grade of safety IAI for diagnostic of white matter brain pathology.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0396

### The importance of cytochrome 2D6 genotype in the revolving door condition of a psychiatric unit

M. La Montagna<sup>1\*</sup>, E. Stella<sup>1</sup>, F. Panza<sup>2</sup>, D. Seripa<sup>3</sup>, G. Miscio<sup>3</sup>, C. Gravina<sup>3</sup>, M. Urbano<sup>3</sup>, A. Greco<sup>3</sup>, G. Logroscino<sup>2</sup>, A. Bellomo<sup>1</sup>, M. Lozupone<sup>2</sup>

<sup>1</sup> University of Foggia, Department of Clinical and Experimental Medicine, Foggia, Italy; <sup>2</sup> University of Bari ‘Aldo Moro’, Department of Basic Medicine Sciences, Neuroscience and Sense Organs, Bari, Italy; <sup>3</sup> IRCCS Casa Sollievo della Sofferenza, Department of Medical Sciences, San Giovanni Rotondo, Italy

\* Corresponding author.

**Introduction.**– There are very little epidemiological data about the prevalence of cytochrome (CYP) P450 polymorphisms in psychiatric setting; pharmacogenetics may provide a very useful tool to identify patients at risk for adverse reactions (ADRs) and therapeutic failures (TFs).

**Objectives.**– To evaluate the prevalence rate of CYP2D6 polymorphisms in the Revolving Door (RD) condition patients admitted to psychiatric unit of Foggia in last two years.

**Methods.**– We introduced the analysis of 16 clinical relevant polymorphisms CYP2D6 genotype in the clinical practice of our psychiatric unit of RD condition to study treatment-resistance patients, by means of the Infiniti™ Analyzer.

**Results.**– We enrolled 29 drug-resistant patients (mean age 43,5 years; 17/29 F= 58,62%; 12/29 M= 41,38%). The average duration of psychiatric disease was 19,38 years. 62,07% (18/29 patients) live alone (unmarried, divorcee or widower). The majority of enrolled patients are affected by bipolar disorder (19/29 patients= 65,52%). Eighteen patients presented mutated CYP2D6 genotypes. The most frequent mutations are \*4 and \*4A (22,22%: 4/18 patients in both cases). CYP2D6 polymorphisms were: B.M. (\*5/\*2A\*2); DP. C. (\*2A/\*4A); D.M. (\*2A/\*4A); DF. S. (\*2A/\*4); LB.T. (\*4/\*17); M. MG. (\*2/\*9); N.P. (\*2A/\*4); P.C. (\*2A/\*4); S. VAP. (\*2A/\*41); S.R. (\*2A/\*4A); S.G. (\*2A/\*4A); Z.F. (\*2A/\*XN); DA. G. (\*5/\*XN); Z.M. (\*2/\*6); C.M. (\*2A/\*4K); V.A. (\*2A/\*41); P.B. (\*2A/\*6A); B.M. (\*41/\*41).

**Conclusions.**– These preliminary results show that approximately 2/3 of the sample of RD patients have CYP2D6 polymorphisms. Since there haven't been previous studies yet to really identify the prevalence rate of CYP2D6 polymorphisms in the RD condition patients, much research remains to be carried out to substantiate this statement.

### **Genomic variants associated with schizophrenia in non-caucasian populations: Qualitative meta-analysis and preliminary results in a caucasian cohort**

G. Chondrou, G. Patrinos, E.E. Tsermpini\*

University of Patras, Department of Pharmacy, patras, Greece

\* Corresponding author.

**Introduction.**– Schizophrenia is a complex mental disorder that affects approximately 1% of the general population. Its etiology is not yet known, however, according to studies, patients' genetic background is strongly associated with the appearance of schizophrenia.

**Objectives.**– The aim of our study was the identification of genomic variants that are associated with schizophrenia's development in non-Caucasian populations, using a qualitative meta-analysis approach in an effort to replicate these findings in Caucasian patient cohorts of various ethnicities. We subsequently verified these findings in a well characterized Caucasian cohort of schizophrenia patients.

**Methods.**– We first conducted a literature review and a qualitative meta-analysis, which indicated genes and variants that have been previously studied in non-Caucasian populations and proven to be associated with schizophrenia's development. Subsequently we genotyped some of the variants identified using the previous approach in a Caucasian schizophrenia patient cohort, comprised of Greek, Italian, Slovenian and Croatian populations.

**Results.**– Eighteen genomic variants were identified from our qualitative meta-analysis that their allele frequencies varied significant between Caucasians and non-Caucasian patients. Studying the top four of these variants, our preliminary genotyping results indicated one of them to be associated with schizophrenia's development in the Caucasian cohort.

**Conclusions.**– Our preliminary results indicated an association of genetic background with schizophrenia development. Our future plan is to expand our analysis into all genomic variants emerged from the qualitative meta-analysis in order to verify their association with schizophrenia's development in Caucasian populations.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Epigenetics; a mystery or a promising science?!**

E. Zaky

Professor of Pediatrics and Head of Child Psychiatry Unit, Faculty of Medicine, Ain Shams University, Pediatrics, Cairo, Egypt

Epigenetics involve studying the biological processes which control switching genes of an organism on and off. There are well orchestrated chemical reactions that stimulate and inhibit regions of the genome at crucial times and in specific loci. Simply, epigenetics is the study of such reactions and the factors which affect them. It is concerned with studying the factors that affect gene expression (phenotype change) and not gene sequence (genotype change); i.e. the factors that control expression or silencing of genes and not genetic mutations. It is linked nearly to all aspects of our lives, it is everywhere, it makes us special and different, can be inherited, and is reversible.

Epigenetic changes do occur naturally and regularly but on the other hand can be triggered by factors as aging, environmental factors, lifestyle, and diseases. Epigenetics not only can explain how different cells of skin, liver, and brain differentiate and mature but also can highlight the underlying mechanisms responsible for the development of many diseases like cancer, autoimmunity, immunodeficiency, intellectual disability disorders (like fragile X, Prader Willi, Angelman syndrome, and Rett syndromes), and neuropsychiatric disorders (as schizophrenia, autism, mood disorders, and neurodegenerative disorders).

The great advances in the field of epigenetics whether in its background knowledge or research technologies over the past decade helped a lot in highlighting the interaction between epigenetic alterations, gene regulation, and development of many diseases. Eventually, such advances will lead to the development of new molecular diagnostic modalities and targeted therapeutic interventions of many complex diseases.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Patterns of psychotropic drug prescription for in-patients in Azerbaijan

R. Aliyeva<sup>1\*</sup>, A. Rasulov<sup>2</sup>, N. Safaraliyev<sup>1</sup>, F. Ismayilov<sup>3</sup><sup>1</sup> National Mental Health Center, Out-patient unit, Baku, Azerbaijan;<sup>2</sup> Psychiatric Hospital of MOH, Director, Baku, Azerbaijan; <sup>3</sup> National Mental Health Center, Director, Baku, Azerbaijan

\* Corresponding author.

**Introduction.**– For the last decades rational drug use became an issue of concern. It is especially important problem for such countries as Azerbaijan with underdeveloped system of drug regulation, inadequate drug supply and increasing promotion by pharmaceutical companies.

**Objectives.**– The study is aimed to describe use of psychotropic drugs in psychiatric hospitals. Specific issues such as rational drug use, monotherapy vs. polypharmacy and administering novel psychotropic drugs were investigated.

**Methods.**– This is a cross-sectional, observational study included a random sample of 626 in-patients, treated at the Psychiatric Hospital of MOH.

**Results.**– The study revealed mostly prescribed antipsychotic were chlorpromazine–272 (43.5%), haloperidol–182(29.1%). Increased odds in use of high dose of antipsychotics were associated with male sex OR= 2.35; 95%CI [1.55; 3.55], diagnosis of schizophrenia OR= 4.11; 95% CI [2.02; 8.36], length of hospitalization more than 1 year OR= 2.31; 95% CI [1.61; 3.32], use of FGA OR= 1.91; 95% CI [1.21; 3.02]. Odds of polypharmacy were higher in regard to male sex OR= 3.29; 95% CI [2.33; 4.65]; repeated hospitalizations OR= 1.84; 95% CI [1.31; 2.59] and length of in-patient treatment more than 1 year OR= 1.92; 95% CI [1.39; 2.65] and lower in schizophrenic patients OR= 0.64; 95% CI [0.41; 1.0]. Use of SGA correlated with young age OR= 1.62; 95% CI [0.81; 3.24] and with diagnosis of schizophrenia OR= 0.37; 95% CI [0.22; 0.62].

**Conclusion.**– Inappropriate dose regimen, polypharmacy and lack of SGA prescription seem to be main challenges of pharmacotherapy in psychiatric hospitals. Implementation of clinical guidelines on rational drug use should improve the current practice.

### The role of organizational culture on social capital from the view of teachers

H. Daeizadeh<sup>1\*</sup>, M. Jani<sup>2</sup><sup>1</sup> Department of Education, Bandargaz Branch, Islamic Azad University, Bandargaz, Iran, Iran;<sup>2</sup> Ministry of Education, Mazandaran Province, Babol City, Iran, Iran

\* Corresponding author.

**Introduction.**– The educational organizations especially schools and universities are very important organizations that has affected all other organizations because their manpower is influenced directly from human beings. Therefore, attention to culture and its effects to social capital in educational organs is an important and fundamental matter in this organization. So this research aimed to study the role of organizational culture on social capital from the view of teachers. Method: The statistical populations were all of teachers in 2014 academic year that with regards to Morgan's sampling table 306 teachers were randomly selected and responded to a self-

constructed questionnaire with 20 questions. Pearson correlation formula was used for analysis of the data.

**Results.**– The findings showed that all the subscales of organizational culture (network culture, collapsed culture, shared culture and the material-oriented culture) had positive and significant correlation with social capital from the view of teachers, that showed the importance of organizational culture on social capital from the view of teachers.

### Audit of physical investigations of patients admitted to burbage ward (an acute inpatient adult psychiatric ward)

M. Liao

Michael Carlisle Centre, Sheffield Health and Social Care NHS Foundation Trust, Sheffield, United Kingdom

**Introduction.**– It is well-documented that mental health patients often suffer from poor physical health due to a combination of lifestyle factors and the side-effects of antipsychotic medication.

**Objective.**– To ensure that patients admitted to an acute inpatient adult psychiatric ward have had the appropriate blood tests, ECG, and a full physical examination within the designated timeframe as per Trust guidelines.

**Methods.**– The 20 most recently admitted patients prior to 10th March 2017 were selected. This included 13 mental health patients and 7 detox patients, i.e. planned admissions for alcohol and benzodiazepine detoxification.

**Results.**– Of 13 mental health patients, 61% had all appropriate blood tests. 54% had an ECG. 86% had a full physical examination. Average time from admission to blood tests was 18 hours; from admission to ECG was 12 hours; from admission to full physical examination was 62 hours. Of 7 detox patients, 0% had all appropriate blood tests done. 0% had an ECG. 100% had a full physical examination. Average time from admission to blood tests was 2 hours; from admission to full physical examination was 5 hours.

**Conclusions.**– Excluding patients who had refused any physical health investigation until their discharge or time of data collection, all mental health patients had all physical health investigations done within 72 hours of admission. All detox patients had a full physical examination during admission, however, none had bloods tests requested as per Trust guidelines, none had an ECG, and there was no documentation for the rationale for outstanding investigations.

### Compilation of the neonatal palliative care clinical guideline in neonatal intensive care unit

M. Marofi

Isfahan University of Medical Sciences, nursing, Isfahan, Iran

**Background.**– Clinical guidelines are important instruments for increasing the quality of clinical practice in the treatment team. Compilation of clinical guidelines is important due to special condition of the neonates and the nurses facing critical conditions in

the neonatal intensive care unit (NICU). This study aimed at compilation of the neonatal palliative care clinical guidelines in NICU. **Materials and methods.**– This study was conducted with multistage comparative strategies with localization in Isfahan in 2013. In the first step, the components of the neonatal palliative care clinical guidelines were determined by searching in different databases. In the second stage, the level of expert group's consensus with each component of neonatal palliative care in the nominal group and focus group was investigated, and the clinical guideline was written based on that. In the third stage, the quality and applicability were determined with the positive viewpoints of medical experts, nurses, and members of the science board of five cities in Iran.

**Results.**– In the second stage, its rank and applicability were determined and after analyzing the responses, with agreement of the focus group, the clinical guideline was written. In the third stage, the means of indication scores obtained were 75%, 69%, 72%, 72%, and 68% by Appraisal of Guidelines for Research and Evaluation (AGREE) instrument.

**Conclusions.**– The compilation of the guideline can play an effective role in provision of neonatal care in nursing.

**M:** Clinical guideline, end-of-life care, neonatal intensive care unit, neonatal palliative care

### **A meta-review of prevention, remediation, and compensation/adaptation approaches to address HIV-associated neurocognitive disorders: implications for an aging population**

D. Vance\*, P. Fazeli

University of Alabama at Birmingham, School of Nursing, Birmingham, USA

\* Corresponding author.

**Introduction.**– Nearly 50% of adults with HIV experience observable cognitive impairments that interfere with everyday functioning and quality of life. By 2020 approximately 70% of the HIV population will be 50 and older; with age-related cognitive problems accompanying HIV-related cognitive impairments, exacerbations of neurological and cognitive issues in this population are expected.

**Objectives.**– This meta-review provides updated information on the biological and psychosocial mechanisms in which aging and HIV interact to impact neurological and cognitive functioning. Topics include neuroinflammation, microbial translocation, cognitive stimulation, neuroplasticity, and cognitive reserve. From this meta-review, approaches for prevention, remediation, and compensation/adaptation for such neurological and cognitive sequelae are provided.

**Methods.**– Using an exhaustive and on-going search of studies on this topic, IRB-approved studies are identified and synthesized for their efficacy in protecting or remediating cognitive reserve and cognitive functioning as well as for compensating/adapting for loss in cognitive functioning.

**Results.**– Numerous approaches are identified to prevent or remediate cognitive loss in adults with HIV such as: (1) lifestyle engagement (e.g., employment, cognitive prescriptions, social stimulation); (2) brain fitness programs (e.g., speed of processing training); (3) neuroprotective and psychostimulant agents; (4) HIV treatments themselves (i.e., combination anti-retroviral therapy); and (5) treatments of comorbid conditions such as depres-

sion/anxiety that can alleviate additional neurological insults. Compensation/adaptation approaches include spaced-retrieval techniques, mnemonics, and low-tech and high-tech solutions. Ineffective approaches are also identified such as: (1) anti-inflammatory medications and (2) acetylcholinesterase inhibitors.

**Conclusions.**– These approaches are important to consider for clinical and research purposes. Novel approaches are provided.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Intellectual disability**

### **Attention deficit hyperactivity disorder in adults with intellectual disabilities: A case series of pharmacological response**

R. Al-Khudairi<sup>1</sup>, B. Perera<sup>2</sup>

<sup>1</sup> North Middlesex University Hospital, Psychiatry, London, United Kingdom; <sup>2</sup> Barnet, Enfield and Haringey Mental Health Trust, Intellectual Disabilities, London, United Kingdom

\* Corresponding author.

**Introduction.**– Despite higher prevalence of ADHD in adults with intellectual disabilities (ID), ADHD is often under diagnosed and undertreated. There are few studies that assess response to medication in this population.

**Objectives.**– A case series of 29 adults diagnosed with ID and ADHD was conducted with an aim to analyse clinical characteristics and pharmacological response to ADHD medications.

**Methods.**– Patient records were screened for the primary outcome measures of symptomatic and functional response to ADHD treatment. Reasons for treatment cessation were also queried. Clinical characteristics of ID severity, EVmorbid mental health disorders and psychotropic medication use was assessed.

**Results.**– Overall, 83% of patients had moderate to severe ID. 76% of patients were diagnosed with autism. Anxiety and mood disorders were present in 21% and 17% of patients respectively. 79% of patients were on anti-psychotics and 48% on anxiolytics. Less than 50% of patients were on ADHD medications. Atomoxetine was the most commonly used ADHD medication (79%). 29% showed a complete response whilst 57% had a partial response. 14% did not respond to ADHD medications. Side effects (36%) and no response (36%) were common reasons for medication withdrawal.

**Conclusion.**– There is high usage of antipsychotic medications without a diagnosis of a psychotic disorder. However, there is low usage of ADHD medications despite the diagnosis of ADHD. Clinicians appear to use anti-psychotic medications instead of ADHD medications for ADHD symptoms. There was a varied response to ADHD medication. Further work is needed to guide decisions on best practise in this field.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0405

### **German mental health care in people with intellectual and developmental disabilities (IDD) in comparison to other European countries**

S. Elstner

Pfeiffersche Stiftungen, MZEB, Magdeburg, Germany

\* Corresponding author.

**Introduction.**– In Germany, Mental Health Care in people with IDD is mostly determined by experts' opinions. Particularities of the psychiatric assessment and treatment of people with IDD and a comorbid psychiatric disorder are taught neither at medical schools nor in the scope of the medical training of psychiatrists.

**Objectives.**– The present study examined the influence of socio-political aspects of Health Care on quality and organisation of Mental Health Care in people with IDD.

**Methods.**– Various aspects of Health Care systems in Germany and three other European countries were explored and juxtaposed subsequently with a special developed questionnaire.

**Results.**– The health care systems of four different European countries differ in socio-economical, educational and system-financed aspects.

**Conclusions.**– Differing organisational levels of national health care systems and socio-economical aspects within these countries contribute to the organisation of the Mental Health Care System in people with IDD. Suggestions for a better harmonisation of European Mental Health Care in people with IDD are offered.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Parent mediated intervention program for the children with neurodevelopmental disorders in South Asia: A systematic review**

K.N. Koly\*, M.S. Islam, A. Naheed

icddr-b, Initiative for Noncommunicable Diseases, Dhaka, Bangladesh

\* Corresponding author.

**Introduction.**– Evidences of parental programs are available mostly from developed countries but resources to address the needs of parents of children with Neurodevelopmental Disorders (NDDs) in south Asian countries are limited.

**Objective.**– The purpose of this systematic review was to identify the published literatures to explore if the parent mediated programs can improve social, behavioural and functional skills of children with NDD's in south Asian countries.

**Methods.**– Literatures were searched by the databases PUB MED, MEDLINE, PsycINFO, Google Scholar and Web of Science prior to February, 2017. Two independent researchers reviewed the articles for inclusion, and assessment of methodological quality.

**Results.**– Nineteen studies met the inclusion criteria includes 6 randomized control trials and 13 pre-post studies. Six (32%) studies conducted on parents of children with ASD followed by 6(31%) on intellectual disability, 3(16%) on ADHD and 4(21%) on the children with cerebral palsy. This review reported significant improvement among parents in terms of parent-child interaction, improving knowledge about the conditions and in children there were positive outcome in social communications skills, cognitive development and also activity in daily living. However, these findings are debatable due to small sample size, limited resource settings, and heterogeneous study settings.

**Conclusion.**– This study is the first one to document the parent mediated programs of the children with NDDs in South Asia. But, critically evaluating these literatures suggest that current evidence is very scant to draw a comprehensive conclusion about the outcomes and recommend further research in large scale to design appropriate programs in South Asia.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **A descriptive clinical profile of adults using neurodevelopmental services in Singapore: A pilot study**

J.P. Moon<sup>1\*</sup>, H.T. Tan<sup>2</sup>, K.F. Lam<sup>3</sup>, J.M. Lim<sup>4</sup>, C.C. Cheak<sup>4</sup>, M.Y.G. Tan<sup>1</sup>

<sup>1</sup> Institute of Mental Health, Adult Neurodevelopmental Service, Singapore, Singapore; <sup>2</sup> Institute of Mental Health, General Psychiatry, Singapore, Singapore; <sup>3</sup> Institute of Mental Health, Pharmacy, Singapore, Singapore; <sup>4</sup> Institute of Mental Health, Psychology, Singapore, Singapore

\* Corresponding author.

**Introduction.**– The Adult Neurodevelopmental Services Multi-disciplinary Team (ANDS MDT) Clinic at the Institute of Mental Health (IMH) in Singapore is a service for adults between 19 and 64 years old with intellectual disability (ID) and/or autism spectrum disorder (ASD). Little is known about the sociodemographic and clinical profile of this patient population.

**Objectives.**– This study aims to determine the sociodemographic and clinical features of outpatients who presented for care at the ANDS MDT Clinic as a new case.

**Methods.**– Initial assessments conducted at the ANDS MDT clinic from January 1<sup>st</sup> to March 31<sup>st</sup> 2015 were retrospectively reviewed. Descriptive data were collected and analysed.

**Results.**– A total of 53 patients were included. There were more males (72%) than females (28%) and the mean age was 27 years. The majority stayed at home (94%) with an immediate family member as their primary caregiver (91%). Nearly one-quarter needed some form of assistance in their basic activities of daily living. ID comprised of 47%, ASD 30%, and ID with ASD 13%. Common comorbidities were psychiatric disorders (40%) and epilepsy (13%). The most prevalent presenting complaint was aggressive behaviour towards others (34%). Psychiatric medications were either newly started or adjusted in 40% of patients and 64% were referred to allied health services.

**Conclusions.**– The profile of patients attending IMH's ANDS MDT Clinic revealed a high proportion of males with ID and/or ASD with EVoccurring psychiatric disorders with multiple behavioural, functional and social issues. The findings of this study support the need for a multi-disciplinary approach in managing this unique group of adults with special needs.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Developing mental health pathways for people with intellectual disability and mental disorders: Experience from a specialist intellectual disability service in North London, UK**

B. Perera<sup>1\*</sup>, K. Courtenay<sup>2</sup>

<sup>1</sup> Barnet, Enfield and Haringey Mental Health Trust, Intellectual Disability, London, United Kingdom; <sup>2</sup> Haringey, Barnet and Enfield NHS trust, Intellectual Disability, London, United Kingdom

\* Corresponding author.

**Introduction.**– Psychiatric illness is significantly high in people with Intellectual disability (ID). Increased prevalence is particularly seen in ASD, ADHD, dementia and challenging behaviour. Treatment of mental disorders often requires multidisciplinary approach, as they are due to multitude of factors. This often can lead to under diagnosis, under treatment, over medication and inequitable service.

**Objectives.**– To create mental health pathways, so people with ID presenting to mental health services are assessed and treated as per national guidelines and best practice.

**Methods.**– Various meetings were carried out involving members of the multidisciplinary team. There were no treatment pathways identified. Quality improvement methodology was applied to identify what changes needed to create pathways. New mental health pathways were created with the involvement of multidisciplinary team. NICE guidelines on mental disorders and other local and national guidelines were used to design these pathways.

**Results.**– Five pathways were created. This included ‘Mental illness’, ‘Challenging behaviour’, ‘ADHD’, ‘Autism’ and ‘Dementia’ pathways. Patients presenting to ID services with mental health problems fit in to one or more of these pathways. Each pathway clearly set out what assessments and interventions are needed within each pathway.

**Conclusions.**– Mental health pathways made sure that every patient receives the right assessment and intervention. This helped to reduce risks to patients and improved staffs’ understanding of what is expected when a patient is referred. It also helped to understand where each patient is in their journey when they get referred to specialist ID services. This also helped to use existing resources more effectively.

**Conflict of interest:**

Main author has been given honoraria to attend and speak in conferences.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Obsessive-compulsive and Psychotic symptoms in adolescent woman with 22q11.2 deletion syndrome and intellectual disability: A case report**

J. Santambrogio<sup>1\*</sup>, F. Colmegna<sup>2</sup>, C. Di Brita<sup>1</sup>, A. Merra<sup>2</sup>, M. Clerici<sup>1</sup>

<sup>1</sup> University of Milano Bicocca, Department of Medicine and Surgery, Monza MB, Italy; <sup>2</sup> S. Gerardo Health Care Trust, Psychiatric Department, Monza, Italy

\* Corresponding author.

**Introduction.**– The 22q11.2 deletion syndrome (22q11DS) occurs at around 1:4000 live births. The phenotype is variable and involves multiple organ systems, with high rates of psychiatric disorders and intellectual disability associated (Philip & Bassett, 2011). COMT, PRODH, GNBIL, PIK4CA, ARVCF are some genes in the 22q.11.2 deleted regions involved in influencing psychiatric phenotypes. In particular, the Val-108/158-Met COMT polymorphism could be possible risk factor for psychosis (Squarcione et al., 2013).

**Objectives.**– We assessed psychiatric condition in a 22q11DS case, referred in 2011 for psychiatric and psychological treatment to Youth Mental Health Service, treated until 2017, showing a good outcome.

**Methods.**– M. showed visual hallucinations, obsessive-compulsive disorder (OCD) with trichotillomania, stalking, challenging behaviours and mild intellectual disability (WAIS-R=67; Vineland Scale = Communication: 256/266; Daily Living Skills: 138/402; Socialization: 202/268; Motor Skills: 111/144). Haloperidol 1 mg was replaced with Aripiprazole 15 mg and Sertraline 100 mg), was replaced with Venlafaxine 150 mg. She started twice a month psychological consultations and protected category jobs.

**Results.**– At 2017 SCID-I, M. shows no more psychotic symptoms, OCD with trichotillomania is less severe, but still persists. At 2017 Vineland Scale = Communication: 248/266; Daily Living Skills: 312/402; Socialization: 226/268; Motor Skills: 136/144

**Conclusions.**– Aripiprazole showed efficacy on psychotic symptoms, and Venlafaxine improved her OCD, but trichotillomania persists. Psychological support has been important for M. to learn accepting her disability and coping with, while her parents still struggle with it.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Naltrexone and the Reduction of Self-injurious Behaviour in Patients With Intellectual Disability and Autism: A Case Series**

S. Zheng<sup>\*</sup>, S.G. Sajith

Institute of Mental Health, Adult Neurodevelopmental Service, Singapore, Singapore

\* Corresponding author.

**Introduction.**– Self-injurious behaviour (SIB) is challenging disorder to treat in patients with intellectual disability (ID) and autism. One of the mechanisms mediating SIB is that of the release of endogenous opiates<sup>1</sup>, leading to its possible treatment through the use of naltrexone, an opioid antagonist<sup>2</sup>.

**Aim.**– To describe two adult patients whose SIB improved with naltrexone.

**Method.**– A retrospective review of case files of patients who were treated with naltrexone was done in a specialist inpatient unit that admits adults with ID and/or autism with severe behavioural problems.

**Results.**– Mr A. (28-years-old) and Mr S. (22-years-old) have a history of severe ID with autism. Despite treatment with behavioural interventions and titration of psychotropics, namely anti-psychotics, anti-depressants and mood stabilisers, both patients continued to demonstrate significant SIB in the form of the hitting and banging of their heads. Following the initiation of naltrexone 50 mg OM, marked improvements in the frequency and intensity of their SIB were observed within weeks. No side effects e.g. liver enzyme derangements were noted. The improvements were sustained for months, particularly in the case of Mr A. The reduction in their SIB may be confounded by the concurrent titration of antipsychotics, though the magnitude of said dose increase was marginal.

**Conclusion.**– Naltrexone may be effective in reducing SIB in patients with ID and autism.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **The role of resilience and spiritual intelligence in life satisfaction of university students**

M. Azadi<sup>1\*</sup>, A. RahimiAsil<sup>2</sup>

<sup>1</sup> Department of Psychology, South Tehran Branch, Islamic Azad University- Tehran, I, Tehran, Iran; <sup>2</sup> Department of Psychology, South Tehran Branch, Islamic Azad University, Tehran, Iran, I, I, Iran

\* Corresponding author.

This study aimed to determine predictive role of resilience and spiritual intelligence in life satisfaction which was descriptive and correlation method. 293 students (158 males, 135 females) were

selected by random sampling stratified among students of different majors from Islamic Azad University South Tehran Branch and they completed the Connor-Davidson Resilience Scale (CD-RISC), Satisfaction with Life Scale and Spiritual Intelligence Self-Report Inventory. Data were analysed using Pearson's correlation, multiple regression analysis. The results indicated significant positive relationship between spiritual intelligence, resilience and life satisfaction. As other result, spiritual intelligence and resiliency 24% explained variance in life satisfaction in students. Also the correlation coefficients between variables were not significantly different in male and female students.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Physical health clinic in an acute mental health ward

A. Beaumont

Aintree University Hospital, Psychiatry, Liverpool, United Kingdom

*Introduction.*– The Physical Health Clinic was set up within acute adult inpatient wards to meet the physical health needs of the patients.

*Aims.*– The aims were:

- to promote patient autonomy and independence;
- to make the junior doctor's workload more manageable;
- to encourage a triaging system in the nursing staff.

*Methods.*– The need for a physical health clinic was identified by the consultant and junior on the wards. An hour of the junior doctor's time was put aside each week to run 10 minute appointments for the patients' physical health needs. Posters were put up on the ward to advertise the concept to the patients, who were asked to sign up themselves. Feedback from patients, ward staff and the junior doctor was taken to determine whether the initiative was successful.

*Results.*– The number of calls to the junior doctor reduced from 7 to 5 per week. Uptake to the clinic was poor but the appointments were appropriate. The junior doctor thought the initiative was a good idea but required better patient uptake and use from ward staff to be more successful. Ward staff agreed with this but asked whether appointments could be offered twice a week in case a physical health needs arose during the week.

*Conclusions.*– The initiative appears to have reduced the number of calls to the junior doctor for patients' physical health needs. However, to improve there needs to be a better awareness amongst patients and ward staff. There is greater onus on ward staff to make decisions about patient's physical health, which may require further training.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0413

### Patient satisfaction questionnaire adaptation process – Experience from Latvia

N. Berzina-Novikova\* M. Taube

Riga Stradins University, Psychiatry and Addiction disorder, Riga, Latvia

\* Corresponding author.

*Introduction.*– According to recent initiatives in quality evaluation in mental health care there appeared a great need of validated tool to assess the mental health care from the patient's point of view. A lot of researches suggest patient opinion as a best evaluation instru-

ment that is why we decided to use patient questionnaires. We have chosen Psychiatric inpatient patient questionnaire - on site (PIPEQ-OS) with a permission of Norwegian colleagues.

*Objectives.*– To determine patients' satisfaction with a quality of health care services in psychiatric inpatients subacute ward by mean of adaptation and validation of PIPEQ-OS in Latvia.

*Methods.*– Questionnaire was translated from English to Latvian and Russian languages and back-wards. Translations were tested in 20 cognitive interviews. The questionnaire was completed on a day before discharge. Item missing was assessed, and factor analysis was conducted. The scales were tested for internal consistency reliability using Cronbach's alfa, item-total correlation.

*Results.*– Pilot study was conducted for 8 months. 204 questionnaires were analysed. Questionnaire translation proved to be maintaining the principal of conceptual equivalent. Cognitive interviews showed the questions and topics were relevant to the patient group. 19 of 21 questions showed low missing data (<20%). Factor analysis identified 3 factors that met the criteria of Cronbach's alfa 0.7.

*Conclusions.*– The factor analysis revealed satisfactory reliability and usefulness in clinical practice. Further study in acute department is needed to be conducted. Further addition of the social and demographic data need to be done with the aim to make correlation analysis in the spectrum of diagnoses.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Quality of life of Tunisian women during pregnancy

I. Bouzouita<sup>1\*</sup>, F. Ellouze<sup>2</sup>, H. El Kefi<sup>1</sup>, A. Baatout<sup>1</sup>, C. Ben Cheikh<sup>1</sup>, M.W. Krir<sup>1</sup>, S. Eddhif<sup>1</sup>, B. Bouguerra<sup>3</sup>, A.A. Oumaya<sup>1</sup>

<sup>1</sup> Hôpital militaire principal d'instruction de Tunis, Psychiatry, Tunis, Tunisia; <sup>2</sup> Razi Hospital, Psychiatry, Manouba, Tunisia; <sup>3</sup> Charles Nicolle Hospital, Gynecology B, Tunis, Tunisia

\* Corresponding author.

*Introduction.*– Many changes can occur during pregnancy. These changes may be important and affect each physical and mental health of women.

*Objective.*– The objectif of our study is to evaluate the quality of life of pregnant women.

*Methods.*– We conducted a cross-sectional study among a population of pregnant women. We collected 100 participants. A questionnaire was used to precise the demographic data. The quality of life was evaluated by the Short-Form Health Survey SF 12 which contains two scores: Mental Component Summary scale score: MCS and Physical Component Summary scale score: PCS. *Results.*– The mean age of the pregnant women was 29,4 ± 5,6 years versus 35,4 ± 6,5 years for the husbands. 67% of the participants were of rural origin and 33% of urban origin. 50% had secondary school education and 22% had high school education. 62% of the sample were housewives. 73% of participants were of medium socioeconomic status and 25% were of high status. The duration of marriage was 18 ± 4,6 months. It was a love marriage in 67% of the cases. Marital agreement was reported in 65%. Overall, 61% of women had the mean score of physical health (PCS) at 50 ± 10 and 65% had the mean score of mental health at 50 ± 10.

*Conclusions.*– Many factors can affect the quality of life of pregnant women which is important during pregnancy. Many other researches can be useful to evaluate the quality of life of women during pregnancy.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Medical-seeking behavior as mediator in relation to posttraumatic growth in oral cancer survivors: A longitudinal study

Y.C. Lu<sup>1</sup>, T.M. Lin<sup>2</sup>, C.C. Chang<sup>3\*</sup>

<sup>1</sup> chung shan medical university, School of Nursing, Taichung, Taiwan R.O.C.; <sup>2</sup> Hsin Sheng College of Medical Care and Management, Department of Nursing, Taoyuan City, Taiwan R.O.C.; <sup>3</sup> chung shan medical university, medical informatics, Taichung, Taiwan R.O.C.

\* Corresponding author.

**Introduction.**– The diagnosis and treatment of oral cancer can be a traumatic experience with long-lasting psychological effects. Research examining the relationship between distress and post-traumatic growth has been inconsistent. Additional research is required to provide enhanced understanding of this complex relationship.

**Objective.**– This present longitudinal study was to examine the mediating effects of medical-seeking behaviour underlying the relationship between distress and posttraumatic growth (PTG).

**Methods.**– The Chinese version of the Impact of Event Scale – Revised (IES-R), Depression scale, Posttraumatic Growth Inventory (PTGI), medical-seeking behaviour (ie., shared decision making/decisional regret/decisional conflict/decisional trust) were completed by 54 oral cancer survivors participating in a surgical reconstruction program at baseline and at 6 and 12 months' follow-up. Hypotheses were tested through the use of hierarchical multiple regression.

**Results.**– The results showed that decisional regret and decisional trust mediate completely the relationship between distress and PTG. Moreover, depression could effectively predict patients' shared decision making and decisional regret behaviours. Finally, testing for the moderating effects provides helpful information regarding the role of medical-seeking behaviour in buffering the relationship between distress and PTG.

**Conclusions.**– Previous studies characterize the relationship between distress and PTG with the potential for positive and negative outcomes. The preliminary findings suggest that interventions should address the perceived effectiveness of medical-seeking behaviour from practitioners. Results indicated that clinicians have to consider the presence of decisional regret and decisional trust among patients with oral cancer to address their psychological well-being.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Exploring the effectiveness of a befriending scheme for individuals with schizophrenia (VOLUME)

A. Chevalier<sup>1\*</sup>, M. Cassidy<sup>2</sup>, S. Priebe<sup>2</sup>

<sup>1</sup> East London NHS Foundation Trust, Unit for Social and Community Psychiatry, London, United Kingdom; <sup>2</sup> Queen Mary, University of London, Unit for Social and Community Psychiatry, London, United Kingdom

\* Corresponding author.

**Introduction.**– People with schizophrenia are often socially isolated, which in turn is linked with poor physical and mental health outcomes. Befriending schemes, where volunteers provide one-to-one support to people who would otherwise be socially isolated, cost relatively little and have the potential to improve outcomes for this patient group. Yet, there is hardly any trial-based evidence for their effectiveness.

**Objectives.**– The VOLUME trial was an exploratory randomised controlled trial (RCT) designed to test the effectiveness and cost-effectiveness of a befriending scheme developed for the UK context. **Methods.**– Patients with a diagnosis of schizophrenia ( $n=127$ ) were randomised to the intervention – which involved regular contact with a volunteer for up to one year – or an active control.

**Results.**– For the first time, the quantitative results of VOLUME trial will be presented in full. Outcomes include time spent engaging in activities, social contacts, quality of life, symptoms and care costs. We also report on retention in the scheme as a proxy for acceptability.

**Conclusions.**– It is possible that befriending is an untapped resource that can have a positive impact for many patients worldwide. This may be especially true for schemes that are flexible to accommodate the preferences and life styles of many patients and volunteers.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0417

### Patient and volunteer experiences of a befriending scheme for individuals with schizophrenia (VOLUME)

A. Chevalier<sup>1\*</sup>, M. Cassidy<sup>2</sup>, S. Priebe<sup>2</sup>

<sup>1</sup> East London NHS Foundation Trust, Unit for Social and Community Psychiatry, London, United Kingdom; <sup>2</sup> Queen Mary, University of London, Unit for Social and Community Psychiatry, London, United Kingdom

\* Corresponding author.

**Introduction.**– Befriending schemes, where volunteers provide one-to-one support to individuals who would otherwise be socially isolated have the potential to be effective for patients with schizophrenia. VOLUME is a programme of research whose main aim was to develop a best-practice befriending scheme to be evaluated in an exploratory randomised control trial.

**Objectives.**– This presentation will focus on the qualitative output of the trial and explore the experiences of befriending and of receiving a befriender.

**Methods.**– Soon after completing the scheme, both patients and volunteers were invited to take part in individual in-depth interviews, to gain a better understanding of acceptability and response to the intervention. For this reason, we also endeavoured to interview those that dropped-out or met less regularly than planned.

**Results.**– A high proportion of eligible patients ( $n=30$ ) and volunteers ( $n=33$ ) agreed to take part in the interviews. Many reported positive experiences and personal growth following the scheme. Others experienced challenges and failed to establish an enduring relationship.

**Conclusions.**– Befriending can have a very positive impact for patients with schizophrenia as well as for volunteers. Understanding the factors which influence a successful befriending relationship can help to target the patients that are likely to benefit the most and maximise their implementation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Evaluation of master of science in integrated clinical and community mental health program in Ethiopia

M. Daba<sup>1\*</sup>, M. Tesfaye<sup>2</sup>, K. Adorjan<sup>3</sup>, S. Dehning<sup>4</sup>, T. Asaminew<sup>5</sup>, M. Abera<sup>1</sup>, A. Jobst<sup>3</sup>, M. Siebeck<sup>6</sup>

<sup>1</sup> Jimma university, Psychiatry, Jimma, Ethiopia; <sup>2</sup> Millennium Medical College, Psychiatry, Addis Ababa, Ethiopia; <sup>3</sup> LMU, Psychiatry and Psychotherapy, Munich, Germany; <sup>4</sup> LMU, Department of Psychiatry and Psychotherapy, Munich, Germany; <sup>5</sup> Jimma University, Ophthalmology, Jimma, Ethiopia; <sup>6</sup> LMU, Department of Surgery, Munich, Germany

\* Corresponding author.

**Introduction.**– The shortage of trained man power in the field of mental health remained an important barrier to the treatment of persons affected by mental illnesses in low and middle income countries. A new graduate program for non-physician clinicians was established at Jimma University to address the scarcity mental health human resource in Ethiopia. Therefore, this study aimed to assess the competency, satisfaction and involvement level of graduates of the program.

**Methods.**– A cross-sectional study was conducted among all the 28 of 32 graduates from the program. Data was collected using a semi-structured self-administered questionnaire that was developed for the study. Likert types of responses were used to assess competency and satisfaction level of graduates. Strengths and weaknesses of the program, courses to be added or removed from the program, and suggestions of graduate on the general program were assessed qualitatively using open ended questions. Both quantitative and qualitative data were collected.

**Results.**– Until June 2015, 32 trainees have graduated from Jimma University. The majority (75%,  $n = 21$ ) of the graduates were directly engaged in clinical care of patients. Also, two-third of the graduates (67.9%,  $n = 19$ ) were involved in mental health research. All of the graduates were confident to conduct psychiatric assessment of adults and to identify and manage common mental disorders (100%,  $n = 28$ ). Similarly, 100% ( $n = 28$ ) of graduates reported they were confident in identifying and managing severe mental illnesses.

**Conclusion.**– Brain drain does not appear to be a challenge among non-physician mental health specialists.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### The diet and aggression study: Reducing aggression among chronic psychiatric inpatients through nutritional supplementation

N.J. de Bles<sup>\*</sup>, N. Rius-Ottenheim, A.M. van Hemert, E.J. Giltay  
Leiden University Medical Center, Department of Psychiatry, Leiden, The Netherlands

\* Corresponding author.

**Background.**– Aggressive incidents are highly prevalent among chronic psychiatric inpatients. Previous studies have already demonstrated the potential of supplementation to reduce aggression in maladjusted children and forensic populations.

**Objectives.**– The aim of the current study is to test the hypothesis that multivitamin-, mineral-, and  $n$ -3FA supplementation reduces the incidence and severity of aggressive incidents among chronic psychiatric inpatients.

**Methods.**– The Diet and Aggression study is a pragmatic, multi-center, randomized, double-blind, placebo controlled, intervention trial. Eligible for the study are psychiatric inpatients aged 18 years

or older, who are residing in open and closed long-stay psychiatric wards. During 6 months one group receives 3 supplements daily: 2 Orthica Multi Energie (containing vitamins and minerals) and 1 Orthica Fish EPA Mini (containing  $n$ -3FA: eicosapentaenic acid [EPA] and docosahexaenic acid [DHA]). The control group receives 3 placebo capsules.

**Outcome parameters.**– The main parameter is the number of aggressive incidents as registered with the Staff Observation Aggression Scale-revised (SOAS-R). At three points during follow-up questionnaires will be administered: the Aangepaste Versie van de Aggressievragenlijst (AVL-AV), a 12 item self-report questionnaire about feelings of aggression; the World Health Organization Quality of Life Questionnaire (WHOQOL-BREF), a 26-item observer rated quality of life instrument; and a 25-item observer rated instrument that includes the Montgomery Asberg Depression Rating Scale (MADRS). Also, blood samples will be taken to determine nutritional status. Lastly, at four time points, nursing staff will fill out the Social Dysfunction Aggression Scale (SDAS), measuring observed levels of aggression and social dysfunction.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Cognitive emotion regulation strategies to mothers raising children with burn injuries in various stages of treatment

D. Dovbysh<sup>1,2</sup>

<sup>1</sup> Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation, Department of Pedagogy and Medical Psychology, Faculty of Higher Nursing Education and Psycho Social Work, Moscow, Russia; <sup>2</sup> Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Moscow Department of Health Care, Scientific-practical Children's and Adolescents Mental Health Center n.a. G. Sukhareva, Moscow Department of Health Care, Moscow, Russia

\* Corresponding author.

**Introduction.**– Processing of mother's own traumatic experience, the availability of adaptive strategies for the regulation of their emotional state is one of the most successful factor of organisation of the child's treatment

**Objective.**– To conduct a comparative analysis of cognitive emotion regulation strategies used by mothers at different stages of child's burn injury treatment.

**Methods.**– The first group included 28 mothers who were hospitalized due to the recent (from 5 to 14 days) burn injury of a child. The second group consisted of 12 mothers who are on planned hospitalization with the child due to the effects of burn injury (12-18 months ago). Mothers were asked to conduct CERQ (N. Garnefski), Beck Depression Inventory (A. Beck), The Trait Anxiety Scale (Spielberger) questionnaires.

**Results.**– In both groups of mothers one of the most popular was the strategy of "Self-blame". is "Planning" and "Positive refocusing" and "Putting into perspective", and in the first group - "Rumination" and "Catastrophizing". In the first group, only the strategy "Rumination" is positively correlated with a reduction of severity of depression and "Catastrophizing" and "Self-blame" - negatively. In the second group "Self-blame" strategy positively associated with the severity of depression and the "Positive refocusing" - negatively. The strategy of "Planning" in the first group is negatively associated with the severity of situational anxiety, and the second - positive.

**Conclusion.**– Emotion regulation strategies do not remain the same and have a multi-directional correlation with symptoms of depression and anxiety at various stages of treatment

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Professionals' attitudes towards medication in mental health care service**

K. Drivenes<sup>1\*</sup>, Y.L. Lauge<sup>2</sup>, J.K. Vederhus<sup>1</sup>, A.C. Irgens<sup>1</sup>, H. Regevik<sup>3</sup>, E. Gro Merethe Grønvold<sup>1</sup>, V.Ø. Haaland<sup>1</sup>

<sup>1</sup> Sørlandet Hospital, Division of mental health, South Norway, Norway; <sup>2</sup> Kristiansand hospital pharmacy, South Eastern Norway Hospital Pharmacy Enterpris, Kristiandand, Norway; <sup>3</sup> Sørlandet Hospital, User representative, Division of mental health, South Norway, Norway

\* Corresponding author.

**Introduction.**– Division of Mental Health at Sørlandet Hospital serves 300 000 inhabitants in South Norway. A diversity of diagnoses are handled, and patients ranging from infants to elderly are targets for the service. The service includes inpatient and outpatient treatment, daycare, and ambulatory supervision. The therapists hold different professions, which can affect treatment provided by the service

**Objectives.**– In Norway there has been focus on medication-free options in mental health care recent years. Political expectations of drug-free treatment options for all patients in mental health care are communicated. Therefore, an initiative to explore therapists' perceptions towards medical treatment was taken.

**Methods.**– A one week cross-sectional study was conducted. All therapists at the division were eligible to respond to Horne's general Beliefs about Medicines Questionnaire (BMQ), which assesses understanding of drug overuse and harm. A higher score represents a more negative perception that drugs are harmful or overused.

**Results.**– Of 405 therapists, 310 responded to the survey. On a scale 4–20 they reported mean 11.97 (SD 2.39) on drug overuse, and 9.63 (SD 2.13) on drug harm. The professions doctor and psychiatrist reported a significant lower score ( $p=0,015$  and  $p=0,001$ , respectively) on the subject drug overuse today, and on perception towards drugs doing harm (both  $p<0,001$ ). Older therapists (>54 years) reported significant higher ( $p=0,009$ ) perception that drugs are more harmful.

**Conclusions.**– The therapists' attitudes towards drug treatment in mental health care vary between the different professionals. If drug-free treatment option accessible for all patients shall be realized, the service needs experienced professionals who appreciate this working mode.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Assertiveness and coping strategies in first year medical students in Sarajevo**

A. Dzubur Kulenovic<sup>1\*</sup>, M. Prndelj<sup>2</sup>, R. Softic<sup>1</sup>

<sup>1</sup> University of Sarajevo Clinical Center, Department of Psychiatry, Sarajevo, Bosnia, Herzegovina; <sup>2</sup> Community Health Center Sanski Most, Family Practice, Sanski Most, Bosnia, Herzegovina

\* Corresponding author.

**Introduction.**– Enrolling into university represents a significant life change and an overall challenge for adaptive potentials of older adolescents. Failing to complete first is an additional major stress,

for students who by the rule have previous history of outstanding achievements in education. This stress may reduce their self-esteem and further compromise academic performance. [1,2] **Aim:** To assess possible relationship and differences between assertiveness and coping strategies in first year medical students. **Subjects:** The study subjects were 225 first-year medical students of Sarajevo Medical Faculty: 133 enrolled for the first time and 92 re-enrolled after failing first year.

**Methods.**– The study used coping strategies scale (Folkman & Lazarus), [3,4] Rathus Assertiveness Schedule, and a socio-demographic questionnaire developed for this study [5].

**Results.**– Our results indicate significant difference between assertiveness measured by Rathus scale and coping strategies assessed by Folkman & Lazarus scale between two groups of students. Significant differences were found between male and female students and students who have moved from the place of origin to Sarajevo and those who did not change residence. We found significant positive correlation between assertiveness measured by the Rathus Assertiveness Schedule and the sub-scales of Folkman & Lazarus scale on confrontation and solution planning on the level of  $p<0,01$ . Assertiveness was found to significantly correlate with acceptance of responsibility and avoidance/escape on the level of  $p<0,05$ .

**Conclusions.**– Our results may provide further evidence for the idea of providing non-stigmatizing counseling and psychoeducation and assertiveness training for first year medical students within the Faculty.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Face-body emotions' recognition and clinical communication – A study in psychiatric nurses**

M. Figueiredo-Braga<sup>\*</sup>, P. Acácio e Correia

Faculty of Medicine, University of Porto, Clinical Neurosciences and Mental Health, Porto, Portugal

\* Corresponding author.

**Introduction.**– Effective communication is a fundamental element of nursing care which requires the ability to recognize emotions, be empathic and to gather and share relevant information. Studies addressing communication skills in the relationship between nurses and their patients in psychiatric contexts are scarce.

**Objectives.**– To examine the ability to recognize emotions in psychiatric nurses and explore the relationship of this ability with the use of specific communication strategies.

**Method.**– This observational study followed a cross sectional design. Fifty-two nurses working in a psychiatric hospital accepted to participate. The Emotions Revealed Photo Set, the Bochum Emotional Stimulus Set, the Face-Body Compound and a socio demographic questionnaire were included in the survey. Nurses were also questioned about their communication strategies. Results were analysed using SPSS version 20.0.

**Results.**– Nurses working in psychiatric settings were able to recognize six basic emotions using static facial and body stimulus. Happiness and surprise facial expression were accurately identified; anger, and fear presented high scores of correct answers in body stimuli. Happiness, fear and surprise identification was associated with the use of specific communication strategies.

**Conclusions.**– The ability to identify basic emotions (face and body stimulus) was associated with the nurse's capacity to dialog and be empathic when dealing with psychiatric patients. Understanding patient's emotions from non-verbal emotions recognition may

have an essential function in health professional communication training.

### **Clinica Dos Decanoatos – A community psychiatry project**

A.R. Figueiredo<sup>1</sup>, A. Soares, S. Nunes, M. Silva, M. Roque  
*Centro Hospitalar Trás-os-Montes e Alto Douro, Psychiatry and Mental Health, Vila Real, Portugal*

\* Corresponding author.

*Objectives.* – Characterize psychiatric population treated with long-acting injectable antipsychotics within a Community Psychiatry project in Centro Hospitalar de Trás-os-Montes e Alto Douro. Evaluate eventual differences in hospital readmission rates as a result of integration in this community psychiatric care.

*Methods.* – Descriptive study, with retrospective analysis of clinical files of patients integrated into a Community Psychiatry project.

*Results/conclusions.* – The direct area of influence of Trás-os-Montes and Alto Douro Hospital Center, in Portugal, covers about 330,000 inhabitants. This Psychiatric Service consists of 5 psychiatrists, psychiatric trainees, 14 nurses, 2 psychologists and 1 social work assistant. In order to enhance treatment adherence among patients with psychosis and initially thinking mainly in those with precarious family or economic conditions, a team of three mental health nurses started making home visits to provide follow-up injectable medication, as well as psychoeducational interventions about antipsychotic medication. Other patients were referred to primary care setting for injectable medication administration. Recently a psychiatrist and psychiatric trainees joined this team, the aim is to provide urgent consultations in case of decompensation, referred by primary care or mental health nurses. Authors reviewed 134 clinical cases to characterize the population (sex, age, diagnosis and prescribed long-acting injectable antipsychotic) and systematize the number of hospital admissions (emergency and hospitalizations) before and after the follow-up by the community team. By the time of this submission all the team is still processing the collected data. The results are important to assess needs and optimize available resources.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0425

### **Complicated grief or do we complicate it? – Clinical cases in ER**

A.R. Figueiredo, M. Roque

*<sup>1</sup>Centro Hospitalar Trás-os-Montes e Alto Douro, Psychiatry and Mental Health, Vila Real, Portugal*

\* Corresponding author.

*Objectives.* – Description of grief reactions clinical cases referenced to a Psychiatric Emergency Room (ER) in Trás-os-Montes and Alto Douro Hospital Center (CHTMAD) for one day.

*Methods.* – Description of grief reaction cases evaluated by the authors during one day at a Psychiatric ER. Review of the literature on the approach to grief reactions in the ER.

*Results.* – The direct area of influence of CHTMAD covers about 330,000 inhabitants. The psychiatric care activity in the ER is performed daily between 8am–8 pm. The interest arose by the fact that in seven cases oriented to Psychiatry, five were grief reactions. Among these, two were related to the death of a family member in the previous day, and another in the previous week. One of these

patients was advised by dissociative symptomatology. As for the two remaining cases, these were complicated grief reactions, one of which was a birthday reaction. Four of these cases were referred by other health professionals. There is no evidence that uncomplicated grief requires professional intervention, but if it is sought, empathic support and validation of normal reactions are important. In complicated grief, a psychotherapeutic intervention addressed to the problem and if necessary psychopharmacs may be relevant, however more in the context of a follow-up rather than in the contact in an ER. It is important to distinguish between normal versus pathological, for a correct orientation and treatment.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0426

### **Giftedness is it a predictor or risk factor for mental health**

F. Gallopeni<sup>1\*</sup>, M. Gomà-i-Freixanet<sup>2</sup>

*<sup>1</sup> Heimerer College, Universitat Autònoma de Barcelona, Clinical and Health Psychology, Prishtine, Kosovo; <sup>2</sup> Universitat Autònoma de Barcelona, Health and Clinical Psychology, Barcelona, Spain*

\* Corresponding author.

Starting with Lewis Terman in the 1920s, many theorists have traditionally looked to high general intelligence, IQ, measured by standardized psychometric instruments as the principal indicator of giftedness.

Rather than being a source of vulnerability, empirical research has shown that giftedness is a protective factor for mental health.

This research was organized in the professional condition, with a sample of gifted and non-gifted adolescents. The Youth Self Report was used to measure mental health problems and Standard Progressive Matrices test SPM+ to assess the IQ.

Results show that intelligence correlates positive and significantly with externalization problems, attention problems and rule-breaking behaviour, although the association is weak. Comparison between both groups showed no significant differences on emotional and behavioural problems.

Linear regression analysis with intelligence, gender, age, place of living and success in school as predictors, and mental health problems as the dependent variable. The model was significant and explained 10% of variance, the significant predictor was Intelligence, gender, age and school success.

Linear regression showed the same results just with higher level of variance as a predictor was intelligence, gender, age, place of living and success in school, where significant predictor was intelligence, age and school success.

According to our results and some other studies, high intelligence is not a predictor of mental health problems, specifically emotional and behavioural problems. It serves more as a predictor of mental health because of high ability and high level of self-resilience.

*Keywords.* Intelligence; Emotional problems; Behavioural problems

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

EV0427

### **Lifestyle habits in a severe mental disorder sample**

B. Girela Serrano<sup>1\*</sup>, M. Guerrero Jiménez<sup>2</sup>, C.M. Carrillo de Albornoz Calahorra<sup>3</sup>

*<sup>1</sup> Hospital Santa Ana Motril, Psiquiatría, Motril- Granada, Spain, <sup>2</sup> Granada, Spain, <sup>3</sup> H, p, Granada, Spain*

\* Corresponding author.

**Aims.**– To analyze lifestyle habits in a sample of patients with Severe Mental Disorder (SMD) in community monitoring. Guess if patients taking more antipsychotic drugs are using tabaco or other drugs to get auto-medicated.

**Methods.**– A total sample of 30 patients was taken (43% (13) were women and 57% (17) men). The inclusion criteria were belonging to the USMC Motril and meeting criteria for a Severe Mental Disorder diagnosis. Data were analysed using SPSS statistical analysis.

**Results.**– Tabaco and number of antipsychotic drugs: Smokers were more than a 76% of the sample. The average of smoked cigarettes a day was 30. 100% of women smoked compared to 58.8% of men, being statistically significant this association. The average age of consumers was lower than nonusers. As for the possible relationship between smoking and the number of antipsychotic drugs, it was not statistically significant. Other Drugs: 23% consumed other toxics, specially alcohol and cannabis. 100% were tabaco consumers at the same time snuff. Physical Activity and other variables: For other variables, the results were not significant, but there was a high degree of physical inactivity among individuals in the sample, of which only 16.7% performed exercise.

**Conclusions.**– In young populations, such as patients with TMG it highlights a sedentary lifestyle mainly, moreover, smoking prevalence is high, especially among women and often comorbid consumption of other toxic, especially alcohol. We did not find an association between number of antipsychotic drugs and smoking, further investigations should be made taking into account the dose.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Describing caffeine consumption among severe mental disorders in Motril, Spain**

B. Girela Serrano<sup>1\*</sup>, C.M. Carrillo de Albornoz Calahorro<sup>2</sup>, M. Guerrero Jiménez<sup>3</sup>

<sup>1</sup> Hospital Santa Ana Motril, Psiquiatría, Motril- Granada, Spain; <sup>2</sup> Psychiatrist, Mental Health Services Granada Sur, Granada, Granada, Spain, <sup>3</sup> Psychiatrist, Mental Health Services Granada Sur, Granada, Psychiatry, Granada, Spain

\* Corresponding author.

**Background.**– Caffeine is a mild stimulant with well characterized cardiovascular actions and effects on neurotransmitter turnover in peripheral and central nervous system. Schneider and Siris suggested that schizophrenia was associated with increased rates of caffeine consumption (1).

**Objectives.**– We aim to evaluate caffeine consumption among serious mental disorder patients treated in day hospital regime carried out by trained personnel and ICD-10 diagnosis of the same and the main sociodemographic characteristics of patients.

**Methods.**– We described the profile of the study population (n=22). Measures were used trend central and dispersion (mean ± standard, quantitative variables and median deviation distribution of absolute and relative frequencies for categorical variables). The results of quantitative variables were expressed as a percentage

**Results.**– The mean age was 35 years old. (15 M, 7 F). The most prevalent diagnosis was paranoid schizophrenia (54%) followed by severe personality disorder (22%). 77% smoked regular cigarettes. The average daily caffeine consumption was 224gr.

**Conclusion.**– Our clinical experience suggests that average schizophrenia inpatients may have more access to caffeine and tobacco products. The limited published information suggests that the extreme use of very high levels of caffeine, or caffeinism, may be particularly associated with schizophrenia. Our survey indi-

cate that no schizophrenia patients show caffeinism, defined as >700 mg/day.

### **Prevalence and correlates of work stress among nurses working in psychiatric inpatient facilities, in Colombo district, Sri Lanka**

J. Gunasekera<sup>1\*</sup>, I. Suraweera<sup>2</sup>

<sup>1</sup> Registrar in Public Health/Community Medicine, Health Education Bureau, Sri Lanka, Kottawa, Sri Lanka, <sup>2</sup> Ministry of Health, Sri Lanka, Department of Environmental and Occupational Health, Colombo, Sri Lanka

\* Corresponding author.

**Introduction.**– Work stress among nurses in psychiatric care is considered an important occupational health problem due to the nature of the services provided. However, studies on work stress in this study group is scarce in Sri Lanka. An understanding of such factors could greatly help in designing policies related to mental health and occupational health.

**Methodology.**– This descriptive cross-sectional study was conducted among nurses working in the three in-ward psychiatric facilities in capital Colombo. The entire population (N=345) was given a pre-tested self-administered questionnaire composed of two parts; validated Job Content Questionnaire and questionnaire on correlates. Prevalence of Work Stress was measured using two indices as described by Karasek in the dynamic job strain model, namely; 'High Job Strain'(HJS) and 'Iso-strain'(IS).

**Results.**– Prevalence of HJS and IS was 37.2% and 21.4% respectively. Factors significantly associated with HJS were; being single (OR=1.84, 95%CI=1.15-2.95), working more than 48 hours weekly (OR=1.71,95%CI=1.05-2.78), violence by patients (OR=3.45,95%CI=1.81-6.57), verbal abuse by patients (OR=3.11, 95%CI=1.80-5.39), mental health concerns (OR=2.68,95%CI=1.595-4.40), stigma (OR=2.21,95%CI=1.24-3.94), lack of assistance at work (OR=4.56,95%CI=1.68-12.27), difficulty in obtaining leave (OR=2.98, 95%CI=1.48-6.00), inadequate welfare facilities (OR=1.62,95%CI=1.01-2.59) and poor work recognition (OR=2.89,95%CI=1.68-4.96).

**Discussion.**– The prevalence of HJS was significant among nurses. It was comparatively higher than the prevalence values obtained among other occupations. More than ten factors were identified as increasing the risk of High Job Strain where Iso-strain was associated with five factors. Some factors that are associated with HJS were not associated with IS indicating that positive social support could counter the negative impacts of work stress.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Developing principles of parents' mental care in NICU**

M. heidarzadeh<sup>1\*</sup>, H. heidari<sup>2</sup>

<sup>1</sup> Mashhad medical university, ministry of neonatal health, neonatal, mashhad, Iran; <sup>2</sup> Shahrekord University of Medical Sciences, Shahrekord, Iran, Faculty of Nursing and Midwifery, Shahrekord, Iran

\* Corresponding author.

**Introduction.**– Hospitalization of infants in NICU will result in appropriate interaction with infants and as a result, it gives rise to anxiety and depression and finally the family can't play its role well. Therefore, it is necessary for the caring team to be familiar with principles of parents' mental care in NICU. Thus, a study with the purpose of codifying principles of parents' mental care in NICU was carried out.

**Method.**– This study is a triangulation study which was carried out in two steps. At first step, principles of mental care for parents in NICU were compiled and translated. In second step, the principles were edited using Delphi technique and experts' opinion (physicians, faculty members, health policymakers) and eventually final principles of parents' mental care in NICU were codified.

**Results.**– Based on our results, 4 general principles of holistic care, relationship with parents in NICU, special care for establishing relation with families in NICU and principles of infants and family care were obtained.

**Conclusion.**– Since caring team is not familiar with principles of parents' mental care in NICU, therefore the results of the present study can be considered as an important step in promoting knowledge of caring team in dealing with parents.

### Pathways to psychiatric care in psychiatric hospital of Sarajevo

A. Hrnjica<sup>1\*</sup>, S. Bise<sup>1</sup>, Š. Šarkić- Bedak<sup>1</sup>, D. Begić<sup>2</sup>, R. Šetić<sup>3</sup>  
<sup>1</sup> Psychiatric hospital of Sarajevo, Women department, Sarajevo, Bosnia, Herzegovina; <sup>2</sup> Psychiatric hospital of Sarajevo, Intensive care unit, Sarajevo, Bosnia, Herzegovina; <sup>3</sup> Mental Health Center, Sarajevo, Psychology department, Sarajevo, Bosnia, Herzegovina  
 \* Corresponding author.

**Background.**– Patients suffering from psychiatric disorders use different pathways to seek psychiatric care. Many get non-professional care before attending specialized services.

**Aims.**– This paper's objective was to study help-seeking behaviour of patients referred to Psychiatric hospital of Sarajevo (PHS).

**Methods.**– Study included all patients referred to the named facility in two month period. Eligible patients were adults, in their first episode of psychiatric illness, or those who were in remission before current episode, and without psychiatric care during previous one year.

**Results.**– The sample consisted of 34 patients; 17 male and 17 female. Most of patients, 23 (67.6%) did have history of psychiatric care, for 11 (32.4%) this was first episode of mental illness. Overall, 11 (32.4%) patients finished their pathway to care on first step; professional care was provided on second step to 23 (67.6%), on third to 6 (17.6%) on fourth step to 4 (11.8%) patients. Majority interpreted symptoms to be a signs of somatic illnesses, therefore were more likely to consult some other specialists, 15 (44.1%), or GP's, 2 (5.9%); 6 (17.6%) patients first consulted traditional healers. In 25 (73.5%) cases, patients were with poor insight, and were advised to seek help, 9 (26.5%) were with insight, and admitted by themselves.

**Conclusion.**– Most of patients were with poor insight, were more likely to seek the help of various sources prior attending PHS. Their pathways to psychiatric care mostly consist of two steps.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Assessment of family burden associated with severe mental illness in Azerbaijan

J. Ismayilova  
 National Mental Health Center, Consultation and Treatment Department, Baku, Azerbaijan

**Introduction.**– The impact of mental disorders on families which one member is suffering from mental illnesses is incredibly large.

**Objective.**– The aim was to answer the following questions: How heavy is the burden of mental illness on family members? What are the caregivers consequences? How mental disease effects on the relationship in the family? If there is a correlation between caregivers' consequences and clinical characteristics.

**Methods.**– This was cross-sectional study which involved 50 family members whose closest relative suffer from Severe Mental Illness and get outpatient treatment at National Mental Health Centre in Baku, Azerbaijan. Involvement Evaluation Questionnaire (IEQ-EU) were used as assessment tool.

**Results.**– The majority of family members considered a patient's illness as a heavy or very heavy burden ( $\chi^2 = 18.4$ ;  $df = 4$ ;  $p = 0.001$ ) Although many family members reported that they had completely got used to patients' mental health problems. But most of them never felt able to cope with these problems ( $\chi^2 = 13.6$ ;  $df = 4$ ;  $p < 0.009$ ). Important that the burden perceived by family members, their tolerance to patients' mental health problems, and their ability to cope with the problems did not correlate with clinical characteristics of mental illness. The most desirable services expressed by the patients and relatives were help in finding employment and sheltered work.

**Conclusions.**– This study highlights a heavy burden in families providing care for people with SMI. Development of family interventions will promote relatives not only to acquire necessary information about SMI, but also to strengthen their coping capacities with the burden and improving well-being of the family as whole.

### Mindfulness and subjective well-being: A correlational study in primary care health professionals

A. Kchaou<sup>1\*</sup>, M. Hajjaji<sup>1</sup>, R. Masmoudi<sup>2</sup>, N. Kotti<sup>1</sup>, M.L. Masmoudi<sup>3</sup>, J. Masmoudi<sup>2</sup>, K. Jmal<sup>3</sup>  
<sup>1</sup> Hospital Hédi Chacker–Sfax, Department of Occupational Medicine, Sfax, Tunisia; <sup>2</sup> Hospital Hédi Chacker–Sfax, Department of psychiatry, Sfax, Tunisia; <sup>3</sup> Hospital Hédi Chacker–Sfax, Department of Occupational Medicine, Sfax, Tunisia  
 \* Corresponding author.

**Introduction.**– Hospital staff usually report high levels of distress and burnout symptoms related to job strain. Mindfulness, defined as non-judgmental-present-moment awareness, seems to be a moderator in the causal association between life stressors and well-being.

**Objectives.**– This study aimed to verify correlations among self-reported mindfulness and subjective well-being in Tunisia hospital staff.

**Methods.**– We carried out a cross-sectional study about a representative sample of hospital staff. We used validated self-reporting instruments: the Mindful Attention Awareness Scale (MAAS) and the Subjective Well-being Scale (SWS). Data were analysed using SPSS-20.

**Results.**– Participants ( $n = 550$ ) were nurses (31.6%), doctors (48.3%) and technicians (10.6%). The sex ratio was 1.59. Most of participants (85%) had worked in the same position for more than one year. Nearly 55% of participants had a well-being index reduced. Mean scores for Mindfulness was  $6, 27 \pm 1, 27$ . MANOVA regression analysis showed none differences across professional categories and length of time in the same job position in relation to mindfulness and well-being index reduced. Correlation analysis indicated strong negative correlations between mindfulness and well-being index reduced ( $P = 0,000$ ,  $R \text{ squared} = 0,031$ ).

**Conclusion.**– There were clear correlations between mindfulness and subjective well-being across different categories of hospital staff. Modified mindfulness training may be a time-efficient tool to help support clinician health and well-being, which may have implications for patient care.

### **Emergency department presentation and readmission after index psychiatric admission: A data linkage study**

X. Li<sup>1\*</sup>, J. Trollor<sup>1,2</sup>, S. Reppermund<sup>1,2</sup>, P. Srasuebku<sup>1</sup>

<sup>1</sup> UNSW Sydney, Department of Developmental Disability Neuropsychiatry 3DN, Sydney, Australia; <sup>2</sup> UNSW Sydney, Centre for Healthy Brain Aging, Sydney, Australia

\* Corresponding author.

**Objective.**– To use linked administrative datasets to assess factors associated with Emergency Department (ED) presentation and psychiatric readmission in three distinctive time intervals after the first ever psychiatric admission.

**Method.**– Four linked datasets containing data from 07/2005–06/2012 in NSW defined the cohort and/or exposure. Logistic regression was used to examine factors associated with psychiatric admission and ED presentation for three intervals: 0–1 month, 2–5 months, and 6–24 months after the index admission.

**Results.**– The sample included 35,056 individuals (51% males) with a median age of 42 years at index admission. Of the 16,281 (45%) individuals with at least one ED presentation after the index admission, 3734 (23%) presented within 0–1 month, 6439 (40%) within 2–5 months and 10,436 (64%) within 6–24 months after index admission. Of the 14,523 (45%) individuals with at least one psychiatric readmission, 8110 (56%) were admitted within 0–1 month, 6539 (45%) within 2–5 months and 7740 (53%) within 6–24 months after index admission. Principle diagnoses at index admission, sociodemographic factors, comorbidity and non-psychiatric inpatient service utilisation significantly impacted ED presentations and psychiatric readmissions. Drug and alcohol comorbidity increased psychiatric readmissions in the last two intervals.

**Conclusions.**– Social determinants of service utilisation, drug and alcohol intervention and addressing the unmet needs of individuals with intellectual disability and mental illness are key areas for investment to improve trajectories after index admission and should be emphasised in recovery-oriented approaches in mental health care. Further research should investigate innovative approaches to support people with complex comorbidities in and beyond inpatient settings.

### **Effect of multidisciplinary management in community dwelling patient with depression: Preliminary study**

K.Y. Lim<sup>\*</sup>, S.J. Son, C.H. Hong

Ajou University School of Medicine, Dept. of Psychiatry, Suwon, Republic of Korea

\* Corresponding author.

**Objective.**– This study aimed to investigate the effect of multidisciplinary management in community-dwelling patients with depression

**Methods.**– We obtained data from Korean subjects with major depressive disorder ( $n = 78$ ) at baseline, taking case management from community mental health center. we decided to manage 3 multidisciplinary factors: physical activity, healthy diet, and social activity. We provided 4 visits and 12 telephone contact in 12 weeks. Subjects were randomly assigned to intervention group ( $n = 38$ ) and control group ( $n = 40$ ). We investigated depressive symptoms through Short Form Geriatric Depression Scale-Korean version (SGDS-K) at baseline and every month for 3 months to all subjects. We tested interaction between group and time in SGDS-K score to evaluate the effect of program. And post hoc test examined between group differences of SGDS-K at each time points.

**Results.**– In quadratic linear mixed effects model analysis, interaction between group and time was statistically significant (Total SGDS-K score: Coefficient = 0.31,  $P < 0.001$ ; SGDS-K dysphoria subscale: 0.22,  $P < 0.001$ ; SGDS-K hopelessness subscale: 0.07;  $P = 0.089$ ; SGDS-K cognitive impairment subscale: 0.08;  $P = 0.004$ ). And significant between group difference was shown in post hoc test at time points of third month (SGDS-K score of control group: SGDS-K score of intervention group =  $10.88 \pm 3.524$ :  $7.50 \pm 4.512$ ,  $P = 0.0186$ ).

**Conclusions.**– These results may suggest that community-based multidisciplinary management program has efficacy in reducing depressive symptoms.

### **Role of NGO's and hospitals in provision of sustainable mental health services in cases of domestic violence in Pakistan**

T. Mansoor<sup>1,2\*</sup>, S. Mansoor<sup>3</sup>

<sup>1</sup> National University of Medical Sciences, Behavioral Sciences Multi-disciplinary Department, Islamabad, Pakistan, <sup>2</sup> Quaid-e-Azam University, Anthropology, Islamabad, Pakistan, <sup>3</sup> Foundation University Medical College, Department of Psychiatry and Behavioral Sciences, Islamabad, Pakistan

\* Corresponding author.

**Objective.**– This preliminary paper looks at mental health as an emerging development issue which causes significant personal distress, and is closely associated with social determinants, notably poverty and gender disadvantage, and with poor physical health.

**Method.**– Semi-structured interviews were conducted with the representatives from hospitals and NGO's to assess the functions and policies related to these facilities.

**Results.**– It is argued that the individual's demographics like age, gender, geographical location and income status may dictate certain restrictive socio-cultural norms limiting the scope and use of available mental health service. NGO's have helplines which provide counselling support to women, youth and children. It specifically addresses violence against women, child sexual abuse, sexual and reproductive health, and other psychological and emotional concerns. In crisis cases, e.g. acid burn or child abuse victims, there is also referral for medical or legal support along with shelter. This strength based counseling, awareness of rights and intervention services assist youth and families to realize their life goals despite past experiences of abuse or violence. In most tertiary care hospitals, health care personnel in emergency department and general practitioners usually are the first point of contact for the cases of domestic violence. These doctors and nurses are trained to screen for domestic violence in suspected cases, and refer them to the mediEVlegal department for further support and management. However it is widely acknowledged that a vast number of such cases go undetected due to inadequate screening protocols used by the hospital staff and doctors.

### Physical health monitoring in psychiatric patients: An audit to assess compliance with best practices

M.K. Munir\*, R.P. Gordon, R. Young, A. Ekelund  
Southern Health NHS Foundation Trust, General Adult Mental Health Unit- Antelope House, Southampton, United Kingdom

\* Corresponding author.

**Introduction.**– Life expectancy of people with mental illness, such as schizophrenia, is 15 to 20 years less than the general population. Many of these early deaths are caused by preventable illness such as heart attack. The need to improve physical health care for people with mental illness was highlighted by the first National Audit of Schizophrenia (NAS, 2014). 'Lester Cardiometabolic Health Resource' is based on screening the well-known determinants of cardiovascular disease. The adaptation, commonly known as the Lester tool, provides a framework of factors that indicate increased risk of poor cardiovascular health and thresholds at which interventions should be offered.

**Objectives.**– The objective was to standardise physical health monitoring (PHM) in a busy inpatient psychiatric unit.

**Materials & methods.**– All adults between 18–65 years admitted to male inpatient ward between July and August 2017. Patient who refused to have PHM were excluded.

**Results.**– Results show that appropriate PHM is only being done in approx. 16% of psychiatric inpatients. Around 53% patients received partial PHM and about 31% of patients received no form of PHM.

**Conclusions.**– Results show that there is significant room of improvement in relation to PHM of patients being admitted. After discussion in MDT meeting, recommendation was made that a dedicated PHM clinic based on Lester tool guidelines would run on every week by trainee advance nurse practitioners (figure 1)

Average age	48.53 (standard deviation 18.09)	Gender	Females 60.1%
Nationality	Spanish 95.4%	Origin	Rural 60.7%
Psychiatry history	46.8%	Didn't finish their follow-up	82.1%
Show-up for their visit	75.4%	Adequacy of the demand	55.7%

### Real-life clinical decision-making: Examining the role of multiple clinical and non-clinical factors on decisions to admit patients to acute psychiatric units

R. Nathan<sup>1</sup>, S. Boyle<sup>2</sup>, P. Elliot<sup>3</sup>, P. Saini<sup>4</sup>

<sup>1</sup> University of Chester, Institute of Medicine, Chester, United Kingdom; <sup>2</sup> CWP NHS Foundation Trust, Crisis Resolution Home Treatment Tea, Birkenhead, United Kingdom; <sup>3</sup> CWP NHS Foundation Trust, Research Department, Chester, United Kingdom; <sup>4</sup> University of Liverpool, Department of Health Services Research, Liverpool, United Kingdom

\* Corresponding author.

**Introduction.**– Whilst there is an extensive literature describing the effectiveness of discrete interventions for circumscribed psychiatric conditions, there is limited research into real-life clinical decision-making about allocation of elements of service provision. Decisions to acutely admit patients to residential psychiatric facilities have serious implications not only for patients, but also for the use of limited resources.

**Objectives.**– The primary objective of this study was to identify factors that influence clinicians in deciding to admit patients to acute psychiatric inpatient units.

**Methods.**– Narrative data regarding admission decisions were gathered over the course of 5 semi-structured focus groups involving a total of 33 practitioners working in acute assessment teams at the interface with 3 inpatient facilities. Key themes were identified by applying inductive thematic analysis to transcribed narratives.

**Results.**– The thematic typology of influencers of decisions to admit comprised (i) 'Formal' risk assessment factors (e.g. intent to harm self, diagnosis, protective factors), (ii) Patient-clinician dynamics (e.g. assumptions about patient's motives), (iii) Clinician-clinician dynamics (e.g. perceptions of inter-disciplinary differences in risk thresholds and tolerance), (iv) Threat/fear factors (e.g. anticipated criticism for decision-making, consequences of worst case scenario'), (v) Personal/environmental context (e.g. fatigue, lone-working), and (vi) Resource availability (e.g. pressure on inpatient/community services).

**Conclusions.**– Although, unsurprisingly, clinical risk assessment factors played a role in decisions to arrange acute admissions, it was striking that parallel non-clinical factors were reported to be so influential in these decisions. The results of this study will inform the shaping of a model of service provision/culture that attenuates adverse influences on practitioner decision-making.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Long-term unemployed people with depression – Is screening for eligibility for disability pension worthwhile?

K. Nurmela<sup>1</sup>, A. Mattila<sup>1</sup>, V. Heikkinen<sup>1</sup>, J. Uitti<sup>2</sup>, A. Ylinen<sup>3</sup>, P. Virtanen<sup>1</sup>

<sup>1</sup> University of Tampere, Faculty of Social Sciences- Health Sciences, University of Tampere, Finland; <sup>2</sup> University of Tampere, Faculty of Medicine and Life Sciences, University of Tampere, Finland; <sup>3</sup> University of Helsinki, Department of Neurological Sciences, Helsinki, Finland

\* Corresponding author.

**Introduction.**– Research on the clinical assessment of work ability of the long-term unemployed is scarce.

**Objectives.**– The present study of long-term unemployed people screened clinically for work disabilities seeks to assess the significance of depression, in particular with respect to being granted disability pension.

**Methods.**– The data consists of medical histories of long-term unemployed people referred to a screening project. Those now diagnosed as clinically depressed were classified into previously diagnosed and not previously so diagnosed. Binary logistic regression models were used to explore the effect of previous depression diagnosis on being granted a disability pension.

**Results.**– From the total of 395 long-term unemployed, 203 (51%) were diagnosed as clinically depressed, and 134 (70%) were granted disability pensions. The pension was significantly more likely (odds ratio 2.64,  $P=0.001$ ) to be granted to those without earlier depression diagnosis than to those whose depression had already been diagnosed in health care. The difference remained significant after adjusting for the set of background factors. Of all those with depression diagnosed and disability pension granted through the project, one fifth, and of men nearly one third, had not attended health care for three years prior to the project.

**Conclusions.**– A significant proportion of the long-term unemployed deemed to have impaired capacity for work are depressed and eligible for a disability pension. This, however, tends to go unnoticed in health care, partly due to these people's marginalization from health services. Clinical screening of the long-term unemployed in terms of work disability seems to be worthwhile.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Factors Associated with non-attendant appointment out-patients at the psychiatric clinic, Chiang Mai University Hospital**

A. Oonarom<sup>\*</sup>, S. Likhitsathian, S. Pilakanta

Faculty of Medicine- Chiang Mai University, Psychiatry, Chiang Mai, Thailand

\* Corresponding author.

**Introduction.**– In psychiatric patients, non-attendant appointment may result in increased frustration of health care providers, decreased levels of providers' empathy. But factors associated with non-attendance were rarely explored.

**Objective.**– To examine the prevalence and risk factors associated with non-attendant appointment in psychiatric out-patients.

**Materials & methods.**– A cross-sectional, observational study in 402 psychiatric outpatients routinely followed-up was conducted. Demographic data was corrected in the 1<sup>st</sup> visit. The associated factors questionnaire developed from the framework of factors influencing adherence and the revised Helping Alliance Questionnaire (HAQ-II) were obtained in the next visit. The non-attendants were identified by not appearing at appointment date or making new appointment less than 1 day and then obtained information next visit. We contacted the non-attendants after the appointment twice within 5 and 10 workdays to revisit. Failed making new appointment or missing twice calls were identified as the loss-follow-ups and excluded from the factor associated analysis.

**Results.**– Sixty-four patients (17.78%) had missed appointment and thirty-four (9.44%) were loss follow-up. Mann-Whitney correlation analyses were used to assess the associated factors. A binary logistic regression analysis, including previous significantly associated factors, found that recognizing the appointment was protective factor

( $B = -0.50$ ,  $P < 0.01$ ) while not perceiving therapeutic relationship enhancement was risk factors ( $B = 0.68$ ,  $P = 0.04$ ).

**Conclusion.**– About one-quarter of psychiatric patients were not attended the appointment on time. Recognizing the appointment and not perceiving therapeutic relationship enhancement were the most common associated factors.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Use and misuse of benzodiazepines and z-drugs in the French psychiatric population, an in-patients cohort**

A. Panes<sup>1\*</sup>, A. Pariente<sup>1,2</sup>, A. Fourrier-Réglat<sup>1</sup>, D. Berdraï<sup>2</sup>, M. Tournier<sup>1,3</sup>

<sup>1</sup> Univ. Bordeaux Inserm, Bordeaux Population Health Research Center UMR 1219, 33000 Bordeaux, France; <sup>2</sup> Centre Hospitalier, Universitaire, 33000 Bordeaux, France; <sup>3</sup> Centre Hospitalier, Charles Perrens, 33000 Bordeaux, France

\* Corresponding author.

**Introduction.**– While benzodiazepines and related z-drugs (zolpidem and zopiclone) are widely used among patients with psychiatric disorders, multiple studies show an association between these drugs and adverse events in this population: aggression, suicide, sedation, ataxia, cognitive impairment, anxiety, depression, lack of effectiveness associated with long duration treatment.

**Objectives.**– The main goal of our study was to investigate the use and the misuse of benzodiazepines among psychiatric in-patients.

**Methods.**– A cohort study was conducted in the hospital Charles Perrens (Bordeaux), including all adults initiating a hospital stay in February or June 2016. They were followed until the end of the hospitalization, or for six months if they are still hospitalized or if they had an ambulatory follow-up in the same hospital permitting data collection. Misuse was defined as a treatment period above 28 days for the hypnotic benzodiazepines and z-drugs, or 84 days for anxiolytic benzodiazepines, according to practice guidelines.

**Results.**– A total of 200 patients were included, with a mean age of 43 years, and almost as many women (47%) as men (53%). A large majority of them had a benzodiazepine treatment ( $n = 175$ , 88%). While more than a half of hypnotic users (52%) were in a misuse situation, only a small number of anxiolytic users (9%) were in a misuse situation.

**Conclusion.**– The number of users and proportion of patients misusing hypnotic benzodiazepines seem concerning. Further analyses are necessary to assess the impact of this misuse and associated factors, in order to better define misuse in this population

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Screening of adult ADHD in acute inpatient wards: a Quality improvement project**

V. Parlatini<sup>1\*</sup>, R. Moroni<sup>2</sup>, R. Rao<sup>2</sup>, S. Sajid<sup>2</sup>, E. Okon-Rocha<sup>2</sup>

<sup>1</sup> Institute of Psychiatry, Psychology & Neuroscience, FANS, London, United Kingdom; <sup>2</sup> SLAM, Ladywell Unit, Lewisham, London, United Kingdom

\* Corresponding author.

**Introduction.**– Attention deficit hyperactivity disorder (ADHD) is a common disorder that is often underdiagnosed in adults (Asherson et al., 2012). This holds especially true in acute settings where

the main presentation, from substance induced psychosis to suicidality, may mask underlying perpetuating factors. Indeed, an audit previously conducted at our Trust suggested that the presence of ADHD might be underestimated when exclusively based on clinical suspicion (about 3% of the acute clinical population).

**Objectives.**– We investigated whether screening measures may improve the detection of adult ADHD in acute inpatient wards.

**Methods.**– We initially screened 28 inpatients by using the long version of the Barkley self-rated scale (BARS-IV). Subsequently, we EVadministered two short versions of the ADHD Self-Report Scale (ASRS), based on either DSM4 or 5, to a separate group of 21 inpatients. As the latter partially differ in the set of symptoms they measure, we also conducted a quantitative and qualitative comparison of the two.

**Results.**– The short ASRSs provided results which were comparable to those of the long BARS-IV, with 23% patients detected as possibly having ADHD, while being less time consuming. The total scores of the two ASRSs showed a modest statistically significant positive correlation ( $r=0.706$ ,  $P=000$ ), suggesting that they may capture partially distinct features of ADHD. Overall, the ASRS-DSM5 was preferred by both patients and clinicians, mainly as the scale was easier to understand and use.

**Conclusion.**– The short ASRSs are simple and effective tools to identify patients that might have ADHD, and thus need additional assessment and treatment, in acute clinical settings.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Kingston primary care mental health team, first quarter referrals (Jan–Mar 2017) Audit

R. Bassi-A Chaturvedi-H Goodwin-R Duncko-H Rahmanian<sup>1</sup>  
Camden & Islington NHS Trust, Primary Care Mental Health, London, United Kingdom

\* Corresponding author.

In the first quarter of 2017, Kingston PCMHT handled 288 cases in total. Of this total, 70 of these were consultations with a professional where advice was provided by PCMHT clinicians regarding specific cases. Of the 218 formal referrals made to the service, 208 (95%) were accepted and were given appointments.

The majority of referrals came from GP practices as expected from the PCMHT. It is worth noting that only 25% of the GP referrals used the standardised iCope referral form, which is requested by PCMHT. The most common purpose of a referral was to request a full assessment or a medication review. Despite the lack of a clear referral purpose, PCMHT still accepted the majority of referrals. Nonetheless, it would be preferable for service users to receive the correct care if referral questions were specifically stated. This point is further raised by recording of risk and urgency on referrals. 191 referrals did not state urgency, and 70 did not report on risk. A total of 65 referrals did not report on both urgency and risk—which may be an important point to address. However, in practice, the PCMHT are not an emergency or high risk service and as such would not distinguish between routine and urgent referrals.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Psychological empowerment and information exchange among the implementers of a psychosocial intervention program for victims of the armed conflict in Colombia

I. Ramos Vidal<sup>1</sup>, A. Uribe<sup>2</sup>, I. Villamil<sup>2</sup>, J. Palacio<sup>3</sup>

<sup>1</sup> Faculty of Psychology, Department of Social Psychology, Sevilla, Spain; <sup>2</sup> Universidad Pontificia Bolivariana, School of Humanities and Social Sciences, Monteria, Colombia; <sup>3</sup> Universidad del Norte, Faculty of Psychology, Barranquilla, Colombia

\* Corresponding author.

**Introduction.**– Information exchange among practitioners implementing intervention programs is crucial for program effectiveness. Empirical evidence suggests that a good working climate and a high degree of psychological empowerment in task development are factors that predict the information exchange among healthcare professionals.

**Objectives.**– To identify the incidence of psychological empowerment and organizational climate on the information exchange between psychologists, social workers and community advocates who provides psychosocial assistance to victims of the war in the Department of Cordoba (Colombia).

**Methods.**– A total of 18 psychologists, 22 social workers, 10 community advocates and a nurse who implement the Psychosocial and Integral Health Care Program (PAPSIVI) were interviewed. Participants are mostly women (94.1%) and on average have been working for 12.12 months in the program ( $SD = 12.41$ ). Non-parametric tests and hierarchical regression analysis were performed to meet the research objectives.

**Results.**– Psychological empowerment predicts the level of activity in the information requests network [ $\beta = 296$ ;  $P < 001$  CI: (95%): 604–3.401]. Organizational climate does not explain the variance of the level of centrality of professionals in the information exchange network [ $\beta = -.097$  (*n.s.*); CI: (95%): -1.002–.443].

**Conclusions.**– Professionals with high levels of empowerment in the workplace are the most active exchanging information. This finding suggests that by generating the conditions to facilitate that the implementers feel empowered is possible to increase the level of activity in information exchange networks that may have a positive impact on the quality of the assistance provided by the practitioners and finally on program outcomes.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Travelling through recovery

D. Romac\*, B. Gracin, Z. Čavar, M. Orban  
Andrija Stampar Teaching Institute of Public Health, Mental health and addiction prevention, Zagreb, Croatia

\* Corresponding author.

**Introduction.**– Addiction is a complex condition with many consequences and requires long-term, individualised and integrated care including a range of pharmacotherapy and various psychological interventions with ongoing monitoring and treatment review.

**Objectives.**– To evaluate treatment of 593 outpatient opiate addicts with medication assisted recovery and practiced during 2016.

**Methods.**– The results are based on data collected from Pompidou questionnaire, urine analysis and measured by the expert consensus document which includes areas of individual response, damage reduction and involvement in the society.

**Results.**– Data show high retention rate, 52,4% abstinent, 10% unchanged/occasionally have taken the main substance, 26,4%

abstinent from the main but have taken other substances. More than half of the addicts (52%) work continuously or occasionally. Material status is most commonly average, while only 5,7% are endangered existentially. The majority of the addicts live with their parents (40%) or with their partner (38%), very few live alone (15%). 44% of the addicts have a child and only (0,34%) have been deprived of custody. 43% of the addicts are emotionally connected. The incidence of HCV (18%) and HIV (0,5%) is without noticeable significant annual statistical discrepancies.

*Conclusion.*– These results suggest that recovery oriented approaches build on and improve treatment interventions also provide benefits not only for individuals but families and the community as well. Having access to good quality mental health care may facilitate recovery. We can use these experiences to suggest clinical and systems-based approaches to improve addiction recovery outcomes.

### **Specialized PTSD team within a tertiary psychiatric care unit in Sweden**

I. Sarajlic Vukovic\*, E. Durakovic, A. Gonzales, G. Bilonic, S. Steingrimsson

Sahlgrenska University Hospital, Department of Psychiatry, Gothenburg, Sweden

\* Corresponding author.

*Introduction.*– The modern world of globalization offers paradoxes such as increased economic activity and forced migration due to wars and natural disasters. Quality of health care services varies in the world and within wealthier countries. The goal of each health system is reasonable cost of care and preserved quality of health care in order to preserve secondary and tertiary prevention. Guidelines for PTSD treatment in the Region Västra-Götaland state that the primary health care has the main role. However, a number of patients receive specialized psychiatric care due to lack of response and a low functional level. Our interest is to observe the factors that lead to psychiatric care as well as needs in order to optimize health care services.

*Objectives.*– To show the development of PTSD team model within subspecialization in psychiatric services in the Region Västra-Götaland.

*Methods.*– This study explores the development of specialized teams for the care of patients with PTSD using descriptive statistics of the observed group of patients with PTSD in the period from 2014 to 2017. The data will be displayed numerically and graphically. Furthermore, to demonstrate the present situation of the system and the development of the PTSD team, which is the only specialized team within the specialist psychiatry in the region for the time being.

*Results and conclusion.*– Results will be presented at the congress along with a discussion of the possibilities of further development of the treatment model.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0447

### **Autism assessment and diagnosis: Evaluation of a multi-disciplinary service for adults in London, UK**

R. Sheehan

University College London, Division of Psychiatry, London, United Kingdom

*Introduction.*– The UK National Autism Strategy (2010) recommended establishing multi-disciplinary teams for assessment and diagnosis of autism in adults.

*Objectives.*– To describe the pattern and characteristics of referrals to a newly-established adult autism assessment and diagnosis service and to audit activity against national best-practice guidelines. To explore results with a view to informing future service development.

*Methods.*– Data were collected retrospectively using the electronic health record of all people referred to the autism service between 2014 and 2017. A subset of the most recent referrals were audited against National Institute for Health and Care Excellence (NICE) guidelines to determine current practice and identify areas for improvement. We conducted logistic regression to explore predictors of autism diagnosis amongst those referred, and calculated specificity and sensitivity of an autism screening tool, the AQ-10.

*Results.*– A total of 289 adults (67% male; average age 33 years) were referred to the service in the first 3 years of operation. The proportion of self-referrals and those from primary care increased over time. Seventy-four individuals underwent comprehensive assessment between May 2015 and April 2016; audit results indicated the majority of quality standards were met. Just under a quarter of those assessed were diagnosed with autism; female gender was the only significant predictor of diagnosis (adjusted odds ratio 7.78,  $P=0.028$ ). The positive predictive value of the AQ-10 screening questionnaire was 31%. Half of those assessed were referred to alternative services.

*Conclusions.*– High-quality multi-disciplinary autism assessment services are important in improving access to diagnosis and appropriate intervention.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **FACT teams at the regional level: The impact of personalised treatment**

V. Švab

Psychiatrist, Medical faculty Ljubljana, Health Center Novo mesto, Logatec, Slovenia

Community mental health teams at the primary level of care were established in Slovenia in 2013 only in four regions with worst mental health indicators, for example high suicide rates. They use Flexible Assertive Outreach methods and include two nurses and half time psychiatrist, occupational therapist and psychologist. These teams were educated in a programme with strong involvement of service users and their carers. First results of their work are to be presented regarding patients' demographic data, diagnosis, needs assessment, service provision and outcomes, as well as regarding financing in comparison with hospital assertive outreach. *Results.*– In all four regions 903 patients were treated and supported, predominantly with schizophrenia and related disorders from 2013-2016. The assessment was made in one of the regions with 134 patients involved. The majority of patients are socially excluded and poor. Patients and staff reported about various needs, among them most prominent need for companionship, regular activity and employment, selfcare and relieving distress. Suicide

danger was present in 12% of patients. One third of patients needed treatment because of severe signs of mental illness. Management of their needs was assessed successful in 33% of patients, in 13% there was no change in their condition, 15% was lost from follow, up and 5 patients died in this period. The public funding of the program is about one third of the funding for hospital outreach that involved about 300 patients altogether. The educational program and examples of CMHTs in Slovenia will be presented.

### **Neuroenhancement: Performance or problem?**

C. Teles

*Psychiatric Resident, Psychiatry Service of Portimão, Centro Hospitalar do Algarve, Portugal, Quarteira, Portugal*

\* Corresponding author.

*Introduction.*– The term neuroenhancement has been coined to denote interventions by which healthy people improve their cognitive, emotional and motivational functions. According to the type of intervention used, it can be divided into pharmacological and non-pharmacological modalities.

*Objectives.*– Review the wide range of methods that can be used by healthy people to augment cognitive abilities.

*Methods.*– Research on Pub Med using the terms “neuroenhancement”, “pharmacological cognitive enhancement” and “non-pharmacological cognition enhancers”. There were only considered systematic reviews from the last 5 years.

*Results.*– The substances commonly used as cognitive enhancers (CE) can be categorized into two groups: (1) drugs being approved for the treatment of certain disorders and being misused as CE: (1.1) drugs to treat attention-deficit/hyperactivity disorder such as methylphenidate or amphetamines (1.2) to treat sleep disorders such as modafinil and (1.3) to treat Alzheimer’s disease such as acetylcholinesterase inhibitors; (2) illicit drugs such as cocaine, “speed”, ecstasy, methamphetamine or others.

Regarding to technologies as CE, there are two modalities: (1) computer and video game based cognitive training; (2) non-invasive brain stimulation techniques: (2.1) repetitive transcranial magnetic stimulation, (2.2) transcranial direct current stimulation. More traditional forms of enhancing cognition are through physical exercise, nutrition, sleep and social engagement.

*Conclusions.*– If neuroenhancement is considered, the decision to do so should be based on the known effects of the chosen method. The advantages should be considered, likewise the potential harm for the individual and those around them must also be avoided, to ensure that all members of society flourish.

### **Experience of a Social worker clinic based within a crisis resolution home treatment team in North East London**

B. Travers\*, T. Barry, L. Ottley

*NELFT, Waltham Forest Home Treatment Team, London, United Kingdom*

\* Corresponding author.

*Background.*– Social workers are imperative to effective Crisis Resolution Home Treatment Teams but are an increasingly limited resource.

*Objectives.*– To assess the effectiveness of the social worker clinic provided by the Home Treatment Team. To assess patients’ satisfaction with attending a clinic location whilst under the care of the Home Treatment Team.

*Results.*– A social worker clinic ran weekly at a location near patients’ homes. Appointments focussed on social problems brought by the patients. We assessed the initial experience of 17 consecutive patients who attended the clinic. All attendees reported that the clinic was easily accessible and that staff listened to patient concerns. Most people who presented (76%) required help with benefits claims. 65% reported the problem was fully resolved. If staff were unable to resolve the problem, the majority (73%) reported that they were provided with other information that was of help. 100% of patients felt that help provided in the social worker clinic had a beneficial effect on their mental health. 94% rated the experience of attending the clinic as very helpful. Patients are willing to attend a clinic base to see a social worker despite the fact that most Team interventions are provided in patients’ homes. The clinic is effective at resolving patients’ social care problems and has a beneficial effect on patients’ subjective reporting of their mental health. A social worker clinic allows scarce social worker manpower to be deployed in an effective manner within in a Crisis Resolution Home Treatment Team.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Mental health care: Violence within psychiatric inpatient units at an urban hospital in British Columbia, Canada**

J. Wilcox<sup>1</sup>, A. Russolillo<sup>2</sup>, I. Culina<sup>2</sup>, S. Carriere<sup>2</sup>

*<sup>1</sup> St. Paul’s Hospital- Providence Health Care, Mental Health, Vancouver, British Columbia, Canada; <sup>2</sup> St. Paul’s Hospital, Mental Health, Vancouver, Canada*

\* Corresponding author.

*Introduction.*– Violence committed by acute psychiatric inpatients represents an important and challenging problem in clinical practice. Increased risk of violence is often associated with patient characteristics, physical layout of in-patient units, and increased turnover of patients.

*Objectives.*– The aim of this study was to describe the types and frequency of violence incidents occurring within an urban acute hospital located in British Columbia, Canada.

*Methods.*– The British Columbia Patient Safety & Learning System (BC PSL) is a web-based safety event reporting system used by healthcare providers. We collected descriptive data from the BC PSL to examine violence incidents spanning 2015 to 2017 among four acute inpatient mental health units.

*Results.*– Between May 2015 and April 2017 a total of 242 violent incidents were recorded. The median number of violence incidents reported per month was 11. Physical and verbal aggression accounted for nearly 30% of all recorded incidents. Time of day influenced unsafe behaviour frequency, with 36% of incidents occurring between 4pm and 8pm. Factors contributing to reported violent events include: unit acuity, unit routines (e.g., medication administration or mealtimes), and off ward privileges.

*Conclusions.*– Our results highlight that time and unit specific characteristics are critical to understanding risk for violence and violence prevention. Further research is required to understand factors contributing to increased violence and to promote a culture of safety for patients and staff. Our findings can be used to improve policy and practice in the management and prevention of violence in psychiatry.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0452

### **Managing mood disorders with psychotic symptoms in Portugal: The role of public mental health inpatient services**

M. Xavier<sup>1,2\*</sup>, P. Mateus<sup>2</sup>

<sup>1</sup> Health Directorate General, Mental Health, Lisbon, Portugal; <sup>2</sup>

NOVA Medical School, Mental Health, Lisboa, Portugal

\* Corresponding author.

*Background.*– The burden of mood disorders with psychotic symptoms has been seriously underestimated in the past, due to the fact that traditional approaches only considered mortality figures. In Portugal, the National Mental Health Plan specially stresses the development of services and programs for the recovery and deinstitutionalization of the seriously mentally ill persons. Thus, it's necessary to characterize the care provided to the patients on a national basis, starting by the evaluation of the use of inpatient units.

*Objective.*– To assess trends in the use of inpatient services by patients with a diagnosis of mood disorder (ICD 10–F30-39) with psychotic symptoms through a 5-year span.

*Methods.*– A time-series analysis of the patterns of use in public mental health services was conducted on representative national data, assembled by the Directorate General of Health - Information Analysis Unit. A five-year time frame was used, ranging from 2007 to 2011 (unit: total number of inpatient episodes).

*Results.*– There was an increase in the number of inpatient episodes (5036 to 5483), in a in the days of hospitalization (94431 to 99267), even if with a smaller average length of stay (18,8 to 18,1). The trend was similar regarding schizophrenia, also showing an increase in the number of inpatient episodes and days of hospitalization.

*Discussion.*– data shows a general increase of inpatient episodes. Although improvement in access to MH services cannot be ruled out, we should expect a decreasing number of inpatient episodes if development of community approaches throughout the country was effective.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

## **Mental health policies**

EV0453

### **Where is the psychiatrist? Factors affecting provision and distribution**

R. Antunes dos Santos<sup>1\*</sup>, S. Queiroga de Araújo<sup>2</sup>

<sup>1</sup> University of Brasilia, Medicine School, Brasília, Brazil; <sup>2</sup> University of Brasilia, Public Health School, Brasília, Brazil

\* Corresponding author.

Mental health care is based on people relationships. Despite the continuous progress of pharmacotherapy, neuroimage and genetics, most of the technology developed and currently in clinical practice is based on the human contact. Psychologists, nurses, occupational therapists, social workers, psychiatrists among other professionals are, and probably will always be needed to have a face to face contact in order to guarantee the best information possible. The content gathered by the professional will be the substrate to base an accurate diagnosis and the clinical decision. Health

professionals supply is an issue all over the world. It has been a big challenge to predict the numerus clausus of students and professionals that will give quality mental health care to populations. Brazil is a country with a huge distance between states and huge differences among the mental health provided by each state. Some states in Brazil have numbers of psychiatrist compared to high-income countries (0.12/1000 population) and others to low-income countries (0.004/1000 population). At this study, data from the number of psychiatrists and residency positions by the region was confronted with suicide rates, extreme poverty rates and indigenous population by region. The results call attention to the importance of the mental health professionals, the role of the training programs and the role of the state to diminish inequities supporting and encouraging migration.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0454

### **Diogenes syndrome: How social services, authorities and medical networks could improve their actions to help and take care, according to ethics?**

J. Gauillard<sup>1\*</sup>, L. Hugonot-Dlener<sup>2</sup>, E. Rossi<sup>1</sup>

<sup>1</sup> Centre d'action sociale de la ville de Paris, Unité de Liaison

Psychiatrique, Paris, France; <sup>2</sup> Réseau Mémoires, Platerforme Saint Jacques et Broca Hospital APHP, Paris, France

\* Corresponding author.

*Introduction.*– After two studies were published on Diogenes syndrome in Paris: a retrospective study and a prospective study designed to improve our knowledge on these syndromes, we have made a multidisciplinary working group, to improve our actions.

*Objectives.*– Our working group will improve and coordinate actions for Diogenes syndrome subjects living in their home in Paris. These situations require time and a coordinated investigation by a mediEVsocial team, as subjects with Diogenes syndrome do not always have an associated disease, but always refuse any intervention. These Diogenes subjects are notified to the community authorities due to risks (fire) or nuisances (stench, parasites, hoarding). Last year, in Paris, the authorities made 176 prefectural orders to clear and clean the Diogenes' home within 15 days.

*Methods.*– Three meetings in one year for the whole territory of Paris strengthen contact between staff of different mediEVsocial, medical and administrative services. Our guidelines were based on clinical cases.

*Results and conclusions.*– The medical team should first make a diagnosis before any decision to clean and empty their home is taken. The diagnosis can be an associated to a disease: like FDT or Schizophrenia. . . Or if no associated disease is found, hoarding can be categorize as a OCD (according to DSM5) due to emotional trauma during the early childhood. We have in preparation a multi-professional directory. We seek project funding for a new mobile coordination team.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0455

**On global approaches to psychiatry**M.C. Michailov<sup>1</sup>, E. Neu<sup>1</sup>, T. Senn<sup>1</sup>, C. Lütge<sup>2</sup>, M. Schratz<sup>3</sup>, G. Weber<sup>4</sup><sup>1</sup> Inst. Umweltmedizin c/o ICSD e.V., PharmaEVPhysiology, Munich, Germany; <sup>2</sup> Techn. Univ. München, Inst. Ethics Dir., Munich, Germany; <sup>3</sup> Univ. Innsbruck, School Education Dean, Innsbruck, Austria; <sup>4</sup> Univ. Lxbg. and Vienna, Fac. Psychology Dean, Vienna, Austria

\* Corresponding author.

**Introduction.**– Enormous global problems are essentially related to mental health incl. education-ecology-economy-medicine-etc. New scientific&organizational models in psychiatry are necessary.

**Conception.**– Discussion about EPA/WPA&national societies under consideration of meritocratic and triumvirate principles as well as interdisciplinarity and international co-operation.

– Enlargement of leading boards/Exec. Committee, etc. by:

– 3 honorary (permanent moral support/continuity) & 3 presidents (fixed-term),

– Interdisciplinary board: Scientists from philosophy/psychology/medicine incl. c. representatives of intern. soc.: philosophy-FISP-IVR-ISB/psychol.-psychosom.-IUPsyS-ICPM/physiol.-IUPS/pharmac.-IUPHAR/med.-FIGO-SIU-ISIM-etc. Enlargement of,

– congress topics by approaches to philosophy (epistemology-ethics-aesthetics), theology (Brahmanism-Yoga/Buddhism incl. Zen-Shintoism/Christianism-Mosaism/Confucianism-Taosism/Mohammedanism-Sufism and;

– congress summaries to 300-500 words, similar to other soc.;

– organization of common interdisc. Congr., see 1c.;

– creation of an International Academy for Psychiatry with national branches by network also of institutes to Intern. Universities (proposal by British Nobel-Laureate B. Russell/G. Menschnig): intern. UNO-employees, e.g. intern. professors, possibility for whole-life work, etc.

**Conclusion.**– Realization of proposals [1-5] by EPA/WPA&other societies could be example for other sciences, i.e. as model for scientific-renewal supporting UNO-Agenda21 for better health on global level (1)

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**The transcultural communication workshop (“MEDI+: Center for the improvement of competence of Poznan University of Medical Science”)**E. Mojs<sup>1</sup>, K. Karolina<sup>1</sup>, G. Katarzyna<sup>2</sup><sup>1</sup> Poznan University of Medical Sciences, Clinical Psychology, Poznan, Poland; <sup>2</sup> Poznan University of Medical Sciences, Social Sciences, Poznan, Poland

\* Corresponding author.

Today's time is characterized by dynamic changes taking place within the cultures that exist side by side and at the same time permeate and benefiting from each other. The idea of the transcultural society (Welsch, 1998) seems to be a suitable theoretical construct describing the perspective of individual and group identity formed by many cultures simultaneously. The consequence of this is the pressure of functioning according to the new norms and rules. In the case of medical professions, where contact with the patient is commonplace, it seems important to deepen the topic among professionals. The answer to this need is The Transcultural Communication Workshop, organized as a part of the project named “MEDI+: Center for the Improvement of Competence of Poznan University of Medical Science” (EVfunded by the European Union under the European Social Fund and implemented under the Operational Program Knowledge Education Development 2014-2020). The classes aim to raise students' awareness of the topic of cultural hybridization and increase their communication skills. The workshops run by members of the UMP Department of Clinical Psychology include a variety of tasks and exercises related to identity, nonverbal and verbal communication, communication barriers, acculturation strategies, group processes, and lecture content. Realizations of goals set before the project started verified the results of the author's questionnaire and the Social Competence Questionnaire. There has been an increase in social competence, a deeper understanding of the issues of cultural diversity and a sense of compassion.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

**The current state of the mental health care reform in the Czech Republic**

P. Winkler

National Institute of Mental Health, Department of Social Psychiatry, Klecany, Czech Republic

**Background.**– Mental health care in the Czech Republic as well as in other countries in the region of Central and Eastern Europe remains to be hospital based and ineffective. The Czech Republic has initiated mental health care reform in 2011. The aim of this analyses is to review the current stage of mental health care reform in the Czech Republic and identify its strengths, weaknesses, opportunities and threads.

**Methods.**– The Strategy of the reform, documentation related to reform's implementation projects, minutes from the meeting of reform executive board, and reform working groups, have been analysed. SWOT analysis was conducted, results are interpreted narratively.

**Results.**– A clear and widely accepted vision for the mental health care reform, good system for mental health care monitoring, and availability of finances for the reform's implementation projects have been identified as strengths; non-existence of a reform plan which would contain SMART goals, non-existence of a consensus on

reform evaluation, and vaguely defined implementation projects were identified as weaknesses; enthusiasm of many stakeholders, increasing public attention to mental health, and high-quality international collaboration were identified as opportunities; and political instability, non-existence of a plan for financial sustainability, and lack of relevant professionals such as psychiatric nurses were identified as potential threads to the reform.

**Conclusions.**– The current reform initiative is the strongest in the post-communist history of the country, however, it is not clear whether it will lead to the true rather than cosmetic changes. Update on the current situation will be provided during the presentation.

**Conflict of interest:**

I am a member of the Executive Committee of Mental Health Care Reform in the Czech Republic, and I am also leading two implementation projects within the reform.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0458

### **An appraisal of the mental health reform in Portugal: The current status of day hospitals**

M. Xavier<sup>1,2\*</sup>, P. Mateus<sup>2</sup>

<sup>1</sup> Health Directorate General, Mental Health, Lisbon, Portugal; <sup>2</sup> NOVA Medical School, Mental Health, Lisbon, Portugal

\* Corresponding author.

**Background.**– In Portugal, the National Mental Health Plan has been launched 10 years ago aiming to improve access to care, develop mental health services in the community and integrate it with other relevant stakeholders. The development of day hospitals throughout the country has been established as a major objective, due to its relevance in modern mental health care, as well as to its scarcity in the National Health Service units.

**Objectives.**– To compare the outline of Day Hospitals in Portugal 10 years after the implementation of the National Mental Health Plan in the following areas: number of units across the country, human resources and use of services.

**Methods.**– A comprehensive assessment was directed by the National Mental Health Plan Evaluation Committee, under the auspices of the Ministry of Health, by means of a evaluation of national longitudinal data.

**Results.**– Between 2005 and 2016, at the national level there was an increase in both the number of patients followed up and number of sessions. The increase in the number of patients was 180% and in the number of sessions it was 106%. In certain regions of the country, the increase reached the 370% (Algarve, in southern Portugal).

**Conclusions.**– Despite some heterogeneity across different geographic areas (with a clear urban/rural asymmetry), the implementation of the National Mental Health Plan led to a huge increase in both the number and the use of day hospitals in Portugal, thus improving the mental health care delivery.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0459

### **Mental Health departments in general hospitals: Is there a need to raise the issue of autonomy?**

M. Xavier<sup>1,2\*</sup>, P. Mateus<sup>2</sup>

<sup>1</sup> Health Directorate General, Mental Health, Lisbon, Portugal; <sup>2</sup> NOVA Medical School, Mental Health, Lisbon, Portugal

\* Corresponding author.

**Background.**– During the 1990's, Portuguese mental health centres (MHC's) have been integrated into general hospitals (and renamed as mental health departments, MHD's), thus losing a significant amount of its former autonomy. Given the need to evaluate the implementation of the National Mental Health Plan, it is important to assess the current level of autonomy the MHD's throughout the country.

**Objectives.**– To characterize the model of management of mental health departments (MHD's) embedded into general hospitals, ii. to characterize the repercussions of the administrative integration of the former Mental Health Centres (MHC) into general hospitals, and iii. to characterize the difficulties associated with routine activity and the development of new mental health teams/programs in the community.

**Methods.**– The National Mental Health Plan Evaluation Committee, under the auspices of the Ministry of Health, conducted a comprehensive cross-sectional survey, to be filled in by the directors of mental health departments across the country.

**Results.**– Among the respondents, the most positive points were: liaison with other medical areas and stigma reduction; the most negative were: scarce autonomy (financing, budgeting, management of human resources), lack of skilled professionals, heavy workloads and insufficient funds to develop services in the community.

**Conclusions.**– Although the integration of the former MHC in general hospital brought several improvements to mental health care in Portugal, the scarce autonomy of the MHD's is strongly associated with the persistent shortage of structured programs (compulsorily based in dedicated teams), which requires a greater technical and resource differentiation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

## **Migration and mental health of immigrants**

EV0460

### **Clinical and demographic variables in a homeless population with mental illness in Madrid**

R.A. Baena Mures<sup>1\*</sup>, R. Fernandez García Andrade<sup>1</sup>, E. Medina Tellez<sup>2</sup>, M.F. Bravo Ortiz<sup>2</sup>, B. Reneses Prieto<sup>1</sup>

<sup>1</sup> Instituto de Psiquiatría San Carlos, Psiquiatria, Madrid, Spain; <sup>2</sup> Hospital Universitario La Paz, Psiquiatria, Madrid, Spain

\* Corresponding author.

**Introduction.**– There are a lot of studies that describes relation between homeless and mental illness. We describe our experience about the treatment of a homeless population and the prevalence of mental illness attended by our team. Homelessness is associated with increased prevalence of mental health disorders, substance use disorders and mental health/substance use disorder comorbidity.

**Aim.**– The aim of this study was to determinate some variables associated to homeless and mental illness in our population.

**Methods.**– A retrospective, cross sectional, descriptive study of patients assessed by ECASAM (Mental health street team) in Madrid.

**Results.**– We attend 91 new patients in 2016. 71% of this patient was transferred since Social Care and 26% since another clinical service. 63% of this patient was in homeless situation. We attend 176 patients since 2004, when this program began. So we assessed 252 patients during 2016, of this patient 77% are men, and 23% are woman. 45% are Spanish and 55% foreign people. About diag-

nosis 57% schizophrenia, 10% paranoia, 11% personality disorder, 3% bipolar disorder, 2% schizoaffective disorder and 5% PTSD and adjustment disorder.

*Conclusions.*– We describe an elevated prevalence of psychotic disorder in our population, however other studies describe most prevalence of affective disorder and use of alcohol in homeless population. We think that's necessary new studies to describe clinical, social and demographic variables in this population in Europe and another countries.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0461

### **Understanding the relation between migration, society and psychosis: Qualitative evidence from narratives of first- and second-generation migrants who experienced psychosis in Europe**

F. Bourque

McGill University, Division of Social and Transcultural Psychiatry, Montreal, Canada

*Introduction.*– Recent epidemiological studies have consistently documented a higher incidence of psychotic disorders among migrant and ethnic minority groups in various countries. However the reasons for this remain unclear. Meta-analytic evidence points at significant variations in the risk magnitude across ethnic groups and countries, further highlighting the importance of the environmental context in which migrants live. Qualitative approaches such as illness narratives, are particularly well suited to explore such social and contextual factors.

*Objectives.*– This study aims a) to explore in-depth the illness experience and the socio-environmental context of first- and second-generation migrants who experienced a first episode of psychosis, and b) to demonstrate how qualitative findings help us understand population-level findings.

*Methods.*– In-depth interviews were conducted with first- and second-generation migrants who first experienced psychosis in diverse European contexts and recruited through purposive sampling. Semi-structured interviews were derived from the McGill Illness Narrative Interview, designed for cross-cultural exploration of illness experience.

*Results.*– Thematic analyses of the 22 participants settled in London UK indicate that they overwhelmingly perceive their illness as arising primarily from adverse socio-environmental experiences. Major themes included unemployment, negative interactions with authorities, housing difficulties and other forms of social exclusion.

*Conclusion.*– Research and clinical innovations are needed to address the relation between migration and the onset of psychosis at the social level, both from preventive and therapeutic perspectives. Qualitative and mixed methods can significantly contextualize and shed light on the socio-environmental factors underlying the increased incidence of psychotic disorders among migrant and minority ethnic groups.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0462

### **Trauma, migration and mental health in a sample of asylum-seeking women in Italy**

L. Islam<sup>1</sup>, R. Lamberti<sup>2</sup>, M. Bardino<sup>3</sup>, B. Grijuela<sup>4</sup>, E. Matarazzo<sup>4</sup>, Y. Rizzo<sup>3</sup>, R. Ranieri<sup>5</sup>

<sup>1</sup> ASST-Santi Paolo e Carlo, Psychiatry, Milan, Italy; <sup>2</sup> ASST-Santi Paolo e Carlo, Clinical Psychology, Milan, Italy; <sup>3</sup> ASST-Santi Paolo e Carlo, Social Worker, Milan, Italy; <sup>4</sup> ASST-Santi Paolo e Carlo, Obstetrics and Gynecology, Milan, Italy; <sup>5</sup> ASST-Santi Paolo e Carlo, Penitentiary Medicine, Milan, Italy

\* Corresponding author.

*Introduction.*– Many refugees are exposed to traumatic events prior to and during their migration process. Women are more vulnerable, and may have less access to health care for multiple reasons.

*Objectives.*– We sought to assess trauma exposure—as defined by BTQ- and psychiatric diagnoses among asylum seeking women.

*Methods.*– A total of 44 women were evaluated in our multidisciplinary outpatient unit for asylum seekers between March and November 2017. They came from 11 different countries, primarily Nigeria, Somalia and China.

*Results.*– Overall, 79.5% of women were exposed to traumatic events prior to their migration or during the migration process. The most frequent events were: rape, torture, witnessing the death of a family member, witnessing torture, rape or death of others, being exposed to life-threatening events, food and water deprivation. 27% fulfilled the criteria for PTSD, 21% for adjustment disorder, 2.3% for generalized anxiety disorder, 2.3% for major depression, 2.3% for somatoform disorder and 4.5% for borderline personality disorder. 16% were pregnant (7% as a consequence of being raped during their migration). Patients with a history of trauma reported more difficulties in coping with the stress of post-migration factors during informal clinical evaluation.

*Conclusions.*– Exposure to trauma and resulting psychiatric symptoms, such as PTSD, are a significant issue among asylum seekers. Women are at increased risk due to gender violence, cultural, and physical factors (i.e. pregnancy). Systematic evaluation of trauma and mental health issues is crucial in order to provide women with early and adequate treatment and promote coping and adaptation to post-migratory conditions.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

EV0463

### **Disposable cameras as a novel research tool in migrant mental healthcare**

A. Lineham

University College London, Medical School, London, United Kingdom

*Introduction.*– In an increasingly globalised society, healthcare must adapt to the diversity of its populations, particularly the specific needs of migrant populations. A method that overcomes barriers such as language and educational attainment is needed to offer a clearer insight into migrant mental health.

*Objectives.*– To assess the feasibility of disposable cameras as a data collection tool in migrant mental health.

*Methods.*– The potential sample included: adult men living in the Porte de la Chapelle Refugee camp in Paris. Recruitment was completed on a single day using signs in French, English, Arabic, Farsi and Pashto. Fifteen disposable cameras were distributed along with 2 blank postcards for participants to write an accompanying message. The cameras were kept for up to 7 days.

**Results.**– Of the 15 cameras, 8 were returned. Participants with better spoken English were more likely to return the camera. Two of those not returned were lost, 2 participants were moved camps during the 7 days and 3 were untraceable. Participants found the cameras easy to use and the 181 developed photographs offered a unique insight into the lives of those involved. The postcards provided anecdotal evidence that the photographers appreciated the process, one reading ‘thank you for giving me hope’.

**Conclusions.**– Disposable cameras offer a cost-effective route to better understand the perspectives of those limited by language and cultural barriers. A shorter window would reduce the risk of camera loss or departure of participants. Porte de la Chapelle is an adult men’s camp—there is a need to trial the method in mixed populations.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0464

### “Inoculated in Pain” – Examining resilience in refugee children in an attempt to elicit possible underlying psychological and ecological drivers of migration

P. Majumder

University of Nottingham, Medicine and Health Sciences, Nottingham, United Kingdom

**Introduction.**– Despite the prolonged and extreme environmental adversities and psychological trauma experienced by unaccompanied young refugees during their odyssey through the geographically and politically treacherous landscape, they have sometimes shown extraordinary psychological resilience, ability to function and recover from such ordeals. However, other than the anecdotal tales of their survival, there haven’t been much systematic scientific efforts to explore this intriguing subject.

**Objectives.**– The objectives of this research paper is to explore to gain important insights into the links and underlying dynamics between resilience and migration.

**Methods.**– A total of 15 unaccompanied young persons and their carers were interviewed using a semi-structured schedule to elicit their perceptions and beliefs of the mental health care they received. The interview transcripts were analysed using Thematic Analysis to elicit several themes and sub-themes of findings, which were developed into possible theories answer the research questions.

**Results.**– Some psychological traits and environmental factors may be important in development of resilience to trauma and adversity. Faith in God, optimism, exposure to adversity, and ability to grow up prematurely were found to be linked with their increased resilience.

**Conclusion.**– The findings of this research may help establish initial theories and stimulate interest in the research community to further explore this important area of resilience and its links with psychological wellbeing and migration.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0465

### Xenophobia and coping strategies among Lebanese population

S. Obeid<sup>1</sup>, S. Hallit<sup>2</sup><sup>1</sup> Psychiatric Hospital of the Cross, Psychology, Beirut, Lebanon;<sup>2</sup> Psychiatric Hospital of the Cross, Research, Beirut, Lebanon

\* Corresponding author.

**Objective.**– To provide a better understanding of the current prevalence of xenophobic attitudes and behaviours amongst Lebanese and individuals currently residing in Lebanon, while also looking at the potential effects of demographic characteristics on the prevalence of xenophobia.

**Methods.**– Subjects were asked to complete a questionnaire that included three parts on: (1) sociodemographic characteristics (age, gender, marital status, educational level and monthly income); (2) 30-items about xenophobia; and (3) 16 items on coping strategies.

**Results.**– A significantly higher mean total xenophobia score was demonstrated by females (103.56) compared to males (101.32) ( $P=0.018$ ). The total xenophobia score was associated with the educational level and reached statistical significance ( $P=0.031$ ). Problem-focused engagement ( $r=0.157$ ;  $P=0.001$ ), emotion focused engagement ( $r=0.212$ ;  $P<0.0001$ ) and age ( $r=0.07$ ;  $P=0.029$ ) were significantly and positively associated with the total xenophobia score. Emotion focused engagement (Beta=0.587), problem focused engagement (Beta=0.25) and female gender (Beta=2.04) were associated with a significant increase in the total xenophobia score.

**Conclusion.**– Xenophobia and acceptance toward immigrants have crucial consequences for the functioning and welfare of a society. Our study supports the prevalence of xenophobia amongst Lebanese, but requires a broader assessment of that trend.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Psychotic disorders in the immigrant population: A case report

P. Ortega Orihuela<sup>1\*</sup>, A.L. Pérez Morenilla<sup>2</sup>, M. Zurita Carrasco<sup>3</sup>, M.D.L.Á. Chacón Gamero<sup>3</sup>, C. Caballero de las Olivas Díaz<sup>3</sup>, A. García Peña<sup>4</sup>, H. Díaz Díaz<sup>3</sup>, C. Rodríguez<sup>4</sup>

<sup>1</sup> Psychiatry Trainee, Puerto Real University Hospital, Chiclana, Spain,<sup>2</sup> Puerta del Mar University Hospital, Psychiatry, Cádiz, Spain, <sup>3</sup>University Hospital Puerto Real, Psychiatry, Puerto Real, Spain, <sup>4</sup>

University Hospital Puerta del Mar, Psychiatry, Cádiz, Spain

\* Corresponding author.

Numerous studies show that the rates of psychotic disorders in the immigrant population are higher than in the general origin population. We present the case of a 28-year-old male patient, Maghreb origin, with no prior psychopathological antecedents, who develops psychotics symptoms. We analyze the case to show the difficulties involved in understanding symptoms due to cultural differences, diagnosis and therapeutic management. On the exploration he was scarcely collaborator, presenting marked irritability, fear, social withdrawal, globalized insomnia, denial of intake because of poisoning ideation. Suspicious and with psychotic anguish, false acknowledgments and experiences of control, without disease awareness.

We emphasize the importance of identifying the symptomatology in the context of the patient, it is important knowing cultural and social base on which the disorder appears. At the same time, social and language differences should be taken into account, which may hinder to describe symptoms. The symptoms have to be understood in terms of these variables, so it allows to evaluate the diagnosis,

treatment and prognosis. In this case we opted for the administration of prolonged release injectable paliperidone palmitate due to the difficulty to medical monitoring because of the social and familiar problems that the patient presented, being forced to make multiple visits from time to time to his native city. The goal was to be able to switch to the option of manageable treatment every 3 months, thus facilitating adherence and improving the prognosis, due to an insufficient health support network in the city of origin. *Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Impact of migration-related trauma on self-harm and suicide in migrants confined to prison: A prospective cohort study**

S. Ferrari<sup>1</sup>, C. Reggiani<sup>1\*</sup>, F. Gualtieri<sup>1</sup>, I. Landi<sup>2</sup>, D. Florio<sup>3</sup>, A.M.C. Petrone<sup>3</sup>

<sup>1</sup> University of Modena and Reggio Emilia, Department of Clinical-Diagnostic and Public Health Medicine- Section of Psychiatry, Modena, Italy; <sup>2</sup> University of Trento, Department of Psychology and Cognitive Science, Trento, Italy; <sup>3</sup> AUSL Modena, Department of Mental Health, Modena, Italy

\* Corresponding author.

*Introduction.* – Although numerous studies have shown that self-destructive behaviour and psychological trauma are more common in immigrated prisoners than in native ones, exposure to traumatic events during the migration process has never been examined as a possible risk factor for suicide.

*Objectives.* – This paper investigates the impact of migration-related trauma on self-harm and suicide in newly detained migrants. A secondary aim is to examine whether certain types of trauma are associated with self-harm rather than suicide.

*Methods.* – A total of 54 migrants recently confined in Modena correctional facility were assessed using a standardized interview (JSAT) and two self-administered questionnaires (LiMEs and BIS) and followed-up for a minimum of one month.

*Results.* – Statistically significant positive associations were found between: pre-migration exposure to wars/conflicts or familial trauma and self-harm ( $P=0.03$ ) and post-migration exposure to wars/conflicts or familial trauma and suicide ( $P=0.03$ ). Additionally, positive associations with other types of trauma were found; however, the number of self-destructive acts occurred during the follow-up period was too small for them to be statistically significant. Pre-migration traumas were found to be associated with higher risk of suicide and self-harm.

*Conclusions.* – These findings suggest that migrants are more vulnerable, and that this vulnerability might result in self-destructive behaviour within the prison system. A history of severe migration-related trauma might be used as a clinic indicator of increased risk of self-destructive behaviour; hence, it should be included in the proper suicide risk assessment in prison. A future multicenter national study might expand upon this analysis.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### **Refugees: Psycho-prophylaxis of social consequences**

S. Shport<sup>1\*</sup>, M. Kachaeva<sup>2</sup>, N. Semenova<sup>3</sup>

<sup>1</sup> VP Serbsky National Medical Research Center for Psychiatry and Addiction, Scientific Secretary, Moscow, Russia, <sup>2</sup> VP Serbsky National Medical Research Center for Psychiatry and Addiction, The Department of forensic psychiatric examination, Moscow, Russia, <sup>3</sup> VP Serbsky National Medical Research Center for Psychiatry and Addiction, The Department of Community Psychiatry and Psychiatric Care, Moscow, Russia

\* Corresponding author.

*Introduction.* – Changes in the social and political environment, which disturb the way in which a society is organized and lead to the break-down of common social values, thus posing a threat for the life of the individual and his/her loved ones, also cause one to move away from one's domicile.

*Goals.* – the main problems, which emerge at locations, where refugees are temporarily settled; the main psychologically traumatizing factors; the clinical picture, observed in refugees at locations, where they live temporarily.

*Methods.* – Psychopathological, psychological, and statistical.

*Results.* – The main problems, encountered at locations, where refugees live temporarily:

- accessibility medical care;
- possibility of providing psychological support to families, as well as to single individuals;
- providing for social needs;
- employment of individuals;
- offering leisure options for children.

The main psychologically traumatizing factors:

- anamnestic history of stress disorders;
- absence of information about the fate of one's relatives;
- loss of housing and property;
- absence of reliable information about the situation and the current events in the area of military conflict;
- victims of physical impact (in the area of military conflict);
- loss of employment;
- loss of habitual social contacts;
- age;
- somatic disorders;
- absence of accessible medical care.

The main "mental" symptoms in refugees:

- hopelessness;
- despair;
- loss of control over living activities;
- boredom;
- worriedness;
- reflections.

Variants of the clinical picture:

- anxious;
- hypochondriac;
- adynamic.

*Conclusions.* –

- the urgent care and psychological support should be provided directly at the locations, where the refugees are staying;
- identifying individuals with the most severe stress reactions;
- acute stress disorders should be alleviated in the short period of time.

*Disclosure of interest.* – The authors have not supplied their declaration of competing interest.

### Post-migration stress induces psychiatric symptoms in unaccompanied Eritrean refugees

F. Asefaw<sup>1\*</sup>, A. Kümin<sup>1</sup>, T. Ackermann<sup>1</sup>, R. Dieterle<sup>2</sup>, N. Morina<sup>3</sup>, L. Wöckel<sup>1</sup>

<sup>1</sup> Clenia Littenheid AG, Center of Child & Adolescent Psychiatry and Psychotherapy, Littenheid, Switzerland, <sup>2</sup> University of Zuerich, Institute of Psychology, Zuerich, Switzerland, <sup>3</sup> University of Zuerich, Clinic of Psychiatry and Psychotherapy, Zuerich, Switzerland

\* Corresponding author.

**Introduction.**– Eritreans belong to one of the largest group of refugees in Switzerland coming from countries outside of Europe. Despite of life threatening circumstances and negative experiences during their flight Eritreans often show good factors of resilience. Being confronted with even more postmigration challenges in the communities of their reception, they are often unable to activate their recourses.

**Methods.**– Currently, there are data of 65 Eritrean ambulant patients available, all between the age of 14 and 21 years (YSR, DISYPS, UCLA). The data were collected during the transcultural interviews. The refugees concerned are unaccompanied youths or young adults.

**Results.**– So far clinical evaluation of the situation of Eritrean refugees is missing. Only very few patients show criteria of PTBS, though we find high levels of post-migration stress disorder correlating with the gravity of PTBS and other symptoms.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Neuropsychiatric disorders in Behcet's syndrome: A case report

N. Hamza<sup>1\*</sup>, O. Hdiji<sup>1</sup>, N. Farhat<sup>2</sup>, H. Hajkacem<sup>2</sup>, S. Sakka<sup>2</sup>, M. Damak<sup>2</sup>, C. Mhiri<sup>2</sup>

<sup>1</sup> Habib Bourguiba hospital, University of Sfax -Tunisia, Neurology, Sfax, Tunisia, <sup>2</sup> Habib bourguiba hospital of sfax, Neurology, Sfax, Tunisia

\* Corresponding author.

**Introduction.**– Behçet's disease (BD) is a rare systemic vasculitis of unknown etiology with a predominance of mucocutaneous and ocular lesions. The prevalence of neurological impairment ranges from 5.3% to over 50% during this disease, which may be associated with psychiatric disorders as Neuro-psycho-Behçet (NPB).

**Objectives.**– Describe the clinical and radiological aspect of an NPB.

**Methods.**– report of one case.

**Case report.**– A 52-year-old man, smoking 10 P/A, was admitted in our departement in January 2015 for gait disorders progressively evolving for a year with a change of character and memory disorder for 6 months following. At the neurological examination there was a subcortical type of dementia syndrome, a small step, a quadripyramidal syndrome and paresis of the right VI with left central facial palsy. The interview revealed ideas of persecution against her brothers, emotional blunting and motor instability with a tendency to wander. The diagnosis of NPB was made in the presence of cerebral MRI diencephalo-mesencephalitis and sequelae of anterior uveitis with right optic atrophy on ophthalmologic examination. The patient was put on high doses of corticosteroid and Endoxan with a slight improvement in gait and psychiatric disorders.

**Conclusion.**– The importance of recognition of psychiatric manifestations by neurologist is crucial, as they may reveal dysimmunitary conditions other than BD such as lupus where rapid initiation of immunosuppressive therapy may improve these disorders.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0471

### Age-related morphometric variances of left dorsolateral prefrontal cortex (DLPFC) and its subregions: MRI-based multiscale measurements of cortical complexity

H. Lu

The Chinese University of Hong Kong, Psychiatry, Hong Kong, Hong Kong S.A.R.

**Background.**– Brain stimulation, as repetitive transcranial magnetic stimulation (rTMS), targeted on left dorsolateral prefrontal cortex (DLPFC) has a controversial therapeutic efficacy for late-life depression. The age-related elevations of heterogeneity within DLPFC might be one of the potential causes of failure of brain stimulation trials.

**Objective.**– To examine the age-related effects on cortical complexity of left DLPFC (medial frontal gyrus) and its subregions (BA9 and BA46) in healthy individuals across adulthood.

**Methods.**– A total of 214 cognitively normal adults were selected from the Open Access Series of Imaging Studies (OASIS). The measurements of cortical complexity of left DLPFC includes cortical thickness (mm), area (mm<sup>2</sup>), volume (mm<sup>3</sup>), density and gyrification. Linear regression was used to examine the age-related effects on the cortical complexity of left DLPFC.

**Results.**– Age was negatively correlated with the volume ( $r = -0.325$ ,  $P < 0.001$ ), surface area ( $r = -0.286$ ,  $P < 0.001$ ) and density (BA9:  $r = -0.491$ ,  $P < 0.001$ ; BA46:  $r = -0.488$ ,  $P < 0.001$ ) of DLPFC ( $r = -0.286$ ,  $P < 0.001$ ), but positively correlated with thickness ( $r = 0.221$ ,  $P = 0.001$ ). Furthermore, the gyrification of DLPFC was marked correlated with the thickness ( $r = -0.673$ ,  $P < 0.001$ ).

**Conclusion.**– The findings indicate that age has differential effects on the cortical complexity of DLPFC. The folding pattern of targeted gyrus with the presence of decreased gyrification and increased thickness might be an alert for the failure of rTMS in senior adults and also highlight the emerging need of an integrative motif in transcranial stimulation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Statistical study of the thickness of retinal nerve fiber layer and macular thickness in the healthy population

G. Ilinoiu, A. Mihai\*

University of Medicine and Pharmacy Tg Mures, Psychiatry, Tg Mures, Romania

\* Corresponding author.

Optical coherence tomography OCT as a non-invasive and relatively inexpensive method for imaging the retinal nerve fiber layer (RNFL), is generally used in the diagnosis of ocular pathology, but in the last decade it has been increasingly used in early detection biomarker group of neurodegenerative diseases, including Alzheimer Disorder.

This study evaluate the normative values regarding retinal parameters for the general population in Romania for a correct interpretation of the pathological differences.

**Material and methods.**– We studied the retinal parameters in the healthy general population of Romania in order to identify normative values in this population and to identify possible differences compared to other studies, known as the fact that there are still no general normative values valid for these parameters. In order to obtain information on potential differences between groups, we compared the thickness of RNFL between sexes and age groups on each quadrant. We also analysed the potential correlations between RNFL thickness and aging.

**Results.**– The study looked at the thickness of the macular thickness to 1387 eyes and the RNFL thickness at 1372 eyes from healthy individuals aged 18 to 94 years. There are differences of RNFL normal values in different populations. The thickness of RNFL in Caucasians is lower than in Asians.

**Conclusions.**– Concerning the age-related RNFL thickness analysis, there is a slight but statistically significant negative correlation between aging and the RNFL thickness at all four quadrants.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0473

### **Effects of harmful alcohol use on brain morphometry among people living with HIV in Western Cape Province, South Africa – A baseline description**

G. Spies<sup>1\*</sup>, G. Hoddinott<sup>2</sup>, F. Ahmed-Leitao<sup>1</sup>, S. Seedat<sup>3</sup>

<sup>1</sup> Stellenbosch University, Psychiatry South African Research Chairs Initiative: PTSD Program, Cape Town, South Africa, <sup>2</sup> Stellenbosch University, Desmond Tutu TB Centre- Department of Paediatrics and Child Health, Cape Town, South Africa, <sup>3</sup> Stellenbosch University, Psychiatry, Cape Town, South Africa

\* Corresponding author.

**Introduction.**– HIV is brain degenerative and long-term infection can alter brain morphology. In South Africa, alcohol remains the dominant substance of abuse and long-term use has equally been linked to poor neuroimaging outcomes. The individual liability of alcohol and HIV on brain structure has been well demonstrated, however there is relatively little evidence of the potentially aggravating effects of this dual burden on brain structural outcomes. Studies have indicated that various brain regions are affected by both HIV infection and chronic alcohol abuse, with a predilection for white matter damage. Alcoholism, therefore, contributes significantly to the scope of structural brain deficits present in people living with HIV. **Objective.**– The present study is ongoing and sought to identify the effects of harmful alcohol use on brain morphometry in the context of HIV infection. Method All participants were living with HIV and on antiretroviral therapy. Participants ( $n = 53$ ) underwent structural magnetic resonance imaging (sMRI) using a 3-Tesla Skyra Magnetom whole-body scanner. Self-reported alcohol use was recorded using the Alcohol Use Identification Test (AUDIT). The sample consisted of 50 women and 3 men.

**Results.**– A total of 26 (49%) participants reported abstaining from alcohol and 27 (51%) reported drinking alcohol. Results revealed a significant difference between groups for left insula, left precuneus, left posterior cingulate cortex and left and right amygdala. Mean volume of the aforementioned regions was significantly smaller in alcohol users compared to abstainers.

**Conclusion.**– Alcohol use in the context of HIV infection significantly contributes to brain structure disruption.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0474

### **Rare neurodegenerative diseases related to dementia symptoms – Characteristic neuroimaging findings**

A. Zacharzewska-Gondek<sup>1\*</sup>, T. Gondek<sup>2</sup>, M. Sasiadek<sup>1</sup>, J. Bladowska<sup>1</sup>

<sup>1</sup> Wroclaw Medical University, Department of General and Interventional Radiology and Neuroradiology, Wroclaw, Poland, <sup>2</sup> Wroclaw Medical University, Department of Psychiatry, Wroclaw, Poland

\* Corresponding author.

**Introduction.**– Rare neurodegenerative diseases include i.a. progressive supranuclear palsy (PSP), multiple system atrophy (MSA), corticobasal degeneration (CBD), Creutzfeldt-Jacob disease (CJD) and Huntington disease (HD). Clinically all of these diseases present variety of neurological alterations and proceed with dementia symptoms.

**Objectives.**– The aim of this study is to present characteristic neuroimaging findings of rare neurodegenerative diseases causing cognitive impairment.

**Results.**– Typical findings of PSP include midbrain atrophy with Mickey Mouse appearance, morning glory sign and hummingbird sign in sagittal view. Neuroimaging findings in MSA differ regarding to subtype–in MSA-C there is predominantly cerebellar atrophy with hot cross bun sign in pons, in MSA-P there are pronounced atrophy and low signal intensity on DWI and SWI within putamen. In course of CBD asymmetric cortical atrophy is found, especially in superior parietal lobule, in peri-Rolandic gyri and in basal ganglia with adjacent T2/FLAIR hyperintensity areas. CJD manifests with rapidly progressive cerebral atrophy and hyperintensities on T2/FLAIR with early restriction of diffusion on DWI within basal ganglia, thalamus (hockey stick/pulvinar sign) and cortex. The most characteristic findings in HD is caudate head and putamen atrophy with increased T2 signal intensity.

**Conclusions.**– Structural magnetic resonance imaging is a useful tool in establishing diagnosis of neurodegenerative diseases ongoing with dementia symptoms and helps in differentiating these conditions. DWI as well as SWI sequences should be incorporated in the routine MR protocol dedicated to neurodegenerative disorders assessment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Neuro-rehabilitation and treatment of neuropsychiatric sequelae post-recovery from NMDA encephalitis**

S.H. Alhabsyi

Tan Tock Seng Hospital, Psychological Medicine, Singapore, Singapore

\* Corresponding author.

**Introduction.**– Neuropsychiatric manifestations post-NMDA Encephalitis is not often discussed in literature. Overlapping psychiatric symptoms are usually cited in the acute presentation

of NMDA Encephalitis, but not in the post-recovery period. The course of illness in NMDA Encephalitis can often be turbulent with a prolonged recovery period, and not much is known about the resultant neuropsychiatric symptoms that may develop thereafter. *Objectives.*– This case report discusses a middle aged male who developed frontal lobe signs, including disinhibition, repetitive behaviours, hyper-sexuality and personality changes, about 3 months post-discharge from a prolonged and turbulent admission due to NMDA encephalitis. It further discusses the treatment, both pharmacological and non-pharmacological, undertaken thereafter. Even as this patient's physical function and strength was improving, the development of neuropsychiatric symptoms were alarming and impeded his recovery and full return to work as an aircraft engineer. A combination of a neuro-rehabilitative approach to manage his behaviour, the use of Methylphenidate and Paroxetine to target his frontal lobe symptoms and close supportive engagement with his family and employer allowed for the graded return to his work role.

*Conclusion.*– There is a lack of research in understanding the neuropsychiatric complications of NMDA encephalitis, symptom patterns, longitudinal prognosis and treatment strategies. There is research suggesting that cognitive recovery could be fully back to baseline or partial, but the timeline and patterns of recovery remain unclear and treatment of psychiatric symptoms has been largely supportive and symptom-driven. More can be done to guide psychiatrists to target their treatment options in post-NMDA encephalitis care.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Serum prolactin levels in antipsychotics naive patients

F. Amdouni\*, H. Maatallah, E. Khelifa, Y. Abid, H. Ben Ammar, A. Feki, A. Aissa, Z. El Hechmi

Razi Hospital, Psychiatry Departement, Mannouba, Tunisia

\* Corresponding author.

*Introduction.*– The role of prolactin hormone is still underestimated. The list of cells secreting this hormone keeps getting longer over time. Neurobiological studies found that prolactin is present even in extra pituitary cerebral space suggesting that it plays other roles in addition to lactation. In literature, authors found high prolactin serum levels among psychiatric patients and especially among those diagnosed with schizophrenia.

*Methods.*– It is a descriptive and comparative study evaluating 58 patients hospitalized in Razi hospital for diverse psychiatric disorders. The serum prolactin levels were assessed at admission. The positive and negative symptoms severity was assessed, at admission and discharge from hospital, by the "Positive and Negative Syndrome Scale" (PANSS). We compared medians using Kruskal-Wallis test. We also tested correlation between PANSS scores and prolactinemia.

*Results.*– Patients suffered from 8 different psychiatric disorders (schizophreniform disorder, schizophrenia, schizoaffective disorder, bipolar disorder, chronic delusional disorder, depressive disorder, substance-induced disorder, and mental retardation). Psychotic disorder group has the higher prolactin medians (22 for schizophreniform disorder, 34 for schizophrenia and 21.5 for schizoaffective disorder) compared to chronic delusional disorder, substance induced disorder, depressive disorder and mental retardation (respective medians = 12; 14.5; 17; 13.5). Medians differences are significant ( $P=0.0018$ ). The analysis of schizophrenia subgroup found a negative correlation between negative PANSS scores and prolactin serum level ( $\rho = -0.512$ ;  $p\text{-value} = 0.06$ ).

*Conclusion.*– In accordance with previous studies, we found the higher serum prolactin levels among schizophrenic group. In addition, elevated prolactin levels are associated to low negative symptoms. These results suggest a probable neurobiological role in schizophrenia process.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Hallucinations in a new light: Study in Parkinson's disease and schizophrenia

I. de Chazeron\*, P.M. Llorca

CHU de Clermont-Ferrand, Psychiatry B, Clermont-Ferrand, France

\* Corresponding author.

*Introduction.*– Hallucinations have been described in various clinical populations. In schizophrenic patients (SCZ), hallucinations are hallmark symptoms. In Parkinson's disease (PD), the descriptions of hallucination modalities are sparse. Hallucinations can be evaluated using The Psycho-Sensory hAllucinations Scale (PSAS) which is a multimodal hetero-evaluation scale that includes four domains (auditory, visual, olfactory/gustatory, and coenesthetic modalities). *Objectives.*– This study aimed to explore the phenomenology of hallucinations in 100 SCZ and 100 PD patients using the PSAS. Is this phenomenology homogenous and/or disease specific? And what about repercussion on patients?

*Methods.*– To identify groups of subjects with similar hallucinations characteristics and independently from pathological groups, factorial analyses (multiple correspondence analysis confirmed by hierarchical clustering) were performed. Comparison between groups on characteristics and repercussion index (frequency, duration, negative aspects, conviction, impact and control of each hallucinations) were compared between clusters of subjects.

*Results.*– Regarding phenomenology of hallucinations, a pronounced clustering structure within patients has been observed. Three groups with a low inter-group-recovery rate (24%) were determined. The majority of G1 group ( $n = 88$ ) are PD patients (82%), majority of G2 group ( $n = 19$ ) are SCZ patients (89%) but G3 group ( $n = 93$ ) is a more mixed pathological group (72% PD vs 28% SCZ). All groups have specific pathway phenomenon but no significantly difference in the control on hallucinations.

*Conclusions.*– We confirmed that there's no strict overlap between pathology and hallucinations phenomenology. This latest have specificities that could help to better understand the complexity of the neurological process involved.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### Brain-derived neurotrophic factor – Major depressive disorder and suicide

R. Galea\*, D. Cassar

University of Malta, Faculty of Medicine and Surgery, Msida, Malta

\* Corresponding author.

The aims and objectives of this systematic review are to look into the different theories underling Major Depression and suicide while investigate the correlation between BDNF, Major Depression and suicide. Literature was researched through the University of Malta research platform and statistical reports published by the Maltese National Statistics Office, Eurostat and World Health Organisation were consulted.

Low blood BDNF levels have been identified to occur in Major Depression which normalise during remission. Additionally, since BDNF is associated with increased neural plasticity and survival and decreased atrophy, exposure to chronic stress was identified to decrease BDNF levels and reverse such traits in laboratory rats. Single nucleotide polymorphism Val66Met on the BDNF gene has been identified to be responsible for decreased activity-dependent secretion of BDNF and resultantly increased depressive features. Sertraline administration in human subjects and laboratory rats has been also identified to have a neurogenic effect on serotonergic and BDNF neurons; increasing their expression.

Despite that suicide is commonly associated as part of the symptomatology of psychiatric disorders, in light that children of suicide attempters are six times more susceptible to attempt suicide than children of non-suicide attempters; recent research considered suicide as an independent phenomenon with a high percentage of heritability. Additionally, higher cholecystokinin receptors and cholecystokinin B receptors have been reported in individuals who died by suicide.

Large randomised replicated research looking into BDNF, Major Depression and suicide is still absent. Further research is necessary to validate the reported findings

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Quantitative prediction of outcome in schizophrenic patients with manic-delusional disorders using background EEG and neuroimmunological parameters**

A. Iznak<sup>1\*</sup>, E. Iznak<sup>1</sup>, T. Klyushnik<sup>2</sup>, G. Kobelkov<sup>3</sup>, I. Oleichik<sup>4</sup>, L. Abramova<sup>4</sup>

<sup>1</sup> Mental Health Research Center, Laboratory of Neurophysiology, Moscow, Russia, <sup>2</sup> Mental Health Research Center, Laboratory of Neuroimmunology, Moscow, Russia; <sup>3</sup> M.V. Lomonosov Moscow State University, Dept. of Computational Mathematics, Moscow, Russia, <sup>4</sup> Mental Health Research Center, Dept. of Endogenous Mental Disorders, Moscow, Russia

\* Corresponding author.

*Introduction.*– The problem of treatment optimization in schizophrenia is actual because of heavy social-economic burden of the illness and rather high percent of non-responders. One of ways to such optimization is prediction of clinical outcome.

*Objectives.*– The goal of the study was the search for some background (registered before the beginning of treatment) neurobiological parameters informative for quantitative individual prediction of therapeutic outcome in schizophrenic patients using innovative approach.

*Methods.*– A total of 45 female in-patients (mean age  $31.3 \pm 11.4$  years) with attack-like paranoid schizophrenia (F20.0 by ICD-10) and manic-delusional disorders were enrolled in the study. Resting eyes closed EEG spectral power values and four neuroimmunological parameters were measured before the treatment course. Quantitative clinical assessments (by PANSS scale) were obtained after treatment course. Background neurobiological data were matched with PANSS scores (PANSS-positive, PANSS-negative and PANSS-sum) of the same patients after treatment course using correlation and multiple regression analyses.

*Results.*– Mathematical models obtained, contained only 3 to 4 EEG parameters (from background 80) and one (of 4 background) neuroimmunological parameter explained from 72% to 87% of PANSS scores variance in patients after treatment course. Deviation of calculated values from real PANSS scores varied from 3% to 24%.

*Conclusions.*– The approach described and the data obtained may be useful for elaboration of innovative methods for quantitative individual prediction of treatment outcome in schizophrenic patients. The study supported from Russian Basic Research Foundation Grant No.15-01-00496a

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **The golf ball and the brain: A case study**

K.W. Lee

*Institute of Mental Health, Early Psychosis Intervention Program, Singapore, Singapore*

*Introduction.*– Traumatic brain injury to the frontal lobe has been known to cause significant personality changes including loss of inhibition, increased aggression, as well as emotional instability. However, whether injury to other parts of the brain leads to similar personality and emotional changes remains yet to be proven.

*Aim.*– To describe an adult patient who sustained injury to his temporal lobe leading to similar changes in personality with increased aggression and impulsivity.

*Results.*– Mr S. (35 years old) was described by his family as a gentle and amicable man whose behaviour started to change 2 years ago, becoming an individual who was increasingly irritable, with moments of impulsivity, aggression and heavy drinking. His family was unable to recall any significant stressor which occurred 2 years ago, besides an occasion when he was hit on the head by a golf ball. A brain MRI with contrast was done, showing significant changes with a focus of T2 W/FLAIR hyperintensity in his left anterior medial temporal white matter and cortex. His adjacent left amygdala appeared bulky, with mass effect on the left temporal horn. In a conversation with our neurology colleagues, it was noted that a lesion in this region could lead to seizures, memory impairment, as well as personality changes. In this particular case, Mr S presented with significant personality changes, and a neuropsychological assessment for his cognition is still pending.

*Conclusion.*– Damage to the brain's temporal lobe can lead to significant personality changes with increased aggression and impulsivity, which may mimic injury to the frontal lobe.

*Disclosure of interest.*– The authors have not supplied their declaration of competing interest.

### **Frontal EEG asymmetry in full-term infants and infants born preterm**

D. Chegodae<sup>1</sup>, P. Pavlova<sup>2</sup>, M. Forghani<sup>2</sup>, N. Pavlova<sup>1</sup>, O. Lvova<sup>1\*</sup>

<sup>1</sup> Ural Federal University named after the first President of Russia B.N. Yeltsin, Laboratory of Brain and Neurocognitive Development, Yekaterinburg, Russia, <sup>2</sup> Ural Federal University named after the first President of Russia B.N. Yeltsin, Clinical Psychology and Psychophysiology Department, Yekaterinburg, Russia

\* Corresponding author.

*Introduction.*– Frontal EEG asymmetry (FEA) is spectral electroencephalogram pattern, which usually defined as relative measure of the difference in absolute alpha-power between the right and left frontal regions. FEA is associated with state-dependent emotional reactivity and individual differences in emotional regulation and may be a risk marker for psychopathology.

*Objectives.*– To evaluate the FEA differences between full-term and preterm infants.

*Methods.*– A total of 10 full-term infant (mean chronological age 11 months (SD = 1,09 months)) and 10 preterm infant (corrected

age 11,4 months (SD = 1,95 months)) were included in the study. EEG was registered with HydroCelGeodesic SensorNet (128 electrodes). 30-second EEG segment was selected for analysis in each case. After EEG preprocessing the power spectrum of each channel that ranged in the of infant alpha frequency band 6–9 Hz was calculated, using a fast Fourier transform for all of frontal left channels (12, 19, 20, 23, 24, 26, 27, 28, 33, 34) and frontal right channels (2, 3, 4, 5, 116, 117, 118, 122, 123, 124). Applied FEA formula is as follow  $\ln(P(\text{Right})/P(\text{Left}))$ , where P is absolute power for channels of corresponding sides.

**Results.**– Frontal EEG asymmetry was significantly lower, which reflects greater relative right frontal neural activity (relative right frontal asymmetry) in preterm infants than full-term infants.

**Conclusions.**– FEA is apparently not stable EEG marker. It's known that FEA can change in young children across the first years of life along with behavioural changes. It probably can also depend on degree of brain maturation.

### **Depression after a stroke: Collapse or improvement of the psychic handicap?**

C. Machado<sup>1\*</sup>, A. Hulin<sup>2</sup>, V. Boucherat Hue<sup>2</sup>

<sup>1</sup> Hôpital Lariboisière, Paris 7 University, neurology- Center of Psychoanalysis, Medicine & Society, Paris, France, <sup>2</sup> Paris 7 university, Center of Psychoanalysis, Medicine & Society, Paris, France

\* Corresponding author.

**Introduction.**– In the immediate aftermath of a stroke, depression is frequent both as a link with the brain injury (spalletta G., 2006), but also as a psychic manifestation of the consequences of the frightening somatic accident. Ms. G. is a 50-year-old woman at the time of her stroke. The motor and cognitive recovery will allow the professional recovery on a fitted post. The psychological state, initially precarious, will evolve favorably in a few months. Several years after a major depressive syndrome will take place in a professional situation, consisting of severe moral harassment.

**Objectives.**– To study what types of psychic rearrangements depression allows the subject in the recovery of the somatic and psychological accident.

**Methods.**– A protocol of intellectual tests (neuropsychological assessment and the Wechsler IV Intelligence Scale), projective (Rorschach and Thematic Apperception Test) and quality of life scales will be passed at a time t and t + 1 year.

**Results.**– The intellectual tests show cognitive sequelae and a fluctuation in the functioning of the psyche at 1 year intervals. The projective tests allow us to understand the emergence of depression in the aftermath (several years after the stroke) as an attempt at somatic recovery.

**Conclusion.**– Depression in cerebral vascular pathologies is common both as a narcissistic collapse but also as a possibility of recovery of psychic functioning.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Psychological handicap in Wilson's disease: When genetics get involved**

C. Machado<sup>1\*</sup>, A. Hulin<sup>2</sup>, V. Boucherat Hue<sup>2</sup>, E. Jacquélet<sup>3</sup>, F. Woimant<sup>3</sup>, A. Poujois<sup>3</sup>

<sup>1</sup> Hôpital Lariboisière, Neurology- Wilson's Disease Center, Center of Psychoanalysis, Medicine and Society, Paris, France, <sup>2</sup> Paris 7 University, Center of Psychoanalysis, Medicine and Society, Paris, France, <sup>3</sup> Hôpital Lariboisière, Neurology, Wilson's Disease Center, Paris, France

\* Corresponding author.

**Introduction.**– José is a 12-year-old boy hospitalized for a Wilson disease (WD) discovered during hepatitis. This genetic pathology due to the accumulation of copper in the liver initially can, if left untreated, result in cerebral organic damage leading to significant cognitive and psychiatric sequelae. In this review, the analysis of the genealogical tree reveals the incestuous birth of José. He is in college in a specialized teaching class for learning and relational difficulties since small classes.

**Objectives.**– To try to understand the psycho-intellectual difficulties of José according to the different causalities: cerebral damage related to WD, original trauma freezing thought, developmental pathology to be characterized.

**Methodology.**– A neuropsychological assessment (memory evaluation, executive and attentional functions), a WISC IV, as well as a complex Rey figure and projective tests (Rorschach and TAT).

**Results.**– The WISC IV finds an intellectual functioning in very weak norms whereas the neuropsychological assessment reports a cognitive functioning quite efficient for the age. The projective tests find a good perceptual adaptation but a psychic inhibition of the thought.

**Conclusion.**– The use of all the intellectual and projective tests allows us to grasp the psychic functioning as close as possible to its reality, taking into account the organic repercussions of the disease and the life history of the patient in which the genetic disease is inscribed. It also eliminated cognitive impairment related to WD.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Heart rate variability and clozapine in schizophrenic patients**

C. Nathou<sup>1\*</sup>, P. Gerard<sup>1</sup>, S. Dollfus<sup>1</sup>, O. Etard<sup>2</sup>

<sup>1</sup> CHU de Caen, Centre Esquirol, Caen, France, <sup>2</sup> CHU de Caen, Service d'explorations fonctionnelles neurologiques, Caen, France

\* Corresponding author.

**Introduction.**– Heart rate variability (HRV) is a measure allowing the assessment of the activity of autonomic nervous system (ANS) and reflects the ability to adapt in a changing environment. This measure is highly influenced by treatments but this is poorly taken into account in the field of psychiatry. For example, clozapine is known to be responsible for induced tachycardia that could drastically influence the data analysis, leading to the confusion in conclusions drawn of a diminished HRV in schizophrenic patients.

**Objective.**– In order to improve HRV data analysis in this population, we propose to evaluate the impact of clozapine on this measure in schizophrenic patients.

**Methods.**– We conducted a prospective study of schizophrenic patients who were referred to the functional laboratory of the Caen University Hospital for the exploration of the autonomic nervous system. Twenty-four patients were examined between December 2014 and November 2016: 11 patients under clozapine, 12 patients

under neuroleptic therapy and one with beta-blocker that was excluded from the study.

**Results.**– Heart rate was significantly higher in patients with clozapine than in other patients (100.2 vs 77.6 bpm), HRV was significantly lower during rest (34.7 vs 8.3) and in the deep breathing test assessed by RMSSD (49.4 vs 10.5). The Valsalva ratio was also lower in the clozapine population (2.0 vs 1.5). There was no difference between the two populations during the orthostatistic test.

**Conclusion.**– Our results show that clozapine treatment profoundly influences HRV in schizophrenic patients. This must be taken into account in further studies to better understand ANS activity in this population.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Huntington's disease with initial psychiatric presentation

J. Nogueira<sup>1\*</sup>, M. Franco<sup>1</sup>, G. Jesus<sup>2</sup>, M.J. Freire<sup>1</sup>, R. Sousa<sup>1</sup>, J. Vieira<sup>1</sup>, M. Salta<sup>1</sup>, I. Fonseca<sup>1</sup>, B. Barata<sup>1</sup>, N. Ribeiro<sup>1</sup>, C. Semedo<sup>3</sup>, A. Gamito<sup>1</sup>

<sup>1</sup> Centro Hospitalar de Setúbal, Departamento de Psiquiatria e Saúde Mental, Setúbal, Portugal, <sup>2</sup> Faculdade de Medicina de Lisboa, Clínica Universitária Psiquiátrica, Lisboa, Portugal, <sup>3</sup> Centro Hospitalar de Setúbal, Departamento de Neurologia, Setúbal, Portugal

\* Corresponding author.

**Introduction.**– Huntington's Disease (HD) is an inherited, progressive and neurodegenerative disease caused by the expansion of cytosine-adenine-guanine (CAG) trinucleotide in Interested Transcript (IT) 15 gene on chromosome 4. The pathology is characterized by abnormal movement, cognitive deficits and psychiatric disorders that usually precede motor and cognitive impairment (major depressive disorder and anxiety disorders are the most common presentations).

**Objectives.**– Description of a case of Huntington disease with an overlapping and ambiguous presentation, constituting a diagnostic challenge.

**Methods.**– Case report was prepared with data obtained from clinical files. Literature review was made using Pub Med database. Specific terms were searched: Huntington, Depressive symptoms, Prodromal symptoms, Mood, Gait, and Treatment).

**Results.**– We present a clinical case of a 65-year-old woman admitted to our Psychiatric Acute Unit. In the previous 6 years, the patient was submitted to several clinical assessments by different specialities, that focused only on isolated symptoms (she presented multiple and varied symptoms, from depressive mood and anxiety to cognitive and behaviour changes, besides movement dysfunction), disregarding the syndrome as a whole. In the course of her last admission, the patient was referred to our Neuropsychiatric Team (NT), which made the provisional diagnostic of late-onset Huntington's Disease, confirmed later by genetic testing. Thereafter the neuropsychiatry team maintained the patient under observation and follow-up. Later on, she developed dementia compatible symptoms and, for this reason, transdermal rivastigmine was initiated.

**Conclusions.**– This clinical vignette highlights the importance of a multidisciplinary approach aimed at neuropsychiatric patients and raises awareness for the relevance of careful investigation of motor symptoms in patients with psychiatric presentation.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### A case report: Misdiagnosed psychiatry patient who in fact had focal epileptic seizures

N. Özgedik<sup>1\*</sup>, Ö. Arısoy<sup>1</sup>, Ş.A. Türkoğlu<sup>2</sup>, M. Önerli<sup>2</sup>

<sup>1</sup> Abant İzzet Baysal University-Faculty of Medicine, Psychiatry, Bolu, Turkey, <sup>2</sup> Abant İzzet Baysal University-Faculty of Medicine, Neurology, Bolu, Turkey

\* Corresponding author.

**Introduction.**– Psychiatric comorbidities, including mood and anxiety disorders, adult attention deficit hyperactivity disorder, psychotic disorders are common in epilepsy. But on the other hand, a lot of patients who have focal epileptic activity are misdiagnosed in psychiatry clinics as various anxiety disorders like panic disorder, psychotic disorder and depression. Most of the time, these patients are either supposed to be treatment resistant or considered to have another psychiatric disorder not otherwise specified.

**Objectives/aims.**– Our case report aimed to draw attention to misdiagnosed patients who have focal epileptic seizures instead.

**Methods/case.**– A 22-year-old female was diagnosed with major depressive disorder and Obsessive-compulsive disorder by a psychiatrist. She used several kinds of antidepressants and had multiple therapy sessions but, there was no response. She had a variable mood during the day with sleeplessness, increase in sexual desire, suicidal thoughts, light sensitivity at nights, bad smelling from time to time throughout the year. Upon a history of bad smelling and light sensitivity, we wanted consultation from department of neurology to rule out epilepsy.

**Results.**– EEG showed the presence of a two sided unformed sharp wave, slow wave activity of 1-2 second duration in the left hemisphere. Upon this finding, the patient was diagnosed as epilepsy.

**Conclusions.**– Epilepsy may be associated with a variety of neuropsychiatric symptoms. Psychiatrists must be aware of these varied presentations while obtaining the medical history in order to investigate and manage these patients effectively.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0487

### Psychotic and depressive symptoms in a patient with left frontoparietal meningioma – Is there a relationship?

#### A case report and literature review

A.S. Sequeira<sup>1\*</sup>, H. Barreto<sup>1</sup>, D. Ferreira<sup>2</sup>, R. Caetano Silva<sup>1</sup>

<sup>1</sup> Centro Hospitalar de Lisboa Ocidental, Psychiatry and Mental Health Department, Lisboa, Portugal, <sup>2</sup> Universidade Lusófona de Humanidades e Tecnologias, Escola de Psicologia e Ciências da Vida, Mestrado de Neuropsicologia, Lisboa, Portugal

\* Corresponding author.

**Introduction.**– Meningiomas are often accompanied by psychiatric manifestations. Affective disorders are a common presentation and psychotic symptoms have been reported. A therapeutic approach is difficult due to symptom resistance.

**Objectives.**– To report the case of a patient with left frontoparietal meningioma that presents persecutory delusion and depressive symptoms; briefly review the current literature on the psychiatric manifestations of meningiomas.

**Methodology.**– We describe the patient's clinical history, diagnostic investigation, therapeutic approach and clinical evolution. We searched the "Pub Med" database with the terms "Meningioma", "Depressive Disorder", "Depression" and "Psychotic Disorders". Only papers published in English were selected.

**Results.**– A total of 23 articles met the selection criteria. We report the case of a 58 year-old woman admitted to our psychiatry community team for depressive symptoms, in 2015. During the assessment we found that in 2011 she experienced persistent headaches and a CT brain scan revealed a left frontoparietal meningioma. In 2012 she suddenly develops persecutory delusion involving her neighbours, with progressive social retirement. The following months she progressively develops depressive symptoms (low mood, anhedonia, avolition). Although there was a partial response to sertraline 100mg and paliperidone 9mg, a complete remission was never achieved. Neuropsychological assessment is consistent with frontal and parietal dysfunction.

**Conclusions.**– We propose a relationship between the meningioma location, the patient's psychopathology and resistance to treatment. (Figure 1)

### Non-motor symptoms in Parkinson disease: Impulse-control disorder. A case report

B. Serván, J. Ibáñez, A. Carabias

Hospital Clínico San Carlos, Psychiatry, Madrid, Spain

\* Corresponding author.

**Introduction.**– The neuropsychiatric manifestations of Parkinson's disease (PD) result of great importance because of their frequency and severity. We highlight the Impulse-Control Disorder (ICD) in the form of: pathological gambling, compulsive buying, eating disorder and sexual behaviour disorder. Its prevalence ranges 6–9%, although it is underdiagnosed.

**Objectives.**– To emphasize the importance of ICD diagnose in PD to improve functionality and prognosis, through a clinical case.

**Case presentation.**– A 45-year-old male patient diagnosed with idiopathic PD at age 39, advanced stage (2.5 Hoehn and Yahr). Past psychiatric history: depressive episode and impulsive personality. Treated with Levodopa 200 mg/4 hours and Bupropion 150 mg/day. Rotigotine was added by Neurology because of motor worsening. The patient started with gambling, compulsive shopping, hyperphagia and hypersexuality with important repercussions in his daily life. It was decided to stop Rotigotine, with partial improvement of the symptomatology. Topiramate was added up to a dose of 100 mg/day, and complete resolution was achieved.

**Discussion.**– Given the frequent association between ICD and PD, a common neurobiological substrate has been suggested. Therefore, it may be difficult to discern primary phenomena from those related to the treatment. The predisposing factors to develop ICD in PD are: male sex, evolution years and early onset of the disease, akinesic/rigid forms, high doses of levodopa, use of dopamine agonists, personal or family history of substance abuse or affective disorders and impulsive personality [1].

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Integrating neuroscience in psychotherapy: Shifting paradigm or language evolution?

N. Staali

Psychiatry, Razi Hospital, Tunis, Tunisia

Recent developments in cognitive neuroscience have changed in many ways our perception of psychotherapy. New findings like unconscious associative network, neural plasticity, mirror neurons, interpersonal neurobiology, and Psychophysiology of dream imagery, provided scientific grounding to our day-to-day practice and shed a new light on how the brain works and how we can improve its functioning.

However, we can ask ourselves if these findings are game changing in the psychotherapist's clinical practice or a "new language" that gives a new credibility and a scientific ground to psychopathology concepts such as the unconscious, traces, empathy, transference, implicit language and dream interpretation.

We will try to illustrate, by comparing these modern and classic entities, that the quest of the modern psychiatry should be to harmonize the understanding of the brain and the mind, in order to be more patient-focused with a more global approach.

### The effects of combined transcranial direct current stimulation and speed of processing training on sleep quality in older HIV-positive and HIV-negative adults

S. Cody<sup>1</sup>, M. Crowe<sup>2</sup>, F. Pariya<sup>1</sup>, H. Karen<sup>1</sup>, K. Mirjam-Colette<sup>1</sup>, M. Linda<sup>1</sup>, S. Despina<sup>2</sup>, D. Vance<sup>1</sup>

<sup>1</sup> University of Alabama at Birmingham, School of Nursing, Birmingham, USA, <sup>2</sup> University of Alabama at Birmingham, Department of Psychology, Birmingham, AL, USA

\* Corresponding author.

**Introduction.**– Many older HIV-negative adults and HIV-positive adults experience poor sleep quality; for older HIV-positive adults, such disturbances may be exacerbated. As separate interventions, transcranial direct current stimulation (tDCS) and cognitive training have been shown to improve sleep quality in older adults; however, their combined influence has not been examined.

**Objectives.**– This study examined the combined influence of tDCS and cognitive training, specifically speed of processing (SOP) training, on improving sleep quality in older HIV-positive and HIV-negative adults.

**Methods.**– Older (age 50+) HIV-positive ( $n=33$ ) and HIV-negative ( $n=33$ ) adults were randomized to receive one of two treatments: 1) tDCS with SOP training or 2) sham tDCS with SOP training. In this study, there were four treatment groups derived from the two interventions between HIV-positive and HIV-negative adults. At both baseline and posttest, sleep quality was examined using the Pittsburgh Sleep Quality Index (PSQI). SOP training consisted of 10 hours of computerized training designed to improve perceptual

speed of processing. tDCS with a current of 2 mA was applied to F10 (right inferior frontal cortex).

**Results.**– At baseline, older HIV-positive adults experienced significantly more disruptions in sleep quality compared to older HIV-negative adults. Unfortunately, no change in sleep quality resulted from the interventions.

**Conclusions.**– Support was found that older HIV-positive adults experienced poorer sleep quality compared to their HIV-negative counterparts. Since treatment did not result in improved sleep quality, using tDCS in combination with cognitive training to ameliorate sleep quality is not warranted at this time.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Skin picking disorder: About a case report

F. Martins Alves<sup>1\*</sup>, D. Brandão<sup>1</sup>, E. Fernandes<sup>2</sup>, M. Alvarez<sup>1</sup>

<sup>1</sup> Local Health Unit of Alto Minho- EPE ULSAM, Department of Psychiatry and Mental Health, Viana do Castelo, Portugal, <sup>2</sup> North Lisbon Hospital Centre, Santa Maria Hospital, Department of Psychiatry and Mental Health, Lisbon, Portugal

\* Corresponding author.

**Introduction.**– Skin Picking Disorder consists of repeated compulsive excoriation of the skin and repeated attempts to decrease or not to do so. Patients report relieving tension and gratification after bruising, although they often feel guilty or ashamed of their behaviour.

**Objectives.**– We aim to emphasize the importance of considering this diagnosis as it causes physical/aesthetic lesions that could endanger physical health and interfere with interpersonal interactions, causing dysfunctional functioning and high psychological distress.

**Methods.**– Single case report.

**Results.**– A 64-year-old woman, retired, with Borderline Personality Disorder and a history of chronic alcoholism presenting “compulsive picking at the skin”. She has several lesions and scars on the face, arms, breasts, abdomen and back (image 1). She performs excoriations mainly when upset or when she has discussion with the mother with whom they have dependency relation, claiming to feel relief when she does. However, sometimes she does not realize that she is doing it. She began bruising around the age of 29, when she was emigrated in the United States and was the victim of domestic violence on her husband’s part.

**Conclusions.**– Often, they do not seek treatment because of shame. This is due to a serious medical complication, and it is important to remember the existence of this disorder and the need for early detection and treatment.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0492

### Symptoms of Anxiety and depression, and female gender are associated with lower quality of life in patients with obsessive-compulsive disorders

L. Jahangard<sup>1</sup>, M. Haghghi<sup>1</sup>, A. Mohammad<sup>1</sup>, U. Lang<sup>2</sup>, D. Sadeghi Bahmani<sup>2</sup>, E. Holsboer-Trachsler<sup>2</sup>, S. Brand<sup>3\*</sup>

<sup>1</sup> Hamadan University of Medical Sciences, Department of Psychiatry, Hamadan, Iran, <sup>2</sup> University of Basel, Psychiatric Clinics, Basel, Switzerland, <sup>3</sup> Psychiatric University Hospital, Center of Affective, Stress and Sleep Disorders, Basel, Switzerland

\* Corresponding author.

**Background.**– One to three percent of the adult population suffers from obsessive-compulsive disorders (OCD). Symptoms of OCD include time-consuming, distressing and impairing persistent intrusive thoughts (obsessions), repetitive and ritualistic behaviours (compulsions), poor insight, and strong avoidance behaviour. Additionally, quality of life is adversely affected. The aim of the present study was to compare the quality of life of patients with OCD with that of healthy controls; gender, and symptoms of depression and anxiety were also taken into account.

**Method.**– A total of 100 patients diagnosed with OCD (mean age: 32 years; 64% females) and 100 controls (mean age: 31 years; 59% females) took part in the present cross-sectional study. All participants completed questionnaires covering socio-demographic characteristics and dimensions of QoL. Experts rated participants’ symptoms of OCD, anxiety and depression.

**Results.**– Compared to healthy controls, patients with OCD reported a lower QoL, and had higher symptoms of depression and anxiety. This pattern was particularly pronounced among female patients with OCD. QoL was lower in patients with OCD, even when controlling for depression and anxiety. Results from binary logistic regressions showed that female gender, low QoL and higher symptoms of OCD, depression and anxiety predicted status as patient with OCD.

**Conclusions.**– Compared to healthy controls, patients with OCD have poorer quality of life and this is independent of depression or anxiety, and is particularly pronounced among female patients. Thus, treatment of OCD might take into account patients’ comorbidities and gender.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### Hoarding behaviour in obsessive-compulsive disorder – An Indian study

R. Dikshit<sup>1\*</sup>, M. Tale<sup>2</sup>, N. Shah<sup>3</sup>, S. Sonavane<sup>4</sup>, A. Desousa<sup>5</sup>, S. Karia<sup>6</sup>

<sup>1</sup> Speciality Medical Officer, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital., Mumbai, India; <sup>2</sup> Assistant Professor, Department of Psychiatry-Government Medical College and Hospital, Akola, India; <sup>3</sup> Professor, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>4</sup> Additional Professor, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>5</sup> Research Associate, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India; <sup>6</sup> Assistant Professor, Department of Psychiatry-Lokmanya Tilak Municipal Medical College and Government Hospital, Mumbai, India

\* Corresponding author.

**Introduction.**– Hoarding as primary symptom has been traditionally related with Obsessive-compulsive disorder (OCD) but in clinical

practice it can be seen as a symptom in other psychiatric conditions as well. Hoarding Disorder follows a chronic and progressively deteriorating course. In adults, prevalence of hoarding is estimated to be 2%–6%. Hoarding symptoms tend to be poor indicator of treatment response. As there was very limited Indian literature available on hoarding in OCD, we took up this study.

**Objectives.**– To study and compare the Prevalence and Phenomenology of Hoarding Behavior in patients of OCD & relatives of patients who don't have any psychiatric disorders.

**Methods.**– A cross-sectional, observational study. 100 patients were randomly divided in two groups. Control Group- no diagnosed psychiatric illness. Study Group diagnosed with OCD. Data was collected through semistructured proforma, Yales Brown Obsessive-compulsive scale (YBOCS), Hoarding rating scale (HRS), Saving inventory–revised (modified format), clutter image rating scale (CIRS).

**Results.**– No statistically significant difference was observed in both the groups in the demographic profile. The prevalence of hoarding in cases was 14%. The phenomenology data revealed most common item hoarded was newspaper, scrap (28.6%) as it was important item (57.1%) showing increased relation with OCD (71.4%), showing irritable reaction on discarding (57.1%) with mild socio-occupational impairment (57.1%).

**Conclusion.**– Hoarding symptom have early onset than OC symptoms with poor predictor to treatment response and socio-occupational functioning. The complaint of hoarding is neglected by the treating doctor. So this study implies that enquiring into hoarding behaviour and treating it can improve the quality of life of these patients.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Compulsive self-harm behavior in obsessive compulsion disorder: A case report**

D. Durães\*, J. Gomes

Centro Hospitalar Barreiro-Montijo, Mental Health and Psychiatry Department, Barreiro, Portugal

\* Corresponding author.

**Objectives.**– Obsessive-compulsive disorder (OCD) represents a complex entity, comprising several different kinds of rituals. Self-harm in the context of OCD is very rare; however a few cases have been reported. Herein is reported a case of a man with OCD who developed a ritualized self-harm compulsive behaviour.

**Methods.**– Case report description and additional review of the literature using Pub Med database (Keywords: self-harm, obsessive-compulsive, compulsive self-harm, self-injury).

**Results.**– A 41-year-old man, previously diagnosed with OCD, started with self-mutilation compulsions, consisting of repeatedly cutting symmetrical and geometrical forms, as a way of relieve tension and anxiety, firstly on his legs and then also on the arms. He maintained these rituals for about a year, while maintaining frequent visits and medication adjustments. Clomipramine (titrated to 150 mg/day) and lamotrigine (titrated to 300 mg/day) were added to his medication (he was initially medicated with sertraline, pregabalin and diazepam). The self-harm compulsive behaviour led to medical complications, namely severe anemia (hemoglobin of 8.5 g/dL) requiring treatment with iron reposition. Over that period the behaviours became scarcer until they finally stopped. There are a few reports of self-inflicted eye injuries in OCD, trichotillomania and two cases of auto castration but, to the authors' knowledge, there are no descriptions of compulsive ritualized self-harm behaviour in the context of OCD.

**Conclusions.**– We concluded that this was a rare form of compulsive rituals and a challenging case. Further investigation seems necessary in order to establish the actual epidemiology of self-harm compulsive behaviour in OCD.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

### **Coimbra obsessive inventory – Short version (COI-SV): Development, factor structure and psychometric properties**

A. Galhardo\*, S. Anastácio, M. Cunha, I. Massano-Cardoso  
Miguel Torga Institute, Psychology, Coimbra, Portugal

\* Corresponding author.

**Introduction.**– The Coimbra Obsessive Inventory (COI) is a self-report instrument encompassing two scales of frequency and degree of emotional disturbance of obsessive-compulsive symptoms (50 items each). The COI would benefit from being shortened to facilitate assessment.

**Objectives.**– The current study sought out to develop a COI short version (COI-SV) and study its factor structure and psychometric properties.

**Methods.**– The COI-SV was developed based on psychometric criteria. This study was conducted in the original sample (604 participants from the general population). Subsequently, in another sample of 338 subjects a 5-factor model was tested through confirmatory factor analysis. Cronbach alpha and composite reliability (CR) were calculated. Convergent and divergent validity were addressed through correlations with the Padua Inventory (PI) and the Depression, Anxiety and Stress Scales (DASS-21). Test-retest reliability was studied in a subsample of 23 participants.

**Results.**– The emotional disturbance subscale was maintained. A 19-items and 5-factor (“contamination/washing”, “indecisiveness/slowness”, “repeated checking/hoarding”, “immoral content”, and “magic thinking”) version was achieved. The COI-SV showed a good model fit (CFI = 0.937; GFI = 0.901; RMSEA = 0.067; MECVI = 1.374). Regarding internal consistency, Cronbach alpha was .93 and the CR was .97. Correlation results between the COI and the COI-SV was .97. The COI-SV revealed a correlation of .75 with the PI and correlations of .44, .46, and .49 with the DASS-21. Test-retest reliability showed to be .66.

**Conclusion.**– The COI-SV showed to be a valid and reliable measure of obsessive-compulsive symptoms among the general population. These results substantiate the use of this scale in research and clinical practice.

**Disclosure of interest.**– The authors have not supplied their declaration of competing interest.

EV0496

### **Mind the gap in OCD: From good to poor insight**

L. Manarte

University of Lisbon, Department of Psychiatry, Lisbon, Portugal

**Objectives.**– The author shows how insight became a miller-stone concept in OCD research, how it can explain OCD variability and the limitations one can find in insight research.
